 - Exclusive read-write transaction support
 - Region-based security firewall in accordance with processor security management

For EMIF features see [Section 9.2.3.4.1.1, Features Supported](#).

9.2.2 SDRC Subsystem Integration

Figure 9-42 shows how the SMS and EMIF modules are integrated into the processor and how they interact with the PRCM module.

Figure 9-42. SDRC Integration to the Processor

sdrc-007

9.2.2.1 Clocking, Reset, and Power Management Scheme

9.2.2.1.1 Clocking

9.2.2.1.1.1 SMS

The SMS is a single clock domain module. The same clock is used for the interconnect system interface, the EMIF interface, and all internal operations.

SMS_CLK comes internally from the PRCM module and runs at the L3 interconnect frequency. It is also used as a functional clock for the SMS module.

The source of the SMS_CLK is the PRCM CORE_L3_ICLK output: CORE_L3_ICLK belongs to the L3 interconnect clock domain.

9.2.2.1.1.2 EMIF

The EMIF is a single-clock domain module. The same clock is used for both the interconnect and the memory interface. The SDRC_CLK clock comes from the PRCM and runs at the L3 interconnect frequency. SDRC_CLK is also used as a functional clock for the EMIF .

The SDRC_CLK clock source is the PRCM CORE_L3_ICLK output: CORE_L3_ICLK belongs to the L3 interconnect clock domain.

An SDRC_CLKX2 clock is provided by the PRCM at a double frequency of the SDRC_CLK clock.

As a power-saving feature, when the EMIF no longer requires the clock domain, the software can disable it at the PRCM level by setting the EN_SDRCLCK bit in the PRCM.CM_ICKLEN1_CORE[1] register.

9.2.2.1.2 Hardware Reset

Global reset of the EMIF is done by activating the CORE_RST signal in the CORE_RST domain (see the *Power, Reset, and Clock Management* chapter).

There is one global reset signal, SDRC_GLOBALRESET, which is qualified by the signal SDRC_POWERON. This qualification differentiates whether the signal is a cold reset or a warm reset.

- On a cold reset (that is, the power-on reset, when SDRC_POWERON = 0 and SDRC_GLOBALRESET is applied), all registers and state-machines within the EMIF are asynchronously reset.
- On a warm reset (that is, any other system reset condition under control of the chip top-level power manager, SDRC_POWERON = 1 when SDRC_GLOBALRESET is applied), the EMIF registers and the FSM are not reset, but the EMIF takes care of completing the ongoing access and putting the external memory into self-refresh mode.

9.2.2.1.3 Software Reset

The SMS modules can be reset under software control through the SMS.SMS_SYSCONFIG[1] SOFTRESET bit.

A software reset has the same action as a hardware cold reset, that is, the FSM and all registers are reset immediately and unconditionally.

9.2.3 SDRC Subsystem Functional Description

The SMS optimizes the SDRAM memory usage to provide:

- The QoS level required by each of the initiators in the system
- A security firewall that controls access protection to the memory
- A VRFB module (also called the 2D rotation engine) that minimizes the SDRAM page-miss penalty when accessing rotated (that is, nonsequentially addressed) lines in a graphic frame buffer

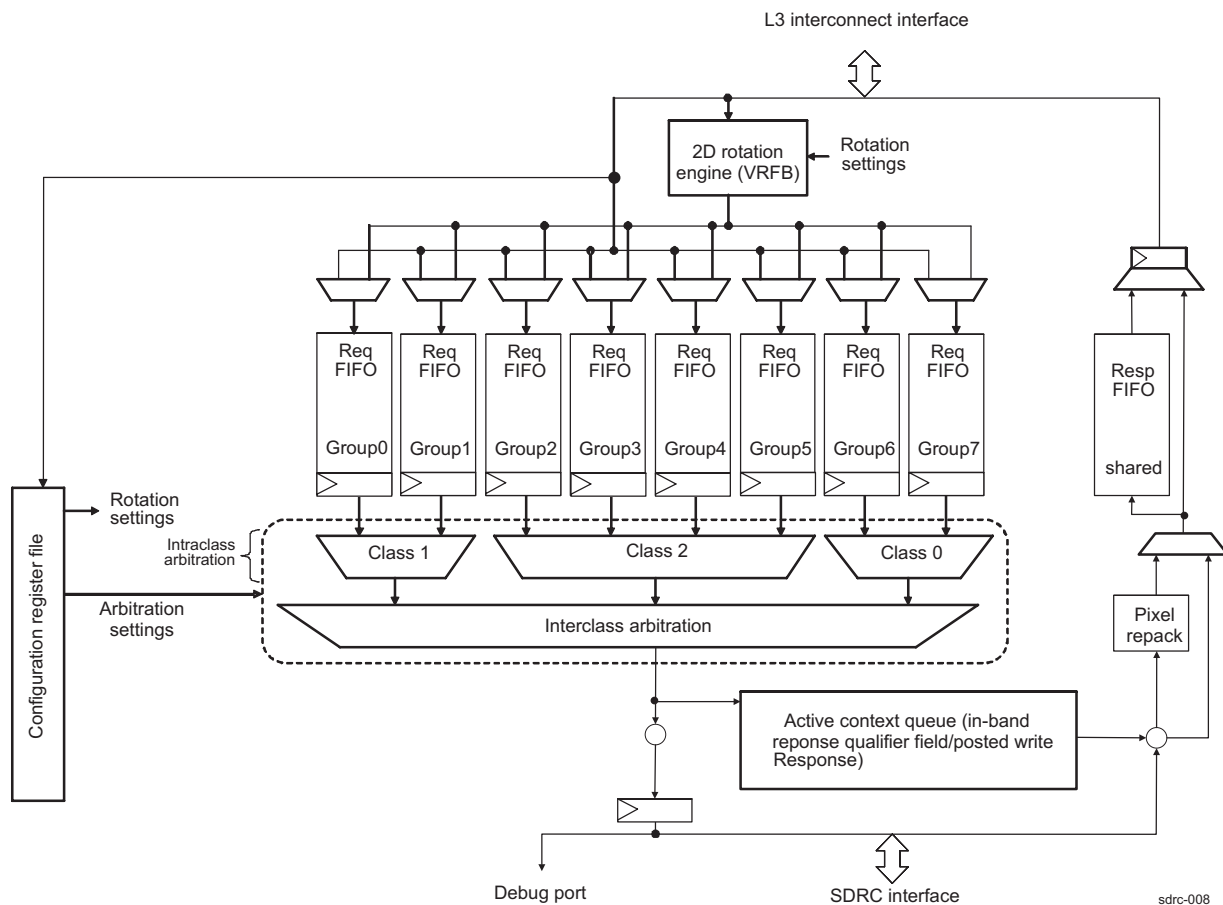

9.2.3.1 SDRAM Memory Scheduler

The SMS module is split into the following subsystems:

- L3 interconnect slave port
- VRFB: rotation engine (RE)
- Configuration register file
- Security check unit
- Request buffers
- Arbitration logic
- EMIF interface: master port
- Debug port
- Response buffer

Figure 9-43 shows the top-level diagram of the SMS.

Figure 9-43. SMS Top-Level Diagram

9.2.3.1.1 Memory Access Scheduling

NOTE: For a description of the SMS mode of operation and arbitration policy, see [Section 9.2.5, SDRC Use Cases and Tips](#).

The SMS includes a set of FIFOs to queue the requests received from the system interconnect or processed by the RE. The FIFO entry contains a complete interconnect request, plus internal qualifiers added by the RE which are required to correctly process the requests modified (or generated) by the RE.

The SMS also includes a response FIFO, which is shared by all response threads. This FIFO provides full support for the response flow-control interconnect extension (handshake protocol).

When a memory transaction request arrives in the memory-access scheduler after being processed by the VRFB module, the request is sent to one of eight FIFO queues. Security firewall comes after the FIFOs.

The allocation to a particular queue is fixed and depends on the source of the request. To prioritize concurrent transactions and optimize memory usage, each FIFO queue (and hence the memory-access request source) is categorized into one of these three arbitration classes:

- **Class 0 (highest priority):** For bandwidth-sensitive devices with severe real-time constraints. The system fails when the bandwidth requirement is not met. LCD or video display cores belong to this category.
- **Class 1:** For latency-sensitive devices where system performance degrades severely when the average memory-access latency increases. These initiators also generally have some significant bandwidth requirements. All CPU cores are class 1 initiators.
- **Class 2:** For all other devices, possibly with high-bandwidth requirements but without being too latency-sensitive. Associated initiators may also have significant requirements in terms of bandwidth, but if the bandwidth budget requirement cannot be serviced, the system performance degrades, but remains functional (the system does not fail). General-purpose system DMA, multimedia accelerators (graphics, imaging, video) belong to this category.

The arbitration between Class 1 and Class 2 is programmable.

[Table 9-61](#) shows the mapping of FIFO queues and memory-access request sources to arbitration classes.

Table 9-61. Arbitration Class Allocation

| Class | FIFO Queue | Source Device |
|-------|------------|---|
| 0 | 7 | Display |
| 1 | 0 | MPU subsystem (instruction and data access) |
| | 1 | |
| 2 | 2 | sDMA WR |
| | 3 | SGX |
| | 4 | USB (HS + FS), DAP, CCDC, USB-OTG, EMAC |
| | 5 | sDMA (read) |

A 2-level arbitration scheme determines the FIFO queue from which the next memory transaction is granted.

NOTE: In the register description, a group represents a FIFO queue of requests from the initiator.

9.2.3.1.2 Arbitration Policy

A 2-level arbitration scheme is implemented to grant access to the EMIF . The arbitration uses fully combinatorial logic, and the granted request is clocked before being issued on the interface master port of the EMIF .

- **Intra-class arbitration:** A first level of arbitration is done in parallel within each class between the different thread groups (request FIFOs).

- Interclass arbitration: A second level of arbitration is done among the three winners of the in-class arbitration.

9.2.3.1.2.1 Arbitration Policy within a Burst and at a Burst Boundary

Arbitration is performed on the transaction boundary. The transaction can be either a single transaction or a burst transaction.

- Within a burst, if the thread cannot provide the subsequent request of the burst, a mechanism provides a wait for one idle cycle before moving the arbitration grant to the next thread. If only one idle cycle appears on one thread, an arbitration grant must not move (the next request served must be from the same thread). One idle cycle is then inserted in the EMIF request path.
- If the thread still cannot provide the request in the next cycle, the slot can be awarded to another initiator to avoid locking the SDRAM resource, if a thread cannot supply a subsequent request within the burst. In this case, there must not be a second idle cycle insertion in the EMIF request path. A burst with fewer than two idle cycles cannot be interrupted by a higher priority request.
- On burst boundary, the arbitration does not wait one idle cycle before moving the arbitration grant. As soon as the thread cannot request one transaction at a burst boundary, the arbitration grant can move to the next thread.

This is also valid within the ExtendedGrant and NOfServices windows; as soon as the thread cannot request a transaction, the arbitration grant can move to the next thread. For more information, see the following descriptions of the ExtendedGrant and NOfServices features.

9.2.3.1.2.2 Burst-Complete Feature (*BURST-COMPLETE* Field in *SMS_CLASS_ARBITER0*, *SMS_CLASS_ARBITER1*, *SMS_CLASS_ARBITER2*)

A burst request can be submitted to the arbitration either as soon as the first request of the burst is received by the SMS, or when at least one complete burst is buffered into the FIFO. The behavior is programmable on a per-group basis using the *BURST-COMPLETE* field of the *SMS_CLASS_ARBITER0*, *SMS_CLASS_ARBITER1*, and *SMS_CLASS_ARBITER2* registers. A per-FIFO counter tracks the number of complete bursts in a FIFO.

9.2.3.1.2.3 ExtendedGrant Feature (*EXTENDEDGRANT* Field in *SMS_CLASS_ARBITER0*, *SMS_CLASS_ARBITER1*, *SMS_CLASS_ARBITER2*)

EXTENDEDGRANT is a programmable control field that allows a group to be granted for N consecutive transactions (single or burst), assuming the group is still requesting service (FIFO is not empty). *EXTENDEDGRANT* is applicable on a single/burst boundary. This multiple-service grant is intended to take advantage of the high probability of two consecutive transactions within a group accessing consecutive memory addresses (that is, in the same SDRAM page). This mechanism does not apply to consecutive transactions that have been split by the RE. The maximum number of consecutive grants is given in the *EXTENDEDGRANT* field of the *SMS_CLASS_ARBITER0*, *SMS_CLASS_ARBITER1*, and *SMS_CLASS_ARBITER2* registers. The allowed range is 1 to 3.

The ExtendedGrant logic is in the internal class arbitration but must be propagated to the interclass arbitration. The flag qualifying a second-service request is provided to the interclass arbiter so the extended grant scheme can be applied at the second level of arbitration.

- Class 0 requests can still override the ExtendedGrant scheme of class 1/class 2. Within an ExtendedGrant window, hand-over to another class/thread (granting another thread) can occur as soon as one idle cycle appears in the thread at burst or single boundary.
- The PWM counter of the interclass arbitration obeys the ExtendedGrant completion before handing priority to the other class.
- When a split transaction from the RE is interleaved within an ExtendedGrant window, completion of the ExtendedGrant window starts with the last ExtendedGrant counter value (not the initial value), because there are two independent counters for ExtendedGrant and NOfServices. The ExtendedGrant counter is reloaded to its programmed value when it reaches 0.

9.2.3.1.2.4 NOFServices Feature (SMS.SMS_CLASS_ROTATIONm[4:0] NOFSERVICES Field)

NOFSERVICES is a programmable control field that allows consecutive transactions (single or burst) coming from the VRFB (with an RE_split qualifier) to be granted consecutively, assuming the group is still requesting service (FIFO is not empty). NOFServices is applicable to the RE single/burst boundary. The maximum number of consecutive grants is given by the NOFSERVICES field of the SMS.SMS_CLASS_ROTATIONm registers. The allowable range is 1 to 31.

The NOFServices logic is in the internal class arbitration, but must be propagated to the interclass arbitration. The flag qualifying a second-service request is provided to the interclass arbiter so the extended grant scheme can be applied at the second level of arbitration.

- Class 0 requests can still override the NOFServices scheme of class 1/class 2. Within a NOFService window, hand-over to another class/thread (granting another thread) can occur as soon as one idle cycle appears in the thread at burst or single boundary. A burst with fewer than two idle cycles cannot be interrupted by a class 0 request.
- The PWM counter of the interclass arbitration obeys the NOFServices completion before handing priority to the other class.
- When a split transaction from the RE is interleaved within an ExtendedGrant window, completion of the NOFservices window starts with the last NOFServices counter value (not the initial value), because there are two independent counters for ExtendedGrant and NOFServices.

If a transaction split by the VRFB follows a nonsplit transaction currently being executed on the EMIF side, an arbitration slot occurs on the nonsplit transaction boundary, regardless of the status of the ExtendedGrant counter. This is because the chances of a nonsplit transaction and a split transaction accessing the same SDRAM page are low. Similar behavior would be observed for a split transaction followed by a nonsplit transaction. The NOFServices counter is reloaded with its programmed value when it reaches 0.

9.2.3.1.3 Internal Class Arbitration

Class 0, class 1, and class 2 internal arbitrations are performed according to the following rules:

- Within a class, a standard least-recently-used (LRU) policy is applied. The LRU thread, if not empty, is granted when an arbitration decision occurs. LRU is applied taking into account the ExtendedGrant/NOFServices counter status. Grant is given to another nonempty LRU thread only if the current thread is serviced for ExtendedGrant/NOFServices times.
- On top of the LRU policy, a high-priority group can be defined through the SMS.SMS_CLASS_ARBITER0[7:6] HIGHPRIOVECTOR field. The high-priority group is unique and programmable. If a high-priority thread in a class, which was previously empty, starts requesting service, the current thread that has been given grant is completely serviced as per ExtendedGrant/NOFServices strategy and then the grant is given to the high-priority thread.

9.2.3.1.3.1 Interclass Arbitration

The interclass arbitration is managed using a time-varying policy driven by the following rules:

- The interclass arbitration is a PWM-like (Pulse Width Modulation) logic that defines two request-based windows:
 - Class 1 has higher priority than class 2 during M requests of class 1, where M is defined by the CLASS1PRIO parameter.
 - Class 2 has higher priority than class 1 during the next N requests of class 2, where N is defined by the CLASS2PRIO parameter. For more information on priority between classes, see [Section 9.2.5.2.2.3](#).
- The PWM counter is decremented each time the class is processing a single 64-bit request in its high-priority window.
- A class 0 request always has the highest priority. The PWM counter is frozen while class 0 requests are being serviced.
- A class 1 transaction can be serviced during the class 2 high-priority window if class 2 is not requesting service (conversely, a class 2 transaction can be serviced during the class 1 high-priority window if class 1 is not requesting service). The PWM counter is frozen when the grant is given to the thread that is not in its high-priority window.

- NOFServices/ExtendedGrant have higher priority than the PWM counter.
- The PWM counter is reloaded with M and N when it reaches 1 and an arbitration decision must be made.
- The priority order is as follows:
 - Current burst service lock (assuming subsequent burst requests available when required)
 - Class 0
 - ExtendedGrant and NOFServices atomicity (assuming subsequent burst requests available when required)
 - Class 1 if PWM priority is to class 1; class 2 if PWM priority is to class 2
 - Class 2 if PWM priority is to class 1; class 1 if PWM priority is to class 2

9.2.3.1.4 Security Firewall

Access permissions can be defined in the target memory address space on a per-initiator basis. Initiators are differentiated using the interconnect ConnID extension.

Permissions are allocated to the various initiators on a per-region basis. The memory regions are programmable using a start address and an end address that are defined with 64 Kbytes granularity. Up to seven distinct regions can be defined; the software must ensure that they do not overlap.

The remaining memory space (total memory space minus the protected areas) is defined as region 0. This region has security attributes programmable in the same manner as the other regions.

Depending on whether the access is a read or a write, and depending on the in-band request qualifiers, a region may be given specific access permissions. When an access is received by the SMS, the access checked against the access attributes.

- The read permission is initiator-based and is controlled using the SMS.SMS_RG_RDPERMi register.
- The write permission is initiator-based and is controlled using the SMS.SMS_RG_WRPERMi register.
- The REQINFO bits taken into account are the incoming MReqInfo attributes: Security, debug, privilege, and attribute, along with the host parameter decoded in the SMS module (see the SMS.SMS_RG_ATTi[31:0] REQINFO field). For the SMS firewall, the host parameter is set for the MPU initiator and the sDMA initiator. The decoding of the host parameter, based on the MPU ConnID and sDMAConnID generic parameters (defined at design time), is done inside the SMS module.
- Whether the access is accepted (there is one valid bit for each ReqInfo pattern) can be specified for each ReqInfo pattern. ReqInfo permission is controlled using the region attributes register SMS.SMS_RG_ATTi[31:0] REQINFO field.

Table 9-62 lists the security ReqInfo parameters ordering.

Table 9-62. Security ReqInfo Parameters Ordering

| Host | Privilege | Security | Debug | Type | Req Info | SMS.SMS_RG_ATTi[31:0] REQINFO Field |
|-----------------------|--------------------------|------------------------|---------------------------|-------------------------------------|----------|-------------------------------------|
| 0: Nonhost 1: Host | 0: User 1: Supervisor | 0: Public 1: Secure | 0: Functional 1: Debug | 0: Data Transfer 1: Opcode Fetch | | |
| N/A ⁽¹⁾ | | | | | | 0b0...000000000 |
| 0 | 0 | 0 | 0 | 0 | 0 | 0b0...000000001 |
| 0 | 0 | 0 | 0 | 0 | 1 | 0b0...000000010 |
| 0 | 0 | 0 | 1 | 0 | 2 | 0b0...000000100 |
| | | | | | ... | |
| 0 | 1 | 1 | 1 | 0 | 14 | 0b0...000001...00 |
| 0 | 1 | 1 | 1 | 1 | 15 | 0b0...00001...000 |
| 1 | 0 | 0 | 0 | 0 | 16 | 0b0...0001...0000 |
| 1 | 0 | 0 | 0 | 1 | 17 | 0b0...001...00000 |
| | | | | | ... | |
| 1 | 1 | 1 | 0 | 1 | 29 | 0b0010...000000 |
| 1 | 1 | 1 | 1 | 0 | 30 | 0b0100...000000 |
| 1 | 1 | 1 | 1 | 1 | 31 | 0b1000...000000 |

⁽¹⁾ Access to the region is not allowed

When all SMS_RG_ATTi[31:0] REQINFO bits are set to 0 the access to the region is not allowed.

Set the REQINFO[0] bit to 1 when NonHost-User-Public-Functional-Data accesses are permitted in this region.

Set the REQINFO[1] bit to 1 when NonHost-User-Public-Debug-Data accesses are permitted in this region.

Set the REQINFO[31] bit to 1 when Host-Supervisor-Secure-Debug-Opcode accesses are permitted in this region.

Any bit of the SMS_RG_ATTi[31:0] REQINFO field corresponds to a particular combination of the five attribute bits. When all SMS_RG_ATTi[31:0] REQINFO bits are set to 1 the region is full-access allowed.

The security unit performs the following checks to authorize or reject an access to the external memory:

- Compute the Region ID based on the transaction address.
- Generate a violation if overlapping of security regions is detected.
- From the Region ID, get the attributes for the region that has been hit.
- Check the transaction REQINFO attributes with respect to the region attributes (security, debug, privilege, type, and host).
- Reject the transaction if the attributes are not compatible.
- From the Region ID and the transaction qualifiers (MCmd, ConnID), check the initiator permissions for performing the access (read, write).
- Reject the transaction if there is no permission.

The protection regions are organized in security priority levels (from Level 0 to Level 2) to prevent problems with overlapping region and corner cases associated with them; the lowest level has the lowest priority (see [Figure 9-44](#)).

Figure 9-44. Security Region Organization

sdr-009

Region 0 (default region containing the whole memory space): Level 0

Region 1 (allows dynamic reprogramming of regions): Level 2

Regions 2–7 (protection regions): Level 1

Region 1 has the highest priority to perform dynamic masking of other already-programmed regions when they are reprogrammed.

Overlapping regions of the same priority level is forbidden and results in a security violation when an access to the concerned region occurs. This security violation is reported in the error-log register. Priority-level handling is done in the hardware; it does not involve any specific software development.

All transactions are checked, including those the RE has processed.

When detecting a security violation on an incoming request, the SMS respects the response ordering within the faulty thread.

A violation flag is raised internally and the MThreadID field is logged. Generation of the interconnect error response is then local to the SMS; the response buffer must be used to manage the potential response collision with regular EMIF responses.

To program a rotation context, set the security level per context through the SMS.SMS_SECURITY_CONTROL ROTCTXTiLOCK bits ($i = [0:11]$). That is, on context i : are all transactions allowed or is access restricted to secure transactions only?

9.2.3.1.5 Rotation Engine

Applications must often perform image rotation between the orientation of images stored in external memory and the orientation with which they must be displayed. The device offers a hardware mechanism that allows rotation tasks to be implemented efficiently, transparent to software applications, thereby keeping the MPU free for other tasks. For a description of the RE mechanism, see [Section 9.2.5, SDRC Use Cases and Tips](#).

The SMS includes address processing support for rotated displays (90, 180, and 270 degrees). This function is realized by the VRFB submodule, also called the rotation engine (RE) in this document.

The primary goal of the VRFB is to eliminate the SDRAM page-miss penalty when reading graphics data in nonnatural raster scan order (that is, top to bottom, bottom to top, right to left).

The 2D-rotation module (the VRFB) is included as a black box that intercepts incoming requests when addressed to the virtual frame buffer. If the address of the request targets the VRFB address space, the request is sent to the RE. It processes the address and reinserts the modified request in the SMS request path. The SMS translates the virtual address into physical SDRAM addresses and reinserts a request or multiple requests in the SMS request path to the EMIF .

NOTE: The use of the word *virtual* does not refer to the usual CPU-related MMU concept; the word is used in a more general context of the address remapping feature, which decouples the system from the actual storage physical organization of the graphics data in the external memory.

The VRFB can be abstracted as a 3-port module:

- Interconnect input port
- Interconnect output port
- Configuration port; all programmable control registers are part of the SMS register file, which is described in [Section 9.2.3.1.5.3, VRFB Configuration Port](#).

9.2.3.1.5.1 VRFB Input Port

The VRFB receives a 29-bit address, and two decoding signals, from the SMS module. The 29-bit address is decoded to determine the context and the rotation view of the request.

The VRFB address space is a 768 Mbytes address space split into two non-contiguous virtual address spaces:

- Address space 0: 256 MB in quarter Q1 (start address: 0x7000 0000, end address: 0x7FFF FFFF)
- Address space 1: 512 MB in quarter Q3 (start address: 0xE000 0000, end address: 0xFFFF FFFF)

It can manage up to 12 concurrent rotation contexts. [Table 9-63](#) details the address space of each context.

Table 9-63. VRFB Contexts Virtual Address Spaces vs Rotation Angle

| Context Number | 0° | 90° | 180° | 270° |
|----------------|-------------|-------------|-------------|-------------|
| 0 | 0x7000 0000 | 0x7100 0000 | 0x7200 0000 | 0x7300 0000 |
| 1 | 0x7400 0000 | 0x7500 0000 | 0x7600 0000 | 0x7700 0000 |
| 2 | 0x7800 0000 | 0x7900 0000 | 0x7A00 0000 | 0x7B00 0000 |
| 3 | 0x7C00 0000 | 0x7D00 0000 | 0x7E00 0000 | 0x7F00 0000 |
| 4 | 0xE000 0000 | 0xE100 0000 | 0xE200 0000 | 0xE300 0000 |
| 5 | 0xE400 0000 | 0xE500 0000 | 0xE600 0000 | 0xE700 0000 |
| 6 | 0xE800 0000 | 0xE900 0000 | 0xEA00 0000 | 0xEB00 0000 |
| 7 | 0xEC00 0000 | 0xED00 0000 | 0xEE00 0000 | 0xEF00 0000 |
| 8 | 0xF000 0000 | 0xF100 0000 | 0xF200 0000 | 0xF300 0000 |
| 9 | 0xF400 0000 | 0xF500 0000 | 0xF600 0000 | 0xF700 0000 |
| 10 | 0xF800 0000 | 0xF900 0000 | 0xFA00 0000 | 0xFB00 0000 |

Table 9-63. VRFB Contexts Virtual Address Spaces vs Rotation Angle (continued)

| Context Number | 0° | 90° | 180° | 270° |
|----------------|-------------|-------------|-------------|-------------|
| 11 | 0xFC00 0000 | 0xFD00 0000 | 0xFE00 0000 | 0xFF00 0000 |

CAUTION

There is no protection in hardware for accesses outside the image resolution. Users can access the full virtual address range for a given context (there is no error reporting). Accessing outside of the image resolution creates aliasing within the image and is also translated as an additional physical memory space requirement on the external memory (some data outside of the image range can be overwritten by mistake). The following formula can be used to calculate the extra memory that will be accessed:

$$\text{extra_mem_size} = (2048 - \text{image_width_roundedup}) \times \text{page_height} \times \text{pixel_size}$$

$$\text{with } \text{image_width_roundedup} = \lceil \text{ROUNDUP}(\text{image_width} \times \text{pixel_size} / \text{page_width}) \rceil \times \text{page_width} / \text{pixel_size}.$$
9.2.3.1.5.2 VRFB Output Port

The VRFB output port can be a delayed copy of the input port, with the address field transformed. Depending on the rotated view that is active, an incoming transaction can also be split into several internal transactions.

The pipeline delay between the input and the output ports is three clock periods.

9.2.3.1.5.3 VRFB Configuration Port

The configuration port allows 12 concurrent rotation settings.

The VRFB address space is a 768 Mbytes (256 + 512) address space split into two noncontiguous spaces. It can manage up to 12 concurrent rotation settings.

The VRFB configuration port includes all the settings required to control the 12 rotation contexts. This is an input-only port. All settings are provided from the SMS control register file.

For each of the 12 contexts, the buffer physical base address, image height and width, and pixel size can be configured through the following registers (where n is the context number, from 0 to 11):

- SMS.SMS_ROT_PHYSICAL_BAn[30:0] PHYSICALBA field
- SMS.SMS_ROT_SIZE n[26:16] IMAGEHEIGHT and SMS.SMS_ROT_SIZE n[10:0] IMAGEWIDTH fields
- SMS.SMS_ROT_CONTROL n[1:0] PS field

The memory arrangement for the pixels of a frame buffer accessed through the RE is tile-based. A tile is a rectangular array of pixels. The tile size should match the page size of the SDRAM component attached to the controller for optimal performance.

The tile size is defined using the SMS.SMS_ROT_CONTROL n[10:8] page height (PH) and [6:4] page width (PW) fields.

The image height and image width (SMS.SMS_ROT_SIZE n[26:16] IMAGEHEIGHT and [10:0] IMAGEWIDTH fields, expressed in bytes) must be multiples of the tile height and width, respectively. Some padding is required if the image size does not fit this requirement.

For a configuration example, see [Section 9.2.4.2](#), *VRFB Context Configuration*.

9.2.3.1.6 Register Security

For the following register groups, use the SMS.SMS_SECURITY_CONTROL register to independently restrict permission to write to the SMS registers to secure accesses:

- VRFB context configuration registers (independently for each context)

- Memory-access scheduler arbitration registers
- Firewall registers, soft reset bit, error registers, and the security control register itself

Writing restrictions to the security firewall memory region registers (including SMS.SMS_SECURITY_CONTROL) depend on the control module configuration.

If an illegal access is attempted (for example, a nonsecure write access to a register configured as secure), a security violation is indicated to the security module. The address where the security violation occurs and the type of violation can be read from the SMS.SMS_ERR_ADDR and SMS.SMS_ERR_TYPE registers.

To determine if a HS version of your device is available and for more information on HS devices, please refer to your device-specific data manual.

9.2.3.1.7 Security Violation Reporting

The SMS firewall can detect security violations and report them to the overall system by using the following qualifiers:

- The in-band error response to a non-authorized access
- The out-of-band error signal generation using two out-of-band error signals

Based on the fact that there is no way to prevent the debugger from generating firewall violations during debug, and that users cannot stop checking for functional violations, two out-of-band security violation signals are set when:

- A functional violation is detected
- A debug violation is detected

These signals are asserted on each error detection from a read, write, or posted write faulty access: they are deasserted when the software clears the error bit in the SMS_ERR_TYPE register.

9.2.3.2 Module Power Saving

Power-saving is managed through the SMS.SMS_SYSCONFIG register.

The SMS_SYSCONFIG[4:3] SIDLEMODE field defines the power management strategy (Force Idle mode, No Idle mode, or Smart Idle mode). See [Section 9.2.3.3](#) for more details on the system power management.

By default, the internal interface clock gating strategy is enabled as the SMS_SYSCONFIG[0] AUTOIDLE bit is set to 0x1 after reset. When all FIFO queues are empty and no ongoing transactions remain, the L3 interconnect clock is disabled inside the SMS thus reducing power consumption. The L3 interconnect clock can be disabled after a programmable delay defined in the SMS_POW_CTRL[7:0] IDLEDELAY bit field.

When there is new activity on the interconnect interface, the interconnect clock is restarted without any latency penalty. It is recommended to enable this mode to reduce power consumption.

9.2.3.3 System Power Management

The SMS can be configured through the SMS.SMS_SYSCONFIG register to be in one of these idle modes:

- No-idle mode (the SMS.SMS_SYSCONFIG[4:3] SIDLEMODE field is set to 0x1): The module never goes into idle state.
- Force-idle mode (the SMS.SMS_SYSCONFIG[4:3] SIDLEMODE field is set to 0x0): The module goes into idle state immediately after receiving the request from the PRCM.
- Smart-idle mode (the SMS.SMS_SYSCONFIG[4:3] SIDLEMODE field is set to 0x2): SideAck is asserted once the module has confirmed there are no more outstanding transactions with the EMIF .

9.2.3.4 External Memory Interface Module (EMIF)

9.2.3.4.1 EMIF Overview

This document is intended to provide programmers with a functional presentation of the External memory Interface module. It provides a register description. In this specification, the External memory Interface will be named EMIF.

9.2.3.4.1.1 Features Supported

The main features of the controller are:

- Open Core Protocol 2.2 (OCP) compliant [7].
- Supports JEDEC standard compliant DDR2 [2] and LPDDR1 [4] devices.
 - SDRAM address range over 2 chip selects.
 - Supports following data bus widths:

| OCP Data Bus Width | SDRAM Data Bus Width |
|--------------------|----------------------|
| 64 and 128-Bit | 16, 32, and 64-Bit |

- Supports following CAS latencies:

| SDRAM Type | CAS Latencies |
|------------|-------------------|
| DDR2 | 2, 3, 4, 5, and 6 |
| LPDDR1 | 2 and 3 |

- Supports following number of internal banks:

| SDRAM Type | Internal Banks |
|------------|----------------|
| DDR2 | 1, 2, 4, and 8 |
| LPDDR1 | 1, 2, and 4 |

- Supports 256, 512, 1024, and 2048-word page sizes.
- Supports following burst lengths:

| SDRAM Type | Burst Length |
|------------|---------------------------|
| DDR2 | 8 (4 not supported) |
| LPDDR1 | 8 (2 and 4 not supported) |

- Supports sequential burst type.
- SDRAM auto initialization from reset or configuration change.
- Supports Bank Interleaving across both the chip selects.
- Supports Clock Stop mode for LPDDR1 for low power.
- Supports Self Refresh and Precharge Power-Down modes for low power.
- Supports Partial Array Self Refresh and Temperature Controlled Self Refresh modes for low power in LPDDR1.
- Temperature Controlled Self Refresh is only supported for mobile SDRAM having on-chip temperature sensor.
- Supports ODT on DDR2.
- Supports prioritized refresh.
- Programmable SDRAM refresh rate and backlog counter.
- Programmable SDRAM timing parameters.
- Supports only little endian.

9.2.3.4.1.2 Features Not Supported

- Interleave burst type not supported.
- Auto Precharge not supported for better Bank Interleaving performance.
- OCD calibration not supported for DDR2.

- Active Power-Down is not supported.

9.2.3.4.2 Functional Description

9.2.3.4.2.1 Functional Overview

The External Memory Interface (EMIF) is a TI developed re-usable IP component targeted for SOC designs, "4" is the major version number and "A" is the configuration type. The EMIF is an OCP slave peripheral providing an interface to a wide variety of DDR SDRAM. This memory controller is a soft macro and must be used with the DDR PHY hard macros to interface to the DDR SDRAM.

Figure 9-45. EMIF4 Top Level Block Diagram

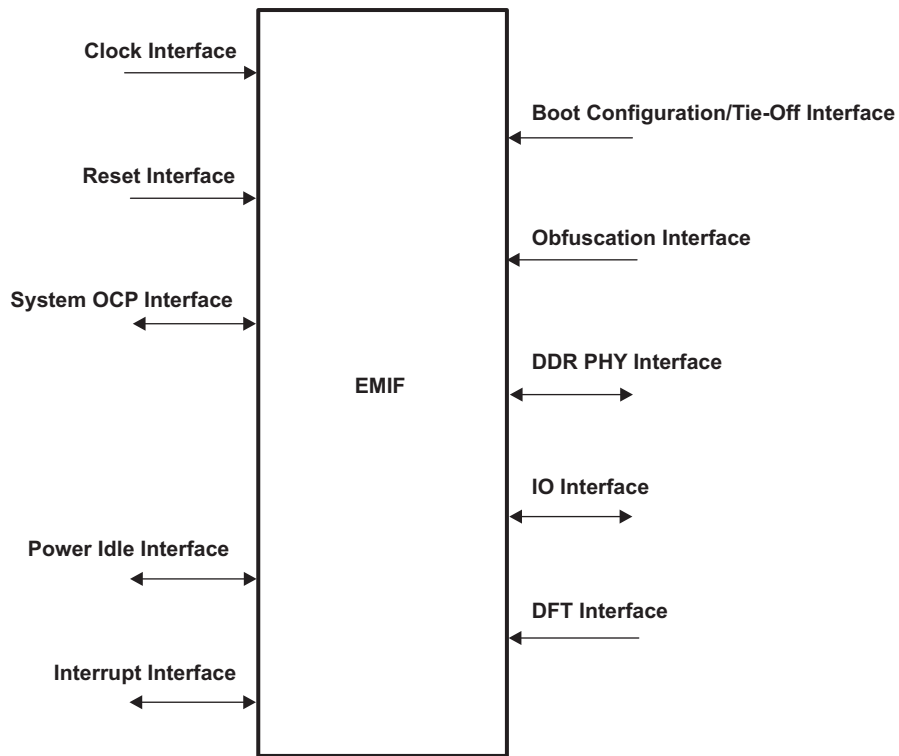

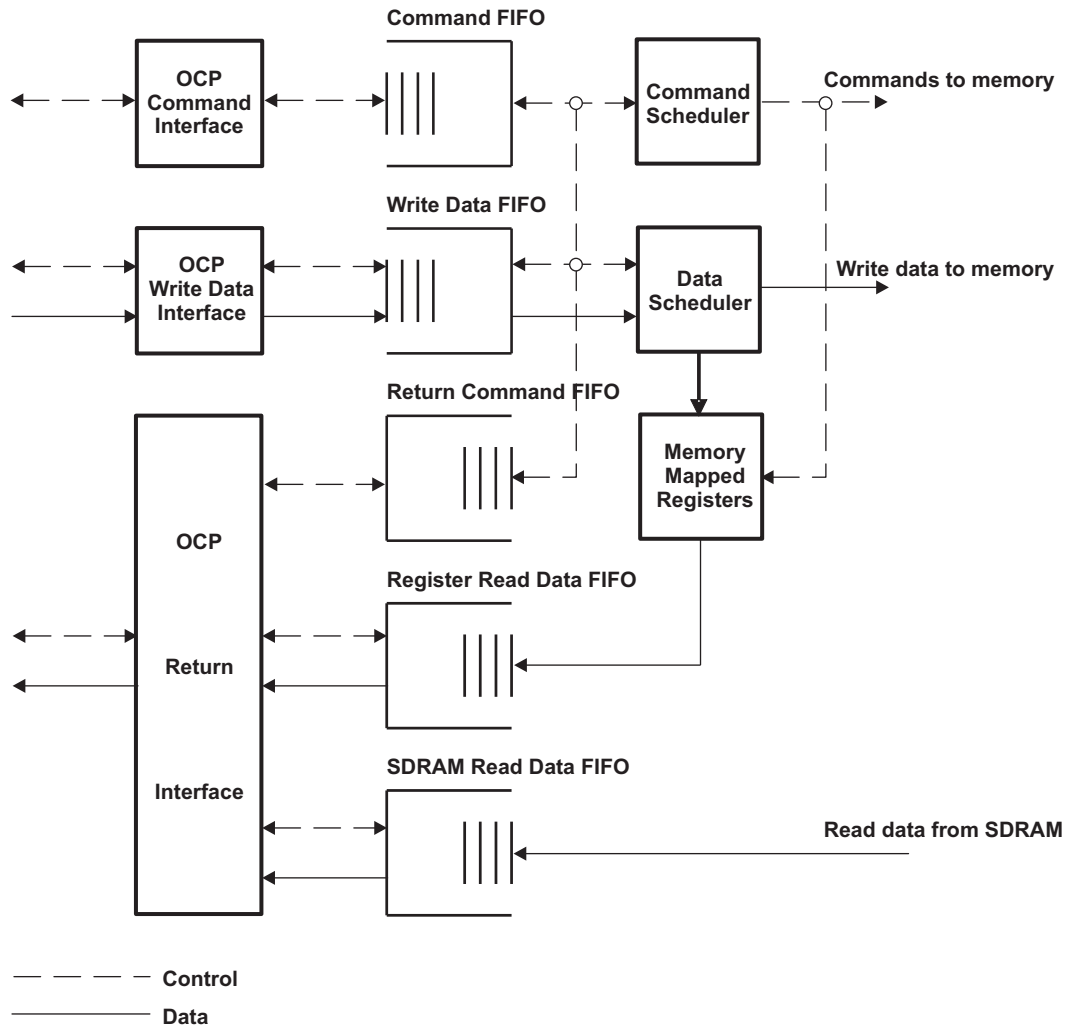

Table 9-64 shows the FIFO configurations of the EMIF.

Table 9-64. EMIF4A Configuration

| Parameter | Value |
|---------------------------------|--------------|
| OCP and Memory Clock Domains | Asynchronous |
| Command FIFO Entries | 7 |
| Write Data FIFO Entries | 14 |
| Return Command FIFO Entries | 22 |
| SDRAM Read Data FIFO Entries | 22 |
| Register Read Data FIFO Entries | 2 |

9.2.3.4.2.2 EMIF4 Architecture
Figure 9-46. EMIF4 Block Diagram

The EMIF contains a Command FIFO, a Write Data FIFO, a Return Command FIFO, and two Read Data FIFOs. These FIFOs are built using flip-flops.

The Command FIFO stores all the commands coming in on the OCP command interface. If the Write Data FIFO is not full, SCmdAccept is always asserted. If the EMIF is busy and the Write Data FIFO is full, the EMIF will de-assert SCmdAccept.

The Write Data FIFO stores the write data for all the write transactions coming in on the OCP write data interface. If the Write Data FIFO is not full, SDataAccept is always asserted. If the EMIF is busy and the Write Data FIFO is full, the EMIF will de-assert SDataAccept. The Write Data FIFO stores the write data for all the write transactions coming in on the OCP write data interface. If the Write Data FIFO is not full, SDataAccept is always asserted. If the EMIF is busy and the Write Data FIFO is full, the EMIF will de-assert SDataAccept.

The Return Command FIFO stores all the return transactions that are to be issued to the OCP return interface. These include the write status return and the read data return commands.

There are two Read Data FIFOs that store the read data to be sent to the OCP return interface. One Read Data FIFO stores read data from the memory mapped registers. The other Read Data FIFO stores read data from external memory.

A write command is executed only when four OCP words of the corresponding data is received in the Write Data FIFO, or MDataLast is set, and if there is space in the Return Command FIFO. The EMIF will schedule a read only if the results can fit into both the Return Command FIFO and the corresponding Read Data FIFOs.

9.2.3.4.2.3 OCP Interface

The EMIF supports one OCP interface that connects to the system interconnect. This interface is used to request all external memory device accesses, to access the EMIF registers, and to transfer all data to/from the EMIF. [Table 9-65](#) shows the MAddrSpace mapping to different chip selects.

Table 9-65. MAddrSpace Mapping to Chip Selects

| MAddrSpace | Chip Select | Description |
|------------|-----------------|--------------------|
| 0x0 | pad_cs_o_n[1:0] | SDRAM |
| 0x1 | N/A | Reserved |
| 0x2 | N/A | Reserved |
| 0x3 | N/A | Internal registers |

The EMIF only supports Idle, Write, Read, and WriteNonPost command types (as indicated by MCmd). If an access request for an unsupported command type is received, the EMIF will send out an interrupt and treat WriteConditional and Broadcast as a Write commands, and ReadEx and ReadLinked as a Read commands. In this case, the EMIF will perform writes on the memory bus with pad_dqm_o_n set to all ones. It will not perform writes to memory mapped registers. It will perform reads on the memory bus as well as memory mapped registers, but will return all zeros for read data.

The EMIF only supports incrementing, wrapping, and 2-dimensional block addressing modes (as indicated by MBurstSeq). If an access request for an unsupported addressing mode is received, the EMIF will send out an interrupt and treat the request as an incrementing request. In this case, the EMIF will perform writes on the memory bus with pad_dqm_o_n set to all ones. It will not perform writes to memory mapped registers. It will perform reads on the memory bus as well as memory mapped registers, but will return all zeros for read data.

If an access request to an unsupported MAddrSpace is received, the EMIF will send out an interrupt. In this case, the EMIF will not perform any writes or reads. However, it will return all zeros for read data.

For all of the above errored transactions, the EMIF will report an error (SResp = 3) on the OCP return interface. The EMIF will also log the MConnID, MCmd, MBurstSeq, and MAddrSpace for the first errored transaction in the OCP Error Log register.

The EMIF supports command priorities through the MReqPriority sideband signal. It supports 8 levels of priority. A value of 0 indicates highest priority and a value of 7 indicates lowest priority.

9.2.3.4.2.4 Arbitration

The EMIF looks at all the commands stored in the Command FIFO to schedule commands to the external memory. All commands with the same MTagID will complete in order, regardless of the MAddrSpace and MReqPriority. The EMIF does not guarantee ordering between commands with different MTagID. However, the EMIF will maintain data coherency. Therefore, the EMIF will block a command, regardless of priority, if that command is to the same block address (2048 bytes) as an older command.

Thus, the EMIF might have one pending read or write for each MTagID. Among all pending reads, the EMIF selects all reads that have their corresponding SDRAM banks already open. Similarly, among all pending writes, the EMIF selects all writes that have their corresponding SDRAM banks already open. Accesses to memory mapped registers are treated as accesses that have open banks.

As a result of the above reordering, the EMIF might now have several pending reads and writes that have their corresponding banks open. The EMIF then selects the highest priority read from pending reads, and the highest priority write from pending writes. If two or more commands have the highest priority, the EMIF selects the oldest command. As a result, the EMIF might now have a final read and a final write command. If the Return Command FIFO and the Read Data FIFO has space and the external bus conflict

is resolved, the EMIF performs the final read command before the final write command. If the Return Command FIFO has space but the Read Data FIFO is full and the external bus conflict is resolved, the EMIF performs the final write command before the final read command. Resolution of external bus conflict means all the SDRAM command to command counters are satisfied and the read to write or write to read turn around time is met.

The EMIF does not support tag interleaving (`tag_interleave_size = 0`). In other words, the EMIF completes executing an OCP command before it switches to another command.

The data coherency inside the EMIF is only guaranteed in a single level of OCP infrastructure. For example, if a write from a secondary OCP bus segment is blocked by a bridge element, the read from a tertiary bus can still beat the write to the EMIF. In such a case, in order to confirm that a write from master A has landed before a read from master B is performed, master A must wait for the write status from the EMIF before indicating to master B that the data is ready to be read. If master A does not use the OCP wait status, it must perform the following sequence of operations:

1. Perform the required write.
2. Perform a dummy write to the EMIF Module ID and Revision register.
3. Perform a dummy read to the EMIF Module ID and Revision register.
4. Indicate to the other master that the data is ready to be read after completion of read in step 3.

The completion of read in step 3 ensures that the previous writes were done.

Apart from reads and writes the EMIF also needs to open and close SDRAM banks, and maintain the refresh counts for an SDRAM. The priority of SDRAM commands with respect to refresh levels are as follows:

1. (Highest priority) SDRAM refresh request due to Refresh Must level of refresh urgency reached.
2. OCP request for a read without a higher priority write.
3. SDRAM refresh request due to Refresh Need level of refresh urgency reached.
4. OCP request for a write.
5. SDRAM Activate commands.
6. SDRAM Deactivate commands.
7. SDRAM Deep Power-Down request.
8. SDRAM clock stop request.
9. SDRAM refresh request due to Refresh May or Release level of refresh urgency reached.
10. (Lowest priority) SDRAM self-refresh or SDRAM Power-Down request.

While performing the above listed scheduling algorithm, the EMIF might run into following two conditions:

1. A continuous stream of high priority commands can block lower priority commands.
2. A continuous stream of SDRAM commands to a row in an open bank can block commands to another row in the same bank.

To avoid a continuous blocking effect, the EMIF momentarily raises the priority of the oldest command over all other commands when the number of memory accesses equals to the value programmed in the `reg_pr_old_count` field of the OCP Configuration register.

On top of the above scheduling, the highest priority condition is a rising edge on the `rst_por_arst_n` or `rst_main_arst_n` port (i.e. removal of reset). If this condition occurs, the EMIF abandons whatever it is currently doing and commences its start-up sequence. In this case, commands and data stored in the FIFOs are lost. The EMIF also commences its start-up sequence whenever the SDRAM Configuration register is written and `reg_initref_dis` field in SDRAM Refresh Control register is set to 0. In this case, commands and data stored in the FIFOs are not lost. The EMIF will ensure that in-flight read or write transactions to the SDRAM are complete before starting the initialization sequence.

All the accesses to an SDRAM are pipelined to maximize the external bus utilization. In other words accesses to an SDRAM are issued back to back such that there are minimum idle cycles between any two accesses. This includes the scheduling listed above to minimize the overhead of opening and closing of SDRAM banks. All of these is done while fulfilling the access timing requirements of an SDRAM.

9.2.3.4.2.5 SDRAM Refresh Scheduling

The EMIF uses two counters to schedule AUTO REFRESH commands: a 13-bit decrementing refresh interval counter and a 4-bit refresh backlog counter. The interval counter is loaded with the `reg_refresh_rate` field value at reset. The interval counter decrements by one each cycle until it reaches zero at which point it reloads from `reg_refresh_rate` and restarts decrementing. The counter also reloads and restarts decrementing whenever the `reg_refresh_rate` field is updated.

The refresh backlog counter records the number of AUTO REFRESH commands the EMIF currently has outstanding. The backlog counter increments by one each time the interval counter reloads (unless it has reached its maximum value of 15). The backlog counter decrements by one each time the EMIF issues an AUTO REFRESH command (unless it is already at zero). For the range of values that the backlog counter can take, there are three levels of urgency with which the EMIF should perform an auto refresh cycle (in which it issues AUTO REFRESH commands), as follows:

- Refresh May level is reached whenever the backlog count is greater than 0, to indicate that there is a refresh backlog, so if the EMIF is not busy and none of the SDRAM banks are open, it should perform an auto refresh cycle.
- Refresh Release level is reached whenever the backlog count is greater than 4, to indicate that the refresh backlog is getting high, so if the EMIF is not busy it should perform an auto refresh cycle even if any banks are open.
- Refresh Need level is reached whenever the backlog count is greater than 5, to indicate that the refresh backlog is getting high and the EMIF should raise the priority of performing an auto refresh cycle above that of servicing new memory write requests. The EMIF starts servicing new memory accesses after Refresh Release level is cleared.
- Refresh Must level is reached whenever the backlog count is greater than 7, to indicate that the refresh backlog is getting excessive and the EMIF should perform an auto refresh cycle before servicing any new memory access requests. The EMIF starts servicing new memory accesses after Refresh Release level is cleared.

The refresh counters do not operate when SDRAM has been put into self-refresh mode. Also, the refresh counters start tracking the missed refreshes only after initialization is complete.

The EMIF issues AUTO REFRESH commands within auto refresh cycles. An auto refresh cycle consists of issuing an AUTO REFRESH command and waiting `t_rfc` (refer to the SDRAM Timing 3 register) cycles before re-checking the refresh levels. If the Refresh Release level is not reached, the EMIF starts another auto refresh cycle, otherwise it returns to the idle state where it can issue any command.

9.2.3.4.2.6 SDRAM Initialization

9.2.3.4.2.6.1 LPDDR1 Initialization

On coming out of reset if the `reg_sdram_type` field in the SDRAM Config register is equal to 1 and the `reg_initref_dis` bit in the SDRAM Refresh Control register is set to 0, the EMIF performs a LPDDR1 SDRAM initialization sequence as follows:

1. Drives `pad_cke_o` high and starts to continuously issues NOP commands.
2. After 16 SDRAM refresh rate intervals, issues a PRECHARGE command with `pad_a_o[10]` held high to indicate all banks. The SDRAM refresh rate is as defined in the `reg_refresh_rate` field description (see description of SDRAM Refresh Control register).
3. After 2 AUTO REFRESH commands, issues a LOAD MODE REGISTER command to the mode register (`pad_ba_o[2:0] = 0x0`) with the `pad_a_o` bits set as follows:

| Bits | Value | Description |
|----------------------------|--------------------------|---|
| <code>pad_a_o[15:7]</code> | 0x0 | Normal operation. |
| <code>pad_a_o[6:4]</code> | <code>reg_cl[2:0]</code> | CAS latency from SDRAM Config register. |
| <code>pad_a_o[3]</code> | 0x0 | Sequential burst type. |
| <code>pad_a_o[2:0]</code> | 0x3 | Burst length of 8. |

- Issues a LOAD MODE REGISTER command to the extended mode register (pad_ba_o[2:0] = 0x2) with the pad_a_o bits set as follows:

| Bits | Value | Description |
|---------------|-----------------|---|
| pad_a_o[15:7] | 0x0 | Reserved. |
| pad_a_o[6:5] | reg_sdram_drive | Drive strength from SDRAM Config register. |
| pad_a_o[4:3] | 0x0 | Internal temperature compensated self-refresh. |
| pad_a_o[2:0] | reg_pasr | Partial array self-refresh from SDRAM Refresh Control register. |

- The EMIF performs an auto refresh cycle (see Refresh Controller section) after which it enters its idle state.

The EMIF also performs the initialization sequence whenever either of the SDRAM Configuration register is written. But in this case, the EMIF starts at step 3.

The LOAD MODE REGISTER command may be referred to as MODE REGISTER SET command in some LPDDR1 data sheets. The EMIF does not perform any transactions until the LPDDR1 initialization sequence is complete.

The reg_refresh_rate value at reset is config_refresh_def_val port value. When the EMIF comes out of reset, the delay time in step 2 resulting from the 16 refresh rate intervals + 8 cycles is approximately $16 * \text{reg_refresh_rate} / \text{input frequency}$. It is up to the user to tie off the config_refresh_def_val port with a correct value to meet the typical LPDDR1 device specified delay time of 200us between power-up and the application of the PRECHARGE all command.

9.2.3.4.2.6.2 DDR2 Initialization

On coming out of reset if the reg_sdram_type field in the SDRAM Configuration register is equal to 2 and the reg_initref_dis bit in the SDRAM Refresh Control register is set to 0, the EMIF performs a DDR2 SDRAM initialization sequence as follows:

- Drives pad_cke_o low.
- After 16 SDRAM refresh rate intervals, issues a NOP command with pad_cke_o held high. The SDRAM refresh rate is as defined in the reg_refresh_rate field description (see description of SDRAM Refresh Control register).
- After 1 SDRAM refresh rate interval, issues a PRECHARGE command with pad_a_o[10] held high to indicate all banks.
- Issues a LOAD MODE REGISTER command to the extended mode register 2 (pad_ba_o[2:0] = 0x2) with pad_a_o[15:0] = 0x0.
- Issues a LOAD MODE REGISTER command to the extended mode register 3 (pad_ba_o[2:0] = 0x3) with pad_a_o[15:0] = 0x0.
- Issues a LOAD MODE REGISTER command to the extended mode register 1 (pad_ba_o[2:0] = 0x1) with the pad_a_o bits set as follows:

| Bits | Value | Description |
|----------------|------------------|---|
| pad_a_o[15:13] | 0x0 | Reserved |
| pad_a_o[12] | 0x0 | Output buffer enabled |
| pad_a_o[11] | 0x0 | RDQS disable |
| pad_a_o[10] | !reg_dds2_ddqs | Differential DQS enable value from SDRAM Configuration register |
| pad_a_o[9:7] | 0x0 | Exit OCD calibration mode |
| pad_a_o[6] | reg_dds2_term[1] | DDR2 termination resistor value from SDRAM Configuration register |
| pad_a_o[5:3] | 0x0 | Additive latency = 0 |
| pad_a_o[2] | reg_dds2_term[0] | DDR2 termination resistor value from SDRAM Configuration register |
| pad_a_o[1] | reg_sdram_drive | SDRAM drive strength from SDRAM Configuration register |
| pad_a_o[0] | 0x0 | Enable DLL |

7. Issues a LOAD MODE REGISTER command to the mode register (`pad_ba_o[2:0] = 0x0`) with the `pad_a_o` bits set as follows:

| Bits | Value | Description |
|-----------------------------|--------------------------|--|
| <code>pad_a_o[15:13]</code> | 0x0 | Reserved |
| <code>pad_a_o[12]</code> | 0x0 | Fast exit active power-down exit time |
| <code>pad_a_o[11:9]</code> | <code>reg_t_wr</code> | Write recovery for auto precharge from SDRAM Timing 1 register |
| <code>pad_a_o[8]</code> | 0x1 | DLL reset |
| <code>pad_a_o[7]</code> | 0x0 | Normal mode |
| <code>pad_a_o[6:4]</code> | <code>reg_cl[2:0]</code> | CAS latency from SDRAM Configuration register |
| <code>pad_a_o[3]</code> | 0x0 | Sequential burst type |
| <code>pad_a_o[2:0]</code> | 0x3 | Burst length of 8 |

8. After 200 clock cycles, issues a PRECHARGE command with `pad_a_o[10]` held high to indicate all banks.
9. After 2 AUTO REFRESH commands, issues a LOAD MODE REGISTER command to the mode register (`pad_ba_o[2:0] = 0x0`) with the `pad_a_o` bits set as follows:

| Bits | Value | Description |
|----------------------------|-----------------|---------------|
| <code>pad_a_o[15:9]</code> | Equal to step 7 | |
| <code>pad_a_o[8]</code> | 0x0 | DLL not reset |
| <code>pad_a_o[7:0]</code> | Equal to step 7 | |

10. Issues a LOAD MODE REGISTER command to the extended mode register 1 (`pad_ba_o[2:0] = 0x1`) with the `pad_a_o` bits set as follows:

| Bits | Value | Description |
|-----------------------------|-----------------|-------------------------|
| <code>pad_a_o[15:10]</code> | Equal to step 6 | |
| <code>pad_a_o[9:7]</code> | 0x7 | Default OCD calibration |
| <code>pad_a_o[6:0]</code> | Equal to step 6 | |

11. Issues a LOAD MODE REGISTER command to the extended mode register 1 (`pad_ba_o[2:0] = 0x1`) with the `pad_a_o` bits equal to step 6.
12. If the `reg_ddr_disable_dll` bit in the SDRAM Configuration register is 1, issues a LOAD MODE REGISTER command to the extended mode register 1 (`pad_ba_o[2:0] = 0x1`) with the `pad_a_o` bits, set as follows:

| Bits | Value | Description |
|----------------------------|-----------------|-------------|
| <code>pad_a_o[15:1]</code> | Equal to step 6 | |
| <code>pad_a_o[0]</code> | 0x1 | Disable DLL |

13. The EMIF performs an auto refresh cycle (see Refresh Controller section) after which it enters its idle state.

The EMIF also performs the initialization sequence whenever either of the SDRAM Configuration register is written. But in this case, the EMIF starts at step 3.

The LOAD MODE REGISTER command may be referred to as MODE REGISTER SET command in some DDR2 datasheets. The EMIF does not perform any transactions until the DDR2 initialization sequence is complete.

The `reg_refresh_rate` value at reset is `config_refresh_def_val` port value. When the EMIF comes out of reset, the delay time in step 2 resulting from the 16 refresh rate intervals + 8 cycles is approximately $16 * \text{reg_refresh_rate} / \text{input frequency}$. It is up to the user to tie off the `config_refresh_def_val` port with a correct value to meet the typical DDR2 device specified delay time of 200us between power-up and the application of the PRECHARGE all command.

9.2.3.4.2.7 EMIF Access Cycles

By default the EMIF keeps SDRAM chip selects active. To direct a command to just one of the SDRAMs it deasserts the chip select to the other SDRAM for the duration of the command. If reg_ebank field in the SDRAM Configuration register is set to 0, chip select 1 will always be driven high except during initialization and for refresh, Power Down, Self Refresh, and Deep Power Down commands.

The EMIF always performs burst accesses to SDRAM. Multiple SDRAM bursts may be needed to service a single OCP burst request. Figure 9-47 to Figure 9-51 show a few examples on how EMIF accesses SDRAM for a linear incrementing transaction type. T0, T1, etc. are clock cycles. R0 is read starting at column 0, R8 is read starting at column 8, and R16 is read starting at column 16. D0-1 is the data from column 0 and 1, D2-3 is the data from column 2 and 3, and so on.

Figure 9-47. 64-Byte Linear Read Starting at Address 0x0

Figure 9-48. 64-Byte Linear Read Starting at Address 0x8 (LPDDR1)

Figure 9-49. 64-Byte Linear Read Starting at Address 0x8

Figure 9-50. 64-Byte Linear Read Starting at Address 0x10

Figure 9-51. 64-Byte Linear Read Starting at Address 0x18

EMIF will use the unused data phases in the above figure by issuing successive read commands if there are reads to open banks pending in the command FIFO.

The write data conversion from single data rate to double data rate must be done outside the EMIF. The SDRAM_DQS signal generation (with right timing) from the phy_dqs_en signal must also be done outside the EMIF.

9.2.3.4.2.8 Turn Around Time

Table 9-66 shows the turn around time that the EMIF introduces on the data bus for various back-to-back accesses. Note that the EMIF takes advantage of the CAS latencies and packs the commands as close as possible on the control bus to introduce the following turn around time on the data bus.

Table 9-66. Turn Around Time

| Previous Access | Next Access | Turn Around Time (# of m_clk cycles) |
|-----------------|-------------------------------------|--------------------------------------|
| SDRAM read | SDRAM read to same chip select | 0 |
| SDRAM read | SDRAM read to different chip select | 2 |

Table 9-66. Turn Around Time (continued)

| Previous Access | Next Access | Turn Around Time (# of m_clk cycles) |
|-----------------|-------------|---|
| SDRAM read | SDRAM write | 2 |
| SDRAM write | SDRAM write | 0 |
| SDRAM write | SDRAM read | 2 |

9.2.3.4.2.9 SDRAM Address Mapping

The SDRAM controller interleaves the internal banks for SDRAM connected to both the chip selects. From the system point of view, the external SDRAM is seen as one block of SDRAM. If smaller devices are used, the memory is seen to rollover. If two external 64 MB devices are used, a 128 MB memory block is observed. If two external 32 MB devices are used, a 64 MB block is observed.

When addressing SDRAM, if the `reg_ibank_pos` field in the SDRAM Configuration register is set to 0, the EMIF uses the 3 fields, `reg_ibank`, `reg_ebank` and `reg_pagesize` in the SDRAM Configuration register to determine the mapping from source address to SDRAM row, column, bank, and chip select. If the `reg_ibank_pos` field in the SDRAM Configuration register is set to 1, 2, or 3, the EMIF uses the 4 fields - `reg_ibank`, `reg_ebank`, `reg_pagesize`, and `reg_rowsize` in the SDRAM Configuration register to determine the mapping from source address to SDRAM row, column, bank, and chip select. In all cases the EMIF considers its SDRAM address space to be a single logical block regardless of the number of physical devices or whether the devices are mapped across 1 or 2 EMIF chip selects. For `reg_ibank_pos = 0`, [Table 9-67](#) and [Table 9-68](#) show which source address bits, MAddr, map to the SDRAM row, column, bank, and chip select bits for all combinations of `reg_ibank`, `reg_ebank`, and `reg_pagesize`. For `reg_ibank_pos != 0`, [Table 9-69](#) to [Table 9-71](#) shows which source address bits, MAddr, map to the SDRAM row, column, bank, and chip select bits for all combinations of `reg_ibank`, `reg_ebank`, `reg_pagesize`, and `reg_rowsize`. The tables also give the maximum size of the resulting SDRAM space.

Table 9-67. Address to SDRAM Address Mapping for 16-Bit SDRAM (reg_ibank_pos=0)

| Reach (Mbytes) | reg_ebank | reg_ibank | reg_page size | MAddr | | | | | | | | | | | | | | | | |
|-------------------|-----------|-----------|---------------|-------|-----|----|----|----|----|----|-------|------|------|------|-----|-----|----|------|------|-----|
| | | | | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24:16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8:01 | |
| 32 | 0 | 0 | 0 | - | | | | | | | row | | | | | | | col | | |
| 64 | 1 | 0 | 0 | - | | | | | | | row | | | | | | | cs | col | |
| 64 | 0 | 1 | 0 | - | | | | | | | row | | | | | | | bank | col | |

| 4096 | 1 | 3 | 3 | row | | | | | | | | | cs | bank | col | | | | |

For reg_ibank_pos = 0, the effect of the address-mapping scheme is that as the source address increments across SDRAM page boundaries, the EMIF moves onto the same page in the next bank in the current device (pad_cs_o_n[0]). This movement along the banks of the current device continues until the page has been accessed in all banks in the current device. The EMIF then proceeds to the same page in the next device (if reg_ebank = 1, pad_cs_o_n[1]) and proceeds through the same page in all its banks before moving over to the next page in the first device (pad_cs_o_n[0]). The EMIF exploits this traversal across internal banks and chip selects while remaining on the same page to maximize the number of open SDRAM banks within the overall SDRAM space.

Thus, the EMIF can keep a maximum of 16 banks (8 internal banks across 2 chip selects) open at a time, and can interleave among all of them.

Table 9-69. OCP Address to SDRAM Address Mapping for reg_ibank_pos=1

| MAddr[31:N] ⁽¹⁾ | | | | |
|--------------------------------|----------------------------------|--------------------------------|--------------------------------|-----------------------------------|
| Bank Address[2] | Row Address | Chip Select | Bank Address[1:0] | Column Address |
| # of bits defined by reg_ibank | # of bits defined by reg_rowsize | # of bits defined by reg_ebank | # of bits defined by reg_ibank | # of bits defined by reg_pagesize |
| reg_ibank=0 => 0 bits | reg_rowsize=0 => 9 bits | reg_ebank=0 => 0 bits | reg_ibank=0 => 0 bits | reg_pagesize=0 => 8 bits |
| reg_ibank=1 => 0 bits | reg_rowsize=1 => 10 bits | reg_ebank=1 => 1 bit | reg_ibank=1 => 1 bit | reg_pagesize=1 => 9 bits |
| reg_ibank=2 => 0 bits | reg_rowsize=2 => 11 bits | | reg_ibank=2 => 2 bits | reg_pagesize=2 => 10 bits |
| reg_ibank=3 => 1 bit | reg_rowsize=3 => 12 bits | | reg_ibank=3 => 2 bits | reg_pagesize=3 => 11 bits |
| | reg_rowsize=4 => 13 bits | | | |
| | reg_rowsize=5 => 14 bits | | | |
| | reg_rowsize=6 => 15 bits | | | |
| | reg_rowsize=7 => 16 bits | | | |

⁽¹⁾ N=1 for 16-bit SDRAM and N=2 for 32-bit SDRAM.

For reg_ibank_pos = 1, the EMIF interleaves banks the same as reg_ibank_pos = 0, but the interleaving of banks within a device (per chip select) is limited to 4 banks. Thus, the EMIF can keep a maximum of 16 banks (8 internal banks across 2 chip selects) open at a time, but can only interleave among 8 of them.

Table 9-70. OCP Address to SDRAM Address Mapping for reg_ibank_pos=2

| MAddr[31:N] ⁽¹⁾ | | | | |
|--------------------------------|----------------------------------|--------------------------------|--------------------------------|-----------------------------------|
| Bank Address[2:1] | Row Address | Chip Select | Bank Address[0] | Column Address |
| # of bits defined by reg_ibank | # of bits defined by reg_rowsize | # of bits defined by reg_ebank | # of bits defined by reg_ibank | # of bits defined by reg_pagesize |
| reg_ibank=0 => 0 bits | reg_rowsize=0 => 9 bits | reg_ebank=0 => 0 bits | reg_ibank=0 => 0 bits | reg_pagesize=0 => 8 bits |
| reg_ibank=1 => 0 bits | reg_rowsize=1 => 10 bits | reg_ebank=1 => 1 bit | reg_ibank=1 => 1 bit | reg_pagesize=1 => 9 bits |
| reg_ibank=2 => 1 bit | reg_rowsize=2 => 11 bits | | reg_ibank=2 => 1 bit | reg_pagesize=2 => 10 bits |
| reg_ibank=3 => 2 bits | reg_rowsize=3 => 12 bits | | reg_ibank=3 => 1 bit | reg_pagesize=3 => 11 bits |
| | reg_rowsize=4 => 13 bits | | | |
| | reg_rowsize=5 => 14 bits | | | |
| | reg_rowsize=6 => 15 bits | | | |
| | reg_rowsize=7 => 16 bits | | | |

⁽¹⁾ N=1 for 16-bit SDRAM and N=2 for 32-bit SDRAM.

For reg_ibank_pos = 2, the EMIF interleaves banks the same as reg_ibank_pos = 0, but the interleaving of banks within a device (per chip select) is limited to 2 banks. Thus, the EMIF can keep a maximum of 16 banks (8 internal banks across 2 chip selects) open at a time, but can only interleave among 4 of them.

Table 9-71. OCP Address to SDRAM Address Mapping for ibank_pos=3

| MAddr[31:N] ⁽¹⁾ | | | |
|--------------------------------|----------------------------------|--------------------------------|-----------------------------------|
| Bank Address | Row Address | Chip Select | Column Address |
| # of bits defined by reg_ibank | # of bits defined by reg_rowsize | # of bits defined by reg_ebank | # of bits defined by reg_pagesize |
| reg_ibank=0 => 0 bits | reg_rowsize=0 => 9 bits | reg_ebank=0 => 0 bits | reg_pagesize=0 => 8 bits |
| reg_ibank=1 => 1 bit | reg_rowsize=1 => 10 bits | reg_ebank=1 => 1 bit | reg_pagesize=1 => 9 bits |
| reg_ibank=2 => 2 bits | reg_rowsize=2 => 11 bits | | reg_pagesize=2 => 10 bits |
| reg_ibank=3 => 3 bits | reg_rowsize=3 => 12 bits | | reg_pagesize=3 => 11 bits |
| | reg_rowsize=4 => 13 bits | | |
| | reg_rowsize=5 => 14 bits | | |
| | reg_rowsize=6 => 15 bits | | |
| | reg_rowsize=7 => 16 bits | | |

⁽¹⁾ N=1 for 16-bit SDRAM and N=2 for 32-bit SDRAM.

For reg_ibank_pos = 3, the EMIF cannot interleave banks within a device (per chip select). However, it can still interleave banks between the two chip selects. Thus, the EMIF can keep a maximum of 16 banks (8 internal banks across 2 chip selects) open at a time, but can only interleave among 2 of them.

Since the EMIF interleave among less number of banks when reg_ibank_pos != 0, these cases are lower in performance than the reg_ibank_pos = 0 case. Thus these cases are only recommended to be used along with partial array self-refresh where performance can be traded off for power savings.

9.2.3.4.2.10 Endian Support

The order in which bytes on the OCP port data bus is written to or read from devices that are not as wide as OCP port data bus is determined by the setting of the config_big_endian pin at the time of an access. The EMIF maintains the natural order of endian operations. That is, if a byte stream of data starting at any address n within any endian environment will always be accessed in the correct or incrementing byte order. The EMIF will always access address n prior to n+1 in all endian modes and in any byte width.

Since the endian mode must be known prior to the CPU booting, the endian mode pin on the EMIF and the booting CPU are normally registered by a boot options register at reset time. The setting of the config_big_endian pin is reflected in the be bit of the Status register.

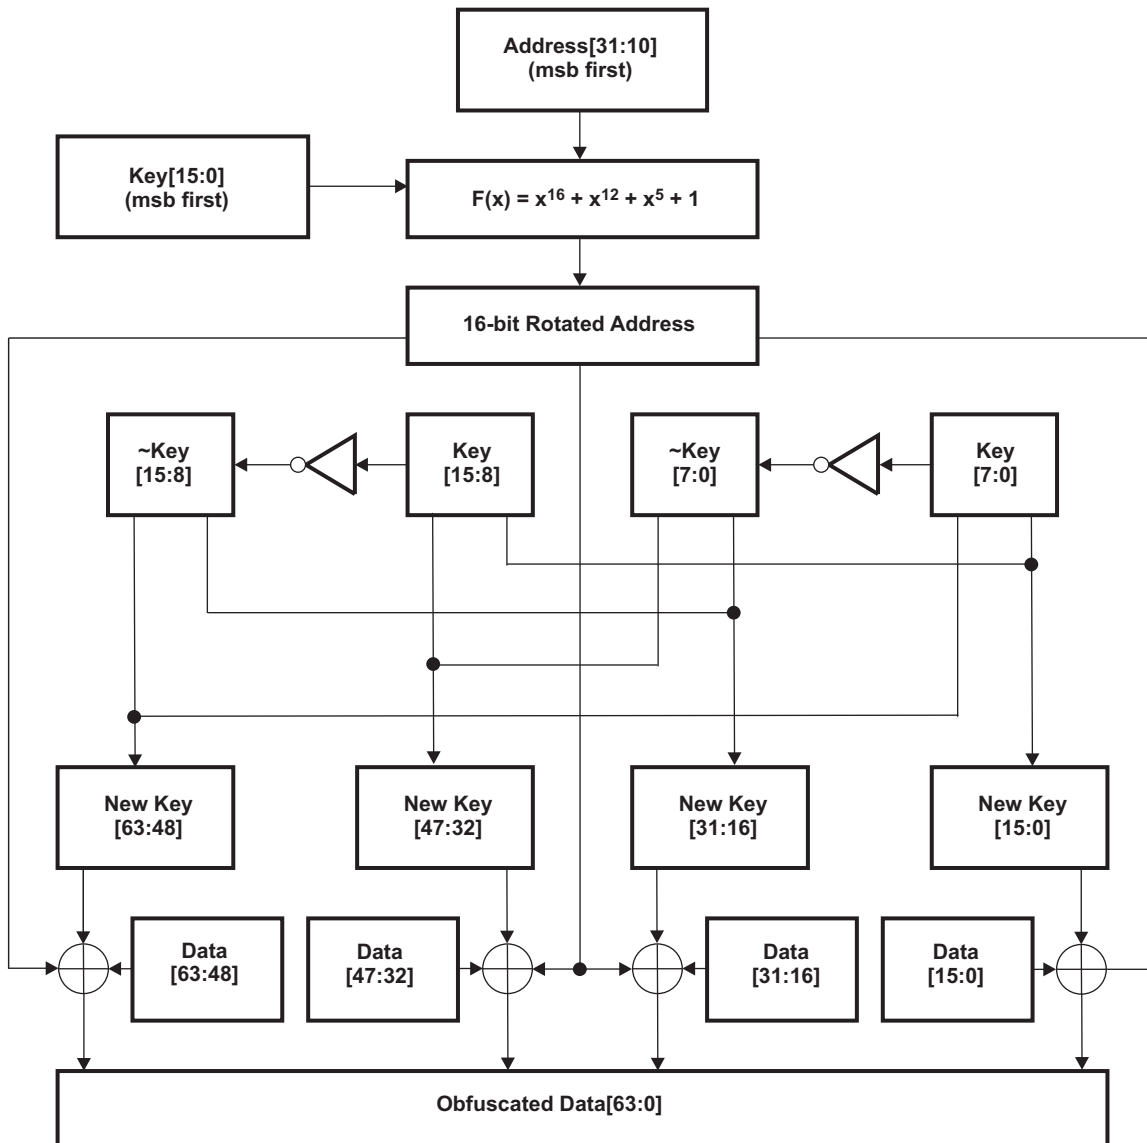

9.2.3.4.2.11 Data Bus Obfuscation

For security, the EMIF supports obfuscation for data written to the SDRAM. The obfuscation scheme for data written to the SDRAM is shown in [Figure 9-52](#). The 16-bit key for obfuscation is sourced from the obfuscation_key port. The key can be a tie-off, or can come from a separate module at chip level, or can also come from efuse. Before it is used, the key is further modified, as shown in [Figure 9-52](#), to create a 64-bit new key. Data will be obfuscated going out of the EMIF to the DDR PHY, and will be de-obfuscated going back to the master.

To ensure that the obfuscation is different for different regions of the memory, the upper address bits, MAddr[31:10], are taken through a LFSR function to generate a 16-bit rotated address. The obfuscation_key is used as a seed for the LFSR.

The data is then XOR'd with four copies of the 16-bit rotated address and the 64-bit new key. This ensures that the obfuscation will be different for each 1 KB page of the memory. It also helps EMIF to keep the obfuscation transparent to a master that reads or writes the memory in different transaction sizes.

Figure 9-52. Data Bus Obfuscation

9.2.3.4.2.12 Pipeline Latency

Following is the information on read latency through the EMIF and DDR PHY sub-system. EMIF is assumed to be idle, i.e., not performing any operations on the external interface and the Command FIFO is empty. Also, the read is assumed to be to an open row.

1 ocp_clk cycle - EMIF captures OCP command

1 ocp_clk cycle - SDRAM address calculation

3 m_clk cycles - synchronizer delay to memory clock (EMIF uses a 2 clock synchronizer plus 1 clock for the flop after the synchronizer)

1 m_clk cycle - command to external interface

1 m_clk cycle - SDRAM registers command

CL m_clk cycles - CAS latency

PL m_clk cycles - DDR PHY latency (minimum 1 to maximum 8 cycles depending on system round trip delay)

DC m_clk cycles - data capture/reassembly to Read Data FIFO

3 ocp_clk cycles - synchronizer delay to memory clock (EMIF uses a 2 clock synchronizer plus 1 clock for the flop after the synchronizer)

1 ocp_clk cycle - read request with data/status to OCP interface

((6 ocp_clk cycles) + ((6+CL+PL+DC) m_clk cycles)) total from request rising to first data produced on the OCP interface

SV and SM = 0 if ocp_clk and m_clk are synchronous

DC = 1 for OCP to SDRAM data width ratio of 1:2

DC = 2 for OCP to SDRAM data width ratio of 1:4

9.2.3.4.2.13 Special Operation for Integration with SMS

The EMIF supports a single bit sys_MReqMisc signal to enable a special operation for integration with SMS. This special mechanism is required by SMS to improve the overall system performance for high priority commands.

The EMIF will deassert sys_SCmdAccept output whenever the Command FIFO inside the EMIF has 4 commands that have the sys_MReqMisc signal set high. A fifth command with sys_MReqMisc high might already be in the pipe in front of the Command FIFO. In other words, either 4 or 5 command that have sys_MReqMisc signal high will be present inside the EMIF when EMIF drives sys_SCmdAccept low.

The SMS will ensure that the sys_MReqMisc signal is asserted high only for the commands required to be counted by the EMIF to apply back pressure. All other commands will have sys_MReqMisc set to 0. For systems without the SMS, the sys_MReqMisc signal must be tied low.

9.2.3.4.3 EMIF Registers

The following section describes the register map and register definition in ascending order. The state of each register after reset is shown.

For an EMIF with OCP data width greater than 32 bits, the 32-bit words are swapped internally depending on the endianness to keep the register memory map same for both little and big endian modes. This allows the same boot code to be run regardless of endianness. For example, for a 64-bit OCP data width, see [Table 9-72](#).

Table 9-72. 64-bit OCP Data Width

| Endian | Bits 63:32 | Bits 31:0 |
|--------|--------------------------------------|--------------------------------------|
| Little | SDRAM Status Register | EMIF Module ID and Revision Register |
| Big | EMIF Module ID and Revision Register | SDRAM Status Register |

9.2.3.4.3.2 Register Descriptions

9.2.3.4.3.2.1 EMIF Module ID and Revision Register (EMIF_MOD_ID_REV)

The EMIF Module ID and Revision Register (EMIF_MOD_ID_REV) is shown in [Figure 9-53](#) and described in [Table 9-74](#).

Figure 9-53. EMIF Module ID and Revision Register (EMIF_MOD_ID_REV)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-74. EMIF Module ID and Revision Register (EMIF_MOD_ID_REV) Field Descriptions

| Bit | Field | Value | Description |
|-------|--------------------|--------|--|
| 31-30 | REG_SCHEME | 0-3h | Used to distinguish between old and current revision schemes. 0 means old scheme. 1 means new scheme. The present register format is compliant to the new scheme. Old scheme had a different format for this register. |
| 29-28 | Reserved | 0 | These reserved bit locations are always read as zeros. A value written to this field has no effect. |
| 27-16 | REG_MODULE_ID | 0-FFFh | EMIF module ID. |
| 15-11 | REG_RTL_VERSION | 0-Fh | RTL Version. |
| 10-8 | REG_MAJOR_REVISION | 0-7h | Major Revision. |
| 7-6 | Reserved | 0 | Reserved. |
| 5-0 | REG_MINOR_REVISION | 0-3Fh | Minor Revision. |

9.2.3.4.3.2.2 SDRAM Status Register (STATUS)

The SDRAM Status Register (STATUS) is shown in [Figure 9-54](#) and described in [Table 9-75](#).

Figure 9-54. SDRAM Status Register (STATUS)

| | | | | |
|--------|-------------------|-------------------|----------|----|
| 31 | 30 | 29 | 28 | 24 |
| REG_BE | REG_DUAL_CLK_MODE | REG_FAST_INIT | Reserved | |
| R-0 | R-0 | R-0 | R-0 | |
| 23 | Reserved | | | 16 |
| R-0 | | | | |
| 15 | Reserved | | | 8 |
| R-0 | | | | |
| 7 | Reserved | | 2 | 0 |
| R-0 | | REG_PHY_DLL_READY | Reserved | |
| R-0 | | R-0 | R-0 | |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-75. SDRAM Status Register (STATUS) Field Descriptions

| Bit | Field | Value | Description |
|------|-------------------|-------|---|
| 31 | REG_BE | | Big Endian. Reflects the value on the config_big_endian port that defines whether the EMIF is in big or little endian mode. |
| 30 | REG_DUAL_CLK_MODE | | Dual Clock mode. Reflects the value on the config_dual_clk_mode port that defines whether the ocp_clk and m_clk are asynchronous. |
| 29 | REG_FAST_INIT | | Fast Initialization. Reflects the value on the config_fast_init port that defines whether the EMIF fast initialization mode has been enabled. |
| 28-3 | Reserved | 0 | Reserved. |
| 2 | REG_PHY_DLL_READY | | DDR PHY Ready. Reflects the value on the phy_ready port (active high) that defines whether the DDR PHY is ready for normal operation. |
| 1-0 | Reserved | 0 | Reserved. |

9.2.3.4.3.2.3 SDRAM Configuration Register (SDRAM_CONFIG)

The SDRAM Configuration Register (SDRAM_CONFIG) is shown in [Figure 9-55](#) and described in [Table 9-76](#).

NOTE:

1. This register can only be written if lock_config_ctrl port is set to 0.
2. A write to this register will cause the EMIF to start the SDRAM initialization sequence for DDR2.
3. If reg_cl field is changed, the read latency in the PHY Control 1 register must also be reprogrammed to the correct value.

Table 9-76. SDRAM Configuration Register (SDRAM_CONFIG) Field Descriptions

| Bit | Field | Value | Description |
|-------|---------------------|-------|--|
| 31-29 | REG_SDRAM_TYPE | 0-7h | SDRAM Type selection. Set to 0 for DDR1, set to 1 for LPDDR1, set to 2 for DDR2. All other values are reserved. |
| 28-27 | REG_IBANK_POS | 0-3h | Internal bank position. Set to 0 to assign internal bank address bits from OCP address as shown in Table 4, 5, and 6. Set to 1, 2, or 3 to assign internal bank address bits from OCP address as shown in Table 7, 8, or 9 respectively. |
| 26-24 | REG_DDR_TERM | 0-7h | DDR2 termination resistor value. Set to 0 to disable termination. Set to 1 for 75 ohm, set to 2 for 150 ohm, and set to 3 for 50 ohm. All other values are reserved. |
| 23 | REG_DDR2_DDQS | 0-1h | DDR2 differential DQS enable. Set to 0 for single ended DQS. Set to 1 for differential DQS. |
| 22-21 | RESERVED | 0 | Reserved. |
| 20 | REG_DDR_DISABLE_DLL | 0-1h | Disable DLL select. Set to 1 to disable DLL inside SDRAM. |
| 19-18 | REG_SDRAM_DRIVE | 0-3h | SDRAM drive strength. For DDR1, set to 0 for normal, and set to 1 for weak drive strength. For DDR2, set to 0 for full, and set to 1 for reduced drive strength. For LPDDR1, set to 0 for full, set to 1 for 1/2, set to 2 for 1/4, and set to 3 for 1/8 drive strength. All other values are reserved. |
| 17-16 | RESERVED | 0 | Reserved. |
| 15-14 | REG_NARROW_MODE | 0-3h | SDRAM data bus width. Set to 0 for 32-bit and set to 1 for 16-bit. All other values are reserved. |
| 13-10 | REG_CL | 0-Fh | CAS Latency. The value of this field defines the CAS latency to be used when accessing connected SDRAM devices. Value of 2, 3, 5, and 6 (CAS latency of 2, 3, 1.5, and 2.5) are supported for DDR1. Value of 2, 3, 4, 5, and 6 (CAS latency of 2, 3, 4, 5, and 6) are supported for DDR2. Value of 2 and 3 (CAS latency of 2 and 3) are supported for LPDDR1. All other values are reserved. |

Table 9-76. SDRAM Configuration Register (SDRAM_CONFIG) Field Descriptions (continued)

| Bit | Field | Value | Description |
|-----|--------------|-------|---|
| 9-7 | REG_ROWSIZE | 0-7h | Row Size. Defines the number of row address bits of connected SDRAM devices. Set to 0 for 9 row bits, set to 1 for 10 row bits, set to 2 for 11 row bits, set to 3 for 12 row bits, set to 4 for 13 row bits, set to 5 for 14 row bits, set to 6 for 15 row bits, and set to 7 for 16 row bits. This field is only used when reg_ibank_pos field in SDRAM Config register is set to 1, 2, or 3. |
| 6-4 | REG_IBANK | 0-7h | Internal Bank setup. Defines number of banks inside connected SDRAM devices. Set to 0 for 1 bank, set to 1 for 2 banks, set to 2 for 4 banks, and set to 3 for 8 banks. All other values are reserved. |
| 3 | REG_EBANK | 0-1h | External chip select setup. Defines whether SDRAM accesses will use 1 or 2 chip select lines. Set to 0 to use pad_cs_o_n[0] only. Set to 1 to use pad_cs_o_n[1:0]. |
| 2-0 | REG_PAGESIZE | 0-7h | Page Size. Defines the internal page size of connected SDRAM devices. Set to 0 for 256-word page (8 column bits), set to 1 for 512-word page (9 column bits), set to 2 for 1024-word page (10 column bits), and set to 3 for 2048-word page (11 column bits). All other values are reserved. |

9.2.3.4.3.2.4 SDRAM Refresh Control Register (SDRAM_REF_CTRL)

The SDRAM Refresh Control Register (SDRAM_REF_CTRL) is shown in [Figure 9-56](#) and described in [Table 9-77](#).

NOTE: The `reg_refresh_rate` is the number of clock cycles required to cause a refresh interval of 7.8 us or 15.7 us for the appropriate SDRAM used. This field is not byte writable, i.e., all 16 bits of this field need to be written simultaneously. A 125 MHz memory system requires a $15.7 * 125 = 1962$ or 0x7AA value to be written to the SDRAM Refresh Control register. If the SDRAM requires a 7.8 us refresh rate instead of a 15.7 us, then one-half the value should be written.

Figure 9-56. SDRAM Refresh Control Register (SDRAM_REF_CTRL)

| | | | | |
|-----------------|------------------|----|----------|----|
| 31 | 30 | 27 | 26 | 24 |
| REG_INITREF_DIS | Reserved | | REG_PASR | |

| R/W- | | | | |
| 7 | REG_REFRESH_RATE | | | 0 |
| R/W- | | | | |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-77. SDRAM Refresh Control Register (SDRAM_REF_CTRL) Field Descriptions

| Bit | Field | Value | Description |
|-------|------------------|---------|--|
| 31 | REG_INITREF_DIS | 0-1h | Initialization and Refresh disable. When set to 1, EMIF will disable SDRAM initialization and refreshes, but will carry out SDRAM write/read transactions. |
| 30-27 | Reserved | 0 | Reserved. |
| 26-24 | REG_PASR | 0-7h | Partial Array Self Refresh. These bits get loaded into the Extended Mode Register of an LPDDR1 during initialization. Set to 0 for full array, set to 1 for 1/2 array, set to 2 for 1/4 array, set to 5 for 1/8 array, and set to 6 for 1/16 array to be refreshed. All other values are reserved. A write to this field will cause the EMIF to start the SDRAM initialization sequence. |
| 23-16 | Reserved | 0 | Reserved. |
| 15-0 | REG_REFRESH_RATE | 0-FFFFh | Refresh Rate. Value in this field is used to define the rate at which connected SDRAM devices will be refreshed. SDRAM refresh rate = EMIF rate / <code>reg_refresh_rate</code> where EMIF rate is equal to <code>m_clk</code> rate. If this value is less than 0x80 and the <code>reg_t_rfc</code> value in SDRAM Timing 3 register is less than 0x40, this field will be loaded with 0x80. If this value is less than <code>reg_t_rfc</code> times 2, than it is loaded with <code>reg_t_rfc</code> times 2. |

9.2.3.4.3.2.5 SDRAM Refresh Control Shadow Register (SDRAM_REF_CTRL_SHDW)

The SDRAM Refresh Control Shadow Register (SDRAM_REF_CTRL_SHDW) is shown in [Figure 9-57](#) and described in [Table 9-78](#).

Figure 9-57. SDRAM Refresh Control Shadow Register (SDRAM_REF_CTRL_SHDW)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

| 31-16 | Reserved | 0 | Reserved. |
| 15-0 | REG_REFRESH_RATE_SHDW | 0-FFFFh | Shadow field for reg_refresh_rate. This field is loaded into reg_refresh_rate field in SDRAM Refresh Control register when SIdleAck is asserted. |

9.2.3.4.3.2.6 SDRAM Timing 1 Register (SDRAM_TIM_1)

The SDRAM Timing 1 Register (SDRAM_TIM_1) is shown in [Figure 9-58](#) and described in [Table 9-79](#).

NOTE: If this register is byte written, care must be taken that all the fields are written before performing any accesses to the SDRAM.

Figure 9-58. SDRAM Timing 1 Register (SDRAM_TIM_1)

| 2-0 | REG_T_CKE_SHDW | 0-7h | Shadow field for reg_t_cke. This field is loaded into reg_t_cke field in SDRAM Timing 2 register when SIdleAck is asserted. |

9.2.3.4.3.2.10 SDRAM Timing 3 Register (SDRAM_TIM_3)

The SDRAM Timing 3 Register (SDRAM_TIM_3) is shown in [Figure 9-62](#) and described in [Table 9-83](#).

NOTE:

1. If this register is byte written, care must be taken that all the fields are written before performing any accesses to the SDRAM.
2. Value for reg_t_ras_max can be calculated as follows:
 - o If tRASmax = 120 us and tREFI = 15.7 us, then $\text{reg_t_ras_max} = ((120/15.7)-1) = 6.64$.
 - o Round down to the next lower integer. Therefore, the programmed value must be 6.

| Bit | Field | Value | Description |
|-------|--------------|-------|--|
| 31-30 | REG_IDLEMODE | 0-3h | Power-Idle IP Generic mode. Set to 0 for force-idle mo Power-Idle IP Generic mode. Set to 0 for force-idle mode, where EMIF acknowledges the system's idle requests unconditionally, i.e. regardless of the EMIF's internal requirements. Backup mode, for debug only. Set to 1 for no-idle mode, where EMIF will never enter idle state. Backup mode, for debug only. Set to 2 for smart-idle mode, where EMIF's idle state eventually follows (acknowledges) the system's idle requests, depending on EMIF's internal requirements. Setting of 3 (smart-idle wakeup-capable mode) is not supported. |
| 31-11 | Reserved | 0 | Reserved. |
| 10 | REG_DPD_EN | 0-1h | Deep Power-Down enable. Set to 0 for normal operation. Set to 1 to enter Deep Power-Down mode. This mode will override the reg_lp_mode field setting. |
| 9-8 | REG_LP_MODE | 0-3h | Automatic Power Management enable. Set to 1 for Clock Stop, set to 2 for Self Refresh, and set to 3 for Power-Down. Set to 0 to disable automatic power management. Reserved for future use. |
| 7-4 | Reserved | 0 | Reserved. |
| 3-0 | REG_PM_TIM | 0-Fh | Power Management timer. The EMIF will put the external SDRAM in a power saving mode after the EMIF is idle for these number of m_clk cycles. The power saving mode is chosen by the reg_lp_mode field. Set to 0 to immediately enter the power savings mode. Set to 1 for 16 clocks, set to 2 for 32 clocks, set to 3 for 64 clocks, set to 4 for 128 clocks, set to 5 for 256 clocks, set to 6 for 512 clocks, set to 7 for 1024 clocks, set to 8 for 2048 clocks, set to 9 for 4096 clocks, set to 10 for 8192 clocks, set to 11 for 16384 clocks, set to 12 for 32768 clocks, set to 13 for 65536 clocks, set to 14 for 131072 clocks, and set to 15 for 262144 clocks. |

9.2.3.4.3.2.13 Power Management Control Shadow Register (PWR_MGMT_CTRL_SHDW)

The Power Management Control Shadow Register (PWR_MGMT_CTRL_SHDW) is shown in [Figure 9-65](#) and described in [Table 9-86](#).

Figure 9-65. Power Management Control Shadow Register (PWR_MGMT_CTRL_SHDW)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-86. Power Management Control Shadow Register (PWR_MGMT_CTRL_SHDW) Field Descriptions

| Bit | Field | Value | Description |
|------|-----------------|-------|---|
| 31-4 | Reserved | 0 | Reserved |
| 3-0 | REG_PM_TIM_SHDW | 0-Fh | Shadow field for reg_pm_tim. This field is loaded into reg_pm_tim field in Power Management Control register when SIdleAck is asserted. |

9.2.3.4.3.2.14 OCP Configuration Register (OCP_CONFIG)

The OCP Configuration Register (OCP_CONFIG) is shown in [Figure 9-66](#) and described in [Table 9-87](#).

Figure 9-66. OCP Configuration Register (OCP_CONFIG)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-87. OCP Configuration Register (OCP_CONFIG) Field Descriptions

| Bit | Field | Value | Description |
|------|------------------|-------|--|
| 31-8 | Reserved | 0 | Reserved |
| 7-0 | REG_PR_OLD_COUNT | 0-FFh | Priority Raise Old Counter. Number of memory transfers after which the EMIF momentarily raises the priority of old commands in the OCP Command FIFO. |

9.2.3.4.3.2.15 OCP Configuration Value 1 Register (OCP_CFG_VAL_1)

The CP Configuration Value 1 Register (OCP_CFG_VAL_1) is shown in [Figure 9-67](#) and described in [Table 9-88](#).

Figure 9-67. OCP Configuration Value 1 Register (OCP_CFG_VAL_1)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-88. OCP Configuration Value 1 Register (OCP_CFG_VAL_1) Field Descriptions

| Bit | Field | Value | Description |
|-------|--------------------|-------|--|
| 31-30 | REG_SYS_BUS_WIDTH | 0-3h | L3 OCP data bus width for a particular configuration. 0 = 32-bit wide, 1 = 64-bit wide, 2 = 128-bit wide, and 3 = Reserved |
| 29-16 | Reserved | 0 | Reserved |
| 15-8 | REG_WR_FIFO_DEPTH | 0-FFh | Write Data FIFO depth for a particular configuration. |
| 7-0 | REG_CMD_FIFO_DEPTH | 0-FFh | Command FIFO depth for a particular configuration. |

9.2.3.4.3.2.16 OCP Configuration Value 2 Register (OCP_CFG_VAL_2)

The OCP Configuration Value 2 Register (OCP_CFG_VAL_2) is shown in [Figure 9-68](#) and described in [Table 9-89](#).

Figure 9-68. OCP Configuration Value 2 Register (OCP_CFG_VAL_2)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

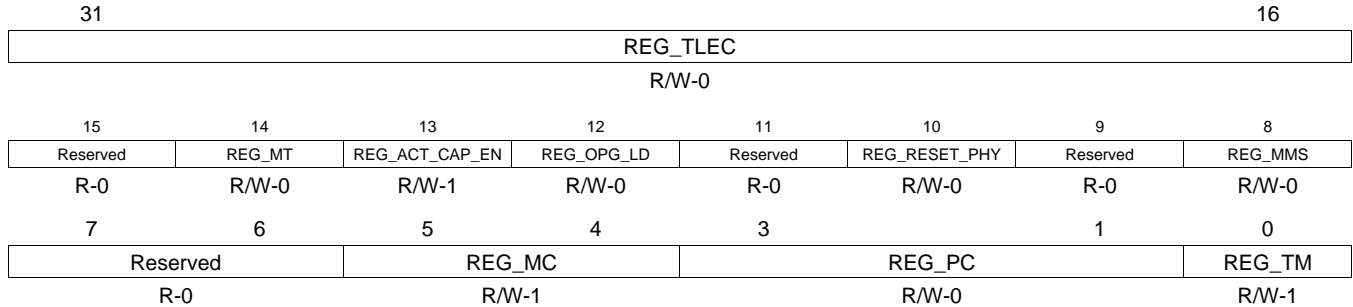

Table 9-89. OCP Configuration Value 2 Register (OCP_CFG_VAL_2) Field Descriptions

| Bit | Field | Value | Description |
|-------|---------------------|-------|---|
| 31-24 | Reserved | 0 | Reserved |
| 23-16 | REG_RREG_FIFO_DEPTH | 0-FFh | Register Read Data FIFO depth for a particular configuration. |
| 15-8 | REG_RSD_FIFO_DEPTH | 0-FFh | SDRAM Read Data FIFO depth for a particular configuration. |
| 7-0 | REG_RCMD_FIFO_DEPTH | 0-FFh | Read Command FIFO depth for a particular configuration. |

9.2.3.4.3.2.17 IODFT Test Logic Global Control Register (IODFT_TLGC)

The IODFT Test Logic Global Control Register (IODFT_TLGC) is shown in Figure 9-69 and described in Table 9-90.

Figure 9-69. IODFT Test Logic Global Control Register (IODFT_TLGC)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-90. IODFT Test Logic Global Control Register (IODFT_TLGC) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------------|---------|--|
| 31-16 | REG_TLEC | 0-FFFFh | IODFT Test Logic Execution Counter. Contains the number of cycle that the MISR signature will be accumulated. Upon the expiration of the counter the MISR capture will be turned off. |
| 15 | Reserved | 0 | Reserved |
| 14 | REG_MT | 0-1h | MISR on/off trigger command. 0x0 = inactive/no affect. 0x1 = MISR capture start on the first write or read command to the memory and continues to update the signature until reg_tlec expires, when mc = 0x3. 0x1 = pattern generator starts on the first write or read command to the memory and continues to update the signature until reg_tlec expires, when pc = 0x1, 0x2, 0x3, 0x5, 0x6, or 0x7. These bits are cleared when reg_tlec expires. |
| 13 | REG_ACT_CAP_EN | 0-1h | Active cycles capture enable. If set to a 1 the MISRs and pattern generators will shift only during active cycles. If set to a 0 the MISRs and pattern generators will shift every clock cycle. |
| 12 | REG_OPG_LD | 0-1h | Load pattern generators' initial value. Set to 1 to load an initial value in the pattern generators from reg_tlec. |
| 11 | Reserved | 0 | Reserved. |
| 10 | REG_RESET_PHY | 0-1h | Reset DDR PHY. Writing a 1 to this bit will reset the DDR PHY. This bit will self clear to 0. |
| 9 | Reserved | 0 | Reserved. |
| 8 | REG_MMS | 0-1h | Chooses the source of the MISR input. Set to 0 for output register, and set to 1 for input capture. |
| 7-6 | Reserved | 0 | Reserved. |
| 5-4 | REG_MC | 0-3h | MISR state. Set to 0 to download results. Set to 1 to hold current value. Set to 2 to load initial value from pc bits. Set to 3 to enable MISR to capture signature. |
| 3-1 | REG_PC | 0-7h | Pattern code. Defines the type of pattern that is selected for the pattern generators. Set to 0 for functional mode and set to 4 to hold current register value. Set to 5 for random XOR, set to 6 for random XNOR, and set to 7 for an 8 bit shifter. All other values are reserved. |
| 0 | REG_TM | 0-1h | Functional mode enable. Set to 1 for functional mode, and set to 0 for IODFT mode. |

9.2.3.4.3.2.18 IODFT Test Logic Control MISR Result Register (IODFT_CTRL_MISR_RSLT)

The IODFT Test Logic Control MISR Result Register is shown in [Figure 9-70](#) and described in [Table 9-91](#).

Figure 9-70. IODFT Test Logic Control MISR Result Register (IODFT_CTRL_MISR_RSLT)

| | | | | |
|----------|--------------|----------|--------------|---|
| 31 | 26 25 | 16 15 | 11 10 | 0 |
| Reserved | REG_DQM_TLMR | Reserved | REG_CTL_TLMR | |
| R-0 | R-0 | R-0 | R-0 | |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-91. IODFT Test Logic Control MISR Result Register (IODFT_CTRL_MISR_RSLT) Field Descriptions

| Bit | Field | Value | Description |
|-------|--------------|--------|---|
| 31-26 | Reserved | 0 | Reserved. |
| 25-16 | REG_DQM_TLMR | 0-3FFh | This contains the MISR result signature of a given test after the download function is executed. This result is for the control signals. Reserved for future use. |
| 15-11 | Reserved | 0 | Reserved. |
| 10-0 | REG_CTL_TLMR | 0-7FFh | This contains the MISR result signature of a given test after the download function is executed. This result is for the control signals. |

9.2.3.4.3.2.19 IODFT Test Logic Address MISR Result Register (IODFT_ADDR_MISR_RSLT)

The IODFT Test Logic Address MISR Result Register (IODFT_ADDR_MISR_RSLT) is shown in [Figure 9-71](#) and described in [Table 9-92](#).

Figure 9-71. IODFT Test Logic Address MISR Result Register (IODFT_ADDR_MISR_RSLT)

| | | |
|----------|---------------|---|
| 31 | 21 20 | 0 |
| Reserved | REG_ADDR_TLMR | |
| R-0 | R-0 | |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-92. IODFT Test Logic Address MISR Result Register (IODFT_ADDR_MISR_RSLT) Field Descriptions

| Bit | Field | Value | Description |
|-------|---------------|------------|--|
| 31-21 | Reserved | 0 | Reserved. |
| 20-0 | REG_ADDR_TLMR | 0-1F FFFFh | This contains the MISR result signature of a given test after the download function is executed. This result is for the address signals. |

9.2.3.4.3.2.20 IODFT Test Logic Data MISR Result 1 Register (IODFT_DATA_MISR_RSLT_1)

The IODFT Test Logic Data MISR Result 1 Register (IODFT_DATA_MISR_RSLT_1) is shown in [Figure 9-72](#) and described in [Table 9-93](#).

Figure 9-72. IODFT Test Logic Data MISR Result 1 Register (IODFT_DATA_MISR_RSLT_1)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-93. IODFT Test Logic Data MISR Result 1 Register (IODFT_DATA_MISR_RSLT_1) Field Descriptions

| Bit | Field | Value | Description |
|------|--------------------|--------------|---|
| 31-0 | REG_DATA_TLMR_31_0 | 0-FFFF FFFFh | This contains the least significant bits of the MISR result signature of a given test after the download function is executed. This result is for data bus. |

9.2.3.4.3.2.21 IODFT Test Logic Data MISR Result 2 Register (IODFT_DATA_MISR_RSLT_2)

The IODFT Test Logic Data MISR Result 2 Register (IODFT_DATA_MISR_RSLT_2) is shown in [Figure 9-73](#) and described in [Table 9-94](#).

Figure 9-73. IODFT Test Logic Data MISR Result 2 Register (IODFT_DATA_MISR_RSLT_2)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-94. IODFT Test Logic Data MISR Result 2 Register (IODFT_DATA_MISR_RSLT_2) Field Descriptions

| Bit | Field | Value | Description |
|------|---------------------|--------------|--|
| 31-0 | REG_DATA_TLMR_63_32 | 0-FFFF FFFFh | This contains the middle bits of the MISR result signature of a given test after the download function is executed. This result is for data bus. |

9.2.3.4.3.2.22 IODFT Test Logic Data MISR Result 3 Register (IODFT_DATA_MISR_RSLT_3)

The IODFT Test Logic Data MISR Result 3 Register (IODFT_DATA_MISR_RSLT_3) is shown in [Figure 9-74](#) and described in [Table 9-95](#).

Figure 9-74. IODFT Test Logic Data MISR Result 3 Register (IODFT_DATA_MISR_RSLT_3)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-95. IODFT Test Logic Data MISR Result 3 Register (IODFT_DATA_MISR_RSLT_3) Field Descriptions

| Bit | Field | Value | Description |
|------|---------------------|-------|--|
| 31-3 | Reserved | 0 | Reserved. |
| 2-0 | REG_DATA_TLMR_66_64 | 0-7h | This contains the most significant bits of the MISR result signature of a given test after the download function is executed. This result is for data bus. |

9.2.3.4.3.2.23 Performance Counter 1 Register (PERF_CNT_1)

The Performance Counter 1 Register (PERF_CNT_1) is shown in [Figure 9-75](#) and described in [Table 9-96](#).

Figure 9-75. Performance Counter 1 Register (PERF_CNT_1)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-96. Performance Counter 1 Register (PERF_CNT_1) Field Descriptions

| Bit | Field | Value | Description |
|------|--------------|--------------|---|
| 31-0 | REG_COUNTER1 | 0-FFFF FFFFh | 32-bit counter that can be configured as specified in the Performance Counter Configuration Register and Performance Counter Master Region Select Register. |

9.2.3.4.3.2.24 Performance Counter 2 Register (PERF_CNT_2)

The Performance Counter 2 Register (PERF_CNT_2) is shown in [Figure 9-76](#) and described in [Table 9-97](#).

Figure 9-76. Performance Counter 2 Register (PERF_CNT_2)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-97. Performance Counter 2 Register (PERF_CNT_2) Field Descriptions

| Bit | Field | Value | Description |
|------|--------------|--------------|---|
| 31-0 | REG_COUNTER2 | 0-FFFF FFFFh | 32-bit counter that can be configured as specified in the Performance Counter Configuration Register and Performance Counter Master Region Select Register. |

9.2.3.4.3.2.25 Performance Counter Configuration Register (PERF_CNT_CFG)

The Performance Counter Configuration Register (PERF_CNT_CFG) is shown in [Figure 9-77](#) and described in [Table 9-98](#).

Figure 9-77. Performance Counter Configuration Register (PERF_CNT_CFG)

| | | | |
|----------------------|---------------------|---------------|----|

| R/W-0 | R/W-0 | R-0 | |
| 23 | 20 | 19 | 16 |
| Reserved | | REG_CNTR2_CFG | |
| R-0 | | R/W-0 | |
| 15 | 14 | 13 | 8 |
| REG_CNTR1_MCONNID_EN | REG_CNTR1_REGION_EN | Reserved | |
| R/W-0 | R/W-0 | R-0 | |
| 7 | 4 | 3 | 0 |
| Reserved | | REG_CNTR1_CFG | |
| R-0 | | R/W-0 | |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-98. Performance Counter Configuration Register (PERF_CNT_CFG) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------------------|-------|--|
| 31 | REG_CNTR2_MCONNID_EN | 0-1h | MConnID filter enable for Performance Counter 2 register. |
| 30 | REG_CNTR2_REGION_EN | 0-1h | Chip Select filter enable for Performance Counter 2 register. |
| 29-20 | Reserved | 0 | Reserved. |
| 19-16 | REG_CNTR2_CFG | 0-Fh | Filter configuration for Performance Counter 2. Refer to Table 9-99 for details. |
| 15 | REG_CNTR1_MCONNID_EN | 0-1h | MConnID filter enable for Performance Counter 1 register. |
| 14 | REG_CNTR1_REGION_EN | 0-1h | Chip Select filter enable for Performance Counter 1 register. |
| 13-4 | Reserved | 0 | Reserved. |
| 3-0 | REG_CNTR1_CFG | 0-Fh | Filter configuration for Performance Counter 1. Refer to Table 9-99 for details. |

[Table 9-99](#) shows the possible filter configurations for the two performance counters. These filter configurations can be used in conjunction with an OCP master ID and/or an external chip select to obtain performance statistics for a particular OCP master and/or an external chip select.

Table 9-99. Performance Counter Filter Configuration

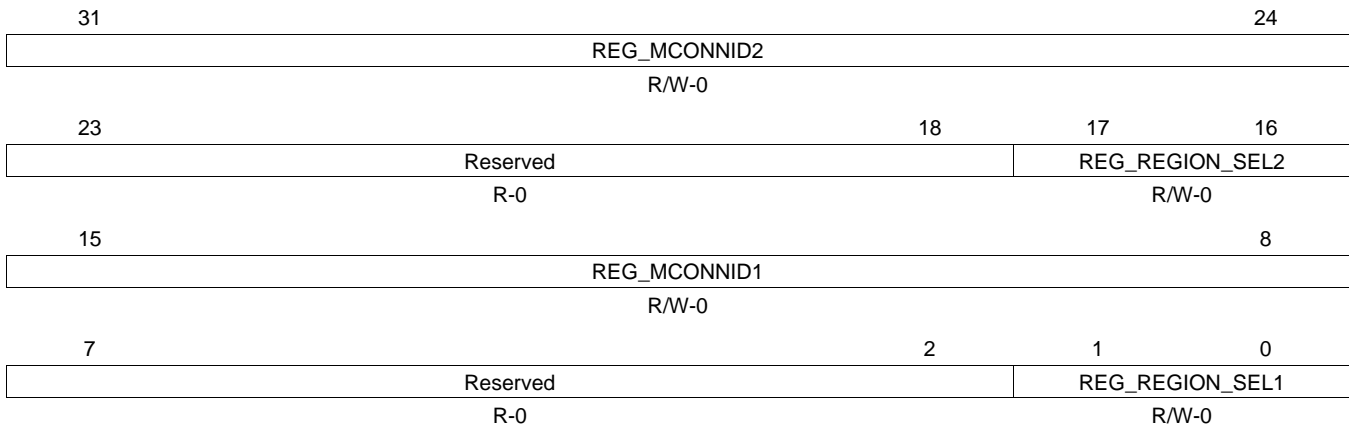

| cntrN_cfg | cntrN_region_en | cntrN_mconnid_en | Description |
|-----------|-----------------|------------------|---|
| 0x0 | 0x0 | 0x0 or 0x1 | Count total SDRAM accesses. |
| 0x1 | 0x0 | 0x0 or 0x1 | Count total SDRAM activates. |
| 0x2 | 0x0 or 0x1 | 0x0 or 0x1 | Count total reads. |
| 0x3 | 0x0 or 0x1 | 0x0 or 0x1 | Count total writes. |
| 0x4 | 0x0 | 0x0 | Count number of m_clk cycles OCP Command FIFO is full. |
| 0x5 | 0x0 | 0x0 | Count number of m_clk cycles OCP Write Data FIFO is full. |
| 0x6 | 0x0 | 0x0 | Count number of m_clk cycles OCP Read Data FIFO is full. |
| 0x7 | 0x0 | 0x0 | Count number of m_clk cycles OCP Return Command FIFO is full. |
| 0x8 | 0x0 or 0x1 | 0x0 or 0x1 | Count number of priority elevations. |
| 0x9 | 0x0 | 0x0 | Count number of m_clk cycles that a command was pending. |
| 0xA | 0x0 | 0x0 | Count number of m_clk cycles for which the memory data bus was transferring data. |
| 0xB - 0xF | 0x0 | 0x0 | Reserved for future use. |

NOTE: When MReqDebug is set to a 1 for a particular OCP command, the performance counters will not be incremented for that particular command if the cntrN_cfg values are equal 0x0, 0x1, 0x2, 0x3, or 0xA.

9.2.3.4.3.2.26 Performance Counter Master Region Select Register (PERF_CNT_SEL)

The Performance Counter Master Region Select Register (PERF_CNT_SEL) is shown in [Figure 9-78](#) and described in [Table 9-100](#).

Figure 9-78. Performance Counter Master Region Select Register (PERF_CNT_SEL)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-100. Performance Counter Master Region Select Register (PERF_CNT_SEL) Field Descriptions

| Bit | Field | Value | Description |
|-------|-----------------|-------|--|
| 31-24 | REG_MCONNID2 | 0-FFh | MConnID for Performance Counter 2 register. |
| 23-18 | Reserved | 0 | Reserved. |
| 17-16 | REG_REGION_SEL2 | 0-3h | MAddrSpace for Performance Counter 2 register. |
| 15-8 | REG_MCONNID1 | 0-FFh | MConnID for Performance Counter 1 register. |
| 7-2 | Reserved | 0 | Reserved. |
| 1-0 | REG_REGION_SEL1 | 0-3h | MAddrSpace for Performance Counter 1 register. |

9.2.3.4.3.2.27 Performance Counter Time Register (PERF_CNT_TIM)

The Performance Counter Time Register (PERF_CNT_TIM) is shown in [Figure 9-79](#) and described in [Table 9-101](#).

NOTE: This is a free running counter and is not affected by MReqDebug value.

Figure 9-79. Performance Counter Time Register (PERF_CNT_TIM)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-101. Performance Counter Time Register (PERF_CNT_TIM) Field Descriptions

| Bit | Field | Value | Description |
|------|----------------|--------------|---|
| 31-0 | REG_TOTAL_TIME | 0-FFFF FFFFh | 32-bit counter that continuously counts number for m_clk cycles elapsed after EMIF is brought out of reset. |

9.2.3.4.3.2.28 End of Interrupt Register (IRQ_EOI)

The End of Interrupt Register (IRQ_EOI) is shown in [Figure 9-80](#) and described in [Table 9-102](#).

Figure 9-80. End of Interrupt Register (IRQ_EOI)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-102. End of Interrupt Register (IRQ_EOI) Field Descriptions

| Bit | Field | Value | Description |
|------|----------|-------|---|
| 31-1 | Reserved | 0 | Reserved. |
| 0 | REG_EOI | | Software End Of Interrupt (EOI) control. Write 0 for system OCP interrupt. This field always reads 0 (no EOI memory). |

9.2.3.4.3.2.29 System OCP Interrupt Raw Status Register (IRQSTATUS_RAW_SYS)

The System OCP Interrupt Raw Status Register (IRQSTATUS_RAW_SYS) is shown in [Figure 9-81](#) and described in [Table 9-103](#).

Figure 9-81. System OCP Interrupt Raw Status Register (IRQSTATUS_RAW_SYS)

LEGEND: WOS = Write one to set field; R = Read only; -n = value after reset

Table 9-103. System OCP Interrupt Raw Status Register (IRQSTATUS_RAW_SYS) Field Descriptions

| Bit | Field | Value | Description |
|------|-------------|-------|---|
| 31-1 | Reserved | 0 | Reserved. |
| 0 | REG_RAW_SYS | | Raw status of system OCP interrupt. Write 1 to set the (raw) status, mostly for debug. Writing a 0 has no effect. |

9.2.3.4.3.2.30 System OCP Interrupt Status Register (IRQSTATUS_SYS)

The System OCP Interrupt Status Register (IRQSTATUS_SYS) is shown in [Figure 9-82](#) and described in [Table 9-104](#).

Figure 9-82. System OCP Interrupt Status Register (IRQSTATUS_SYS)

LEGEND: WOC = Write one to clear field; R = Read only; -n = value after reset

Table 9-104. System OCP Interrupt Status Register (IRQSTATUS_SYS) Field Descriptions

| Bit | Field | Value | Description |
|------|-----------------|-------|---|
| 31-1 | Reserved | 0 | Reserved. |
| 0 | REG_ENABLED_SYS | | Enabled status of system OCP interrupt. Write 1 to clear the status after interrupt has been serviced (raw status gets cleared, i.e. even if not enabled). Writing a 0 has no effect. |

9.2.3.4.3.2.31 System OCP Interrupt Enable Set Register (IRQENABLE_SET_SYS)

The System OCP Interrupt Enable Set Register (IRQENABLE_SET_SYS) is shown in [Figure 9-83](#) and described in [Table 9-105](#).

Figure 9-83. System OCP Interrupt Enable Set Register (IRQENABLE_SET_SYS)

| | | | |
|-----|----------|---|------------|
| 31 | Reserved | 1 | 0 |
| | | | REG_EN_SYS |
| R-0 | | | WOS-0 |

LEGEND: WOS = Write one to set field; R = Read only; -n = value after reset

Table 9-105. System OCP Interrupt Enable Set Register (IRQENABLE_SET_SYS) Field Descriptions

| Bit | Field | Value | Description |
|------|------------|-------|---|
| 31-1 | Reserved | 0 | Reserved. |
| 0 | REG_EN_SYS | | Enable set for system OCP interrupt. Writing a 1 will enable the interrupt, and set this bit as well as the corresponding Interrupt Enable Clear Register. Writing a 0 has no effect. |

9.2.3.4.3.2.32 System OCP Interrupt Enable Clear Register (IRQENABLE_CLR_SYS)

The System OCP Interrupt Enable Clear Register (IRQENABLE_CLR_SYS) is shown in [Figure 9-84](#) and described in [Table 9-106](#).

Figure 9-84. System OCP Interrupt Enable Clear Register (IRQENABLE_CLR_SYS)

| | | | |
|-----|----------|---|------------|
| 31 | Reserved | 1 | 0 |
| | | | REG_EN_SYS |
| R-0 | | | WOC-0 |

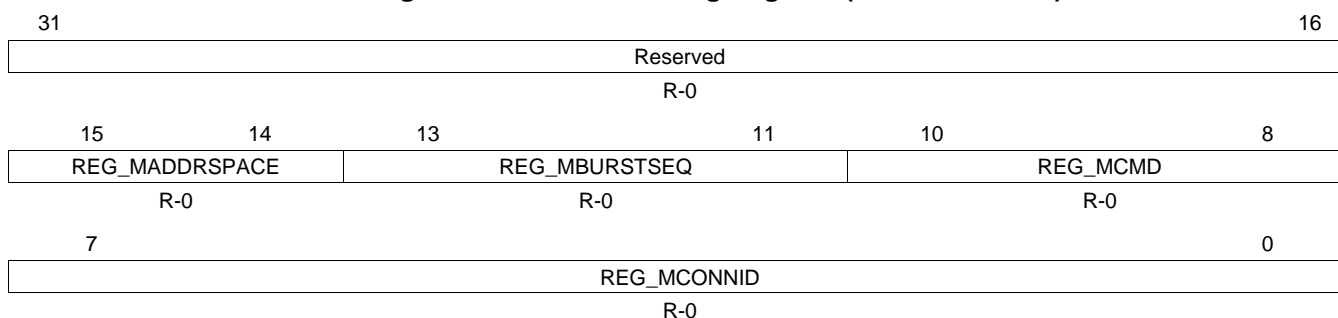

LEGEND: WOC = Write one to clear field; R = Read only; -n = value after reset

Table 9-106. System OCP Interrupt Enable Clear Register (IRQENABLE_CLR_SYS) Field Descriptions

| Bit | Field | Value | Description |
|------|------------|-------|--|
| 31-1 | Reserved | 0 | Reserved. |
| 0 | REG_EN_SYS | | Enable clear for system OCP interrupt. Writing a 1 will disable the interrupt, and clear this bit as well as the corresponding Interrupt Enable Set Register. Writing a 0 has no effect. |

9.2.3.4.3.2.33 OCP Error Log Register (OCP_ERR_LOG)

The OCP Error Log Register (OCP_ERR_LOG) is shown in [Figure 9-85](#) and described in [Table 9-107](#).

Figure 9-85. OCP Error Log Register (OCP_ERR_LOG)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-107. OCP Error Log Register (OCP_ERR_LOG) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------------|-------|---|
| 31-16 | Reserved | 0 | Reserved. |
| 15-14 | REG_MADDRSPACE | 0-3h | Address space of the first errored transaction. |
| 13-11 | REG_MBURSTSEQ | 0-7h | Addressing mode of the first errored transaction. |
| 10-8 | REG_MCMD | 0-7h | Command type of the first errored transaction. |
| 7-0 | REG_MCONNID | 0-FFh | Connection ID of the first errored transaction. |

9.2.3.4.3.2.34 DDR PHY Control 1 Register (DDR_PHY_CTRL_1)

The DDR PHY Control 1 Register (DDR_PHY_CTRL_1) is shown in [Figure 9-86](#) and described in [Table 9-108](#).

Figure 9-86. DDR PHY Control 1 Register (DDR_PHY_CTRL_1)

| | | | | | |
|---------------------------|----------------------|----------|----|-----------------------|----|
| 31 | Reserved | | | | 24 |

| 7 | 6 | 5 | 3 | 2 | 0 |
| CONFIG_EXT_STRBEN | CONFIG_PWRDN_DISABLE | Reserved | | READ_LATENCY | |
| R/W-0 | | R/W-0 | | R-0 | |
| R/W-0 | | R-0 | | R/W-0 | |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-108. DDR PHY Control 1 Register (DDR_PHY_CTRL_1) Field Descriptions

| Bit | Field | Value | Description |
|-------|---------------------------|-------|--|
| 31-24 | Reserved | 0 | Reserved |
| 23 | TESTIN_LB_CK_SELECT | 0 | This bit controls the value assigned to the TESTIN_LB_CK_SELECT input on the command macro. |
| 22-16 | Reserved | 0 | Reserved |
| 15 | CONFIG_VTP_DYNAMIC_UPDATE | 0 | This bit controls the value assigned to the CONFIG_VTP_DYNAMIC_UPDATE input on the command macro. |
| 14-12 | CONFIG_DLL_MODE | 0 | This bit controls the value assigned to the CONFIG_DLL_MODE input on the data macros. |
| 11-9 | Reserved | 0 | Reserved |
| 8 | DDR_16B_MODE_PWRSERVE | 0 | This bit can be set to gate the clock of second data macro when DDR is used in 16b mode. |
| 7 | CONFIG_EXT_STRBEN | 1h | This bit controls the value assigned to the CONFIG_EXT_STRBEN input on the DDR PHY data macro. |
| 6 | CONFIG_PWRDN_DISABLE | 0 | This bit controls the value assigned to the CONFIG_PWRDNEN input on the DDR PHY data macro. 0: DDR receive IO buffer will be powered down (disabled) when there no read. 1: DDR receive IO buffer will be always enabled. |
| 5-3 | Reserved | 0 | Reserved |
| 2-0 | READ_LATENCY | 3h | This field defines the latency for read data from DDR SDRAM in number of X1_CLK_OUT cycles. The value applied should be equal to the required value minus one. The maximum read latency supported by the DDR PHY is equal to CAS latency plus 2 X1_CLK_OUT CYCLES. The minimum read latency must be equal to CAS latency plus 1 X1_CLK_OUT CYCLES. |

9.2.3.4.3.2.35 DDR PHY Control 1 Shadow Register (DDR_PHY_CTRL_1_SHDW)

The DDR PHY Control 1 Shadow Register (DDR_PHY_CTRL_1_SHDW) is shown in [Figure 9-87](#) and described in [Table 9-109](#).

Figure 9-87. DDR PHY Control 1 Shadow Register (DDR_PHY_CTRL_1_SHDW)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-109. DDR PHY Control 1 Shadow Register (DDR_PHY_CTRL_1_SHDW) Field Descriptions

| Bit | Field | Value | Description |
|------|-------------------------|--------------|--|
| 31-3 | REG_DDR_PHY_CTRL_1_SHDW | 0-1FFF FFFFh | Shadow field for REG_DDR_PHY_CTRL_1. This field is loaded into REG_DDR_PHY_CTRL_1 field in DDR PHY Control 1 register when SidleAck is asserted. |
| 2-0 | REG_READ_LATENCY_SHDW | 0-7h | Shadow field for REG_READ_LATENCY. This field is loaded into REG_READ_LATENCY field in DDR PHY Control 1 register when SidleAck is asserted. |

9.2.3.4.3.2.36 DDR PHY Control 2 Register (DDR_PHY_CTRL_2)

The DDR PHY Control 2 Register (DDR_PHY_CTRL_2) is shown in [Figure 9-88](#) and described in [Table 9-110](#).

Figure 9-88. DDR PHY Control 2 Register (DDR_PHY_CTRL_2)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 9-110. DDR PHY Control 2 Register (DDR_PHY_CTRL_2) Field Descriptions

| Bit | Field | Value | Description |
|------|---------------------------|-------|--|
| 31-2 | Reserved | 0 | Reserved |
| 1 | CONFIG_RX_DLL_BYPASS | 0 | This bit controls the value assigned to the CONFIG_RX_DLL_BYPASS input on the DDR PHY data macro. |
| 0 | CONFIG_TX_STRB_DATA_ALIGN | 0 | This bit controls the value assigned to the CONFIG_TX_STRB_DATA_ALIGN input on the DDR PHY data macro. |

9.2.3.4.4 Interrupt Conditions

This section defines the module interrupt capabilities and requirements.

9.2.3.4.4.1 Interrupt Description

The EMIF sources one interrupt for the system OCP. The system OCP interrupts are `sys_err_intr_req` (pulse) and `sys_err_intr_pend` (level). The pulse and level interrupt signals for a particular interface are both sourced from the same raw interrupt for the corresponding interface internal to the module.

9.2.3.4.4.2 Interrupt Condition Control

The EMIF only supports Idle, Write, Read, and WriteNonPost command types (as indicated by MCmd). Also, the EMIF only supports incrementing, wrapping, and 2-dimensional block addressing modes (as indicated by MBurstSeq). If an access request for an unsupported command type or an unsupported addressing mode is received, the EMIF will set the `reg_raw_sys` bit in the Interrupt Raw Status register. The EMIF will also set the `reg_raw_sys` bit in Interrupt Raw Status register, if an access request to an unsupported MAddrSpace is received.

The EMIF will only output the interrupts on the interrupt lines if they are enabled by writing a 1 to the corresponding bits in the Interrupt Enable Set register. The interrupts can be disabled by writing a 1 to the corresponding bits in the Interrupt Enable Clear register.

When enabled, the corresponding bits in the Interrupt Status register will also be set if the above error condition occurs. The interrupts can be cleared once serviced by writing a 1 to the corresponding bits either in the Interrupt Raw Status or Interrupt Status register. The software must also write to the End of Interrupt register to indicate that the interrupt was serviced.

9.2.3.4.5 Power Management

This section defines the module Power Management capabilities and requirements.

9.2.3.4.5.1 SDRAM Self-Refresh Mode

The EMIF supports self-refresh mode for low power. The EMIF automatically puts the SDRAM into self-refresh after the EMIF is idle for `reg_pm_tim` number of `m_clk` cycles and the `reg_lp_mode` field is set to 2. The `reg_lp_mode` and `reg_pm_tim` fields can be programmed in the Power Management Control register. The EMIF will complete all pending refreshes before it puts the SDRAM into self-refresh. Therefore, after the expiration of `reg_pm_tim`, the EMIF will start issuing refreshes to complete the refresh backlog, and then issue a SELF REFRESH command to the SDRAM.

In self-refresh mode, the EMIF automatically stops the clocks to the SDRAM, by asserting the `phy_sdramclkstop` port. The EMIF maintains `pad_cke_o` low to maintain the self-refresh state.

When the SDRAM is in self-refresh, the EMIF services register accesses as normal.

If the `reg_lp_mode` field is set not equal to 2, or an SDRAM access is requested while it is in self-refresh, and `reg_t_cke + 1` cycles have elapsed since the SELF-REFRESH command was issued, the EMIF will bring the SDRAM out of self-refresh. The value of `reg_t_cke` is taken from SDRAM Timing 2 register.

For DDR2 the EMIF:

- Drives `phy_sdramclkstop` low to enable clocks.
- Drives `pad_cke_o` high.
- Waits for `reg_t_xsnr + 1` cycles. The value of `reg_t_xsnr` is taken from SDRAM Timing 2 register.
- If the `reg_ddr_disable_dll` bit in the SDRAM Configuration register is 1, issues a LOAD MODE REGISTER command to the extended mode register 1 (`pad_ba_o[2:0] = 0x1`) with the `pad_a_o` bits set as follows:

| Bits | Value | Description |
|-----------------------------|-------|-----------------------|
| <code>pad_a_o[15:13]</code> | 0x0 | Reserved |
| <code>pad_a_o[12]</code> | 0x0 | Output buffer enabled |
| <code>pad_a_o[11]</code> | 0x0 | RDQS disable |

| Bits | Value | Description |
|--------------|---------------------|---|
| pad_a_o[10] | !reg_dds2_ddqs | Differential DQS enable value from SDRAM Configuration register |
| pad_a_o[9:7] | 0x0 | Exit OCD calibration mode |
| pad_a_o[6] | reg_dds2_term[1] | DDR2 termination resistor value from SDRAM Configuration register |
| pad_a_o[5:3] | 0x0 | Additive latency = 0 |
| pad_a_o[2] | reg_dds2_term[0] | DDR2 termination resistor value from SDRAM Configuration register |
| pad_a_o[1] | reg_sdrdrv_drive[0] | SDRAM drive strength from SDRAM Configuration register |
| pad_a_o[0] | 0x1 | Disable DLL |

- Starts an auto-refresh cycle in the next cycle.
- Enters its idle state and can issue any other commands except a write or a read. A write or a read will only be issued after $\text{reg_t_xsrd} + 1$ clock cycles have elapsed since pad_cke_o is driven high. The value of reg_t_xsrd is taken from SDRAM Timing 2 register.

To use partial array self-refresh, reg_pasr bits in the SDRAM Refresh Control register must be appropriately programmed. The EMIF performs bank interleaving when reg_ibank_pos = 0 in SDRAM Configuration register. Since the SDRAM is partially refreshed during partial array self-refresh, for software ease, it is recommended that reg_ibank_pos be set to 1, 2, or 3 depending on the scheme used. If reg_ibank_pos is set to 0, it is the responsibility of software to move critical data into the banks that are going to be refreshed during partial array self-refresh.

For LPDDR1 the EMIF:

- Drives phy_sdrclkstop low to enable clocks.
- Drives pad_cke_o high.
- Waits for $\text{reg_t_xsnr} + 1$ cycles. The value of reg_t_xsnr is taken from SDRAM Timing 2 register.
- Starts an auto-refresh cycle in the next cycle.
- Enters its idle state and can issue any commands.

9.2.3.4.5.2 SDRAM Power-Down Mode

The EMIF also supports Power-Down mode for low power. The EMIF automatically puts the SDRAM into Power-Down after the EMIF is idle for reg_pm_tim number of m_clk cycles and the reg_lp_mode field is set to 3. The reg_lp_mode and reg_pm_tim fields can be programmed in the Power Management Control register. The EMIF will complete all pending refreshes before it puts the SDRAM into Power-Down. Therefore, after the expiration of reg_pm_tim, the EMIF will start issuing refreshes to complete the refresh backlog, and then issue a POWER-DOWN command to the SDRAM.

In Power-Down mode, the EMIF does not stop the clocks to the SDRAM. The EMIF maintains pad_cke_o low to maintain the Power-Down state.

When the SDRAM is in Power-Down, the EMIF services register accesses as normal.

If the reg_lp_mode field is set not equal to 3, or an SDRAM access is requested, or the Refresh Must level is reached while the SDRAM is in Power-Down, the EMIF will bring the SDRAM out of Power-Down.

For DDR2 the EMIF:

- Drives pad_cke_o high after $\text{reg_t_cke} + 1$ cycles have elapsed since the POWER-DOWN command was issued. The value of reg_t_cke is taken from SDRAM Timing 2 register.
- Waits for $\text{reg_t_xp} + 1$ cycles. The value of reg_t_xp is taken from SDRAM Timing 2 register.
- Enters its idle state and can issue any commands.

For LPDDR1 the EMIF:

- Drives pad_cke_o high.
- Waits for $\text{reg_t_xp} + 1$ cycles. The value of reg_t_xp is taken from SDRAM Timing 2 register.
- Enters its idle state and can issue any commands.

9.2.3.4.5.3 SDRAM Deep Power-Down Mode

For ultimate power savings, the EMIF supports Deep Power-Down mode for LPDDR1.

The SDRAM can be forced into Deep Power-Down through software by setting the `reg_dpd_en` field in the Power Management Control register to 1. In this case, the EMIF will continue normal operation until all SDRAM memory access requests have been serviced. At this point the EMIF will issue a DEEP POWER-DOWN command. The EMIF then maintains `pad_cke_o` low to maintain the Deep Power-Down state. In Deep Power-Down mode, the EMIF automatically stops the clocks to the SDRAM, by asserting the `phy_sdramclkstop` port.

Setting the `reg_dpd_en` field to 1 overrides the setting of `reg_lp_mode` field. Therefore, if the SDRAM is in Clock Stop, Self Refresh, or Power-Down mode, and `reg_dpd_en` field is set to 1, the EMIF will exit those modes and go into Deep Power-Down mode.

When the SDRAM is in Deep Power-Down, the EMIF services register accesses as normal. If the `reg_dpd_en` field is set to 0, or an SDRAM access is requested, the EMIF will bring the SDRAM out of Deep Power-Down.

The EMIF:

- Performs SDRAM initialization as specified in the LPDDR1 Initialization section.
- Enters its idle state and can issue any commands.

Since the EMIF performs initialization upon Deep Power-Down exit, the `reg_refresh_rate` field in the SDRAM Refresh Control register must be set appropriately to meet the 200us wait requirement for LPDDR1 during initialization.

9.2.3.4.5.4 Save and Restore

The EMIF supports save and restore mechanism to completely switch off power to the EMIF. The following sequence of operations is followed to put EMIF in off mode.

- An external master reads the following memory mapped registers using the system OCP interface and saves their value external to the EMIF.
 - SDRAM Configuration register
 - SDRAM Refresh Control register
 - SDRAM Refresh Control Shadow register
 - SDRAM Timing 1 register
 - SDRAM Timing 1 Shadow register
 - SDRAM Timing 2 register
 - SDRAM Timing 2 Shadow register
 - SDRAM Timing 3 register
 - SDRAM Timing 3 Shadow register
 - Power Management Control register
 - Power Management Control Shadow register
 - OCP Configuration register
 - System OCP Interrupt Enable Set Register
 - DDR PHY Control 1 register
 - DDR PHY Control 1 Shadow register
 - DDR PHY Control 2 register
- The `pwr_SIdleReq` port is asserted keeping the `pwr_Fclken=0`.
- EMIF requests OCP disconnect on both OCP interfaces through the `sys_SConnect` port.
- EMIF waits for the OCP disconnection confirmation on both OCP interfaces through the `sys_MConnect` port.
- EMIF completes all pending transactions and drains all its FIFOs.
- EMIF puts the SDRAM in Self Refresh.
- EMIF copies all shadow memory mapped registers to its main registers. It is assumed that the shadow register always has the same value as its corresponding main register.
- EMIF waits for all interrupts to be serviced.

- EMIF gates internal ocp_clk and m_clk.
- EMIF acknowledges assertion of pwr_SIdleReq through the pwr_SIdleAck port.
- The rst_por_arst_n reset is asserted.
- The clocks and power to the EMIF can now be switched off.

To restore power to the EMIF the following sequence of operations is followed:

- The power and clocks to the EMIF are switched on.
- The rst_por_arst_n reset is deasserted keeping prcm_deviceoff_wkup_core_rstactst=1 indicating to the EMIF that it is waking up from off mode. The prcm_deviceoff_wkup_core_rstactst port is synchronized inside the EMIF and therefore must be stable before rst_por_arst_n is deasserted.
- The EMIF does not perform SDRAM initialization and forces its state machine to be in Self Refresh.
- The pwr_SIdleReq port is deasserted.
- EMIF acknowledges deassertion of pwr_SIdleReq through the pwr_SIdleAck port.
- The external master restores all of the above memory mapped registers.
- The system can now perform access to the external memory.
- The EMIF will exit Self Refresh state once it receives accesses to the external memory.

9.2.3.4.5.5 Clock Frequency Change

If dual_clk_mode port is set to 1, the ocp_clk and the m_clk are asynchronous to each other. In this case, the ocp_clk frequency can be changed at any time. However, the m_clk frequency can only be changed after putting the external SDRAM in Self Refresh.

If dual_clk_mode port is set to 0, the ocp_clk and the m_clk are synchronous to each other. In this case, the ocp_clk and the m_clk frequency can only be changed after putting the external SDRAM in Self Refresh. Thus the clock frequencies can be changed through software by putting the EMIF in Self Refresh.

In case software intervention is not required, EMIF supports two modes for clock frequency change. The first mode uses a similar sequence of operation as the Save and Restore mechanism. Following is the sequence of operations.

- All shadow memory mapped registers are programmed for target frequency values.
- The pwr_SIdleReq port is asserted keeping the pwr_Fclken=0.
- EMIF requests OCP disconnect on both OCP interfaces through the sys_SConnect port.
- EMIF waits for the OCP disconnection confirmation on both OCP interfaces through the sys_MConnect port.
- EMIF completes all pending transactions and drains all its FIFOs.
- EMIF puts the SDRAM in Self Refresh.
- EMIF copies all shadow memory mapped registers to its main registers.
- EMIF waits for all interrupts to be serviced.
- EMIF gates internal ocp_clk and m_clk.
- EMIF acknowledges assertion of pwr_SIdleReq through the pwr_SIdleAck port.
- The frequency of clocks can now be changed.

The second mode allows lower latency by bypassing the OCP disconnect protocol. The config_freq_change port must be set to a 1 for this mode. This mode allows a use case where the system does not want to wait for the EMIF FIFOs to be drained to change the clock frequency. Following is the sequence of operations.

- All shadow memory mapped registers are programmed for target frequency values.
- The pwr_SIdleReq port is asserted keeping the pwr_Fclken=1.
- EMIF completes the on-going access and then puts the SDRAM in Self Refresh.
- EMIF copies all shadow memory mapped registers to its main registers.
- EMIF acknowledges assertion of pwr_SIdleReq through the pwr_SIdleAck port.
- The frequency of clocks can now be changed.

To start performing access to SDRAM, the following sequence of operations is followed:

- The pwr_SIdleReq port is deasserted.
- EMIF acknowledges deassertion of pwr_SIdleReq through the pwr_SIdleAck port.
- The system can now perform access to the external memory.
- The EMIF will exit Self Refresh state once it receives accesses to the external memory.

9.2.3.4.5.6 Retention Mode

EMIF supports full-retention mode, i.e., if retention is required, all flip-flops must be retention flip-flops. It does not support partial retention. The following sequence of operations is followed to put EMIF in retention.

- The pwr_SIdleReq port is asserted keeping the pwr_Fclken=0.
- EMIF requests OCP disconnect on both OCP interfaces through the sys_SConnect port.
- EMIF waits for the OCP disconnection confirmation on both OCP interfaces through the sys_MConnect port.
- EMIF completes all pending transactions and drains all its FIFOs.
- EMIF puts the SDRAM in Self Refresh.
- EMIF copies all shadow memory mapped registers to its main registers. It is assumed that the shadow register always has the same value as its corresponding main register.
- EMIF waits for all interrupts to be serviced.
- EMIF gates internal ocp_clk and m_clk.
- EMIF acknowledges assertion of pwr_SIdleReq through the pwr_SIdleAck port.
- The clocks to the EMIF can now be switched off.
- The can now be put into retention.

To exit retention state the following sequence of operations is followed:

- The EMIF flip-flops value is restored from retention flops and clocks to the EMIF are switched on.
- The pwr_SIdleReq port is deasserted.
- EMIF acknowledges deassertion of pwr_SIdleReq through the pwr_SIdleAck port.
- The system can now perform access to the external memory.
- The EMIF will exit Self Refresh state once it receives accesses to the external memory.

9.2.3.4.5.7 Global Warm Reset

EMIF supports global warm reset mode where the EMIF will follow the following sequence of operations.

- The prcm_globalwarm_rstactst port is asserted indicating to the EMIF that it needs to enter global warm reset mode.
- EMIF completes the on-going access and then puts the SDRAM in Self Refresh.
- EMIF clears all its FIFO contents and deasserts sys_SCmdAccept and sys_SDataAccept ports.

To exit global warm reset state the following sequence of operations is followed:

- The prcm_globalwarm_rstactst port is deasserted indicating to the EMIF that global warm reset has finished.
- The system can now perform access to the external memory.
- The EMIF will exit Self Refresh state once it receives accesses to the external memory.

9.2.3.4.6 Programming/Usage Guide

9.2.3.4.6.1 Connecting to SDRAM

Figure 9-89 and Figure 9-90 show the ODT signal connections between the EMIF and DDR2.

Figure 9-89. Connecting Two DDR2 on One Chip Select

Figure 9-90. Connecting Two DDR2 on Two Chip Selects

9.2.4 SMS Basic Programming Model

9.2.4.1 SMS Firewall Usage

Use the SMS.SMS_SECURITY_CONTROL register to allow access to the registers.

Because region 0 always has level 0 priority, it can be masked by any protected region.

To configure a region:

1. Set the SMS.SMS_RG_ATT_i register (where *i* is the region index from 0 to 7).
2. Set the SMS.SMS_RG_RDPERM_i register.
3. Set the SMS.SMS_RG_WRPERM_i register.
4. Set the SMS.SMS_RG_START_j register (except for region 0. *j* is the region index from 1 to 7).
5. Set the SMS.SMS_RG_END_j register (except for region 0. *j* is the region index from 1 to 7).

Region 0 is always active. There are no start and an end address for region 0. As soon as the SMS.SMS_RG_START_j[30:16] STARTADDRESS and SMS.SMS_RG_END_j[30:16] ENDADDRESS registers (where *j* = 1 to 7) are programmed, the firewall is activated. To prevent unexpected violations, ensure that the protection regions do not overlap.

Region 1 ensures the proper dynamic programming of protection for regions 2 through 7. For example, the protected region A is set and currently accessed, but it must be enlarged. To avoid deactivating region A and exposing its content to unwanted leakage, region 1 can be used to mask this whole area during reprogramming. When region A is correctly reprogrammed, region 1 can be deactivated.

If the secure system wants to restrict use of the firewall to secure mode, the security control register allows setting of a bit that locks the access to all registers to secure supervisor only.

On general-purpose (GP) devices, when all the required regions are programmed, the locking mechanism allows freezing the configuration, thus ensuring no further reprogramming.

To program the SMS firewall region in secure and supervisor privilege only, the SMS_SECURITY_CONTROL register allows any transaction or only secure and supervisor privilege accesses to:

- Rotation context registers (only secure privilege required)
- Arbitration control registers (only secure privilege required)
- Region 1 security firewall registers
- Error log registers (only secure privilege required)
- Security control register configuration lock bit
- Firewall lock bit
- Soft-reset lock bit (only secure privilege required)

If these fields are programmed to 0x1 (meaning that secure and supervisor privilege transaction is required), then nonsecure and supervisor privilege accesses to corresponding registers do not modify the register values and generate an ERRORSECREG error in the SMS_ERR_TYPE register.

9.2.4.2 VRFB Context Configuration

Using the RE requires several initialization programming steps. After an RE context is set up, an application can use it transparently, as if addressing a frame buffer object with a standard raster-based memory arrangement.

1. Define the page configuration. This operation usually depends only on the external memory device. The same page settings are then applied to any newly created rotated frame buffer.

Consider an SDRAM device with 1024-byte pages. The page can be defined as a 16 × 64 array. The page is not necessarily a square (32 × 32 is also a suitable value). It is recommended that the longest side corresponds to the access direction requiring the maximum bandwidth.

In terms of register settings, in any context that uses that page size:

Page (page) width = 2^{pw} bytes (that is, $pw = 6$)

Page (page) height = 2^{ph} rows (that is, $ph = 4$)

2. The application must allocate the appropriate amount of memory in the SDRAM address space, as required by the size of the frame buffer object.

Example: Create a 400 × 300 frame buffer, 16 bits per pixel

- Pixel size = 2^{ps} bytes (that is $ps = 1$)
- Number of pages per line: $400 \times 2/64 = 12.5$, rounded up to 13
- Number of pages per column: $300/16 = 18.75$, rounded up to 19

In terms of register settings, the image size parameters correspond to the enlarged image, and are programmed to:

- Image width = w pixels (that is, $w = 13 \times 64 / 2 = 416$)
- Image height = h pixels (that is, $h = 19 \times 16 = 304$)

NOTE: In this example, the values obtained are not integer values, but are rounded up to the closest integer value. This results in a loss of physical memory, generally negligible compared to the total size of the image.

In terms of memory allocation (in the physical memory), this corresponds to a 416 × 304 × 2 = 252,928-byte buffer.

The physical base address of this buffer must be aligned on a page boundary (in that example, a 1024-byte boundary; that is, the 10 LSBs of the base address must be all zeros). This buffer must be allocated as a contiguous memory segment.

All these parameters, once determined, must be loaded in the registers of the chosen context (there are 12 VRFB contexts with 12 independent sets of registers).

Example, context 1:

- Configure the physical base address of the frame buffer. Example: 512 Mbytes, start of CS0, SMS.SMS_ROT_PHYSICAL_BAn[30:0] PHYSICALBA = 0x20000000 (where $n = 1$)
- Configure the image height and width:
Image width (416): SMS.SMS_ROT_SIZEEn[10:0] IMAGEWIDTH = 0x1A0 (where $n = 1$)
Image height (304): SMS.SMS_ROT_SIZEEn[26:16] IMAGEHEIGHT = 0x130
- Configure the control parameters:

Pixel size (example: 2 bytes, 2^1 bytes): SMS.SMS_ROT_CONTROLn[1:0] PS = 0x1 (where n = 1)
 Page (page) size (example: 1024 bytes = 64 bytes × 16 bytes)
 Page height (example: 16 rows, 2^4 rows): SMS.SMS_ROT_CONTROLn[10:8] PH = 0x4
 Page width (example: 64 bytes, 2^6 bytes): SMS.SMS_ROT_CONTROLn[6:4] PW = 0x6

- The frame buffer just created is now ready for use by the different system initiators (MPU, sDMA, LCD controller, etc.).

From the perspective of these modules, the frame buffer object can be accessed at the following VRFB address-space memory locations:

- Context 1 0-degree view: 0x7400 0000
- Context 1 90-degree view: 0x7500 0000
- Context 1 180-degree view: 0x7600 0000
- Context 1 270-degree view: 0x7700 0000

The start address of the view corresponds to the logical origin of the image ($x = 0, y = 0$). The image pitch parameter, commonly defined as the distance between two vertically adjacent pixels, is fixed to 2048 pixels.

Example of usage by the application:

In a system using an 400 × 300 LCD panel that has a native landscape orientation, the natural scan order is as shown in [Figure 9-91](#).

Figure 9-91. Natural Scan Order

sdrc-018

The display buffer is the one created in the example sequence.

When the application is running and uses the portrait orientation for the display (typically, a PDA-type application):

- The LCD controller accesses the frame buffer using the 0-degree view.
- The processor and other initiators, such as 2D DMA or 3D accelerators, use the 90-degree view.

When the application is running and uses the landscape orientation for the display (typically, a video recorder/player or gaming application):

- The LCD controller still accesses the frame buffer using the 0-degree view.
- The processor and other initiators, such as 2D DMA or 3D accelerators, also use the 0-degree view. See [Section 9.2.5.1.1](#).

9.2.4.3 Memory-Access Scheduler Configuration

The memory-access scheduler is configured as follows:

- Register security settings
 - SMS.SMS_SECURITY_CONTROL register
 - Arbitration control registers security level (SMS.SMS_SECURITY_CONTROL[5] ARBITRATIONREGSLOCK bit)

- For each of the three classes, the arbitration parameters are:
 - SMS.SMS_CLASS_ARBITER0 through SMS.SMS_CLASS_ARBITER2
 - One high-priority FIFO queue in the class (HIGHPRIOVECTOR field)
 - Number of consecutive transactions to perform (EXTENDEDGRANT field)
 - Burst transaction submitted for arbitration immediately or after the burst has been buffered (BURST-COMPLETE field)

9.2.4.4 Error Logging

All data transfers in the SMS are full handshake. The SMS uses this capability to signal the system when a transaction error is detected.

The SMS captures the address of the faulty access in the SMS.SMS_ERR_ADDR register. The error type is logged in the SMS.SMS_ERR_TYPE register. Once a faulty access is logged and the SMS.SMS_ERR_TYPE[0] ERRORVALID bit is set, the next faulty accesses cannot be logged before clearing the ERRORVALID bit.

In the case of an interconnect transaction, an error response is generated if any of the following occur:

- An incoming request arrives after an idle request from the PRCM.
- An illegal command is received.
- A protection region overlap is detected.
- A nonsecure or non-supervisor write access to the security control register is detected.
- Protection errors.

It is assumed that the system interconnect on which the SMS is plugged is responsible for signaling the error event to the host MPU based on the interconnect response. The MPU error handler can then consult the error logging registers.

The security control register allows locking the SMS.SMS_ERR_ADDR and SMS.SMS_ERR_TYPE registers to secure- and supervisor-only accesses. This configuration is highly recommended for high-security devices. For GP devices, ErrorLog can remain public.

9.2.5 SDRC Use Cases and Tips

9.2.5.1 How to Program the VRFB

9.2.5.1.1 VRFB Rotation Mechanism

An inherent limitation of SDRAM technology is high-memory latency caused by page-miss penalties incurred when downloading to a memory cache. For example, switching from one page to another in external memory can cause a page-miss, indicating that the page accessed for the current pixel is different from that for the previous pixel.

A DMA engine is used to rotate pictures in external DRAM, but this rotation method increases the number of page misses.

The efficient way to rotate image data in external SDRAM is to use the VRFB module, which is an RE embedded in the SMS of the processor, as shown in [Figure 9-92](#). It is configured in the SMS registers.

Accessing images stored in external SDRAM in a non-natural order requires an address transaction: the virtual address of an image is translated into a physical address in the corresponding buffer. Address translation causes an image to be rotated in 0-, 90-, 180-, or 270-degree views. With multiple views of the image, the RE can change addresses and issue multiple requests to the EMIF so that a maximum of consecutive accesses is performed, thus decreasing the number of page-miss penalties. The RE cannot reorder requests to the SDRAM.

A VRFB context defines the configuration used to access a picture in external SDRAM. For each VRFB context, a set of registers in the SMS describes:

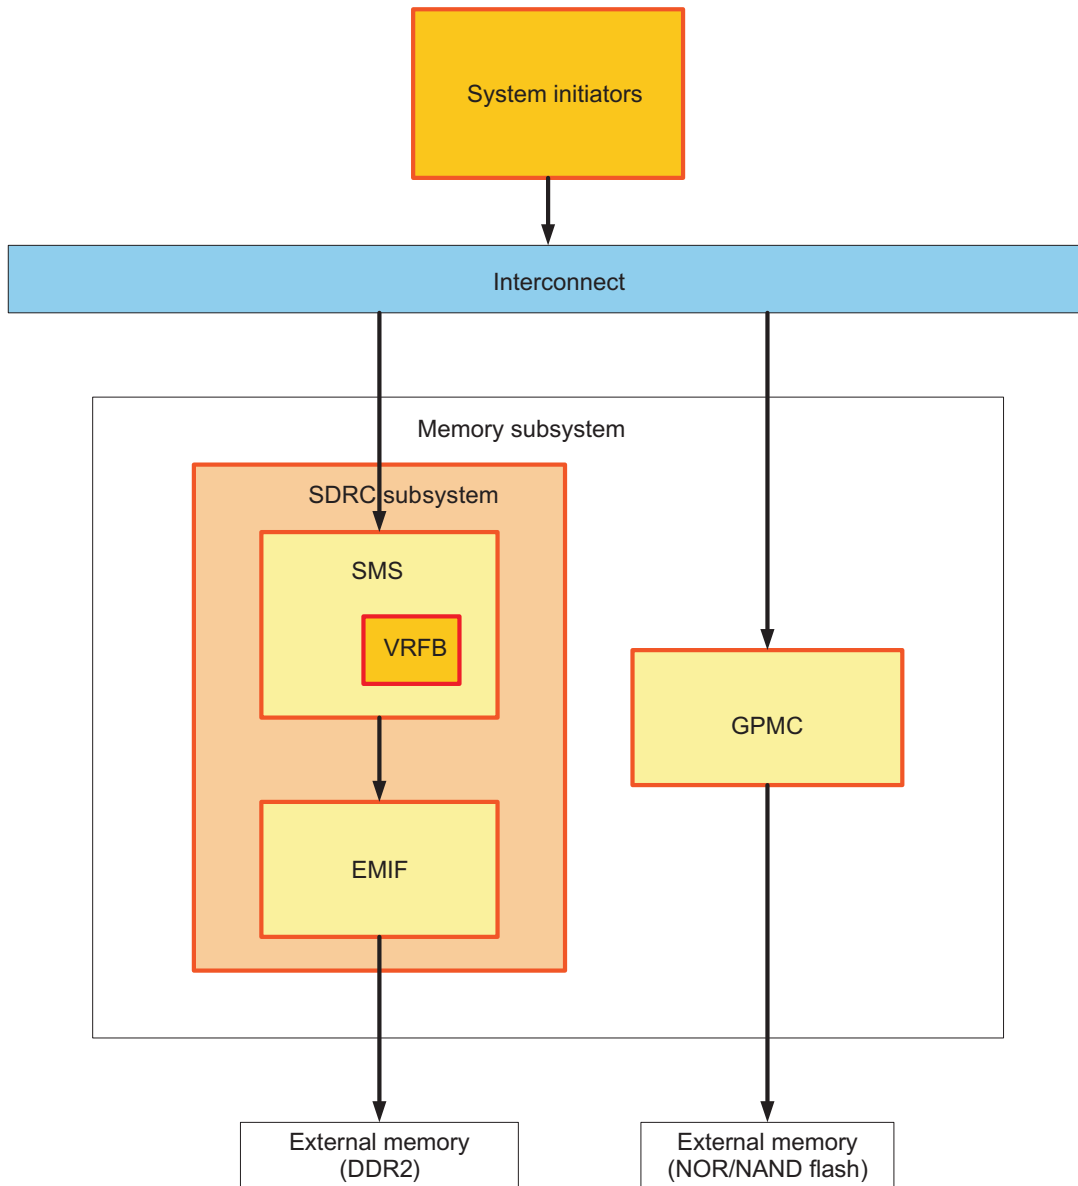

- The size of the page (height and width)
- The picture parameters before rotation (width, height, and pixel format)
- The rotation angle (0-, 90-, 180-, or 270-degree)
- The physical base address in external memory

Any initiator in the processor can access up to 12 images simultaneously, each image having an independent context. These 12 contexts is considered virtually addressed image buffers. Each context is assigned to a physical image buffer.

The virtual address space of each context is subdivided into four separate address regions pointing to the same physical image buffer but corresponding to the four possible rotations: 0/90/180/270.

After the VRFB context is configured, all data accesses to an address space are automatically translated when accessing SDRAM through the RE.

Figure 9-92. SDRC Subsystem Overview

sdr-019

9.2.5.1.2 Setting a VRFB Context

NOTE: YUV Format

The YUV standard shows a color space with three elements:

- Y for luminance
- U for chrominance
- V for chrominance

As shown in [Figure 9-93](#), pixel format (not pixel size) used in the YUV standard is spread onto a 32-bit data structure:

- This 32-bit data structure represents a packet of two pixels: P0 and P1.
- Each element (Y0, Y1, U, and V) is coded in 8 bits.
- P0 = Y0; U, V, and P1 = Y1, U, V.

There are 24 bits of information per pixel (Y, U, and V); however, because the chrominance elements U and V are common to both P0 and P1 pixels, only 16 bits are used to store a pixel in YUV format. The YUV standard uses a 32-bit data structure to represent 2 pixels; the pixel format uses 32 bits (4 bytes).

Thus, when defining YUV image parameters, the image width must be set to one-half the number of pixels per row and the pixel format must be set to 4 bytes, because the YUV pixel data is spread onto a 32-bit word representing 2 pixels.

[Figure 9-93](#) shows the pixel representation of the YUV format.

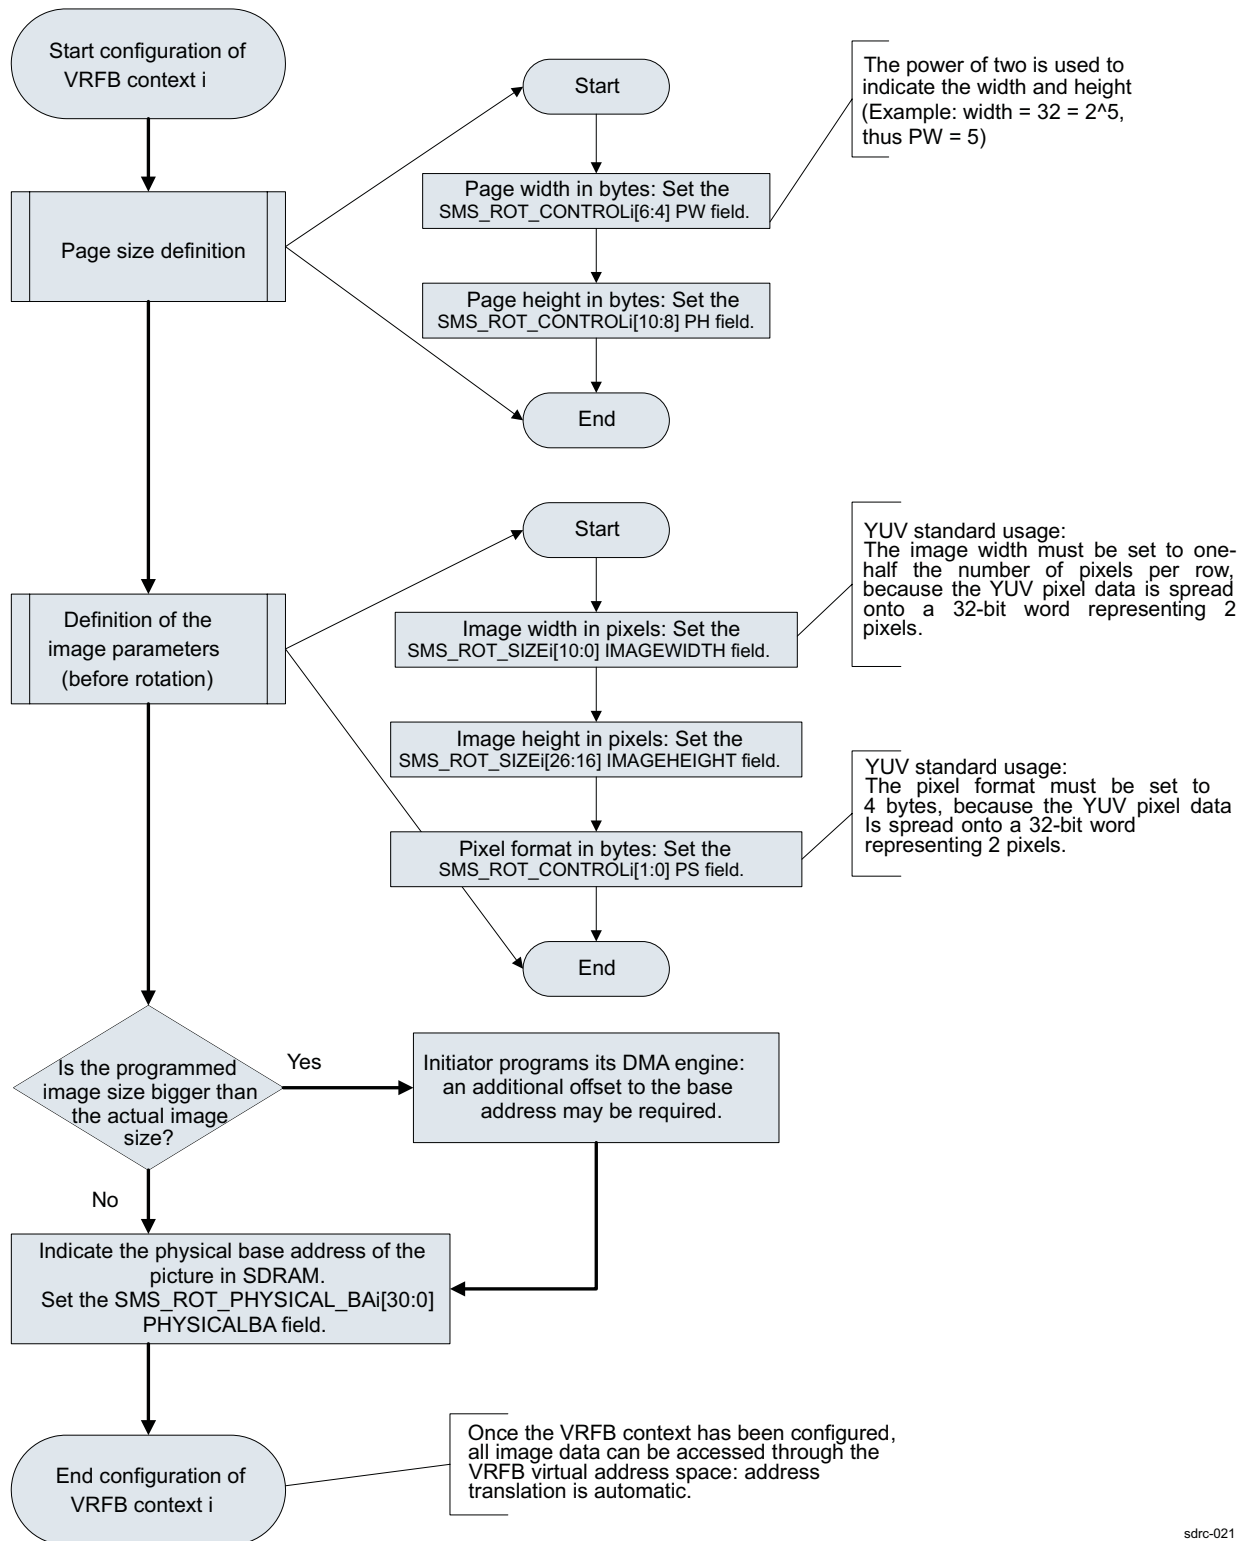

Figure 9-93. YUV Format: Pixel Representation

sdr-020

Figure 9-94 shows a generic way to configure a VRFB context to perform a rotation view on pixel data in external DRAM.

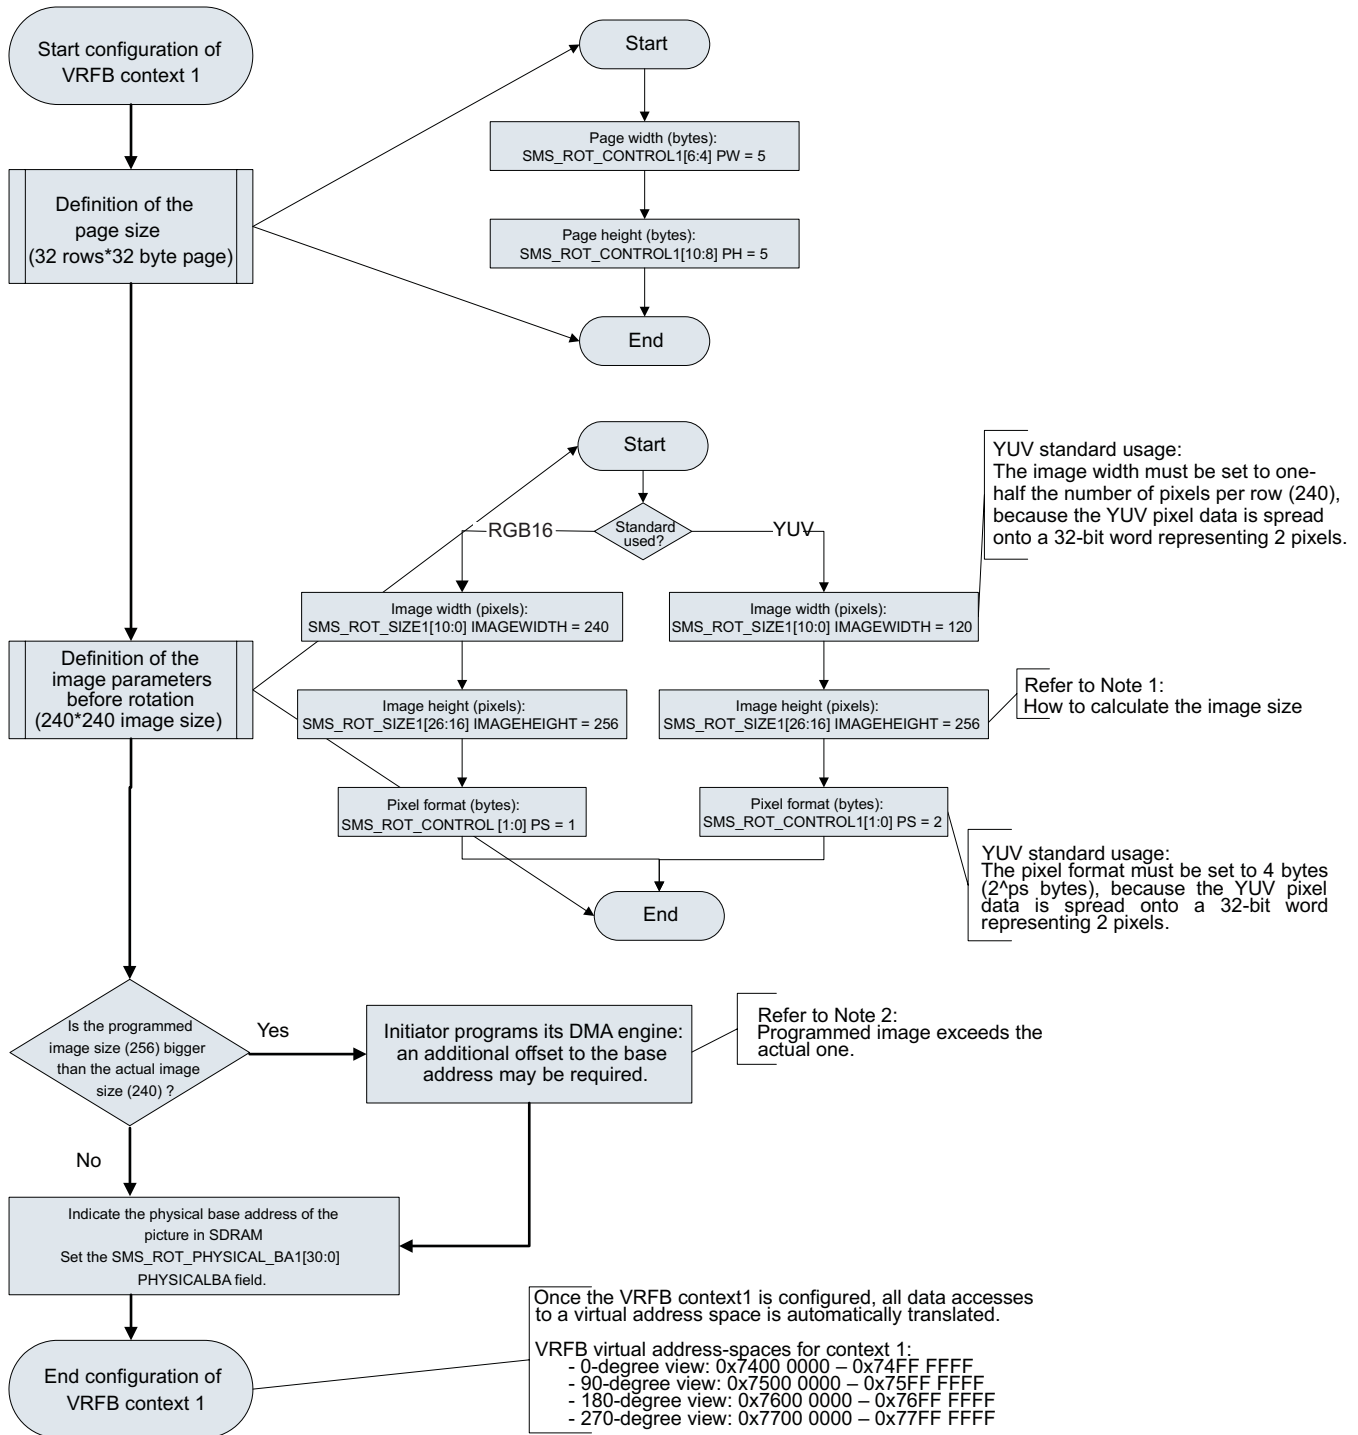

Figure 9-94. VRFB Context Configuration

sdrc-021

Figure 9-95 is an example of VRFB context configuration using both RGB and YUV image formats. This example represents the configuration of a 1024-byte page size (32 x 32 byte page) and a 240 x 240 image size using VRFB context 1.

Figure 9-95. Example of VRFB Context 1 Configuration

sdrc-022

Table 9-111 lists guidelines for calculating image size.

Table 9-111. Calculating Image Size^{(1) (2)}

| Steps | | RGB16 Format (16-bit Pixel Format) | | YUV Format (32-bit Pixel Format) | |
|-------|---|---|--|---|---------------------------------|
| | | IMAGEWIDTH | IMAGEHEIGHT | IMAGEWIDTH | IMAGEHEIGHT |
| 1 | Calculate the required number of pages per line and per column. | 240 pixels/32 bytes × 2 bytes per pixel = 15 pages per line | 240/32 rows = 7.5, rounded to 8 pages per column | 120 pixels/32 bytes × 4 bytes per pixel format = 15 | 240/32 rows = 7.5, rounded to 8 |
| 2 | Using the number of pages calculated in Step 1, calculate the image size in pixels. | 15 × 32 bytes/2 bytes per pixel = 240 | 8 × 32 rows = 256 | 15 × 32 bytes/4 bytes per pixel format = 120 | 256 |

⁽¹⁾ Working on a page basis, the image size must be a multiple of the page size.

⁽²⁾ Depending on the page dimensions and the image size, the programmed image size (256) is larger than the actual image size (240).

To use VRFB rotation, each initiator must configure its DMA engine correctly; an additional offset to the base address may be required. For details, see the *Display Subsystem* chapter.

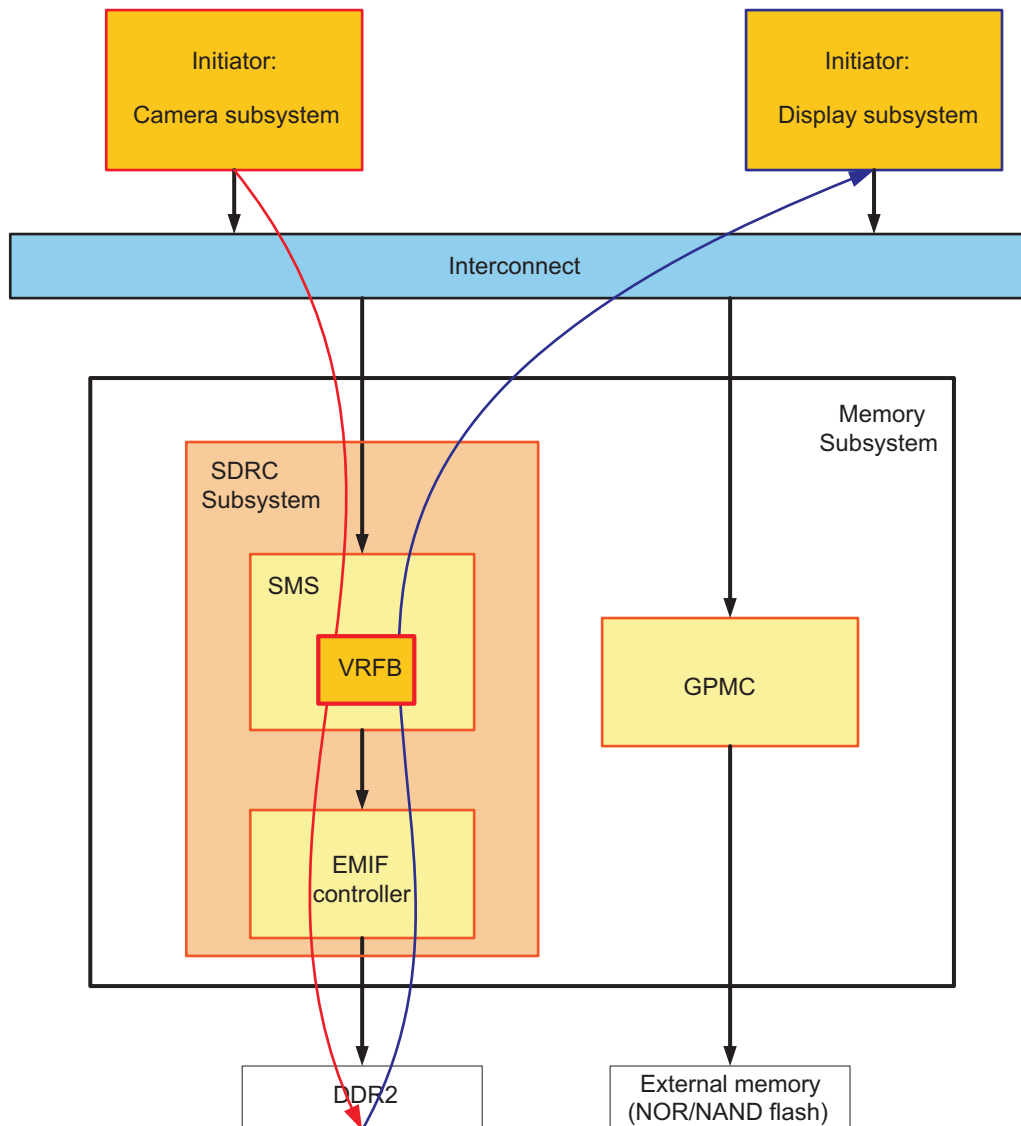

9.2.5.1.3 Applicative Use Case and Tips

Use Case Scenario: Display a Rotated QVGA Image

Figure 9-96 this use case. The camera captures an image with a particular rotation and stores the pixel data in external memory. Displaying the image on the LCD requires different orientation.

The following components interact while displaying the rotated image:

- SDRC subsystem
- Camera subsystem
- Display subsystem
- External DDR
- VRFB

Figure 9-96. Display a Rotated QVGA Image

sdr-023

The following conditions exist for this application:

- QVGA image size is 320 × 240 (width × height).
- Pixel format is YUV4:2:2 (YUV2) in little endian.
- The rotation view is 90 degrees.
- The VRFB context is VRFB context 1.
- The camera module writes QVGA images to external DRAM at 15 fps.
- The display subsystem reads QVGA images from external DDR2 at 60 fps and displays them on the LCD screen.
- Read and write initiators use burst mode:
 - The camera uses 8 × 64-bit burst size.
 - The display uses 8 × 32-bit burst size.
 - Double-indexing mode is selected.
- The physical address of the buffer in external memory is 0x8030 0000.
- The memory allocation for the buffer is 320 × 240 × 16-bit (or 160 × 240 × 32-bit).
- The camera subsystem uses its dedicated DMA channel 0.

- The display subsystem uses its video channel 1.

Configuring the VRFB through the SMS Registers

The size of the page supported by the DDR2 memory is 1K byte, which is arranged as 32 × 32 bytes page (width × height).

Configuring the page size:

- SMS_ROT_CONTROL_n[6:4] PW = 5 (where n = 1)
- SMS_ROT_CONTROL_n[10:8] PH = 5

Configuring the image parameters:

- SMS_ROT_SIZE_n[10:0] IMAGEWIDTH = 160 (where n = 1)
- SMS_ROT_SIZE_n[26:16] IMAGEHEIGHT = 256
- SMS_ROT_CONTROL_n[1:0] PS = 2

Physical base address and rotation angle:

- SMS_ROT_PHYSICAL_BA_n[30:0] PHYSICALBA = 0x8030 0000 (where n = 1).

The image data is accessed at the following virtual address range for 90-degree rotation: 0x7500 0000 – 0x75FF FFFF.

CAUTION

Image rotation using the YUV2 image format causes the stream to become untidy. The display must be specifically configured to read and reorganize the stream to conform to the YUV2 standard.

Tips for Configuring Successful Rotation

The following guidelines ensure optimal image rotation:

- Page arrangement:

Usually, the recommendation is to have a *square* page. If this is not possible, the longest page side should correspond to the access direction that requires the maximum bandwidth; set the longest page side to optimize the page break.

Using a 1024-byte page size, a 32 × 32-byte page arrangement is used as an example. With a 2K-byte page organized as a 32 × 64 byte page, depending on the read or write operation, set the longest page size to optimize the page break. If 0 is written and the 270-degree view is read, page height is greater than page width (PH > PW). Set PH to 64 bytes (PH = 6).
- Virtual address memory arrangement:

When accessing image data through virtual addresses, the maximum line size supported by the VRFB is 2,048 pixels.

In the memory buffer, the distance between two vertically adjacent pixels is fixed at 2,048 multiplied by the pixel format in bytes. This means that when reading or writing image data through virtual addresses, there must be an offset of: (2048 – IMAGEWIDTH) × PS bytes at the end of every line.
- Base address alignment:

For optimization, the base address is aligned on the page size. For instance, a 1K-byte page size organized as a 32 × 32-byte page is aligned on 0x400 (to be adjusted on the base address).
- To improve performance on 90° rotation consider two things:
 - Because a read access can appear more critical than a write access, a posted write may be appropriate.
 - When performing burst accesses with 90° or 270° rotation views, the burst is split on the memory side, adding latency.

For a burst access with 90° rotation, split the data of the burst on the write side (not the read side):

 - Write in 270° and read in 0°.

9.2.5.2 SMS Mode of Operation

9.2.5.2.1 The SDRAM Memory Scheduler and Arbitration Policy

The SDRAM memory scheduler improves access to external memory by:

- Optimizing SDRAM bandwidth
- Prioritizing requests to external memory

This mechanism relies on a complex arbitration policy that employs specific terminology:

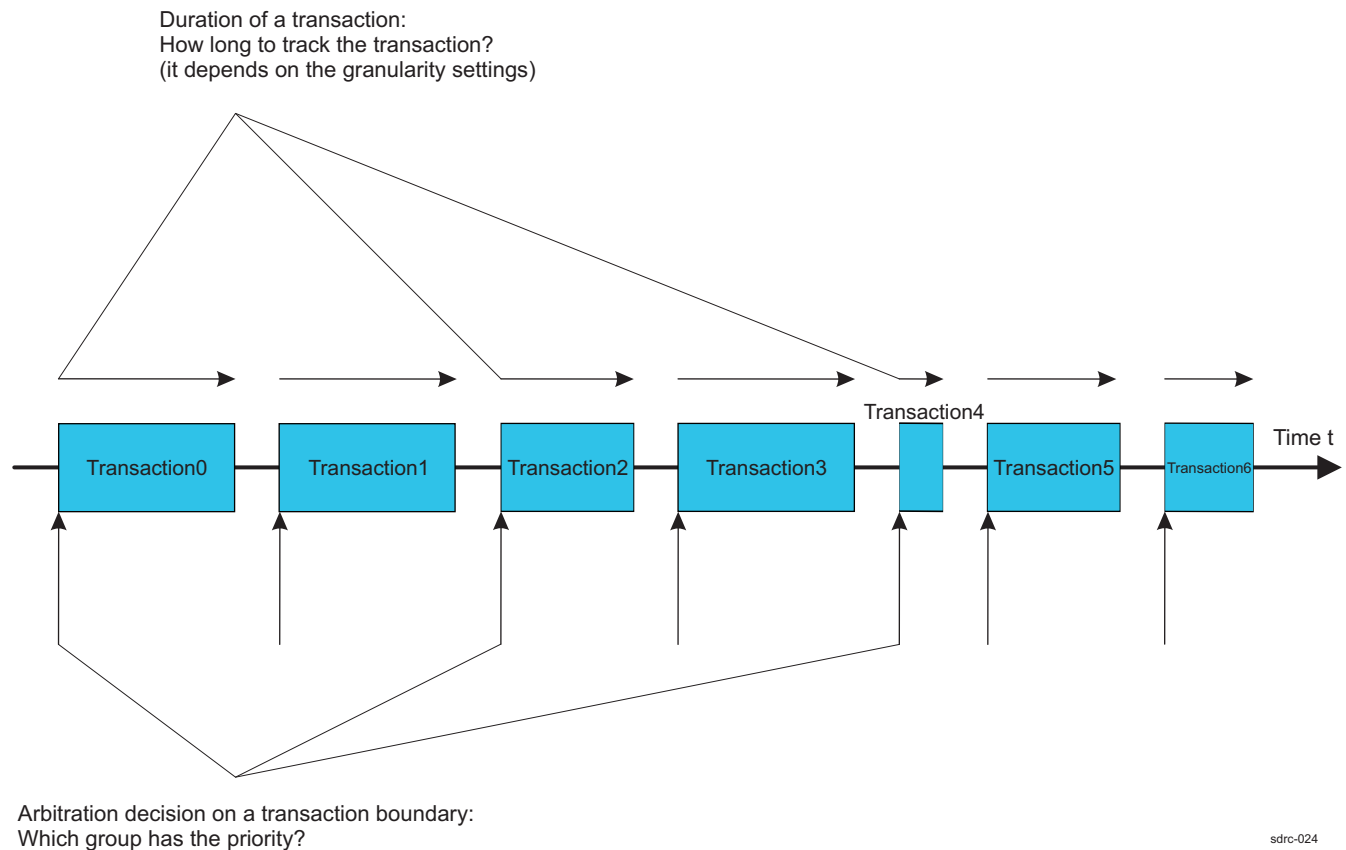

- Group: a FIFO queue of requests from initiators
- Class: A collection of groups
- Transaction: A full burst request
- Arbitration grant: Authorization of a service requested by an initiator

The arbitration policy operates on two interdependent mechanisms:

- The arbitration decision, which establishes priority for processing requests. The question: Which request is processed next? occurs on a transaction boundary.
- Arbitration granularity, which determines the length of an arbitration grant. The question: How long to keep the grant? defines the boundary of the arbitration decision point in time.

Figure 9-97, shows the link between these two concepts. On a transaction boundary, the questions: What request is serviced next, and for how long? merge the two mechanisms. The mechanisms for specifying the granularity of requests also influence the boundary of a transaction.

Figure 9-97. Arbitration Granularity Versus Arbitration Decision

9.2.5.2.2 The Arbitration Decision

The SMS module controls arbitration. Requests from initiators for access to the external SDRAM are collected into several independent FIFO queues, and each queue is assigned to a class. Priority is then assigned to groups and classes; this defines the next request to be serviced.

9.2.5.2.2.1 Burst-Complete Mechanism

The burst-complete mechanism applies granularity to the arbitration scheme. Access cannot be granted to a group within a class until a complete burst has been stored in the FIFO.

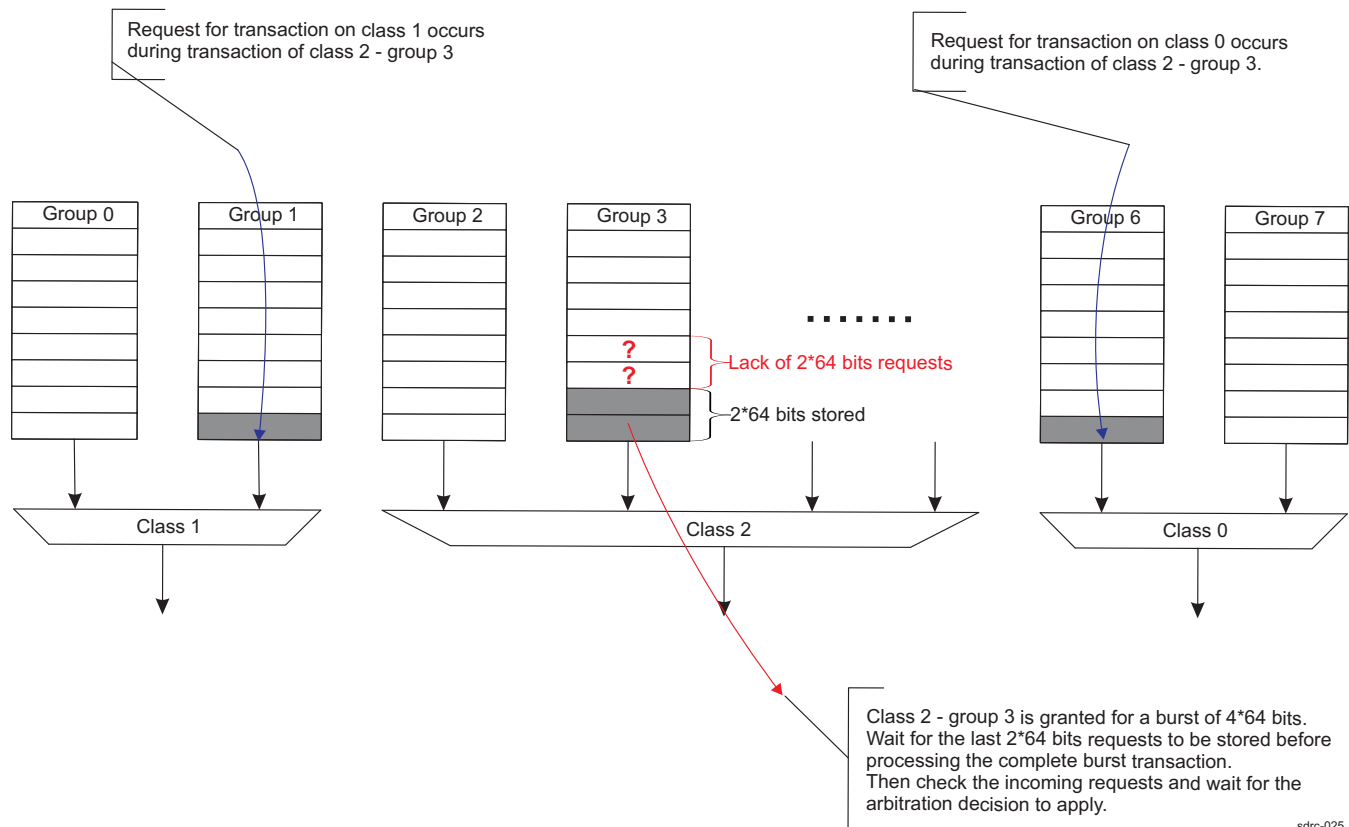

Example:

There is no ongoing transaction on Class 0. The initiator requests a 4 x 64-bit burst on Group 3 of Class 2 (SMS_CLASS_ARBITER2[27] BURST-COMPLETE = 0x1). Only 2 x 64-bit requests are stored in the FIFO.

The mode of operation is:

- Wait for the last 2 x 64-bit request to be stored in the FIFO.
- Arbitration is requested once all requests of a burst have been received.
- After the 4 x 64-bit burst is complete, the transaction occurs.
- The arbitration choice mechanism resumes:
 - Were there any incoming requests during the last transaction?
 - What is the next request to be serviced/granted?

Figure 9-98. BURST-COMPLETE on Class 2-Group 3

sdrc-025

9.2.5.2.2 Priority Between Groups

The SMS.SMS_CLASS_ARBITERi[7:6] HIGHPRIOVECTOR field defines the priority between groups in a class.

9.2.5.2.3 Priority Between Classes

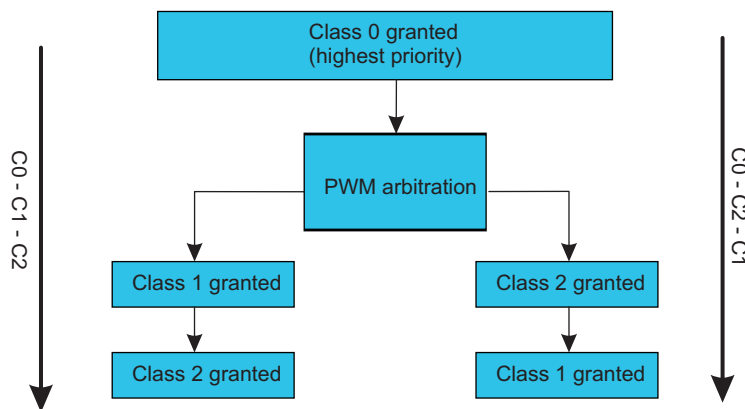

Class 0 always has the highest priority. Then you program a weight within the arbitration of Class 1 and Class 2:

- The SMS.SMS_INTERCLASS_ARBITER[23:16] CLASS1PRIO field specifies the number (M) of transactions dedicated to Class 1.
- The SMS.SMS_INTERCLASS_ARBITER[7:0] CLASS2PRIO field specifies the number (N) of transactions dedicated to Class 2.

M and N parameters are used to set a PWM arbitration. For instance, two schemes appear: at time t, Class 1 is serviced for M cycles, directly followed by service to Class 2 for N cycles. On the opposite, if Class 2 is serviced first for N cycles, then Class 1 is granted for M cycles. Arbitration is given more importance; Class 1/2 is favored over Class 2/1. As shown in Figure 9-99, two arbitration schemes can appear:

- Class 0 is serviced first, followed by Class 1, then Class 2 (C0 - C1 - C2).
- Class 0 is serviced first, followed by Class 2, then Class 1 (C0 - C2 - C1).

Figure 9-99. Priority Between Classes

SMS_INTERCLASS_ARBITER[7:0] CLASS1PRIO field:
defines the number M of transactions dedicated to class 1.

SMS_INTERCLASS_ARBITER[23:16] CLASS2PRIO field:
defines the number N of transactions dedicated to class 2.

sdrc-026

9.2.5.2.3 Arbitration Granularity

Arbitration is the mechanism that give more or less importance to incoming requests depending on the initiator origin. Granularity influences the boundary of a transaction because it imposes the following questions:

- How many requests to service?
- How long to track the current transaction?
- When to make the next arbitration decision, or when does the next transaction boundary occur?

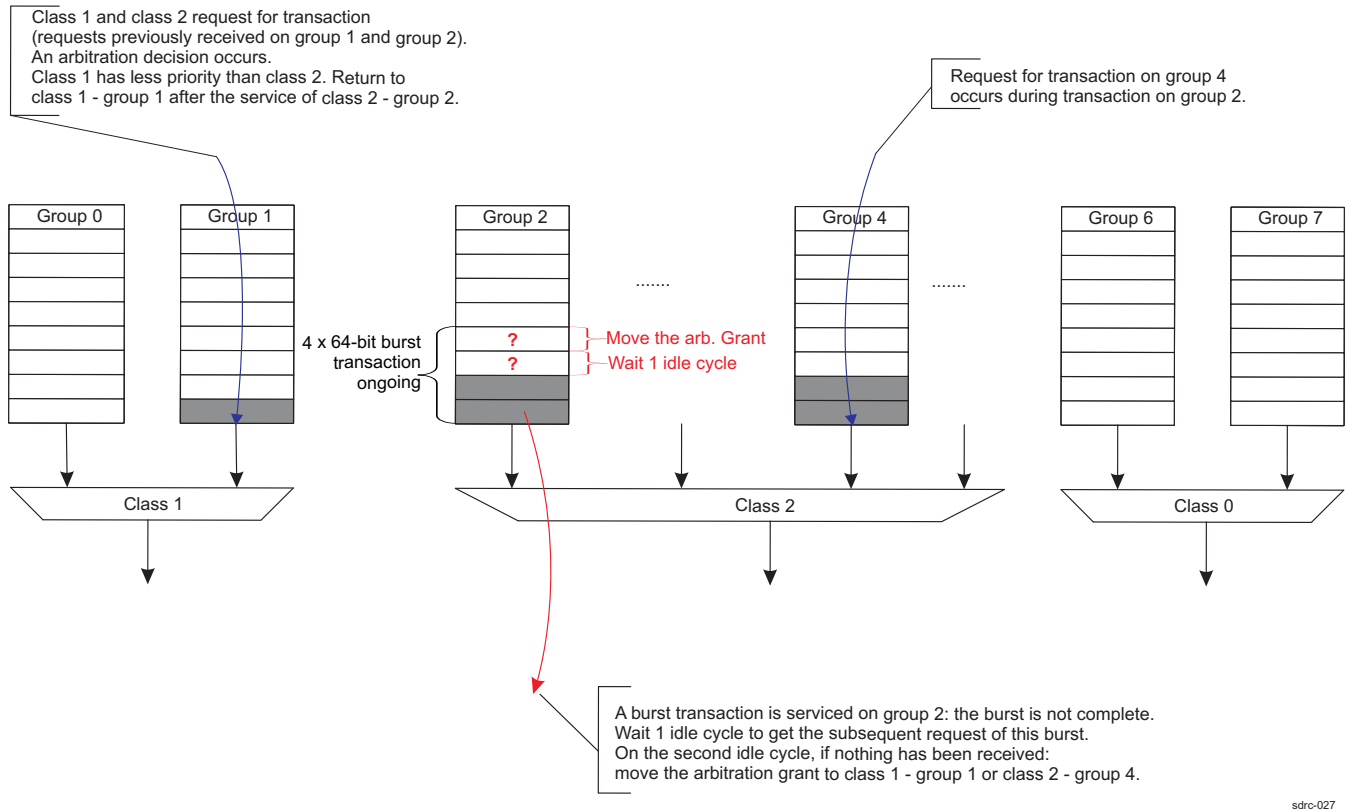

9.2.5.2.3.1 Idle Cycle

The idle gives more granularity to the arbitration; it lets the arbiter wait one idle cycle before moving the arbitration grant to another thread.

Within a burst (see Figure 9-100 for an example):

1. A thread requests a burst transaction. According to the thread ID, the last request was serviced on Class 2 – Group 2.
2. The thread cannot provide the subsequent request of the burst. The module waits for one idle cycle without moving the arbitration grant, to receive the subsequent request (from the same thread).
3. On the second idle cycle, if the subsequent request has not been received, the arbitration grant is moved so that a request from another thread is serviced.

Figure 9-100. Idle Cycle Mechanism within a Burst

Two bursts must be serviced at the burst boundary. One idle cycle after servicing these two bursts, the arbitration grant is moved.

9.2.5.2.3.2 Extended-Grant Mechanism

The extended-grant mechanism gives additional granularity to the arbitration. An extended grant defines the number of consecutive transactions (from 1 to 3) a group is granted.

Example:

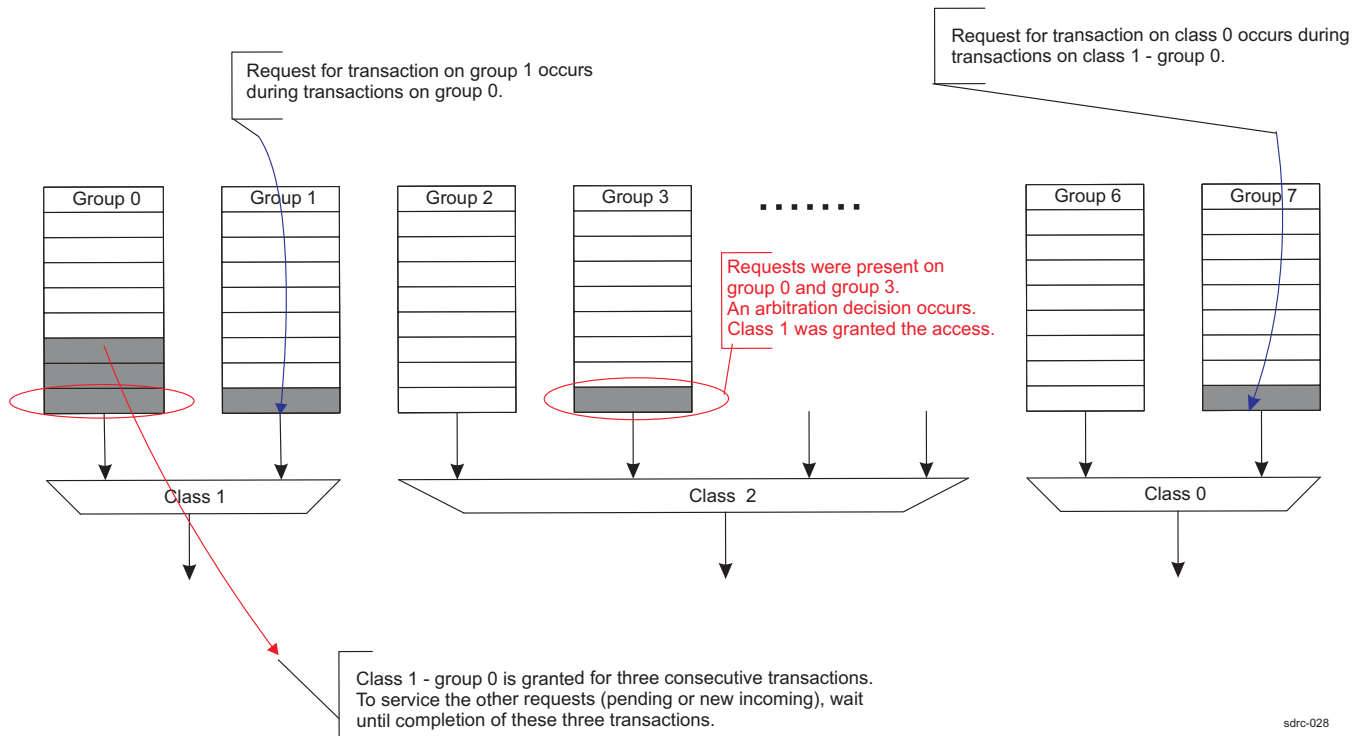

Requests were already available on Class 1-Group 0 and Class 2-Group 3.

An arbitration decision occurs: grant access to Class 1-Group 0.

A request is now being serviced on Class 1-Group 0 with SMS_CLASS_ARBITER1[9:8] EXTENDEDGRANT = 0x3 (three consecutive transactions are granted to Group 0). The mode of operation is:

- Process the request for three cycles.
- If another request comes from another class (even Class 0) during the processing, it is ignored; the arbiter does not treat incoming requests.
- After three consecutive transactions, return to the arbitration decision:
 - Were there any incoming requests during the last transaction?
 - What is the next request to be serviced?

Figure 9-101 shows this mechanism on Class 1 - Group 0:

Figure 9-101. Example of EXTENDEDGRANT Mechanism

9.2.5.2.3.3 Number of Service Mechanism

The SMS_CLASS_ROTATIONm[4:0] NOFSERVICES field defines the number of consecutive transactions (from 1 to 31) the VRFB is granted. For more information on LRU policy and Number of Service, refer to [Section 9.2.3.1.3](#).

9.2.5.2.4 How these Mechanisms Interact

As described in the previous sections, the arbitration within the SMS module is based on several mechanisms giving even more importance to the arbitration. When we need to grant the access on a transaction boundary, we recall that the question we have to answer is: what will be the next request to be serviced and for how long?

Thus, the two important concepts regarding the SMS mode of operation are:

- The arbitration decision: we choose the next request to be serviced and so we grant it the access to the external memory.
- The arbitration granularity: depending on the mechanism used, we define the boundary of the transaction: how long do we keep the grant?

[Figure 9-102](#) describes the decision happening between classes.

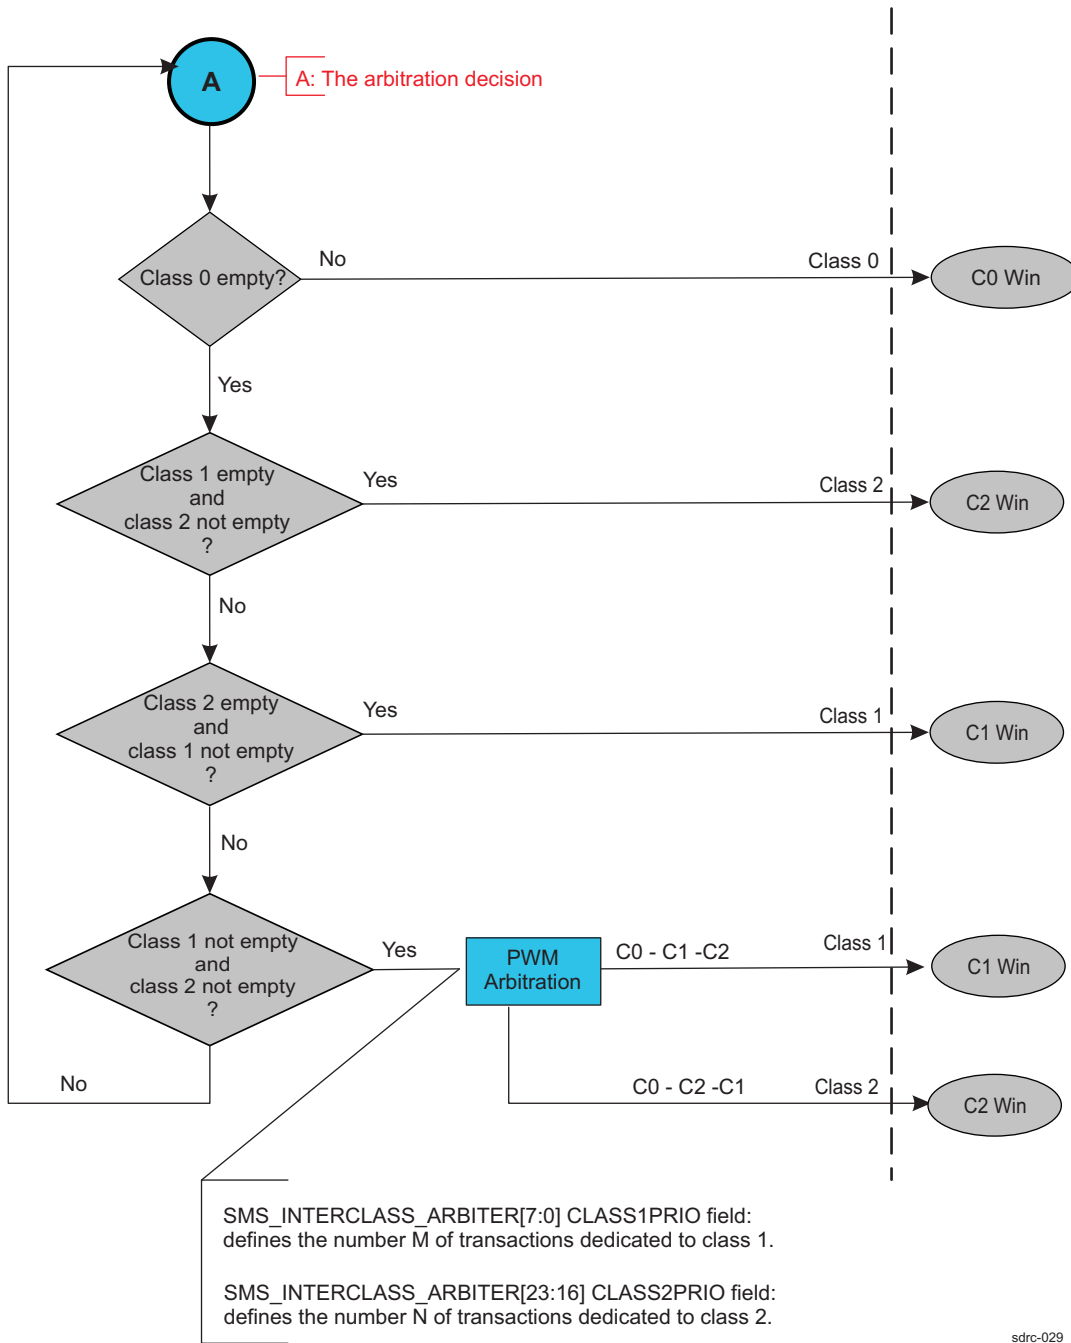

[Figure 9-103](#) explains the priority between groups within Class 1.

So far, the arbitration decision has taken place at class boundaries and within a class containing 2 groups.

[Figure 9-104](#) recalls the generic way to service and so prioritize the requests within a class.

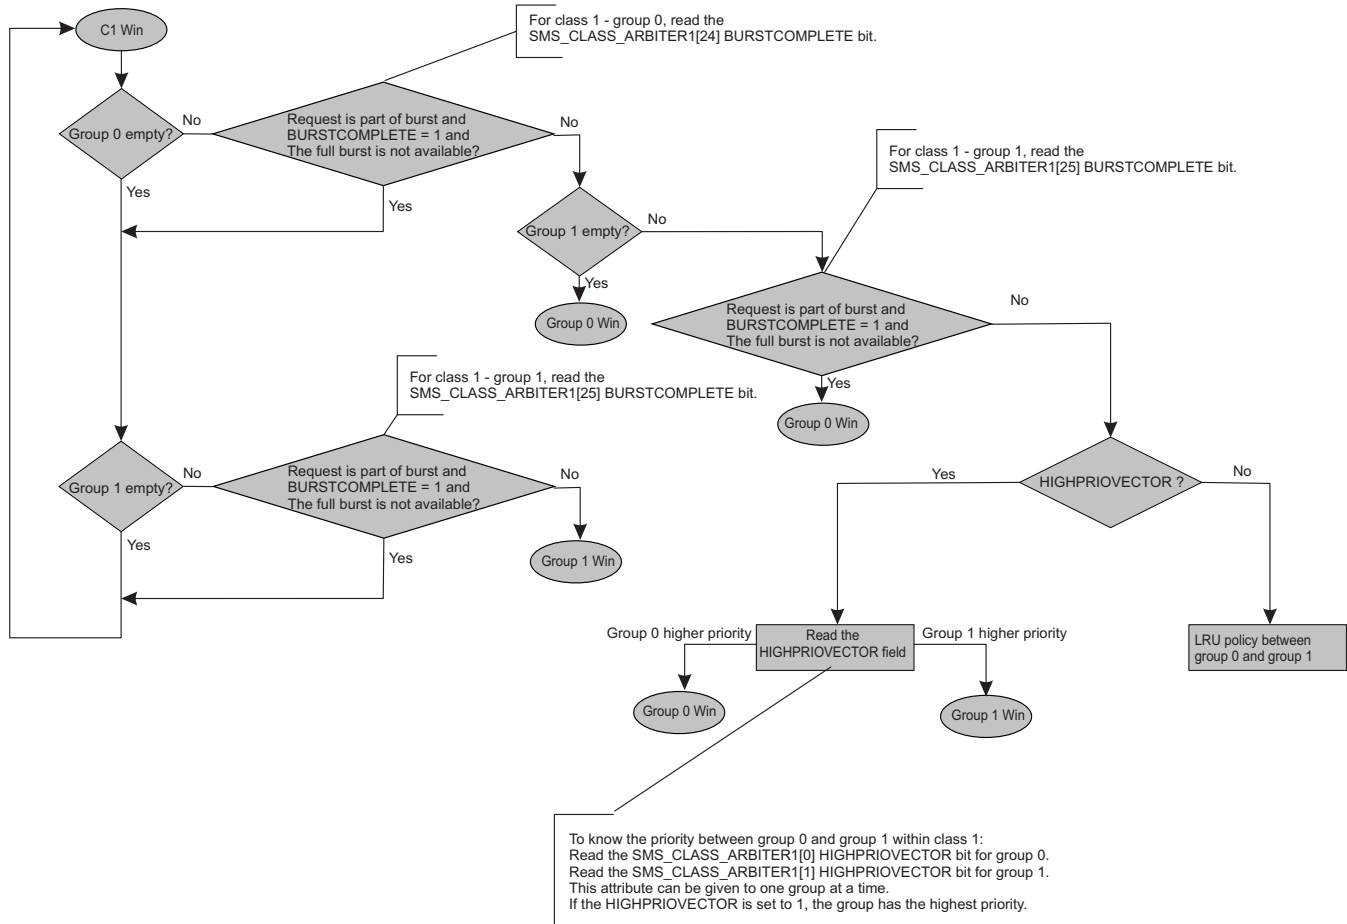

Finally, [Figure 9-105](#) recalls mechanisms used to define the boundary of the transaction being serviced (how long do we keep the grant?).

9.2.5.3 Camcorder Use Case: How to Configure the VRFB

9.2.5.3.1 Overview

This section discusses the configuration of the VRFB for rotating the video from the camera subsystem. The VRFB receives a video from the camera subsystem as a sequence of images. These images are then saved into SDRAM through the EMIF. Figure 9-106 is an overview of the VRFB in the camcorder use case.

Figure 9-106. SDRC Camcorder Use Case Overview

After the VRFB configuration, the rotation process is transparent to the MPU operations. Four buffers are required in SDRAM to ensure stabilization, a smooth encoding process, and a tearing-free preview on the LCD display. Each of the four buffers uses a concurrent context. For each context, the following parameters must be configured:

- Page and pixel size
- Picture parameter (image height and width)
- Buffer physical base address

9.2.5.3.2 Data Path

In this use case, the VRFB manages the rotation of the video stream, which is a sequence of images in YUV 4:2:2 format received from the camera subsystem.

- Write actual image received from the camera subsystem into SDRAM through the VRFB in the first view (0°).
- Display the image in SDRAM on the external display through the display subsystem in any of the four available VRFB views (0°, 90°, 180°, or 270°).

See Figure 9-96 for the VRFB data path of this use case.

The row increment in the SDRAM is programmed in the display subsystem registers and depends on the VRFB rotation angle.

9.2.5.3.3 Programming Flow

A main function automatically configures the VRFB contexts. This function is called four times to configure each of the four contexts. For each context, a set of parameters is given to the function:

- The actual image width and height (from the camera subsystem)
- The physical address (of the given context)

- The rotation of the context

The main function initializes the VFRB in three steps:

1. Virtual frame buffer configuration. This is done with a page size calculation function, as described in [Section 9.2.5.3.3.1](#).
2. Image size configuration. This is done with a picture size calculation function, as described in [Section 9.2.5.3.3.2](#).
3. Physical base address configuration, as described in [Section 9.2.5.3.3.3](#).

9.2.5.3.3.1 Page Size Calculation Function

The page size is configured through three parameters: page width (PW), page height (PH), and pixel size (PS). The three page size parameters are configured into the SMS_ROT_CONTROL_n registers, where *n* is the context number (*n* = 0 to 3):

- Page width: SMS_ROT_CONTROL_n[6:4] PW. The PW parameter defines the page width according to the value of 2^{PW} bytes.
- Page height: SMS_ROT_CONTROL_n[10:8] PH. The PH parameter defines the page height according to the value of 2^{PH} lines.
- Pixel format: SMS_ROT_CONTROL_n[1:0] PS. The PS parameter defines the pixel size according to the value of 2^{PS} bytes. In this use case, the pixel size is a constant linked to the YUV 4:2:2 format. For more details about YUV 4:2:2 format, see [Section 9.2.5.1.2, Setting a VFRB Context](#).

The recommendation is to have a squared page arrangement. The page can be defined as a 32-byte × 32-byte array (1024-byte page) or 16-byte × 16-byte array (256-byte page). This arrangement is pixel-based, which means the pixel size must be part of the calculation. Other settings are possible, but from a performance point of view it is recommended to have the page size consistent with the SDRAM page (that is, 2K bytes for the Mobile DDR SDRAM).

In this use case, however, the page size calculation function defines the page width and the page height. The pixel size is not part of the calculation. Hence, instead of having a 64 × 32 page (because a pixel takes 2 bytes) the function calculates a 32 × 32 page. This gives a page size of 1K-byte, and memory area usage is optimized.

First, the function checks whether the width of the image received from the camera is a multiple of 32 bytes. If the width is not a multiple of 32 bytes, the function checks whether the image is a multiple of 16 bytes. If the image from the camera is neither a multiple of 32 bytes nor 16 bytes, the function sets the page width to 32 bytes as the default. In this use case, the image received from the camera has a width of 736 pixels.

1. Check that 736 is a multiple of 32: $736 / 32 = 23$. It is. As a consequence, the page width is 32 (bytes).
2. Configure a page width of 32 with the 2^{PW} bytes formula: SMS_ROT_CONTROL_n[6:4] PW = 0x5.

Then, the function checks whether the height of the image received from the camera is a multiple of 32 (rows). If the height is not a multiple of 32 (rows), the function checks whether the image is a multiple of 16 rows. If the image from the camera is neither a multiple of 32 rows nor 16 rows, the function sets the page height to 32 rows as the default. In this use case, the image received from the camera has a height of 560 lines.

3. Check that 560 is a multiple of 32: $560 / 32 = 17.5$. It is not.
4. Check that 560 is a multiple of 16: $560 / 16 = 35$. It is. As a consequence, the page height is 16 (lines).
5. Configure a page height of 16 with the 2^{PH} lines formula: SMS_ROT_CONTROL_n[10:8] PH= 0x4.
The pixel format of this use case is YUV 4:2:2. Two pixels are stored on 4 bytes.
6. Configure a pixel size of four bytes with the 2^{PS} bytes formula: SMS_ROT_CONTROL_n[1:0] PS = 0x2.

9.2.5.3.3.2 Picture Size Calculation Function

The picture size is configured through two parameters: image width (IMAGEWIDTH) and image height (IMAGEHEIGHT). Two sizes must be distinguished:

- Actual image width and actual image height . This is the size of the image received by the camera subsystem.
- Programmed image width and programmed image height. This is the size of the image programmed in the VRFB.

Figure 9-107 shows the actual image width (IW) and image height (IH) versus the programmed image width (IW + ΔIW) and programmed image height (IH + ΔIH).

Figure 9-107. VRFB Actual Image Size vs Programmed Image Size

sdr-040

The programmed image size parameters are configured into the SMS_ROT_SIZE_n registers, where n is the context number (n = 0 to 3):

- Image width: SMS_ROT_SIZE_n[10:0] IMAGEWIDTH. This parameter is expressed in the number of pixels.
- Image height: SMS_ROT_SIZE_n[26:16] IMAGEHEIGHT. This parameter is expressed in the number of pixels.

The picture size calculation function determines the required number of pages per line and per column using the page size calculated previously. That is a page width of 8 pixels (32 bytes and 4-byte pixel) and a page height of 16 pixels.

1. Determine the required number of pages per line with the formula:

$$[(\text{actual_image_width} / 2) \text{ pixels} / \text{page_width bytes}] \times \text{pixel_size bytes/pixel}$$

This gives a required number of pages per line of $[(736 / 2) / 32] \times 4 = 46$.
 If the number of pages per line is not an integer, it must be rounded up; for instance, if the result was 46.25 the number of pages required per line would be 47. Figure 9-107 shows this point.
2. Determine the required number of pages per column with the formula:

$$(\text{actual_image_height pixels}) / \text{page_height lines}$$

This gives a required number of pages per column of $(560) / 16 = 35$.
 If the number of pages per column is not an integer, it must be rounded up.

Finally, calculate the programmed image size in pixels using the number of pages calculated above:

1. Calculate the programmed image width with the formula:

$$(\text{rounded_up_number_of_pages_per_line} \times \text{page_width bytes}) / \text{pixel_size bytes/pixel}$$

This gives a programmed image width of $(46 \times 32) / 4 = 368$.

The function sets SMS_ROT_SIZE_n[10:0] IMAGEWIDTH = 0x170.

2. Calculate the programmed image height with the formula:
 (rounded_up_number_of_pages_per_column × page_height lines)
 This gives a programmed image height of (35 × 16) = 560.
 The function sets SMS_ROT_SIZE_n[26:16] IMAGEHEIGHT = 0x230.

Because the actual image is a multiple of the page size (both width and height, as explained in [Section 9.2.5.3.3.1](#)), the actual image size and the programmed size are the same. In other words, ΔIW and ΔIH are null in this use case.

9.2.5.3.3.3 Physical Base Address Configuration

The physical base address is the address of the picture in the external SDRAM. In this use case, the address space of CS0 is 512 Mbits, ranging from 0x8000 0000 to 0x83FF FFFF because the Mobile DDR SDRAM is a 512 Mbits memory device.

The physical address of the picture is a parameter entered by the user. It is directly written into the SMS_ROT_PHYSICAL_BA_n[30:0] PHYSICALBA bit field (where n = 0 to 11, for the 12 contexts).

9.2.5.3.3.4 VRFB Use Case Summarizing Register Values

[Table 9-112](#) summarizes all the VRFB registers to be configured with the required values.

Table 9-112. VRFB Use Case Summarizing Register Print

| Register Name | Context Number n | Physical Address | Value | Value Description |
|----------------------------------|------------------|------------------|-------------|---|
| SMS_ROT_CONTROL _n | 0 | 0x6C00 0180 | 0x0000 0452 | The page size is 8-pixel wide and 16-pixel high. This is a width of 32 bytes and a height of 16 lines. The pixel format is YUV 4:2:2 (2 pixels take 4 bytes). |
| | 1 | 0x6C00 0190 | | |
| | 2 | 0x6C00 01A0 | | |
| | 3 | 0x6C00 01B0 | | |
| SMS_ROT_SIZE _n | 0 | 0x6C00 0184 | 0x0230 0170 | Actual image size is 736 × 560. This gives 368 × 560 with the YUV 4:2:2 pixel format |
| | 1 | 0x6C00 0194 | | |
| | 2 | 0x6C00 01A4 | | |
| SMS_ROT_PHYSICAL_BA _n | 3 | 0x6C00 01B4 | 0x8090 0000 | Example of physical base address |
| | 0 | 0x6C00 0188 | | |
| | 1 | 0x6C00 0198 | | |
| | 2 | 0x6C00 01A8 | | |
| | 3 | 0x6C00 01B8 | 0x8190 0000 | |
| | | | 0x8200 0000 | |

9.2.5.4 Understanding SDRAM Subsystem Address Spaces

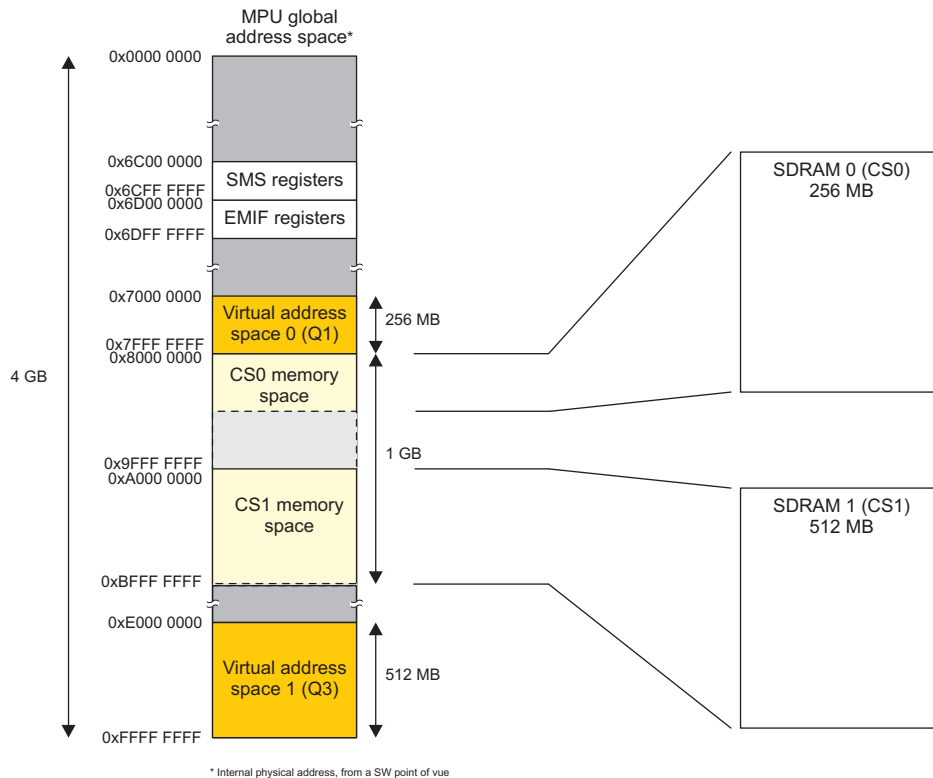

9.2.5.4.1 Physical vs Virtual Address Spaces

One thing that the SMS does is to translate virtual addresses into physical SDRAM addresses in case of rotation only, i.e. when accessing virtual address space 0 (quarter 1) and virtual address space 1 (quarter 3) as depicted in [Figure 9-108](#). The SMS then reinserts a request, or multiple requests depending on the SMS parameters, in the SMS request path to the EMIF controller (through the VRFB or not).

The SDRAM subsystem global memory space mapping reaches 1.768 GBytes:

- 1 GByte of CS memory space (CS0 and CS1 memory spaces): the EMIF controller automatically accesses the two external memory devices through direct accesses (addresses are simply translated).
- 768 MBytes of virtual address space (address space 0 and address space 1): the EMIF controller automatically accesses the two external memory devices through re-organized access (requests are modified accordingly to the context number and rotation angle before address translation). See [Section 9.2.5.4.1.2](#) for more information on VRFB contexts and rotation angles.

Figure 9-108. SDRC Address Space in MPU Global Address Space

Configuration registers space is detailed in the following table:

Table 9-113. EMIF and SMS Configuration Registers Space

| Module | Start Address | End Address | Total Space |
|--------|---------------|-------------|-------------|
| SMS | 0x6C00 0000 | 0x6CFF FFFF | 16MB |
| EMIF | 0x6D00 0000 | 0x6DFF FFFF | 16MB |

9.2.5.4.1.1 Physical Address Space

The physical address space of the SDRC is 1 GByte (maximum addressing capability).

The EMIF has a memory device capacity of 16 Mbits to 2 Gbits. 16 Mbits / 2 MBytes is the smallest granularity of supported memory device.

9.2.5.4.1.2 Virtual Address Space

The SMS virtual memory space is a memory space used to access a subset of the EMIF memory space through the rotation engine (Virtual Rotation Frame Buffer). The virtual address space size is 768 MBytes split into two parts: the first 256-MByte part is in the second quarter (Q1) of the memory; the second 512-MByte part is in the fourth quarter (Q3) of the memory. See chapter 2, *Memory Mapping*, for more information on global memory mapping.

The VRFB is a rotation engine that:

- supports rotations of 0, 90, 180, and 270 degrees
- can handle up to 12 concurrent rotation contexts

The VRFB has therefore 48 different contexts in the virtual address space. Table 9-114 gives the VRFB address-space memory locations at which the frame buffer object can be accessed. The table summarizes the virtual addresses of all 48 available image buffer from a global memory space (top level) point of view.

Table 9-114. VRFB Contexts vs Rotation Angle

| Context Number | 0° | 90° | 180° | 270° |
|----------------|-------------|-------------|-------------|-------------|
| 0 | 0x7000 0000 | 0x7100 0000 | 0x7200 0000 | 0x7300 0000 |
| 1 | 0x7400 0000 | 0x7500 0000 | 0x7600 0000 | 0x7700 0000 |

| 9 | 0xF400 0000 | 0xF500 0000 | 0xF600 0000 | 0xF700 0000 |
| 10 | 0xF800 0000 | 0xF900 0000 | 0xFA00 0000 | 0xFB00 0000 |
| 11 | 0xFC00 0000 | 0xFD00 0000 | 0xFE00 0000 | 0xFF00 0000 |

The physical address of a page is calculated with the formula:

$$\text{Physical address} = \text{Physical base address} + \text{Base address of page} \quad (1)$$

where *Physical base address* is defined through the SMS_ROT_PHYSICAL_BAn[30:0] PHYSICALBA field (buffer physical base address on which the rotation occurs), and *Base address of page* is the address obtain in function of the context number and rotation angle as given in [Table 9-114](#).

9.2.6 SDRAM Memory Scheduler (SMS) Registers

Table 9-115 shows the base address and address space for the SMS module instances.

Table 9-115. SMS Instance Summary

| Module Name | Base Address | Size |
|-------------|--------------|-----------|
| SMS | 0x6C00 0000 | 64 Kbytes |

9.2.6.1 SMS Register Mapping Summary

Table 9-116 summarizes the SMS register mapping.

Table 9-116. SMS Register Mapping Summary

| Register Name | Type | Register Width (Bits) | Address Offset | Physical Address | Section |
|--|------|-----------------------|--|--|------------------------------------|
| SMS_SYSCONFIG | RW | 32 | 0x0000 0010 | 0x6C00 0010 | Section 9.2.6.2.1 |
| SMS_SYSSTATUS | R | 32 | 0x0000 0014 | 0x6C00 0014 | Section 9.2.6.2.2 |
| SMS_RG_ATTi ⁽¹⁾ | RW | 32 | 0x0000 0048 + (0x0000 0020 * i) | 0x6C00 0048 + (0x0000 0020 * i) | Section 9.2.6.2.3 |
| SMS_RG_RDPERMi ⁽¹⁾ | RW | 32 | 0x0000 0050 + (0x0000 0020 * i) | 0x6C00 0050 + (0x0000 0020 * i) | Section 9.2.6.2.4 |
| SMS_RG_WRPERMi ⁽¹⁾ | RW | 32 | 0x0000 0058 + (0x0000 0020 * i) | 0x6C00 0058 + (0x0000 0020 * i) | Section 9.2.6.2.5 |
| SMS_RG_STARTj ⁽²⁾ where k = j - 1 | RW | 32 | 0x0000 0060 + (0x0000 0020 * (k)) ⁽³⁾ | 0x6C00 0060 + (0x0000 0020 * (k)) ⁽³⁾ | Section 9.2.6.2.6 |

| SMS_CLASS_ARBITER1 | RW | 32 | 0x0000 0154 | 0x6C00 0154 | Section 9.2.6.2.10 |
| SMS_CLASS_ARBITER2 | RW | 32 | 0x0000 0158 | 0x6C00 0158 | Section 9.2.6.2.11 |
| SMS_INTERCLASS_ARBITER | RW | 32 | 0x0000 0160 | 0x6C00 0160 | Section 9.2.6.2.12 |
| SMS_CLASS_ROTATIONm ⁽⁴⁾ | RW | 32 | 0x0000 0164 + (0x0000 0004 * m) | 0x6C00 0164 + (0x0000 0004 * m) | Section 9.2.6.2.13 |
| SMS_ERR_ADDR | R | 32 | 0x0000 0170 | 0x6C00 0170 | Section 9.2.6.2.14 |
| SMS_ERR_TYPE | RW | 32 | 0x0000 0174 | 0x6C00 0174 | Section 9.2.6.2.15 |
| SMS_POW_CTRL | RW | 32 | 0x0000 0178 | 0x6C00 0178 | Section 9.2.6.2.16 |
| SMS_ROT_CONTROLn ⁽⁵⁾ | RW | 32 | 0x0000 0180 + (0x0000 0010 * n) | 0x6C00 0180 + (0x0000 0010 * n) | Section 9.2.6.2.17 |
| SMS_ROT_SIZE n ⁽⁵⁾ | RW | 32 | 0x0000 0184 + (0x0000 0010 * n) | 0x6C00 0184 + (0x0000 0010 * n) | Section 9.2.6.2.18 |
| SMS_ROT_PHYSICAL_BAn ⁽⁵⁾ | RW | 32 | 0x0000 0188 + (0x0000 0010 * n) | 0x6C00 0188 + (0x0000 0010 * n) | Section 9.2.6.2.19 |

⁽¹⁾ i = 0 to 7.

⁽²⁾ j = 1 to 7

⁽³⁾ k = 0 to 6.

⁽⁴⁾ m = 0 to 2.

⁽⁵⁾ n = 0 to 11.

9.2.6.2 SMS Register Descriptions

9.2.6.2.1 SMS_SYSCONFIG

Table 9-117. SMS_SYSCONFIG

| | | | |
|-------------------------|--|-----------------|-----|
| Address Offset | 0x0000 0010 | Instance | SMS |
| Physical Address | 0x6C00 0010 | | |
| Description | This register controls the various parameters of the Interconnect. | | |
| Type | RW | | |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----------|----------|-----------|----------|-----------|----------|---|---|---|---|---|---|---|---|---|---|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| RESERVED | | | | | | | | | | | | | | | | RESERVED | RESERVED | SIDLEMODE | RESERVED | SOFTRESET | AUTOIDLE | | | | | | | | | | |

| Bits | Field Name | Description | Type | Reset |
|------|------------|--|------|----------|
| 31:9 | RESERVED | Write 0s for future compatibility. Read returns 0s. | RW | 0x000000 |
| 8 | RESERVED | Write 0s for future compatibility. Read returns 0s. | RW | 0x0 |
| 7:5 | RESERVED | Write 0s for future compatibility. Read returns 0s. | RW | 0x0 |
| 4:3 | SIDLEMODE | Power management Req/Ack Control 0x0: Force Idle - An idle request is acknowledged unconditionally 0x1: No Idle - An idle request is never acknowledged. 0x2: Smart Idle - Acknowledgment to an idle request is based on the internal activity of the module 0x3: Reserved - Do not use. | RW | 0x0 |
| 2 | RESERVED | Write 0s for future compatibility. Reads return 0. | RW | 0x0 |
| 1 | SOFTRESET | Software reset 0x0: Normal mode (no reset applied) 0x1: Software reset is activated | RW | 0x0 |
| 0 | AUTOIDLE | Internal interface clock gating strategy 0x0: Interface clock is free-running 0x1: Automatic interface clock gating strategy is applied, based on the interconnect activity | RW | 0x1 |

9.2.6.2.2 SMS_SYSSTATUS

Table 9-118. SMS_SYSSTATUS

| | | | |
|-------------------------|--|-----------------|-----|
| Address Offset | 0x0000 0014 | Instance | SMS |
| Physical Address | 0x6C00 0014 | | |
| Description | This register provides module status, excluding interrupt status info. | | |
| Type | R | | |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----------|----|----|----|----|----|---|-----------|---|---|---|---|---|---|---|---|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| RESERVED | | | | | | | | | | | | | | | | RESERVED | | | | | | | RESETDONE | | | | | | | | |

| Bits | Field Name | Description | Type | Reset |
|------|------------|---|------|----------|
| 31:8 | RESERVED | Reserved for module-specific status information. Read returns 0s. | R | 0x000000 |
| 7:1 | RESERVED | Reserved for interconnect socket status information. Read returns 0s. | R | 0x00 |
| 0 | RESETDONE | Internal reset monitoring 0x0: Internal module reset is ongoing. 0x1: Reset complete. The module is ready to be used. | R | 0x- |

9.2.6.2.3 SMS_RG_ATTi

Table 9-119. SMS_RG_ATTi

| | | | |
|-------------------------|---------------------------------|-----------------|------------|
| Address Offset | 0x0000 0048 + (0x0000 0020 * i) | Index | i = 0 to 7 |
| Physical Address | 0x6C00 0048 + (0x0000 0020 * i) | Instance | SMS |
| Description | | | |
| Type | RW | | |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|---------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| REQINFO | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |

| Bits | Field Name | Description | Type | Reset |
|------|------------|--|------|---------|
| 31:0 | REQINFO | Request information permission The REQINFO field is a bit vector of permissions, one per MReqInfo encoding: NonHost/Host - User/Supervisor - Public/Secure - Functional/Debug - Data Transfer/Opcode Fetch ⁽¹⁾ | RW | 0x----- |

⁽¹⁾ See [Table 9-62](#) for more information on REQINFO values

9.2.6.2.4 SMS_RG_RDPERMi
Table 9-120. SMS_RG_RDPERMi

| | | | |
|-------------------------|---|-----------------|------------|
| Address Offset | 0x0000 0050 + (0x0000 0020 * i) | Index | i = 0 to 7 |
| Physical Address | 0x6C00 0050 + (0x0000 0020 * i) | Instance | SMS |
| Description | This register provides the list of all initiators that have permission for reading from that memory region. | | |
| Type | RW | | |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|--------------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| RESERVED | | | | | | | | | | | | | | | | CONNIDVECTOR | | | | | | | | | | | | | | | |

| Bits | Field Name | Description | Type | Reset |
|-------|--------------|--|------|-----------------------|
| 31:16 | RESERVED | Write 0s for future compatibility. Read returns 0s. | RW | 0x0000 |
| 15:0 | CONNIDVECTOR | One bit per initiator group. Bit 0 set to 1 means that initiator whose ConnID = 0 has read permission to the protected region i. | RW | 0x---- ⁽¹⁾ |

⁽¹⁾ Reset value exported from control module for region 0 and region 1; reset value equal to 0x0000 for other

9.2.6.2.5 SMS_RG_WRPERMi
Table 9-121. SMS_RG_WRPERMi

| | | | |
|-------------------------|---|-----------------|------------|
| Address Offset | 0x0000 0058 + (0x0000 0020 * i) | Index | i = 0 to 7 |
| Physical Address | 0x6C00 0058 + (0x0000 0020 * i) | Instance | SMS |
| Description | This register provides the list of all initiators that have permission for writing to that memory region. | | |
| Type | RW | | |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|--------------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| RESERVED | | | | | | | | | | | | | | | | CONNIDVECTOR | | | | | | | | | | | | | | | |

| Bits | Field Name | Description | Type | Reset |
|-------|--------------|---|------|-----------------------|
| 31:16 | RESERVED | Write 0s for future compatibility. Read returns 0s. | RW | 0x0000 |
| 15:0 | CONNIDVECTOR | One bit per initiator group. Bit 0 set to 1 means that initiator whose ConnID = 0 has write permission to the protected region i. | RW | 0x---- ⁽¹⁾ |

⁽¹⁾ Reset value exported from control module for region 0 and region 1; reset value equal to 0x0000 for other

9.2.6.2.6 SMS_RG_STARTj

Table 9-122. SMS_RG_STARTj

| | | | |
|-------------------------|--|-----------------|------------|
| Address Offset | 0x0000 0060 + (0x0000 0020 * (k)) | Index | k = 0 to 6 |
| Physical Address | 0x6C00 0060 + (0x0000 0020 * (k)) | Instance | SMS |
| Description | This register provides the region #j start address (lowest address inside the region), with a 64-KB granularity. | | |
| Type | RW | | |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----------|--------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----------|----|----|----|----|---|---|---|---|---|---|---|---|---|---|--|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 | |
| RESERVED | STARTADDRESS | | | | | | | | | | | | | | | | RESERVED | | | | | | | | | | | | | | | |

| Bits | Field Name | Description | Type | Reset |
|-------|--------------|---|------|--------|
| 31 | RESERVED | Write 0s for future compatibility. Reads return 0. | RW | 0x0 |
| 30:16 | STARTADDRESS | Region #j start address (included in the region) Aligned on 64-KB boundary. [15:0] must be written with 0s. No STARTADDRESS parameter for region 0. | RW | 0x---- |
| 15:0 | RESERVED | Write 0s for future compatibility. Read returns 0. | RW | 0x0000 |

9.2.6.2.7 SMS_RG_ENDj

Table 9-123. SMS_RG_ENDj

| | | | |
|-------------------------|---|-----------------|------------|
| Address Offset | 0x0000 0064 + (0x0000 0020 * (k)) | Index | k = 0 to 6 |
| Physical Address | 0x6C00 0064 + (0x0000 0020 * (k)) | Instance | SMS |
| Description | This register provides the region #j end address (lowest address outside the region), with a 64-KB granularity. | | |
| Type | RW | | |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----------|------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----------|----|----|----|----|---|---|---|---|---|---|---|---|---|---|--|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 | |
| RESERVED | ENDADDRESS | | | | | | | | | | | | | | | | RESERVED | | | | | | | | | | | | | | | |

| Bits | Field Name | Description | Type | Reset |
|-------|------------|---|------|--------|
| 31 | RESERVED | Write 0s for future compatibility. Read returns 0s. | RW | 0x0 |
| 30:16 | ENDADDRESS | Region #j end address (not included in the region) Aligned on 64-KB boundary. [15:0] must be written with 0s. No ENDADDRESS parameter for region 0. | RW | 0x---- |
| 15:0 | RESERVED | Write 0s for future compatibility. Read returns 0s. | RW | 0x0000 |

9.2.6.2.8 SMS_SECURITY_CONTROL
Table 9-124. SMS_SECURITY_CONTROL

| | | | |
|-------------------------|---|-----------------|-----|
| Address Offset | 0x0000 0140 | Instance | SMS |
| Physical Address | 0x6C00 0140 | | |
| Description | This register provides the security level required to access all SMS registers. | | |
| Type | RW | | |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|----|----|---------------|---------------|--------------|--------------|--------------|--------------|--------------|--------------|--------------|--------------|--------------|--------------|----------|----|---|---|---|---|---|---|---------------------|-----------------|---------------|---------------|-------------|------------------------|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 | | |
| RESERVED | | | | | | | | ROTCTXT11LOCK | ROTCTXT10LOCK | ROTCTXT9LOCK | ROTCTXT8LOCK | ROTCTXT7LOCK | ROTCTXT6LOCK | ROTCTXT5LOCK | ROTCTXT4LOCK | ROTCTXT3LOCK | ROTCTXT2LOCK | ROTCTXT1LOCK | ROTCTXT0LOCK | RESERVED | | | | | | | | ARBITRATIONREGSLOCK | REGION1REGSLOCK | SOFTRESETLOCK | ERRORREGSLOCK | FIREWALLOCK | SECURITYCONTROLREGLOCK |

| Bits | Field Name | Description | Type | Reset |
|-------|---------------|--|------|-------|
| 31:28 | RESERVED | Write 0s for future compatibility. Read returns 0s. | RW | 0x0 |
| 27 | ROTCTXT11LOCK | Sets the security level to program rotation context 11 0x0: Any transaction is allowed. 0x1: Secure transaction required | RW | 0x0 |
| 26 | ROTCTXT10LOCK | Sets the security level to program rotation context 10 0x0: Any transaction is allowed. 0x1: Secure transaction required | RW | 0x0 |
| 25 | ROTCTXT9LOCK | Sets the security level to program rotation context 9 0x0: Any transaction is allowed. 0x1: Secure transaction required | RW | 0x0 |
| 24 | ROTCTXT8LOCK | Sets the security level to program rotation context 8 0x0: Any transaction is allowed. 0x1: Secure transaction required | RW | 0x0 |
| 23 | ROTCTXT7LOCK | Sets the security level to program rotation context 7 0x0: Any transaction is allowed. 0x1: Secure transaction required | RW | 0x0 |
| 22 | ROTCTXT6LOCK | Sets the security level to program rotation context 6 0x0: Any transaction is allowed. 0x1: Secure transaction required | RW | 0x0 |
| 21 | ROTCTXT5LOCK | Sets the security level to program rotation context 5 0x0: Any transaction is allowed. 0x1: Secure transaction required | RW | 0x0 |
| 20 | ROTCTXT4LOCK | Sets the security level to program rotation context 4 0x0: Any transaction is allowed. 0x1: Secure transaction required | RW | 0x0 |
| 19 | ROTCTXT3LOCK | Sets the security level to program rotation context 3 0x0: Any transaction is allowed. 0x1: Secure transaction required | RW | 0x0 |

| Bits | Field Name | Description | Type | Reset |
|------|------------------------|--|------|--------------------|
| 18 | ROTCTXT2LOCK | Sets the security level to program rotation context 2 0x0: Any transaction is allowed. 0x1: Secure transaction required | RW | 0x0 |
| 17 | ROTCTXT1LOCK | Sets the security level to program rotation context 1 0x0: Any transaction is allowed. 0x1: Secure transaction required | RW | 0x0 |
| 16 | ROTCTXT0LOCK | Sets the security level to program rotation context 0 0x0: Any transaction is allowed. 0x1: Secure transaction required | RW | 0x0 |
| 15:6 | RESERVED | Write 0s for future compatibility. Read returns 0s. | RW | 0x000 |
| 5 | ARBITRATIONREGSLOCK | Sets the security level to program arbitration control registers 0x0: Any transaction is allowed. 0x1: Secure privilege transaction required | RW | 0x0 |
| 4 | REGION1REGSLOCK | Region 1 security firewall registers lock bit 0x0: Region1 configuration registers can be accessed by all accesses (R/W) but depend on Full Secure Program value 0x1: Region1 configuration registers are restricted to secure supervisor accesses only (R/W) and do not depend on Full Secure Program value | RW | 0x- ⁽¹⁾ |
| 3 | SOFTRESETLOCK | Soft reset lock bit 0x0: The SMS soft reset can be triggered with any access 0x1: The SMS soft reset can be triggered only with secure supervisor accesses. When this bit is set to 1, a non secure soft reset has no effect on SMS module | RW | 0x- ⁽¹⁾ |
| 2 | ERRORREGSLOCK | Error registers lock bit 0x0: The SMS_ERR_TYPE and SMS_ERR_ADDR registers can be read and cleared with any access 0x1: The SMS_ERR_TYPE and SMS_ERR_ADDR registers can be read and cleared only with secure supervisor accesses | RW | 0x- ⁽¹⁾ |
| 1 | FIREWALLOCK | All security firewall registers lock bit 0x0: The SMS firewall registers can be programmed and read with any access 0x1: The SMS firewall registers can be programmed and read only with secure supervisor accesses | RW | 0x- ⁽¹⁾ |
| 0 | SECURITYCONTROLREGLOCK | SMS_SECURITY_CONTROL register configuration lock bit 0x0: The SMS_SECURITY_CONTROL register is unlocked 0x1: The SMS_SECURITY_CONTROL register is locked to secure supervisor access only. Only a secure supervisor access or component reset can reset this bit to 0 | RW | 0x- ⁽¹⁾ |

⁽¹⁾ Reset value exported from control module

9.2.6.2.9 SMS_CLASS_ARBITER0
Table 9-125. SMS_CLASS_ARBITER0

| | | | |
|-------------------------|---|-----------------|-----|
| Address Offset | 0x0000 0150 | Instance | SMS |
| Physical Address | 0x6C00 0150 | | |
| Description | This register controls the arbitration parameters between the class 0 request groups. | | |
| Type | RW | | |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |

| Bits | Field Name | Description | Type | Reset |
|-------|---------------|---|------|-------|
| 31:27 | RESERVED | Write 0s for future compatibility. Read returns 0s. | RW | 0x00 |
| 26:24 | ERRORREGIONID | ID of the region that has been illegally accessed 0x0: Region 0 0x1: Region 1 ... 0x7: Region 7 0x8 to 0xF: reserved | R | 0x0 |
| 23 | RESERVED | Write 0s for future compatibility. Read returns 0s. | RW | 0x0 |
| 22:20 | ERRORMCMC | Interconnect command that caused the error | R | 0x0 |
| 19:16 | ERRORCONNID | Identifies the illegal access initiator interconnect ConnID of the illegal access initiator. Refer to the top level documentation of the device using the SMS module | R | 0x0 |
| 15:11 | RESERVED | Write 0s for future compatibility. Read returns 0s. | RW | 0x00 |

| Bits | Field Name | Description | Type | Reset |
|------|-----------------|--|------|-------|
| 10 | UNEXPECTEDADD | Request targeting non-defined rotation contexts (such as contexts 12, 13, 14, or 15) or non-defined L3 Interconnect request signals used for context number decoding. Read 0x0: No unexpected request received Write 0x0: No effect Read 0x1: A request has been received on the interconnect with address decoding targeting rotation contexts 12, 13, 14, or 15, or a signal used for context number decoding was undefined. Write 0x1: Clear UNEXPECTEDADD bit. | RW | 0x0 |
| 9 | UNEXPECTEDREQ | Unexpected request received during SMS idle state Read 0x0: No unexpected request received Write 0x0: No effect Read 0x1: A request has been received on the interconnect after the SMS was put in idle mode by the system power manager. Write 0x1: Clear the UNEXPECTEDREQ bit field. | RW | 0x0 |
| 8 | ILLEGALCMD | Illegal command on the L3 interface Read 0x0: No illegal command received Write 0x0: No effect Read 0x1: Illegal command has been received. Write 0x1: Clear ILLEGALCMD bit field. | RW | 0x0 |
| 7:4 | RESERVED | Write 0s for future compatibility. Read returns 0s. | RW | 0x0 |
| 3 | ERRORSECOVERLAP | Protection region overlapping error Read 0x0: No overlap violation detected Write 0x0: No effect Read 0x1: A protection region overlap violation has been detected. Write 0x1: Clear ERRORSECOVERLAP bit field. | RW | 0x0 |
| 2 | ERRORSECREG | SMS security register accessed by nonsecure write transaction Read 0x0: No violation detected on secure registers Write 0x0: No effect Read 0x1: A nonsecure write access to the security control registers has been detected. Such writes are not allowed (reads are always allowed). 0x1: Clear ERRORSECREG bit field | RW | 0x0 |
| 1 | ERRORSECURITY | Security violation error Read 0x0: No illegal command received Write 0x0: No effect Read 0x1: Security violation detected Write 0x1: Clear ERRORSECURITY bit field. | RW | 0x0 |
| 0 | ERRORVALID | Error validity status - Must be explicitly cleared with a write transaction Read 0x0: No effect Write 0x0: All error fields no longer valid Read 0x1: Error detected and logged in the other error fields Write 0x1: Clear ERRORVALID bit field | RW | 0x0 |

9.2.6.2.16 SMS_POW_CTRL
Table 9-132. SMS_POW_CTRL

| | | | |
|-------------------------|--|-----------------|-----|
| Address Offset | 0x0000 0178 | Instance | SMS |
| Physical Address | 0x6C00 0178 | | |
| Description | This register controls the SMS power management in conjunction with the regular interconnect socket registers. | | |
| Type | RW | | |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|-----------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|

| Bits | Field Name | Description | Type | Reset |
|------|------------|---|------|------------|
| 31 | RESERVED | Write 0s for future compatibility. Read returns 0s. | RW | 0x0 |
| 30:0 | PHYSICALBA | Physical base address of the frame buffer for context #n in SDRAM | RW | 0x00000000 |

9.3 On-Chip Memory (OCM) Subsystem

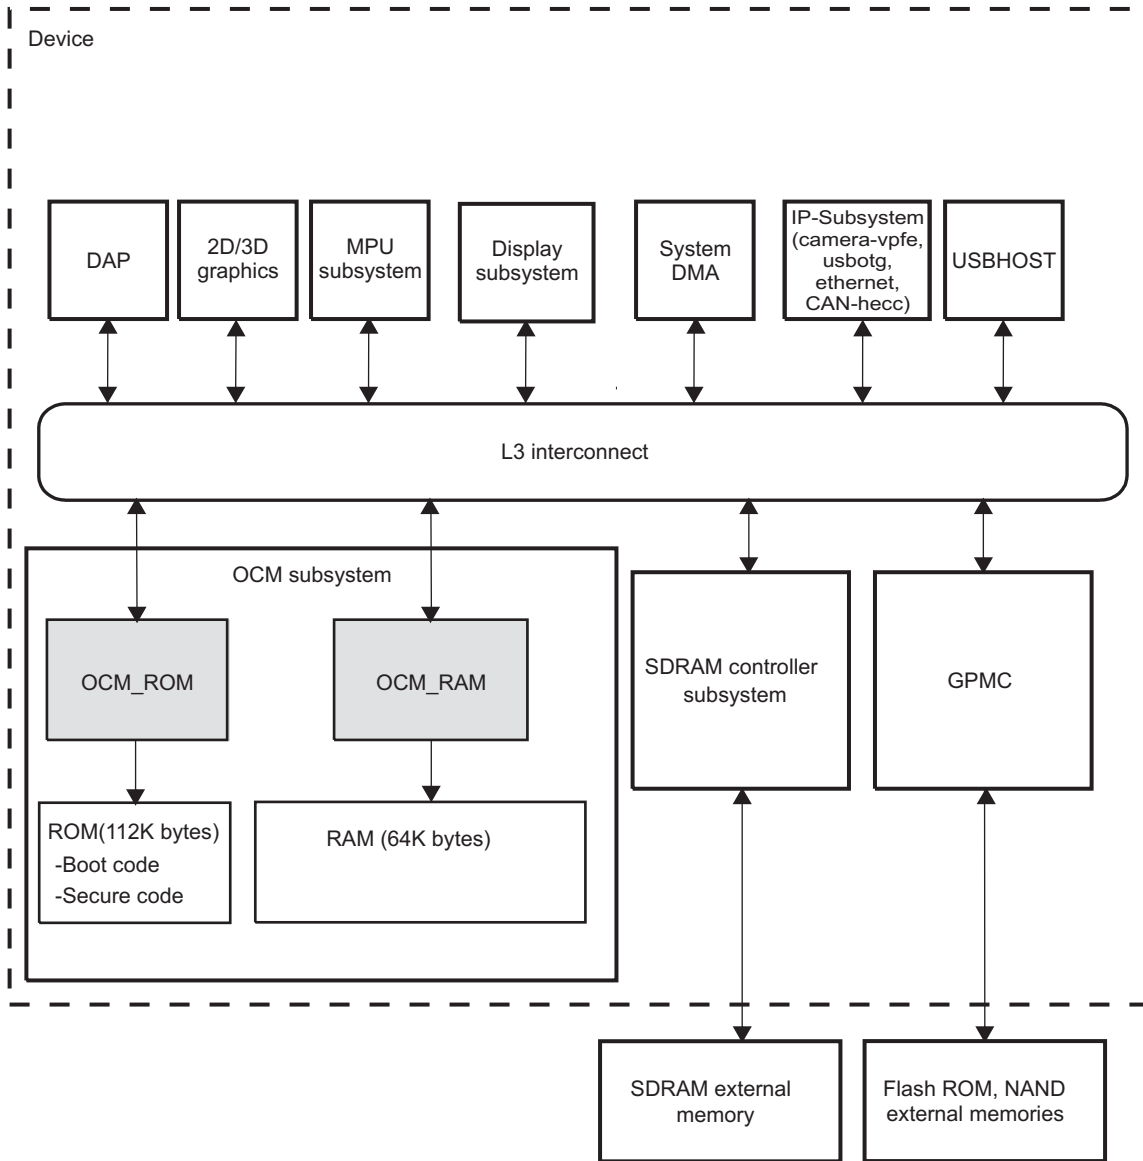

9.3.1 OCM Subsystem Overview

The on-chip memory subsystem consists of two separate on-chip memory controllers, one connected to an on-chip ROM (OCM_ROM) and the other connected to an on-chip RAM (OCM_RAM). Each memory controller has its own dedicated interface to the L3 interconnect.

NOTE: Some features may not be available or supported in your particular device. For more information, see Chapter 1, the *Device Family* section, and your device-specific data manual.

Figure 9-109 is an overview of the OCM subsystem.

Figure 9-109. OCM Subsystem Overview

ocm-001

Multiple L3 initiators (such as remote devices) have access to the RAM through 2D/3D graphics, the MPU subsystem, sDMA, the IP subsystem, the display subsystem, and USBHOST.

ROM is used for direct boot code, boot from external NAND flash, and secure code.

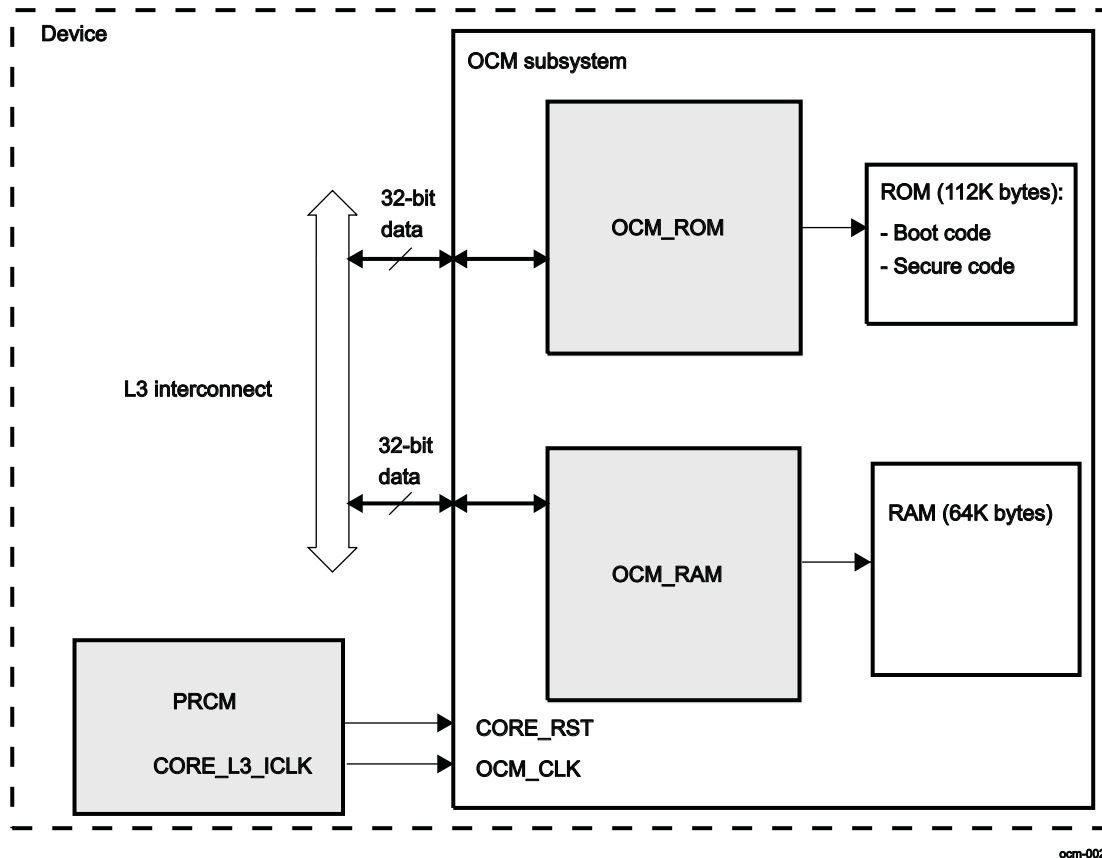

9.3.2 OCM Subsystem Integration

9.3.2.1 Description

The OCM_ROM and OCM_RAM allow transactions between the system initiators and the multiple memories, through the L3 interconnect.

Figure 9-110 shows the integration of the OCM subsystem to the processor.

Figure 9-110. OCM Subsystem Integration to the Device

ocm-002

9.3.2.2 Clocking, Reset, and Power-Management Scheme

9.3.2.2.1 Clocking

The on-chip boot ROM and RAM are clocked only when they are accessed.

The interface clock OCM_CLK comes from the PRCM module and runs at the L3 interconnect frequency. The OCM_CLK source is PRCM CORE_L3_ICLK output. This clock is also used as the functional clock for the OCM module.

For the OCM subsystem, no register enables the gating of OCM_CLK.

However, OCM does support the handshaking protocol with the PRCM module. It is not programmable by software. The following signals support the handshaking protocol for ROM and RAM devices:

- OCMROM_IDLREQ/OCMROM_SIDLEACK (for ROM devices)
- OCMRAM_IDLREQ/OCMRAM_SIDLEACK (for RAM devices)

OCM_CLK is gated if all modules (including the OCM) belonging to the L3 CLK domain send a SidleAck back to the PRCM module after reception of the MidleReq request.

For details, see the *Power, Reset, and Clock Management* chapter.

When the memory is not accessed by the system, the module performs automatic clock gating. Because the clock to the memory is dynamically gated, there is no extra latency when the clock must be switched on after an idle state.

9.3.2.2.2 Hardware Reset

Global reset of the module is performed by activation of the CORE_RST in the core reset domain (see the *Power, Reset, and Clock Management* chapter).

9.3.2.2.3 Power Domain

OCM power is supplied by the CORE power domain (see the *Power, Reset, and Clock Management* chapter).

9.3.3 OCM Subsystem Functional Description

9.3.3.1 OCM_ROM

The embedded ROM is used primarily for booting, flashing, and context restoring.

The device-embedded ROM (total 32K bytes) has the following characteristics:

- The ROM contains the boot area.
- The OCM_ROM supports single and burst access transactions.
- The OCM_ROM operates at full interconnect clock frequency.
- The COM_ROM needs three cycles for initial access and one cycle per subsequent access.

The memory space of the embedded ROM starts at 0x4001 4000 and ends at 0x4001 BFFF.

9.3.3.2 OCM_RAM

By default, only 2K bytes are nonsecure after reset; however, the configuration can then be changed to adapt to booting/flashing, normal boot, or to any application requirement.

The device-embedded RAM has the following characteristics:

- Operates at full L3 interconnect clock frequency
- Fully pipelined, one 32-bit access per cycle
- Restricted access support, based on:
 - A region-based partitioning (see the L3 firewall description)
 - The module owner of the access, with respect to its read and write permission to that region
 - The transaction attributes of the access, with respect to the region permission properties:
 - Secure/nonsecure
 - User/supervisor
 - Code/data access

The OCM_RAM can be partitioned using the L3 firewall (see the *Interconnect* chapter) and used as:

- Public RAM for normal RAM, or
- Secure RAM:
 - For secure data and instructions
 - For secure Level 2 data and instruction cache:
 - Secure stack
 - Secure global data
 - Secure heap
 - Secure decrypted applications
 - Crypto keys

The OCM_RAM can be partitioned using the L3 firewall and used as:

- Public RAM for a video frame buffer
- Secure RAM for a secure video frame buffer
- Secure RAM for computing heavy DRM applications such as real-time video decryption
- Secure RAM for any application

The RAM memory space starts at 0x4020 0000 and ends at 0x4020 FFFF.

9.4 Revision History

[Table 9-136](#) lists the changes made since the previous version of this document.

Table 9-136. Document Revision History

| Reference | Additions/Modifications/Deletions |
|---------------------------------------|--|
| Section 9.2.3.4.1.1 | Added LPDDR1 information to tables and list. |
| Section 9.2.3.4.2.6.1 | Added subsection. |

| Section 9.2.3.4.5.3 | Added subsection. |

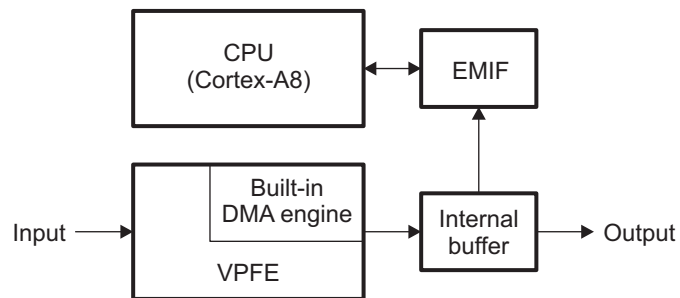

Video Processing Front End (VPFE)

10.1 Overview

The video processing subsystem (VPSS) includes a video processing front-end (VPFE) controller, which is the video input portion of the processor. The VPFE controller receives input video/image data from external capture devices and stores it to external memory. A built-in DMA engine transfers the capture data into the external memory. An internal buffer block provides a high bandwidth path between the VPSS module and the external memory. The CPU, Cortex-A8, will process the image data based on application requirements.

A simple LCD controller is available. Reference LCD chapter. [Figure 10-1](#) illustrates the high-level block diagram of the VPSS module.

Figure 10-1. VPSS Module, Memory, and the CPU

10.1.1 Features

The VPFE controller supports the following features:

- It supports conventional Bayer pattern and Foveon sensor formats.
- It is flexible in synchronization timing generation. It can be programmed to synchronize to the external horizontal/vertical sync and field ID signals with various timings.
- It supports progressive and interlaced sensors (hardware support for up to two fields and firmware support for a higher number of fields, typically 3, 4, and 5-field sensors).
- The max pixel clock is 75 MHz.
- It supports the REC656/CCIR-656 standard.
- It supports YCbCr 422 format, either 8-bit or 16-bit with discrete horizontal and vertical sync signals.
- The input capture data can be up to 16 bits.
- It can generate optical black clamping signals.
- It has built-in digital clamping and black level compensation.
- 10-bit to 8-bit A-law compression hardware is provided.
- It has a low-pass filter that can be applied prior to writing the capture data to external memory. If this filter is enabled, two pixels in each the left and the right edges of each line are cropped from the output.
- The output data can range from 16 bits to 8 bits wide (8-bit width allows for a 50% savings in memory).
- It has a programmable culling block that can perform down-sampling of the input data.
- An external write enable signal is provided to control the timing of outputting data to the external memory.
- It supports up to 16K pixels (image size) in both the horizontal and vertical directions.

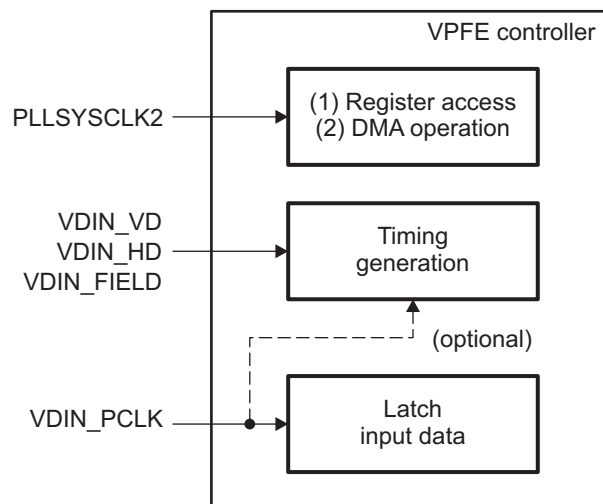

10.2 VPFE Controller - The System View

10.2.1 Clocks

The VPFE controller requires two clock sources:

- Internal clock source - PLLSYSCLK2. This clock is the reference clock used by the VPFE internal logic, including the built-in DMA operation.
- External clock source – External pixel clock signal VDIN_PCLK, which is used to generate internal synchronization signals to latch input data.

Figure 10-2. Clock Sources

10.2.2 Reset

The power, reset and clock management module can reset the VPFE controller. See the *Power, Reset and Clock Management* chapter for more details.

10.2.3 Interrupts

The VPFE controller can generate three interrupts to the CPU, as shown in [Table 10-1](#).

Table 10-1. ARM Interrupts - VPFE

| Interrupt Number | Acronym | Source |
|------------------|--------------|--------|
| M_IRQ_88 | CCDC_VD0_INT | VPFE |
| M_IRQ_92 | CCDC_VD1_INT | VPFE |
| M_IRQ_93 | CCDC_VD2_INT | VPFE |

10.3 Functional Description

10.3.1 External IO Interface

The following subsections explain how to connect VPFE signal pins to various input devices.

10.3.1.1 Raw Data Mode

Raw data mode is a generic parallel interface that supports up to a 16-bit data path to a CMOS or CCD sensor. The signal interface is described in [Table 10-2](#).

Table 10-2. CCD Interface Signals

| Name | I/O | Function |
|--------------|-----|--|
| VDIN_D[15:0] | I | Image data – A mode set by INPMOD (not R6560N). <ul style="list-style-type: none"> Bit width is configurable between 8 and 16 bits (DATSIZ). The polarity of the input image data is configurable (DATAPOL). |
| VDIN_VD | I | VSYNC - vertical sync signal |
| VDIN_HD | I | HSYNC - horizontal sync signal |
| VDIN_FIELD | I | Field identification signal (optional – FLDMODE) <ul style="list-style-type: none"> This signal can be configured to be latched by the VD signal (FIDMD). The polarity of the field identification signal is configurable (FLDPOL). |
| VDIN_WEN | I | VPFE write enable signal (optional – EXWEN) <ul style="list-style-type: none"> The EXWEN signal determines when data is captured, processed, and saved to memory or sent for further processing. If EXWEN is enabled, image data will be captured, processed, and saved to memory or sent for further processing, depending on the state of WENLOG. Data can be saved either when VDIN_WEN is active and the pixels are within the internal frame (SPH, NPH, SLV, NLV) or when the pixels are within the internal frame (WENLOG). |
| VDIN_PCLK | I | Pixel clock <ul style="list-style-type: none"> The PCLK signal is the signal used to latch input image data. The input image data can be captured on either the rising or on the falling edge of the PCLK signal which is configured by field PCLK_INV. The maximum pixel clock rate is 75 MHz. |

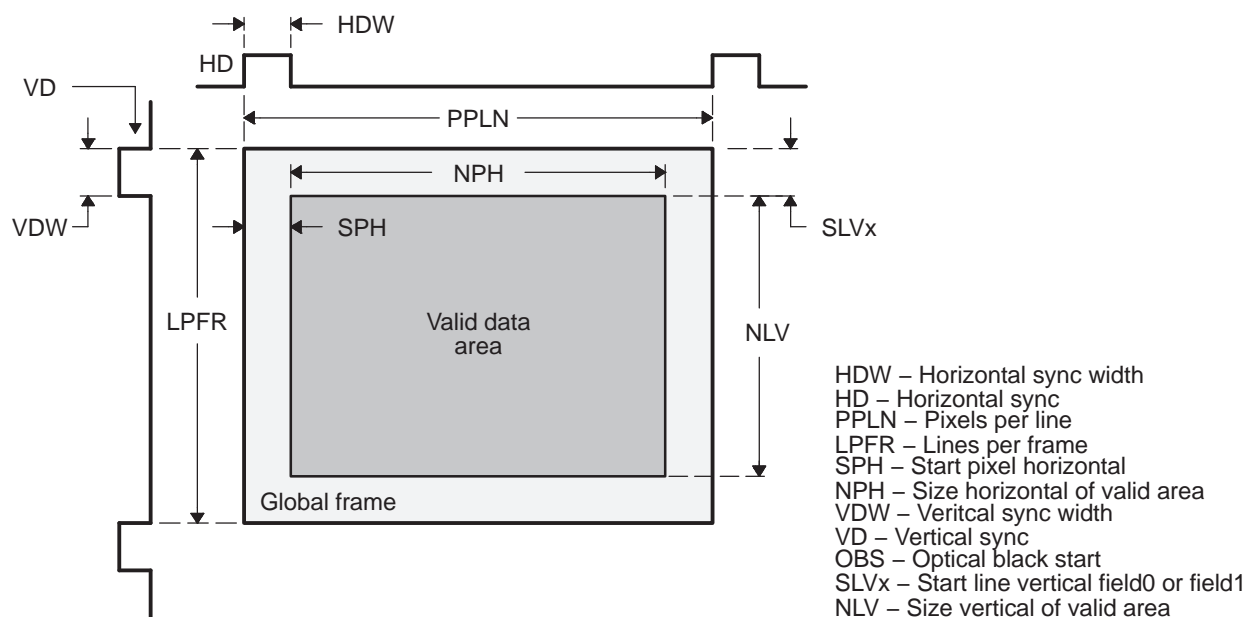

10.3.1.1.1 Mode Information – Always Required

- INPMOD – input mode
- DATSIZ – size (bit width) of input data – always stored in LSBs
- DATAPOL – polarity of input data
- VDPOL – VD polarity
- HDPOL – HD polarity
- FLDMOD – field mode

10.3.1.1.2 Timing Information – Optional, Depending on Control Signals and Sensor Mode

- If FLDMODE is enable
 - FLDPOL – VDIN_FIELD polarity
 - FIDMD – VDIN_FIELD latch information
- EXWEN – external VDIN_WEN signal
 - WENLOG – determines when data is valid along with frame settings

Figure 10-3. CCD Controller Frame and Control Signal Definitions

10.3.1.2 ITU-R BT.656 Interface

The BT.656 interface supports either 8-bit or 10-bit processing of input video YCbCr data. See [Section 10.4](#) for instructions on how to configure this mode.

Since the data synchronization information is carried along with the data lines, no synchronization signals (i.e., VDIN_HD, VDIN_VD, and VDIN_FIELD) are necessary in this mode.

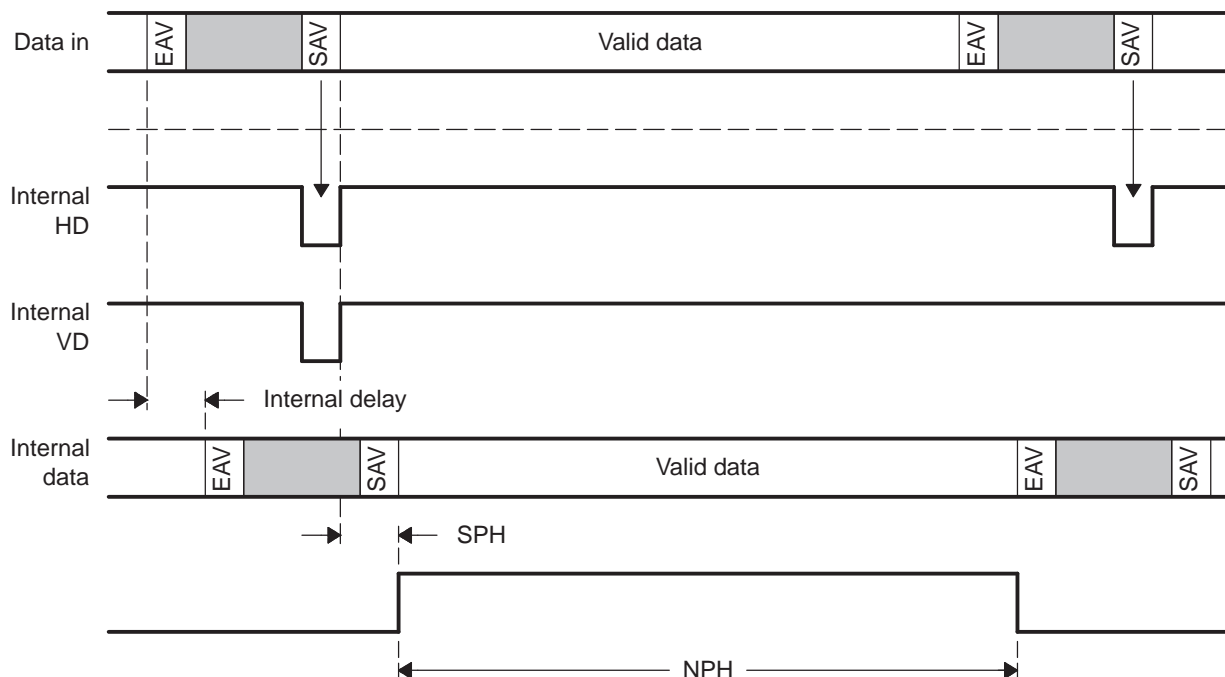

The signal interface is described in [Table 10-3](#).

Table 10-3. ITU-R BT.656 Interface Signals

| Name | I/O | Function |
|-------------|-----|--|
| VDIN_D[9:0] | I | Image data – mode set by R656ON <ul style="list-style-type: none"> • Bit width is configurable to either eight or ten bits (BW656). • The polarity of the input image data is configurable (DATAPOL). |
| VDIN_PCLK | I | Pixel clock <ul style="list-style-type: none"> • The PCLK signal is the signal used to latch input image data. • The input image data can be captured on either the rising or on the falling edge of the PCLK signal which is configured by field PCLK_INV. (see for more details). • The maximum pixel clock rate is 75 MHz. |

Two timing reference codes are transmitted as the synchronization signal. At the start and end of each video data block, two unique codes are sent, respectively. The start code is called the start of active video signal (SAV), and the end code is called the end of active video signal (EAV). The SAV and EAV codes proceed and follow valid data, as shown in [Figure 10-4](#). The VPFE controller internally bases on SAV and EAV codes to generate the necessary synchronization signals, i.e., horizontal sync, vertical sync, and field ID.

Figure 10-4. BT.656 Signal Interface

Both timing reference signals, SAV and EAV, consist of a four-word sequence in the following format: FF 00 00 XY, where FF 00 00 are a set preamble and the fourth word defines the field identification, the state of vertical field blanking, the state of horizontal line blanking, and protection (error correction) codes. The bit format of the fourth word is shown in [Table 10-4](#) and the definitions for bits, F, V, and H, are given in

Table 10-5. F, V, and H are used in place of the usual horizontal sync, vertical sync, and blank timing control signals. Bits P3, P2, P1, and P0 are protection (error correction) bits for F, V, and H. The relationship between F, V, and H and the protection (error correction) bits is given in [Table 10-6](#). To enable error correction, set the ECCFVH bit in the REC656IF register. The VPFE controller automatically detects and applies error correction when the ECCFVH bit is set.

Table 10-4. Video Timing Reference Codes for SAV and EAV

| Data Bit Number | First Word (FF) | Second Word (00) | Third Word (00) | Fourth Word (XY) |
|-----------------|-----------------|------------------|-----------------|------------------|
| 9 (MSB) | 1 | 0 | 0 | 1 |
| 8 | 1 | 0 | 0 | F |
| 7 | 1 | 0 | 0 | V |
| 6 | 1 | 0 | 0 | H |
| 5 | 1 | 0 | 0 | P3 |
| 4 | 1 | 0 | 0 | P2 |
| 3 | 1 | 0 | 0 | P1 |
| 2 | 1 | 0 | 0 | P0 |
| 1 | 1 | 0 | 0 | 0 |
| 0 | 1 | 0 | 0 | 0 |

Table 10-5. F, V, H Signal Descriptions

| Signal | Value | Command |
|--------|-------|----------------|
| F | 0 | Field 1 |
| | 1 | Field 2 |
| V | 0 | 0 |
| | 1 | Vertical blank |
| H | 0 | SAV |
| | 1 | EAV |

Table 10-6. F, H, V Protection (error correction) Bits

| F | V | H | P3 | P2 | P1 | P0 |
|---|---|---|----|----|----|----|
| 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| 0 | 0 | 1 | 1 | 1 | 0 | 1 |
| 0 | 1 | 0 | 1 | 0 | 1 | 1 |
| 0 | 1 | 1 | 0 | 1 | 1 | 0 |
| 1 | 0 | 0 | 0 | 1 | 1 | 1 |
| 1 | 0 | 1 | 1 | 0 | 1 | 0 |
| 1 | 1 | 0 | 1 | 1 | 0 | 0 |
| 1 | 1 | 1 | 0 | 0 | 0 | 1 |

NOTE: The VPFE controller outputs the XY code in the SAV and EAV into the external memory. In order to eliminate this, set the SPH register field to +1. Also set the NPH register field to accurately represent the number of active pixels.

10.3.1.3 Digital YCbCr Interface

The digital YCbCr interface supports either 8-bit or 16-bit devices. The signal interface is described in [Table 10-7](#).

Unlike the BT.656 mode, discrete horizontal sync (VDIN_HD) and vertical sync (VDIN_VD) signals are required. An NTSC/PAL decoder is an example device that can be connected to the YCbCr interface.

You can use data lines YI[7:0] or CI [7:0] for input in 8-bit mode. Alternately, you can connect two separate devices; however, only one can be active at any given time. Setting the YCINSWP bit in the CCDCFG register determines which set of 8-bit inputs are active.

Use data lines YI [7:0] and CI[7:0] for input in 16-bit mode. Use the YCINSWP bit in the CCDCFG register to swap the Y and Cr/Cb data lines.

Table 10-7. CCD Interface Signals

| Name | I/O | Function |
|-------------------------------------|-----|---|
| VDIN_D [15:0] = YI [7:0] / CI [7:0] | I | Image data – mode set by INPMOD (not R656ON) <ul style="list-style-type: none"> • Bit width is only configurable to either 8 bits or 16 bits (INPMOD). • The polarity of the input image data is reversible (DATAPOL). • When the 16-bit interface is used, you can swap the Y and C inputs (YCINSWP). • When the 8-bit interface is used, you can connect either half of the bus (YCINSWP). • When the 8-bit interface is used, you can set the position of the Y data to either the even or odd pixel (Y8POS). |
| VDIN_VD | I | VSYNC - vertical sync signal |
| VDIN_HD | I | HSYNC - horizontal sync signal |
| VDIN_FIELD | I | Field identification signal (optional – FLDMODE) <ul style="list-style-type: none"> • This signal can be configured to be latched by the VD signal (FIDMD). • The polarity of the field identification signal is configurable (FLDPOL). |
| VDIN_PCLK | I | Pixel clock <ul style="list-style-type: none"> • The PCLK signal is the signal used to latch input image data. • The input image data can be captured on either the rising or on the falling edge of the PCLK signal which is configured by field PCLK_INV. • The maximum pixel clock rate is 75 MHz. |

10.3.2 VPFE Data / Image Processing

This section describes the image/data processing of each module in the VPFE in more detail. [Section 10.3.2.1](#) describes the raw data mode while [Section 10.3.2.2](#) explains the YCbCr and BT656 modes.

10.3.2.1 Raw Data Mode

Raw data mode is enabled by setting SYN_MODE.INPMODE to 0 and setting REC656IF.REC656ON to 0. [Figure 10-5](#) shows the corresponding data processing diagram.

Figure 10-5. Data Processing in Raw Data Mode

Typically, raw sensor data is one color per pixel in a color filter array (CFA). The color filter array applied is typically a Bayer pattern, as shown in [Figure 10-6](#) for RGB color space. Alternatively, the special Foveon X3-family sensors capture R, G, and B lights at each pixel location. Both Bayer and Foveon sensors are supported by the VPFE controller.

Figure 10-6. Color Patterns

Bayer format with R/Gr and Gb/B in alternate lines
– Horizontal distance between same colors is 2.

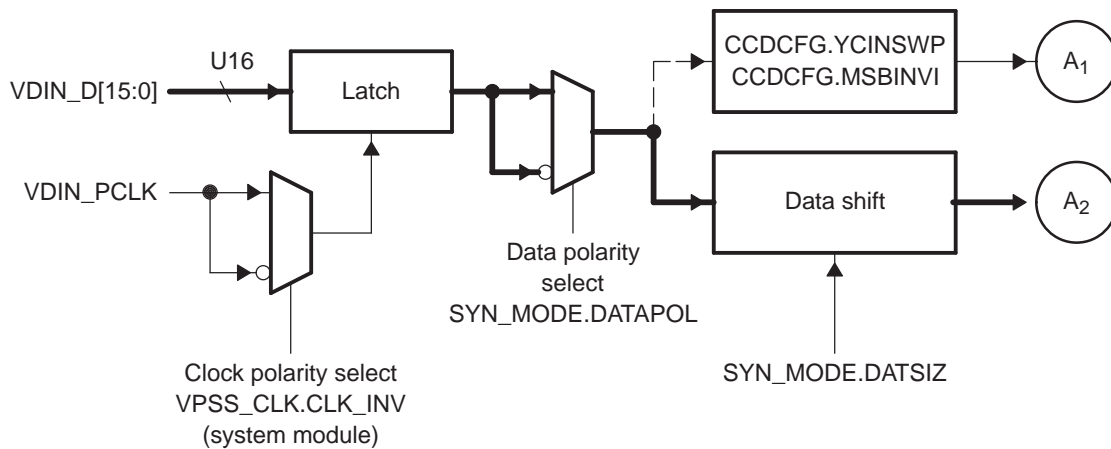

Foveon sensor with R, G, and B in same line
– Horizontal distance between same colors is 3.

10.3.2.1.1 Input Sampling and Formatting

The data path of raw data mode is shown in the thicker lines in Figure 10-7 (i.e., A2). Data path A1 is applicable to YUV input mode only.

- The pixel clock (VDIN_PCLK) latches the data.
- Pixel clock polarity can be either rising or falling edge and is set in VPSS clock control register (VPSS_CLK).PCK_INV).
- DATAPOL bit in the SYN_MODE register affects the data representation.
- Data is right-shifted to align the data in the least significant bits of the data bus and provide the maximum dynamic range for the remainder of the processing (DATSIZ bit in the SYN_MODE register). This also sets the maximum data size allowed in subsequent clipping/limiting operations and is the output data alignment when it is written to external memory.

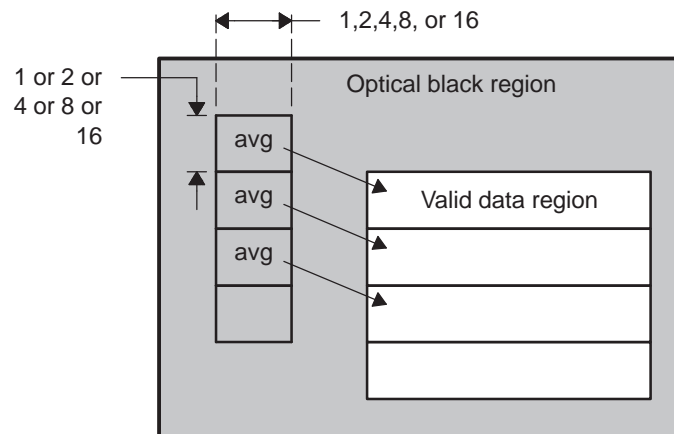

Figure 10-7. Input Formatter

10.3.2.1.2 Optical Black Clamping

Sensor manufacturers typically provide some optically masked pixels at the beginning/end of each line to allow you to determine the noise floor on any given frame of data. The optical black clamping function provides a means to average the optically black pixels and subtract that value from each input pixel as the first step in reducing the noise on the input pixels.

Figure 10-8. Optical Black Averaging & Application

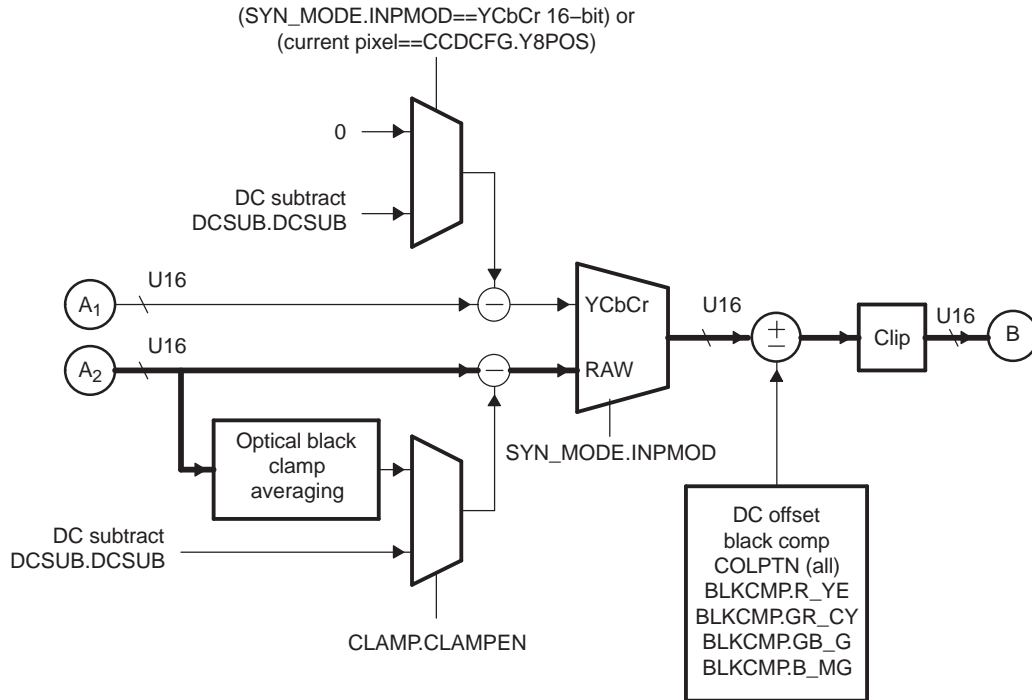

The averaging circuit takes an average of masked (black) pixel values from the image sensor, averaging pixels at the start (OBST bit in the CLAMP register) of each line (OBSLEN bit in the CLAMP register) and for the number of indicated lines (OBSLN bit in the CLAMP register), plus an optional gain adjustment (OBGAIN bit in the CLAMP register). The resultant value is subtracted from the image data at the succeeding line. You can control the position of the black pixels, the number of pixels (8 or 16) in each line that are averaged, and the number of lines (8 or 16) that are averaged.

Alternately, you can disable black clamp averaging (CLAMPEN bit in the CLAMP register) and select a constant black value for subtraction (DCSUB bit in the DCSUB register) instead of using the calculated average value.

The corresponding data path is shown in the thicker lines in [Figure 10-9](#).

Figure 10-9. Black Clamping and Black Level Compensation

10.3.2.1.3 Black Level Compensation

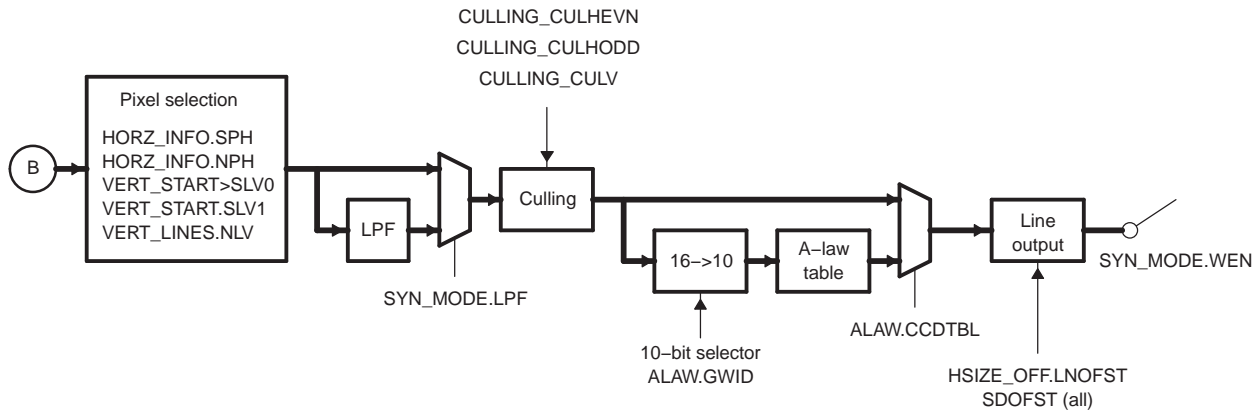

After the digital clamping is applied to the data, black level compensation is applied (Figure 10-9). In this operation, a fixed value is subtracted from the data depending on the color (i.e., R/Ye, Gr/Cy, Gb/G, and B/Mg). The offset (BLKCMP register, fields R_YE, GR_CY, GB_G, B_MG) that is applied to each data sample is selected according to the 0/1/2/3 phase and the color (0/1/2/3) specified for each phase (COLPTN). The color pattern definition is very flexible in order to accommodate many different capture devices, including normal Bayer CFA sampling, Foveon sensors, and VGA movie mode CCDs, whose VGA draft mode output does not follow the typical Bayer pattern.

10.3.2.1.4 Output Formatter

The final stage of VPFE processing is the output formatter, as shown in Figure 10-10. A framing selection is applied to limit the processing area by the settings in the HORZ_INFO, VERT_START and VERT_LINES registers.

NOTE: In addition to the framing applied at the beginning and end of the data formatter operation, you must apply a framing selection to limit the processing area. Please ensure that the settings are relative to that frame.

Figure 10-10. Output Formatter

10.3.2.1.4.1 Low Pass Filter

Use the LPF bit in the SYN_MODE register to apply an optional low-pass filter after the reframing. The low-pass filter consists of a simple 3-tap ($\frac{1}{4}$, $\frac{1}{2}$, $\frac{1}{4}$) filter. Two pixels on the left and two pixels on the right of each line are cropped if the filter is enabled.

10.3.2.1.4.2 Culling

Use the CULEVEN and CULODD bits in the CULLING register (8-bit repeating mask, one per field) to enable an optional culling operation, which culls (deletes) selected pixel data from a line. Use the CULV bit in the CULLING register to select lines from a frame.

Table 10-8 illustrates how the register values apply the decimation pattern to the data. The pixels in white will be saved to external memory and the shaded pixels are discarded.

In this case:

- CULLING = 0x59C40066, with
- CULHEVN = 0x59,
- CULHODD = 0xC4, and
- CULV = 0x66.

Table 10-8. Example for Decimation Pattern

| | | LSB | | | | | | | |
|----------|---------|-----|---|---|---|---|---|---|------|
| | | 0 | 0 | 1 | 0 | 0 | 0 | 1 | 1 |
| CULHEVN | CULHODD | 1 | 0 | 0 | 1 | 1 | 0 | 1 | 0 |
| 0th line | | | | | | | | | |
| 1st line | | | | | | | | | |
| 2nd line | | | | | | | | | |
| 3rd line | | | | | | | | | |
| 4th line | | | | | | | | | |
| 5th line | | | | | | | | | |
| 6th line | | | | | | | | | |
| 7th line | | | | | | | | | |
| | | | | | | | | | CULV |

10.3.2.1.4.3 A-Law Transformation

Use the CCDTBL bit in the ALAW register to apply an optional 10-to-8-bit A-Law transformation using a fixed A-Law table as the final processing stage. Using this causes the data width to reduce to 8 bits and allows packing to 8 bits/pixel when saving to external memory. Since the data resolution can be greater than 10 bits at this stage, you must select the 10 bits for input to the A-Law operation. Use the GWID bit in the ALAW register to select the 10 bits for input.

Figure 10-11. A-Law Table

Table 10-9. A-Law Table – Part 1

| Inp ut | A-Law | Inp ut | A-Law | Inp ut | A-Law | Inp ut | A-Law | Inp ut | A-Law | Inp ut | A-Law | Inp ut | A-Law | Inp ut | A-Law |

10.3.2.1.4.4 Line Output Control

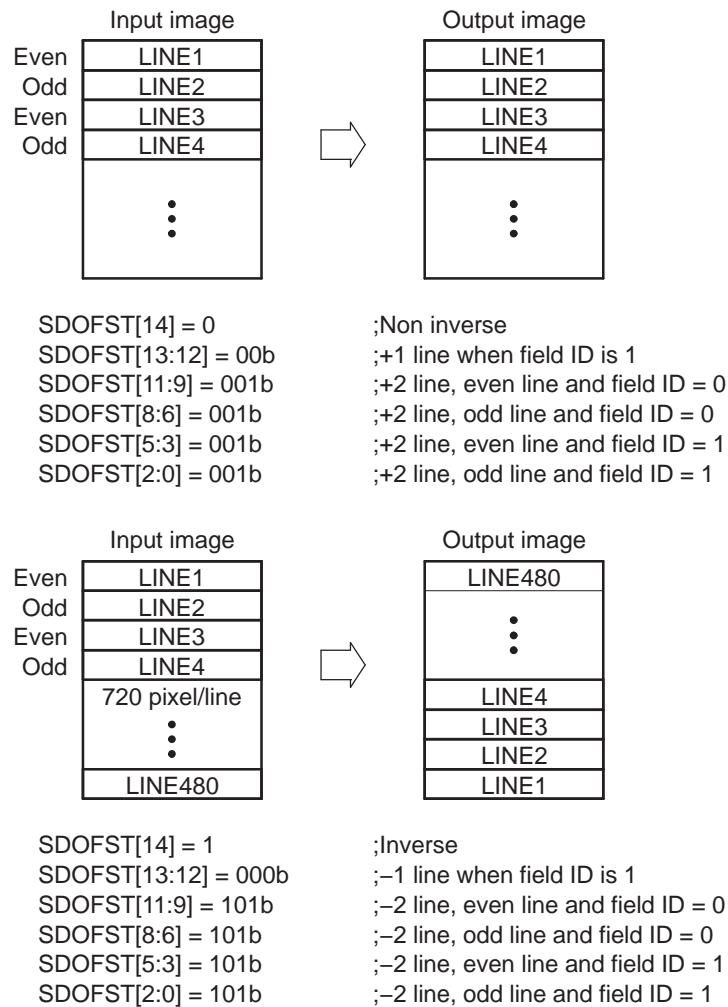

The final stage of the raw data mode is the line output control, which controls how the input sensor lines are written to external memory. The value of the ADR bit in the SDR_ADDR register defines the starting address where the frame should be written in external memory. The value of the LNOFST bit in the HSIZE_OFF register defines the distance between the beginning of output lines in bytes. Both the starting address and line offset must be aligned to 32-byte boundaries (i.e., either 16 or 32 pixels, depending on the PACK8 bit in the SYN_MODE register). Use the SDOFST register to define additional offsets, depending on the field ID and the even/odd line numbers. Defining additional offsets provides a means to de-interlace an interlaced, two-field input and also inverts an input image vertically. See [Figure 10-12](#) and [Figure 10-13](#) for example usage.

Figure 10-12. Image De-interfacing

*1 – SDOFST[13:12]=00b, +1 line for FID=1 lines

*2 – SDOFST[11:9]=SDOFST[8:6]=SDOFST[5:3]=SDOFST[2:0]=001b, +2 lines

Figure 10-13. Non-inversed vs Inversed Format

10.3.2.1.4.5 Output Format

The pixel data format in external memory is shown in [Table 10-12](#).

- If pixel data format is 8-bit, every 16-bit word in external memory stores two pixel data.
- If pixel data format is greater than 8-bit, every 16-bit word in external memory stores one pixel data, and the unused bits are MSB which are filled with 0.

Table 10-11. Storage Format in external memory for Raw Data Mode

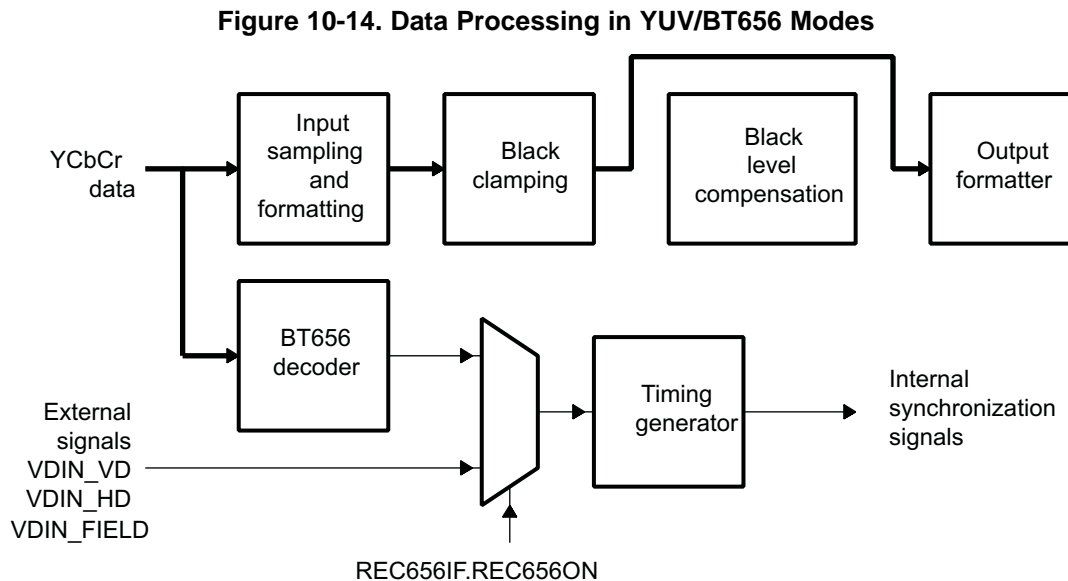

| | Upper Word | | Lower Word | |
|------------|------------|----------|------------|---------|
| | MSB (31) | LSB (16) | MSB (15) | LSB (0) |
| 16-bit | | Pixel1 | | Pixel0 |
| 15-bit | 0 | Pixel1 | 0 | Pixel0 |
| 14-bit | 0 | Pixel1 | 0 | Pixel0 |
| 13-bit | 0 | Pixel1 | 0 | Pixel0 |
| 12-bit | 0 | Pixel1 | 0 | Pixel0 |
| 11-bit | 0 | Pixel1 | 0 | Pixel0 |
| 10-bit | 0 | Pixel1 | 0 | Pixel0 |
| 9-bit | 0 | Pixel1 | 0 | Pixel0 |
| 8-bit | 0 | Pixel1 | 0 | Pixel0 |
| 8-bit pack | Pixel3 | Pixel2 | Pixel1 | Pixel0 |

10.3.2.2 YCbCr and BT656 Modes

YCbCr mode and BT656 mode are similar in operation, as shown in [Figure 10-14](#). The additional logic used in BT656 mode is the CCIR656 decoder, which extracts synchronization information from input YCbCr data and regenerates the corresponding timing for internal operation.

- YCbCr mode is enabled by setting field INPMODE in register SYN_MODE to 1 or 2 and clearing field REC656ON in register REC656IF.
- BT656 mode is enabled by setting REC656ON in register REC656IF to 1.

YCbCr mode typically has 8 bits per luma/chroma sample while BT656 mode has 8 bits or 10 bits per luma/chroma sample.

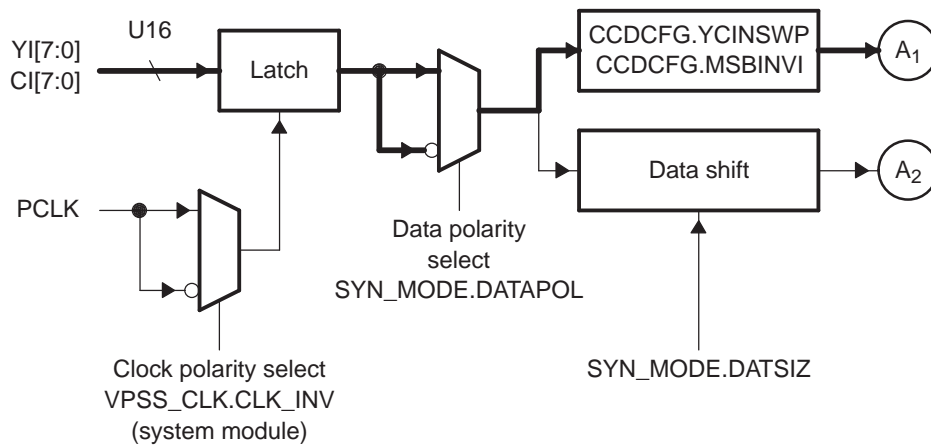

10.3.2.2.1 Input Sampling and Formatting

The data path of YCbCr/BT656 modes is shown in thicker lines in [Figure 10-15](#) (i.e., A1). Data path A2 is applicable to raw data mode only.

- The pixel clock (VDIN_PCLK) latches data.
- Pixel clock polarity can be either rising or falling edge and is set in VPSS clock control register (VPSS_CLK).PCLK_INV).
- DATAPOL bit in the SYN_MODE register affects the data representation.
- Bit YCINSWP in register CCDCFG can be used to swap the upper and lower portions of the 16-bit YCbCr data bus.
 - In 16-bit YCbCr mode, this swap bit determines which part of the bus luma and chroma samples occupy respectively.
 - In 8-bit mode, this swap bit determines which part of the bus is the effective 8-bit input. In other words, two external 8-bit YCbCr capture devices can be tied to VPFE module directly.
- Bit MSBINVI in register CCDCFG can be used to invert the MSB of the chroma signal.

Figure 10-15. CCD Controller

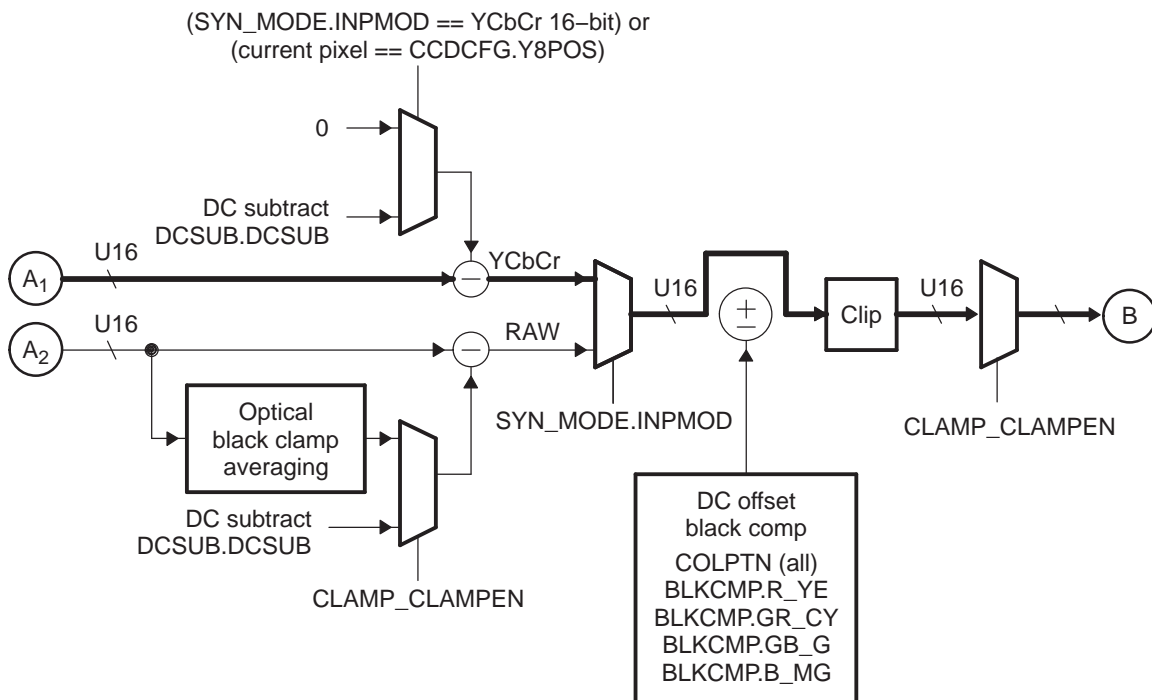

10.3.2.2.2 Black Clamping

The second step in BT.656/YCbCr processing is black clamping

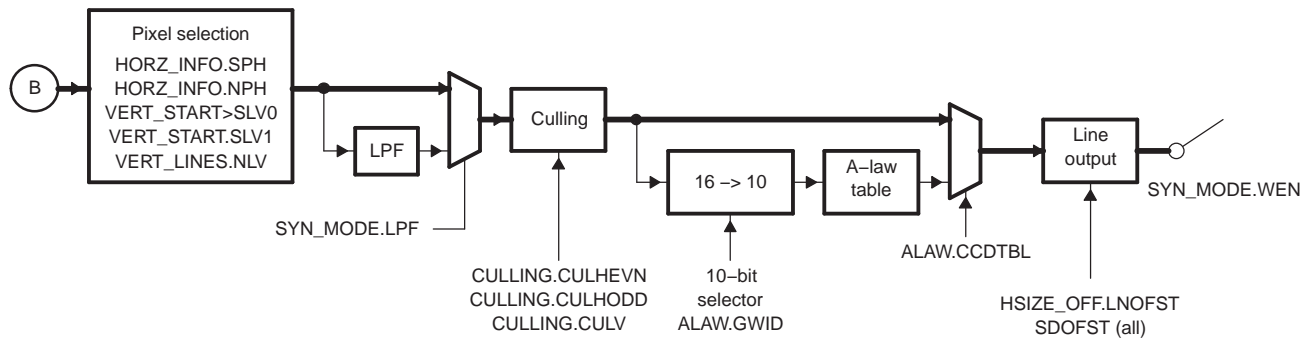

Use the DCSUB bit in the DCSUB register to subtract a fixed value from the luma sample for YUV data. Set the subtraction value to zero to disable the operation. See Figure 10-16 for more details. You may notice that black compensation (BLKCMP) is not used in YCbCr and BT656 modes.

Figure 10-16. Black Clamping and Block Level Compensation

10.3.2.2.3 Output Formatter

The output formatter is the final stage of VPFE processing (as shown as thicker lines in Figure 10-17). Apply a framing selection to limit the processing area by the settings in the HORZ_INFO, VERT_START and VERT_LINES registers.

Figure 10-17. Output Formatter

- Use the LFP bit in the SYN_MODE register to disable the LPF by setting the LFP bit equal to 0.
- Culling can be used in YCbCr and BT656 modes; however, care must be taken to preserve the 422 output format.
- Do not use the A-Law transformation in YCbCr or BT.656 mode (the CCDBTL bit in the ALAW register = 0).

The pixel data in external memory is shown in [Table 10-12](#).

Table 10-12. Storage Format in external memory for BT.656/YCbCr Modes

| external memory Address | Upper word | | Lower word | |
|----------------------------|------------|----------|------------|---------|
| | MSB (31) | LSB (16) | MSB (15) | LSB (0) |
| N | Y1 | Cr0 | Y0 | Cb0 |
| N + 1 | Y3 | Cr2 | Y2 | Cb2 |
| N + 2 | Y5 | Cr4 | Y4 | Cb4 |

10.4 Programming Model

The following programming procedures should be followed to enable the VPFE controller to receive video or image capture data.

1. Power-up the VPFE via the power sleep controller (PSC) module (see *TDRx40x/41x Automotive Digital Radio and Infotainment Applications Processor ARM Subsystem Reference Guide* (SPRUF07))
2. Disable the VPFE controller
3. Configure the VPFE registers to match the system requirements, including interrupt setup
4. Enable the VPFE controller

Once the VPFE controller is enabled, it starts to process input data continuously. No user intervention is necessary to re-start the process. As a result, the VPFE interrupt must be set up correctly in order to operate properly. Users can terminate its operation by disabling the VPFE controller.

The remaining sections describe the programming procedure in more detail.

10.4.1 Enabling and Disabling the VPFE Controller

The following steps describe how to enable and disable the VPFE controller:

- Clearing the ENABLE bit in the VPFE_PCR register disables the VPFE controller.
- Setting the ENABLE bit in the VPFE_PCR register enables the VPFE controller.
 - The VPFE controller should be enabled prior to data transmission from the external device to avoid data loss.

10.4.2 Configuring VPFE Registers

10.4.2.1 General Register Setup

Table 10-13 lists the minimum register fields that must be configured.

Table 10-13. Basic Configuration of VPFE Registers

| Function | Register | Fields |
|--|----------|---|
| External signal configuration (This includes signals VDIN_VD, VDIN_HD, VDIN_FIELD, and VDIN_WEN.) | SYN_MODE | VDHDEN VDPOL HDPOL FLDMODE FLDPOL EXWEN DATAPOL |
| | CCDCFG | VDLC |
| Input data mode | REC656 | R656ON |
| | SYN_MODE | INPMOD |
| Color pattern | COLPTN | All |
| Black compensation | BLKCOMP | All |
| Data path configuration | SYN_MODE | WEN |

Table 10-14 describes additional configuration requirements when certain conditions are met.

Table 10-14. Conditional Configuration of VPFE Registers

| Category | If... | Then program... |
|------------------------------|--|--|
| Interlace mode | Field FLDMODE in register SYN_MODE is 1 | Field FIDMD in register CCDCFG |
| External WEN | Field EXWEN in register SYN_MODE is 1 | Field WENLOG bit in register CCDCFG |
| REC656 input | Field R656ON in register REC656 is 1 | Field ECCFVH in register REC656 Field BW656 in register CCDCFG |
| RAW input | Field INPMOD in register SYN_MODE is 0 and Field R656ON in register REC656 is 1 | Field DATSIZ in register SYN_MODE Field CLAMPEN in register CLAMP |
| 16-bit YCC input | Field INPMOD in register SYN_MODE is 1 and Field R656ON in register REC656 is 1 | Field YCINSWP in register CCDCFG Field MSBINVI in register CCDCFG Register DCSUB |
| 8-bit YCC input | Field INPMOD in register SYN_MODE is 2 and Field R656ON in register REC656 is 1 | Field Y8POS in register CCDCFG |
| Optical black clamp enabled | Field CLAMPEN in register CLAMP is 1 and Field INPMOD in register SYN_MODE is 0 | Field OBGAIN in register CLAMP Field OBST in register CLAMP Field OBSLN in register CLAMP Field OBSLEN in register CLAMP |
| Optical black clamp disabled | Field CLAMPEN in register CLAMP is 0 and Field INPMOD in register SYN_MODE is 0 | Register DCSUB |
| Write to external memory | Field WEN in register SYN_MODE is 1 | Field LPF in register SYN_MODE Field PACK8 in register SYN_MODE Field CCDTBL in register ALAW Field BSWD in register CCDCFG Register HORZ_INFO Register VERT_START Register VERT_LINES Register CULLING Register SDR_ADDR Register HSIZE_OFF Register SDOFST |
| A-law | Field CCDTBL in register ALAW is 1 | Field GWID in register ALAW |
| Interrupt | Interrupts CCDC_VD0_INT and CCDC_VD1_INT are to be used | Register VDINT |

10.4.2.2 Interrupts

The VPFE controller can generate three interrupts: CCDC_VD0_INT, CCDC_VD1_INT, and CCDC_VD2_INT.

NOTE: Enable the VDHDEN field in register SYN_MODE to receive any of these VPFE controller interrupts.

The CCDC_VD0_INT and CCDC_VD1_INT interrupts occur relative to the VD pulse, as shown in Figure 10-18 and Figure 10-19. Please note that field VDPOL in register SYN_MODE changes the trigger timing.

- If field VDPOL is 1, the VDINT0 and VDINT1 counters begin counting VDIN_HD pulses from the falling edge of signal VDIN_VD.
- If field VDPOL is 0, the VDINT0 and VDINT1 counters begin counting VDIN_HD pulses from the rising edge of signal VDIN_VD.
- Interrupts CCDC_VD0_INT and CCDC_VD1_INT occur after receiving the number of horizontal lines

(VDIN_HD pulse signals) set in the VDINT0 bit in the VDINT register and the VDINT1 bit in the VDINT register, respectively.

Figure 10-18. VDPOL is 0

Figure 10-19. VDPOL is 1

The CCDC_VD2_INT interrupt always occurs at the falling edge of the VDIN_WEN signal (via an external pin), as shown in Figure 10-20. There are no registers in the VPFE module to configure this interrupt.

Figure 10-20. CCDC_VD2_INT Interrupt

10.4.2.3 Status

The BUSY status bit in the VPFE_PCR register is set when the start of frame occurs (if the ENABLE bit in the VPFE_PCR register is 1 at that time). It automatically resets to 0 at the end of a frame.

10.4.2.4 VDIN_VD latched Registers

The VDLC field in register CCDCFG affects the access of the following registers and register fields.

Registers

- VPFE_PCR
- HORZ_INFO
- VERT_START
- VERT_LINES
- CULLING
- HSIZE_OFF
- SDOFST
- SDR_ADDR

Register Fields

- WEN in SYN_MODE
- LPF in SYN_MODE
- CLAMPEN in CLAMP

Registers

YCINSWP in CCDCFG

NOTE:

1. If the VDLC field is 0, changes to the above registers/register fields will take effect immediately.
2. If the VDLC field is 1, changes to the above registers/register fields will take effect at the start of a new frame (i.e., the changes are latched by the VDIN_VD signal). Reads from these registers/register fields will return the most recent write value (even though these values may not take effect).

Be careful to avoid undesired effects when using the first approach.

10.4.2.5 Inter-frame Operations

As described in the previous section, the VPFE_PCR and SDR_ADDR registers will be latched by the VDIN_VD signal if the VDLC field in the CCDCFG register is 0. This important feature provides a reliable way for programmers to enable/disable the VPFE module and/or modify the memory pointers in-between frames. For example, the VPFE interrupt service routine (ISR) can program the SDR_ADDR register to a new value before the end of the current frame. By doing so, the current frame is received without any interruption and the new external memory address (SDR_ADDR register) will be used for receiving the next frame.

10.4.3 VPFE Limitations

The major limitations of the VPFE module are summarized as follows:

- The VDIN_PCLK (pixel clock) signal cannot be higher than 75 MHz.
- The SDR_ADDR and HSIZE_OFF registers should be programmed to values with 5 LBS bits as 0; namely, the memory space they point to should be on a 32-byte boundary.
- The COLPTN register should be set to 0 in YCbCr and BT.656 modes.
- The BLKCMP register should be set to 0 in YCbCr and BT.656 modes.
- Low-pass filter (LPF field in SYN_MODE register) should be disabled in YCbCr and BT.656 modes.
- A-LAW should be disabled in YCbCr and BT.656 modes.

10.5 Video Processing Front End (VPFE) Registers

Table 10-15 lists the memory-mapped registers for the VPFE controller.

Table 10-15. CCD Controller (CCDC) Register Map

| Offset | Acronym | Register Description | Section |
|-----------|------------|---|---------------------------------|
| 00h | PID | Peripheral Revision and Class Information | Section 10.5.1 |

10.5.1 Peripheral Revision and Class Information Register (PID)

The peripheral revision and class information register (PID) is shown in [Figure 10-21](#) and described in [Table 10-16](#).

Figure 10-21. Peripheral Revision and Class Information Register (PID)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 10-16. Peripheral Revision and Class Information Register (PID) Field Descriptions

| Bit | Field | Value | Description |
|------|-------|---------------|--|
| 31-0 | PID | 4D00 2101h | Peripheral identification that uniquely identifies the specific revision of the VPFE |

10.5.2 VPFE_Peripheral Control Register (VPFE_PCR)

The VPFE_peripheral control register (VPFE_PCR) is shown in [Figure 10-22](#) and described in [Table 10-17](#).

Figure 10-22. VPFE_Peripheral Control Register (VPFE_PCR)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 10-17. VPFE_Peripheral Control Register (VPFE_PCR) Field Descriptions

| Bit | Field | Value | Description |
|------|----------|-------|---|
| 31-2 | Reserved | 0 | Any writes to these bit(s) must always have a value of 0. |
| 1 | BUSY | 0 | VPFE busy bit Not busy |
| | | 1 | Busy |
| 0 | ENABLE | 0 | VPFE enable Disable |
| | | 1 | Enable |

Table 10-18. Sync and Mode Set Register (SYN_MODE) Field Descriptions (continued)

| Bit | Field | Value | Description |
|-----|----------|-------|--|
| 6 | DATAPOL | 0 | Input data polarity Normal (no change) |
| | | 1 | One's complement |
| 5 | EXWEN | 0 | External WEN selection. When set to 1 and when VDHDEN is set to 1, the WEN signal is used as the external memory write enable (to external memory). The data is stored to memory only when the external sync (HD and VD) signals are active. Do not use external WEN (write enable) |
| | | 1 | Use external WEN (write enable) |
| 4 | FLDPOL | 0 | Field indicator polarity Positive |
| | | 1 | Negative |
| 3 | HDPOL | 0 | HD sync polarity Positive |
| | | 1 | Negative |
| 2 | VDPOL | 0 | VD sync polarity Positive |
| | | 1 | Negative |
| 1-0 | Reserved | 0 | Any writes to these bit(s) must always have a value of 0. |

10.5.4 Horizontal Pixel Information Register (HORZ_INFO)

The horizontal pixel information register (HORZ_INFO) is shown in [Figure 10-24](#) and described in [Table 10-19](#).

Figure 10-24. Horizontal Pixel Information Register (HORZ_INFO)

| | | |
|----------|-------|----|
| 31 | 30 | 16 |
| Reserved | SPH | |
| R-0 | R/W-0 | |
| 15 | 14 | 0 |
| Reserved | NPH | |
| R-0 | R/W-0 | |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 10-19. Horizontal Pixel Information Register (HORZ_INFO) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|---------|---|
| 31 | Reserved | 0 | Any writes to these bit(s) must always have a value of 0. |
| 30-16 | SPH | 0-7FFFh | Start pixel, horizontal. The SPH sets the pixel clock position at which data output to external memory begins, measured from the start of HD. This bit field is latched by VD. |
| 15 | Reserved | 0 | Any writes to these bit(s) must always have a value of 0. |
| 14-0 | NPH | 0-7FFFh | Number of pixels, horizontal. NPH sets the number of horizontal pixels that is output to external memory = (NPH + 1) and 0xFFF0 (i.e., the number of horizontal output pixels truncates to multiples of 16). This bit field is latched by VD. |

10.5.5 Vertical Line - Settings for the Starting Pixel Register (VERT_START)

The vertical line - settings for the starting pixel register (VERT_START) is shown in [Figure 10-25](#) and described in [Table 10-20](#).

Figure 10-25. Vertical Line - Settings for the Starting Pixel Register (VERT_START)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 10-20. Vertical Line - Settings for the Starting Pixel Register (VERT_START) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|---------|---|
| 31 | Reserved | 0 | Any writes to these bit(s) must always have a value of 0. |
| 30-16 | SLV0 | 0-7FFFh | Start line, vertical (field 0). SLV0 sets line at which data output to external memory will begin, measured from the start of VD. This bit field is latched by VD |
| 15 | Reserved | 0 | Any writes to these bit(s) must always have a value of 0. |
| 14-0 | SLV1 | 0-7FFFh | Start line, vertical (field 1). SLV1 sets line at which data output to external memory will begin, measured from the start of VD. For a progressive sensor this field is ignored. This bit field is latched by VD |

10.5.6 Number of Vertical Lines Register (VERT_LINES)

The number of vertical lines register (VERT_LINES) is shown in [Figure 10-26](#) and described in [Table 10-21](#).

Figure 10-26. Number of Vertical Lines Register (VERT_LINES)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 10-21. Number of Vertical Lines Register (VERT_LINES) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|---------|--|
| 31-15 | Reserved | 0 | Any writes to these bit(s) must always have a value of 0. |
| 14-0 | NLV | 0-7FFFh | Number of lines, vertical. NLV sets the number of vertical lines that will be output to external memory. The number of lines output to external memory = (NLV + 1). This bit field is latched by VD. |

10.5.7 Culling Information in Horizontal and Vertical Directions Register (CULLING)

The culling information in horizontal and vertical directions register (CULLING) is shown in [Figure 10-27](#) and described in [Table 10-22](#).

Table 10-22. Culling Information in Horizontal and Vertical Directions Register (CULLING) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|-------|--|
| 31-24 | CULHEVN | 0-FFh | Horizontal Culling Pattern for Even Line, 8-bit mask. LSB is first pixel, MSB is 8th pixel, then pattern repeats. This bit field is latched by VD. |
| | | 0 | CULLING (deletion) |
| | | 1 | Retain (to be saved to external memory). |
| 23-16 | CULHODD | 0-FFh | Horizontal Culling Pattern for Odd Line, 8-bit mask. LSB is first pixel, MSB is 8th pixel, then pattern repeats. This bit field is latched by VD. |
| | | 0 | CULLING (deletion) |
| | | 1 | Retain (to be saved to external memory). |
| 15-8 | Reserved | 0 | Any writes to these bit(s) must always have a value of 0. |
| 7-0 | CULV | 0-FFh | Vertical Culling Pattern, 8-bit mask. LSB is first line, MSB is 8th line, then pattern repeats. This bit field is latched by VD. |
| | | 0 | CULLING (deletion) |
| | | 1 | Retain (to be saved to external memory). |

10.5.8 Horizontal Size (HSIZE_OFF)

The horizontal size register (HSIZE_OFF) is shown in [Figure 10-28](#) and described in [Table 10-23](#).

Figure 10-28. Horizontal Size Register (HSIZE_OFF)

LEGEND: R = Read only; -n = value after reset

Table 10-23. Horizontal Size Register (HSIZE_OFF) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|----------|--|
| 31-16 | Reserved | 0 | Any writes to these bit(s) must always have a value of 0. |
| 15-0 | LNOFST | 0 - FFFh | Address offset for each line. LNOFST Sets offset for each output line in external memory Either 16 or 32 pixels depending on setting of PACK8. The 5 LSB are ignored, and a zero is returned when read; the offset will be on a 32-byte boundary. For optimal performance in the system, the address offset should be on a 256-byte boundary. This bit field is latched by VD. |

10.5.9 External Memory Line Offset Register (SDOFST)

The external memory line offset register (SDOFST) is shown in [Figure 10-29](#) and described in [Table 10-24](#).

Figure 10-29. External Memory Line Offset Register (SDOFST)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 10-24. External Memory Line Offset Register (SDOFST) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|--|---|
| 31-15 | Reserved | 0 | Any writes to these bit(s) must always have a value of 0. |
| 14 | FIINV | 0 1 | Field identification signal inverse. This field is latched by VD. Non inverse Inverse |
| 13-12 | FOFST | 00 01 10 11 | Line offset value of field ID = 1. This field is latched by VD. +1 line +2 line +3 line +4 line |
| 11-9 | LOFTS0 | 000 001 010 011 100 101 110 111 | Line offset values of even line and even field ID = 0. This field is latched by VD. +1 line +2 lines +3 lines +4 lines -1 line -2 lines -3 lines -4 lines |
| 8-6 | LOFTS1 | 000 001 010 011 100 101 110 111 | Line offset values of odd line and even field ID = 0. This field is latched by VD. +1 line +2 lines +3 lines +4 lines -1 line -2 lines -3 lines -4 lines |

Table 10-24. External Memory Line Offset Register (SDOFST) Field Descriptions (continued)

| Bit | Field | Value | Description |
|-----|--------|----------|--|
| 5-3 | LOFST2 | | Line offset values of even line and odd field ID = 1. This field is latched by VD. |
| | | 000 | +1 line |
| | | 001 | +2 lines |
| | | 010 | +3 lines |
| | | 011 | +4 lines |
| | | 100 | -1 line |
| | | 101 | -2 lines |
| | | 110 | -3 lines |
| | 111 | -4 lines | |
| 2-0 | LOFST3 | | Line offset values of odd line and odd field ID = 1. This field is latched by VD. |
| | | 000 | +1 line |
| | | 001 | +2 lines |
| | | 010 | +3 lines |
| | | 011 | +4 lines |
| | | 100 | -1 line |
| | | 101 | -2 lines |
| | | 110 | -3 lines |
| | 111 | -4 lines | |

10.5.10 external memory Address Register (SDR_ADDR)

The external memory address register (SDR_ADDR) is shown in [Figure 10-30](#) and described in [Table 10-25](#).

Figure 10-30. external memory Address Register (SDR_ADDR)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 10-25. External Memory Address Register (SDR_ADDR) Field Descriptions

| Bit | Field | Value | Description |
|------|----------|--------------|---|
| 31-0 | SDR_ADDR | 0-FFFF FFFFh | 32-bit external memory starting address for VPFE output. This bit field is latched by VD. The address should be aligned on a 32-byte boundary. Therefore, the 5 LSB's are ignored. Furthermore, reading this register will always show the 5 LSB's as 0. For optimal performance in the system, the address should be on a 256-byte boundary. |

10.5.11 Optical Black Clamping Settings Register (CLAMP)

The optical black clamping settings register (CLAMP) is shown in [Figure 10-31](#) and described in [Table 10-26](#).

Figure 10-31. Optical Black Clamping Settings Register (CLAMP)

| | | | | | | |
|---------|--------|-------|----------|-------|--------|----|
| 31 | 30 | 28 | 27 | 25 | 24 | 16 |
| CLAMPEN | OBSLEN | OBSLN | | OBST | | |
| R/W-0 | R/W-0 | R/W-0 | | R/W-0 | | |
| 15 | 10 | | 9 | 5 | 4 | 0 |
| OBST | | | Reserved | | OBGAIN | |
| R/W-0 | | | R-0 | | R/W-0 | |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 10-26. Optical Black Clamping Settings Register (CLAMP) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|--|---|
| 31 | CLAMPEN | 0 1 | Clamp enable. Enable or disable clamping of CCD data based on the calculated average of optical black samples. This bit is latched by VD. Disable Enable |
| 30-28 | OBSLEN | 000 001 010 011 100 5-7 | Optical black sample length. Number of Optical Black Sample pixels per line to include in the average calculation 1 pixels 2 pixels 4 pixels 8 pixels 16 pixels Reserved. |
| 27-25 | OBSLN | 000 001 010 011 100 5-7 | Optical black sample lines. Number of Optical Black Sample lines to include in the average calculation 1 lines 2 lines 4 lines 8 lines 16 lines Reserved |
| 24-10 | OBST | 0-7FFh | Start pixel of optical black samples. The start pixel position of optical black samples, specified from the start of HD in pixel clocks. |
| 9-5 | Reserved | 0 | Any writes to these bit(s) must always have a value of 0. |

Table 10-26. Optical Black Clamping Settings Register (CLAMP) Field Descriptions (continued)

| Bit | Field | Value | Description |
|-----|--------|-------|---|
| 4-0 | OBGAIN | 0-1Fh | Gain to apply to the optical black average. Multiply the optical black average with the specified gain. |
| | | 1Fh | 1 + 15/16 |
| | | 1Eh | 1+ 14/16 |
| | | ... | ... |
| | | 10h | 1 + 0/16 |
| | | 0Fh | 0 + 15/16 |
| | | 0Eh | 0 + 14/16 |
| | | 0Dh | 0 + 13/16 |
| | | ... | ... |
| | | 02h | 0 + 2/16 |
| | | 01h | 0 + 1/16 |
| | | 00h | 0 + 0/16 |

10.5.12 DC Clamp Register (DCSUB)

The DC clamp register (DCSUB) is shown in [Figure 10-32](#) and described in [Table 10-27](#).

Figure 10-32. DC Clamp Register (DCSUB)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 10-27. DC Clamp Register (DCSUB) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|---------|--|
| 31-14 | Reserved | 0 | Any writes to these bit(s) must always have a value of 0. |
| 13-0 | DCSUB | 0-3FFFh | DC level to subtract from CCD data. The DC value set here is subtracted from the CCD data when OBS clamping is disabled - CLAMP.CLAMPEN. |

10.5.13 CCD Color Pattern Register (COLPTN)

The CCD color pattern register (COLPTN) is shown in [Figure 10-33](#) and described in [Table 10-28](#).

Figure 10-33. CCD Color Pattern Register (COLPTN)

| GB_G | | B_MG | |
| R/W-0 | | R/W-0 | |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 10-29. Black Compensation Register (BLKCMP) Field Descriptions

| Bit | Field | Value | Description |
|-------|-------|-------|---|
| 31-24 | R_YE | 0-FFh | Black level compensation for R/Ye pixels (-128:+127). 2's complement, MSB is sign bit. |
| 23-16 | GR_CY | 0-FFh | Black level compensation for Gr/Cy pixels (-128:+127). 2's complement, MSB is sign bit. |
| 15-8 | GB_G | 0-FFh | Black level compensation for Gb/G pixels (-128:+127). 2's complement, MSB is sign bit. |
| 7-0 | B_MG | 0-FFh | Black level compensation for B/Mg pixels (-128:+127). 2's complement, MSB is sign bit. |

10.5.15 VPFE Interrupt Control Register (VDINT)

The VPFE interrupt control (VDINT) register is shown in [Figure 10-35](#) and described in [Table 10-30](#).

Figure 10-35. VPFE Interrupt Control (VDINT) Register

| | | |
|----------|--------|----|
| 31 | 30 | 16 |
| Reserved | VDINT0 | |
| R-0 | R/W-0 | |
| 15 | 14 | 0 |
| Reserved | VDINT1 | |
| R-0 | R/W-0 | |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 10-30. VPFE Interrupt Control (VDINT) Register Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|---------|---|
| 31 | Reserved | 0 | Any writes to these bit(s) must always have a value of 0. |
| 30-16 | VDINT0 | 0-7FFFh | CCDC_VD0_INT interrupt timing. Specify VDINT0 in units of horizontal lines from the start of VD pulse. Resulting value is VDINT0+1. Note that if the rising edge (or falling edge if programmed) of the HD lines up with the rising edge (or falling edge if programmed) of VD, the 1st HD is not counted. |
| 15 | Reserved | 0 | Any writes to these bit(s) must always have a value of 0. |
| 14-0 | VDINT1 | 0-7FFFh | CCDC_VD1_INT interrupt timing. Specify VDINT1 in units of horizontal lines from the start of VD pulse. Resulting value is VDINT1+1. Note that if the rising edge (or falling edge if programmed) of the HD lines up with the rising edge (or falling edge if programmed) of VD, the 1st HD is not counted. |

10.5.16 ALAW Configuration Register (ALAW)

The ALAW configuration register (ALAW) is shown in [Figure 10-36](#) and described in [Table 10-31](#).

Figure 10-36. ALAW Configuration (ALAW) Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 10-31. ALAW Configuration (ALAW) Register Field Descriptions

| Bit | Field | Value | Description |
|------|----------|----------|---|
| 31-4 | Reserved | 0 | Any writes to these bit(s) must always have a value of 0. |
| 3 | CCDTBL | 0 | Disable |
| | | 1 | Enable |
| 2-0 | GWDI | 000 | Bits 15-6 |
| | | 001 | Bits 14-5 |
| | | 010 | Bits 13-4 |
| | | 011 | Bits 12-3 |
| | | 100 | Bits 11-2 |
| | | 101 | Bits 10-1 |

| R/W-0 | | | R/W-0 | | R/W-0 | | R-0 | | | | | | | | |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 10-33. CCD Configuration Register (CCDCFG) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|----------------------|---|
| 31-16 | Reserved | 0 | Any writes to these bit(s) must always have a value of 0. |
| 15 | VDLC | 0 1 | Enable latching function registers on internal VSYNC. If this bit is set, all the register fields that are VSYNC latched will take on new value immediately. Care should be taken not to alter fields that can cause undesired behavior to the output data. Latched on VSYNC Not latched on VSYNC |
| 14 | Reserved | 0 | Any writes to these bit(s) must always have a value of 0. |
| 13 | MSBINVI | 0 1 | MSB of Chroma input signal stored to external memory inverted. Normal MSB inverted |
| 12 | BSWD | 0 1 | Byte Swap Data stored to external memory. Number of pixels must be even if byte packing is selected if this bit is set. Normal Swap Bytes |
| 11 | Y8POS | 0 1 | Location of Y signal when YCbCr 8bit data is input. Even pixel Odd pixel |
| 10-9 | Reserved | | Any writes to these bit(s) must always have a value of 0. |
| 8 | WENLOG | 0 1 | Specifies CCD valid area Internal valid signal & WEN signal is ANDed logically Internal valid signal & WEN signal is Ored logically |
| 7-6 | FIDMD | 00 01 10 11 | Setting of FID detection function FID signal is latched at the VSYNC timing. The external Field signal is latched when the VD is active and the active edge of the HD signal FID signal is not latched. The field signal is not latched at all. FID signal is latched at edge of VD. The field signal is latched on the active edge of the VD signal. FID signal is latched based on phase of VD and HD. The field signal is latched when the VD signal is active and the HD signal is inactive (opposite phase). |
| 5 | BW656 | 0 1 | The data width in CCIR656 input mode. BW656 takes precedence over the SYN_MODE fields INPMOD and DATSIZ if 656 mode is enabled. 8-bits 10-bits |

Table 10-33. CCD Configuration Register (CCDCFG) Field Descriptions (continued)

| Bit | Field | Value | Description |
|-----|----------|-------|---|
| 4 | YCINSWP | | Y input (YIN[7:0]) and C input (CIN[7:0]) are swapped. This bit is latched on the VSYNC/VD signal |
| | | 0 | YIN[7:0] = Y signal/CIN[7:0] = C signal |
| | | 1 | YIN[7:0] = C signal/CIN[7:0] = Y signal |
| 3-0 | Reserved | 0 | Any writes to these bit(s) must always have a value of 0. |

10.5.19 DMA Control Register (DMA_CNTL)

The DMA control (DMA_CNTL) register is shown in [Figure 10-39](#) and described in [Table 10-34](#).

Figure 10-39. DMA Control (DMA_CNTL) Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 10-34. DMA Control (DMA_CNTL) Field Descriptions

| Bit | Field | Value | Description |
|------|-----------|----------|---|
| 31 | OVERFLOW | 0 1 | DMA Overflow Flag. Flag bit that is set when data is dropped due to a delay in writing data out of the DMA interface. This bit remains set until a "1" is written by the software. No overflow has occurred Overflow has occurred |
| 30-3 | Reserved | | Any writes to these bit(s) must always have a value of 0. |
| 2-0 | CPRIORITY | 0 0x7 | Command Priority. Sets the priority that all commands should be sent with on the DMA bus. This register should only be modified when the module is inactive or it could cause violations of the CBA specifications. Highest priority Lowest priority |

2D/3D Graphics Accelerator

This chapter describes the 2D/3D graphics accelerator (SGX).

NOTE: Some features may not be available or supported in your particular device. For more information, see Chapter 1, the Device Family section, and your device-specific data manual.

NOTE: The SGX subsystem is an instantiation by Texas Instruments of the POWERVR™ SGX530 core from Imagination Technologies Ltd.

This document contains materials that are ©2003-2007 Imagination Technologies Ltd.

POWERVR and USSE are trademarks or registered trademarks of Imagination Technologies Ltd.

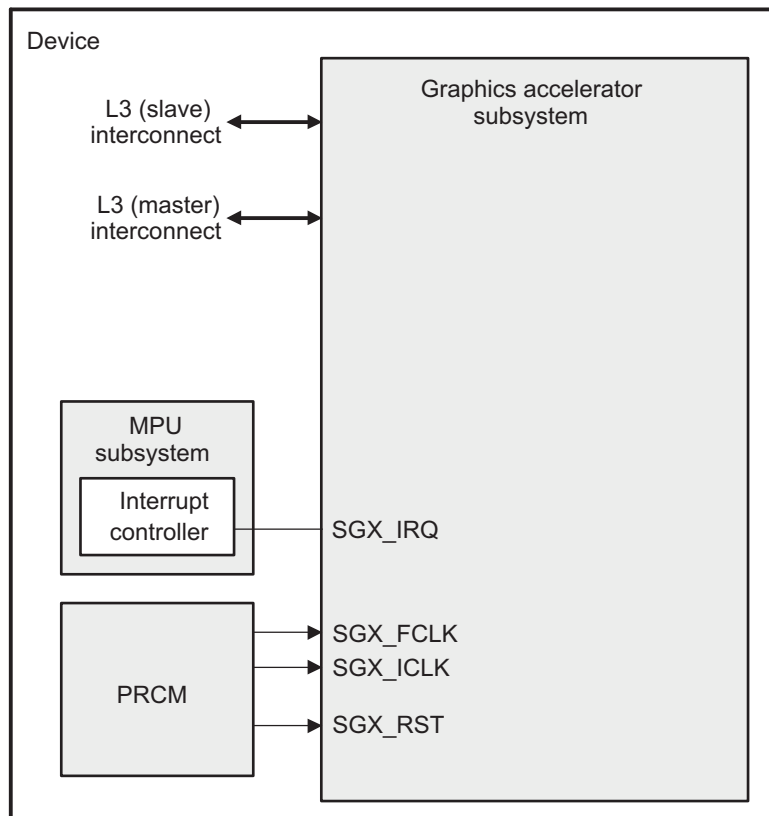

| Topic | Page |
|--|-------------|
| 11.1 SGX Overview | 1180 |
| 11.2 SGX Integration | 1183 |
| 11.3 SGX Functional Description | 1185 |
| 11.4 SGX Register Mapping | 1186 |

11.1 SGX Overview

The 2D/3D graphics accelerator (SGX) subsystem accelerates 2-dimensional (2D) and 3-dimensional (3D) graphics applications. The SGX subsystem is based on the POWERVR™ SGX core from Imagination Technologies. SGX is a new generation of programmable POWERVR graphic cores. The POWERVR™ SGX530 v1.2.1 architecture is scalable and can target all market segments from mainstream mobile devices to high-end desktop graphics. Targeted applications include feature phone, PDA, and hand-held games.

Figure 11-1 shows the SGX subsystem in the device.

Figure 11-1. Graphics Accelerator Highlight

sgx-001

The SGX graphics accelerator efficiently processes a number of various multimedia data types concurrently:

- Pixel data
- Vertex data
- Video data
- General-purpose processing

This is achieved using a multithreaded architecture using two levels of scheduling and data partitioning enabling zero overhead task switching.

The SGX subsystem is connected by a 64-bit master and a 32-bit slave interface to the L3 interconnect.

11.1.1 POWERVR SGX Main Features

- 2D graphics, 3D graphics, vector graphics, and programming support for GP-GPU functions
- Tile-based architecture
- USSE™ – multithreaded engine incorporating pixel and vertex shader functionality
- Advanced shader feature set – in excess of Microsoft VS3.0, PS3.0, and OpenGL2.0

- Industry standard API support – Direct3D Mobile, OpenGL ES 1.1 and 2.0, OpenVG v1.0.1
- Fine-grained task switching, load balancing, and power management
- Advanced geometry direct memory access (DMA) driven operation for minimum CPU interaction
- Programmable high-quality image anti-aliasing
- POWERVR SGX core MMU for address translation from the core virtual address to the external physical address (up to 4GB address range)
- Fully virtualised memory addressing for OS operation in a unified memory architecture
- Advanced and standard 2D operations [e.g., vector graphics, BLTs (block level transfers), ROPs (raster operations)]

11.1.2 SGX 3D Features

- Deferred pixel shading
- On-chip tile floating point depth buffer
- 8-bit stencil with on-chip tile stencil buffer
- 8 parallel depth/stencil tests per clock
- Scissor test
- Texture support:
 - Cube map
 - Projected textures
 - 2D textures
 - Nonsquare textures
- Texture formats:
 - RGBA 8888, 565, 1555
 - Monochromatic 8, 16, 16f, 32f, 32int
 - Dual channel, 8:8, 16:16, 16f:16f
 - Compressed textures PVR-TC1, PVR-TC2, ETC1
 - Programmable support for all YUV formats
- Resolution support:
 - Frame buffer maximum size = 2048 x 2048
 - Texture maximum size = 2048 x 2048
- Texture filtering:
 - Bilinear, trilinear, anisotropic
 - Independent minimum and maximum control
- Antialiasing:
 - 4x multisampling
 - Up to 16x full scene anti-aliasing
 - Programmable sample positions
- Indexed primitive list support
 - Bus mastered
- Programmable vertex DMA
- Render to texture:
 - Including twiddled formats
 - Auto MipMap generation
- Multiple on-chip render targets (MRT).

Note: Performance is limited when the on-chip memory is not available.

11.1.3 Universal Scalable Shader Engine (USSE) – Key Features

The USSE is the engine core of the POWERVR SGX architecture and supports a broad range of instructions.

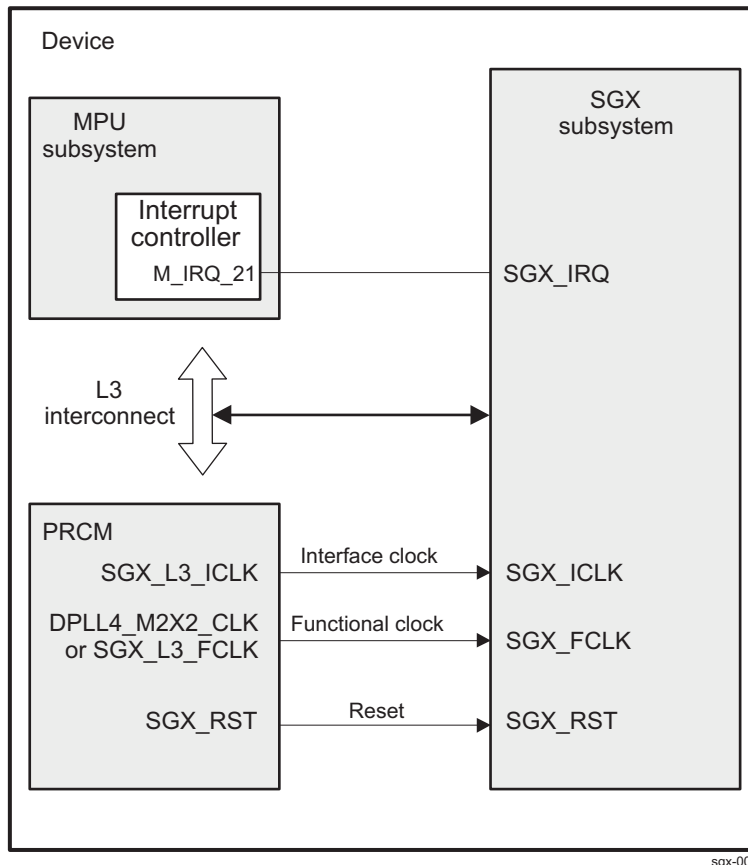

- Single programming model:

- Multithreaded with 16 simultaneous execution threads and up to 64 simultaneous data instances
- Zero-cost swapping in, and out, of threads
- Cached program execution model
- Dedicated pixel processing instructions
- Dedicated video encode/decode instructions
- SIMD execution unit supporting operations in:
 - 32-bit IEEE float
 - 2-way 16-bit fixed point
 - 4-way 8-bit integer
 - 32-bit bit-wise (logical only)
- Static and dynamic flow control:
 - Subroutine calls
 - Loops
 - Conditional branches
 - Zero-cost instruction predication
- Procedural geometry:
 - Allows generation of primitives
 - Effective geometry compression
 - High-order surface support
- External data access:
 - Permits reads from main memory using cache
 - Permits writes to main memory
 - Data fence facility
 - Dependent texture reads

11.2 SGX Integration

Figure 11-2 highlights the SGX subsystem integration in the device.

Figure 11-2. SGX Subsystem Integration

sgx-002

11.2.1 Clocking, Reset, and Power-Management Scheme

11.2.1.1 Clocks

The SGX subsystem operates from two clocks: an interface clock (SGX_ICLK) and a functional clock (SGX_FCLK). The power, reset, and clock management (PRCM) module generates and distributes both clocks inside the device. The SGX clock tree is depicted in Figure 4-31, SGX Power Domain Clocking Scheme, in , Power, Reset, and Clock Management.

Table 11-1. Clock Descriptions

| Signal Name | I/O ⁽¹⁾ | Description |
|-------------|--------------------|--|
| SGX_FCLK | I | Functional clock (two possible clock sources) -> Functional clock domain |
| SGX_ICLK | I | Interface clock (L3 interconnect clock domain) -> Interface clock domain |

⁽¹⁾ I=Input, O=Output,

- The SGX_ICLK interface clock manages the data transfer on the L3 master and slave ports. The source of SGX_ICLK is the PRCM clock (SGX_L3_ICLK), which belongs to the SGX clock domain and runs at the L3 interconnect clock speed. The SGX_ICLK frequency is selected based on the whole device L3 interconnect clock frequency. For more information on the interface clock, see , Power, Reset, and Clock Management.
When no longer required by the SGX subsystem, SGX_ICLK can be disabled by software at the PRCM level by setting the PRCM.CM_ICLKEN_SGX[0] EN_SGX bit to 0. For more information, see Figure 4-47, SGX Power Domain Clock Controls, in , Power, Reset, and Clock Management.

NOTE: SGX_ICLK is cut only if the SGX is ready to go into idle state. For more information, see , *Power, Reset, and Clock Management*.

- SGX_FCLK is the functional clock and is used inside the SGX subsystem to generate SGX 2D and 3D domain clock signals.

The source of SGX_FCLK is either the PRCM clock (SGX_L3_FCLK, which is derived from SGX_ICLK) or the peripheral DPLL clock DPLL4_M2X2_CLK as depicted in [Figure 4-47](#), *SGX Power Domain Clock Controls*. Selection is made at the PRCM level by setting the PRCM.CM_CLKSEL_SGX[2:0] CLKSEL_SGX bit field. A divider of 3, 4, or 6 is applied to the SGX_FCLK frequency with regard to the PRCM SGX_L3_FCLK frequency. By default the SGX_FCLK clock is SGX_L3_FCLK / 3.

Whether SGX_FCLK is provided by SGX_L3_FCLK or DPLL4_M2X2_CLK, its gating depends on the PRCM.CM_FCLKEN_SGX[1] EN_SGX bit. Clearing this bit to 0 indicates that both SGX clocks are no longer needed and can be cut at the PRCM level, if the module is ready to enter the idle state. For more information, see [Section 4.5.5.6](#), *SGX Power Domain*, in , *Power, Reset, and Clock Management*

11.2.1.2 Resets

The SGX subsystem has its own reset domain. Global reset of the SGX is performed by activating the SGX_RST signal in the SGX_RST domain. Software controls the release of SGX_RST using the PRCM.RM_RSTCTRL_SGX[0] SGX_RST bit.

11.2.1.3 Power Management

The SGX subsystem has its own power domain (SGX power domain). See , *Power, Reset, and Clock Management*, for additional information about the SGX power domain.

As described in [Section 11.2](#), *SGX Integration*, the SGX subsystem receives two clock signals from the PRCM module. The functional clock is either a division of the interface clock with a ratio of 1:3, 1:4, or 1:6, or a 96-MHz clock issued from a DPLL4. The functional clock is used inside the SGX to generate clock signals to the multiple internal module SGX clock domains. The division ratio depends on the PRCM registers setting. For more information, see , *Power, Reset, and Clock Management*.

Three power-management modes are defined:

- Deep power sleep (All clocks are gated.)
- Idle (2D and 3D clocks are gated.)
- 3D (No clock is gated.)

The SGX handles the automatic clock gating performed on the multiple internal module clock domains.

11.2.2 Hardware Requests

11.2.2.1 Interrupt Request

The SGX subsystem can generate one interrupt (SGX_IRQ) to the MPU subsystem interrupt controller mapped on M_IRQ_21.

11.3 SGX Functional Description

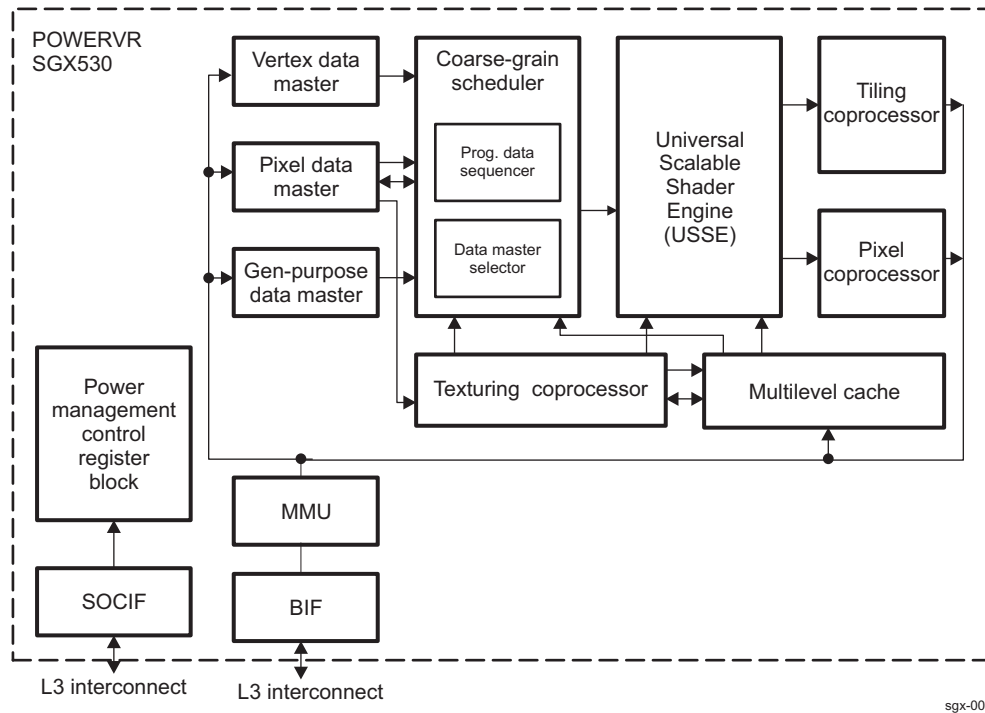

11.3.1 SGX Block Diagram

The SGX subsystem is based on the POWERVR SGX530 core from Imagination Technologies. The architecture uses both programmable and hard coded pipelines to perform various processing tasks required in 2D, 3D, and video processing. The SGX architecture comprises the following elements:

- Coarse grain scheduler
 - Programmable Data Sequencer (PDS)
 - Data Master Selector (DMS)
- Vertex data master (VDM)
- Pixel data master (PDM)
- General-purpose data master
- USSE
- Tiling coprocessor
- Pixel coprocessor
- Texturing coprocessor
- Multilevel cache

Figure 11-3 shows a block diagram of the SGX cores.

Figure 11-3. SGX Block Diagram

sgx-003

11.3.2 SGX Elements Description

The coarse grain scheduler (CGS) is the main system controller for the POWERVR SGX Architecture. It consists of two stages, the DMS and the PDS. The DMS processes requests from the data masters and determines which tasks can be executed given the resource requirements. The PDS then controls the loading and processing of data on the USSE.

There are three data masters in the SGX core:

- The VDM is the initiator of transform and lighting processing within the system. The VDM reads an input control stream, which contains triangle index data, and state data. The state data indicates the PDS program, size of the vertices and the amount of USSE output buffer resource available to the VDM. The triangle data is parsed to determine unique indices that must be processed by the USSE. These are grouped together according to the configuration provided by the driver and presented to the DMS.
- The PDM is the initiator of rasterization processing within the system. Each pixel pipeline processes pixels for a different half of a given tile which allows for optimum efficiency within each pipe due to locality of data. For each task it determines the amount of resource required within the USSE. It merges this with the state address and issues a request for execution on the USSE to the DMS.
- The general-purpose data master responds to events within the system (such as end of a pass of triangles from the ISP, end of a tile from the ISP, end of render, or parameter stream breakpoint event). Each event causes either an interrupt to the host or synchronized execution of a program on the PDS. The program may, or may not cause a subsequent task to be executed on the USSE.

The USSE is a user-programmable processing unit. Although general in nature, its instructions and features are optimized for three types of task: processing vertices (vertex shading), processing pixels (pixel shading), and video/imaging processing.

The multilevel cache is a 2-level cache consisting of two modules: the main cache and the mux/arbiter/demux/decompression unit (MADD). The MADD is a wrapper around the main cache module designed to manage and format requests to and from the cache, as well as providing Level 0 caching for texture and USSE requests. The MADD can accept requests from the PDS, USSE, and texture address generator modules. Arbitration is performed between the three data streams; any required texture decompression is also performed.

The texturing coprocessor performs texture address generation and formatting of texture data. It receives requests from either the iterators or USSE modules and translates these into requests into the multilevel cache. Data returned from the cache are then formatted according to the texture format selected and sent to the USSE for pixel-shading operations.

To process pixels in a tiled manner, the screen is divided into tiles and arranged as groups of tiles by the tiling coprocessor. An inherent advantage of tiling architecture is that a large amount of vertex data can be rejected at this stage, thus reducing both the memory storage requirements and the amount of pixel processing to be performed.

The pixel coprocessor is the final stage of the pixel-processing pipeline and controls the format of the final pixel data sent to the memory. It supplies the USSE with an address into the output buffer, and the USSE returns the relevant pixel data. The address order is determined by the frame buffer mode. The pixel coprocessor contains a dithering and packing function.

11.4 SGX Register Mapping

Table 11-2 describes the SGX memory mapping in the device.

Table 11-2. Instance Summary

| Module Name | Start Address | End Address | Size |
|-------------|---------------|-------------|-----------|
| SGX | 0x5000 0000 | 0x5000 FFFF | 64K bytes |

CAUTION

The SGX registers are limited to 32-bit data accesses; 8- and 16-bit accesses are not allowed because they can corrupt register content.

Display Subsystem

This chapter describes the display subsystem.

NOTE: Some features may not be available or supported in your particular device. For more information, see Chapter 1, the Device Family section, and your device-specific data manual.

12.1 Display Subsystem Overview

The display subsystem provides the logic to display a video frame from the memory frame buffer (either SDRAM or SRAM) on a liquid-crystal display (LCD) panel or a TV set. The display subsystem integrates the following elements:

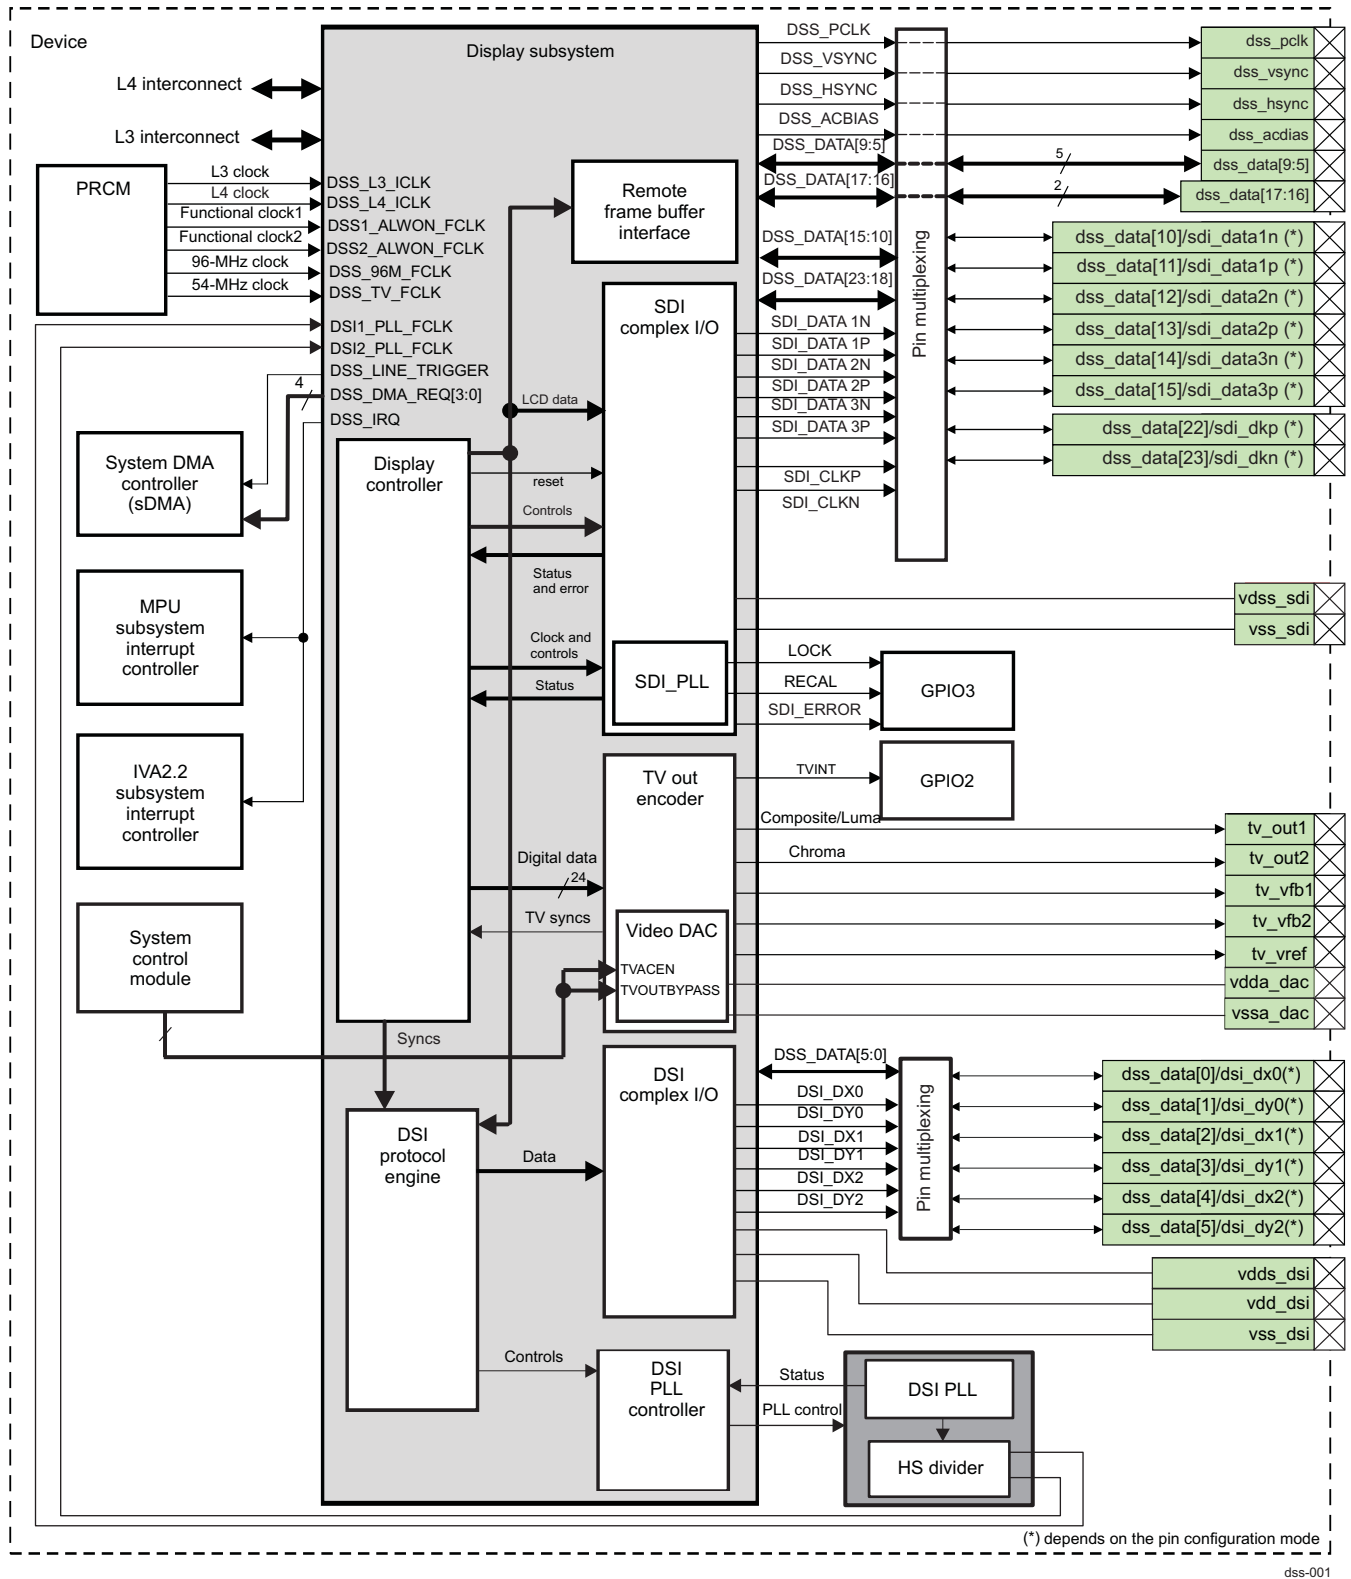

- Display controller (DISPC) module
- Remote frame buffer interface (RFBI) module
- Serial display interface (SDI) complex input/output (I/O) module with the associated phased-locked loop (PLL)
- Display serial interface (DSI) complex I/O module and a DSI protocol engine
- DSI PLL controller that drives a DSI PLL and high-speed (HS) divider.
- NTSC/PAL video encoder

The display controller and the DSI protocol engine are connected to the L3 and L4 interconnect; the RFBI and the TV out encoder modules are connected to the L4 interconnect.

NOTE: The SDI module, the DSI complex I/O module, and the DSI PLL controller are not connected to an L3 or L4 interconnect. Specific display subsystem registers manage their programmable features.

Figure 12-1 shows a block diagram of the display subsystem.

Figure 12-1. Display Subsystem Highlight

(*) depends on the pin configuration mode
dss-001

NOTE: For more information about connecting the LOCK, RECAL, SDI_ERROR, and TVINT signals through the GPIO2 and GPIO3 modules, see [Chapter 21, GPIO](#).

The display subsystem includes the following main features:

- Display controller
 - Display modes
 - Programmable pixel display modes (1, 2, 4, 8, 12, 16, and 24 bits-per-pixel [BPP] modes)
 - Programmable display size supported:
 - XGA - 1024 × 768 VESA timings at 60 fps (pixel clock = 63.5 MHz)
 - WXGA - 1280 × 800 VESA timings at 59.91 fps (pixel clock = 71 MHz)
 - SXGA+ - 1400 × 1050 direct drive of LCD with minimal blanking at 50 fps (pixel clock = 75 MHz)
 - HD 720p - 1280 × 720 at 60 fps (pixel clock = 74.25 MHz)
 - 256 × 24-bit entries palette in red, green, and blue (RGB)
 - Programmable pixel rate up to 75 MHz

NOTE: The panel size is programmable and can be any width that is a multiple of 8 pixels (line length) in the range [1:2048] pixels (in the case of the RFBI mode, the minimum transfer size is a byte). The maximum resolution is 2048 (lines) × 2048 (pixels).

- Display support
 - Four types of displays are supported: Passive (super-twist nematic [STN]) and active (thin-film transistor [TFT]) colors, passive (STN), and active (TFT) monochromes.
 - 4-/8-bit monochrome passive matrix panel interface support (15 grayscale levels supported using dithering block)
 - 8-bit color passive matrix panel interface support (3375 colors supported for a color panel using dithering block)
 - 12-/16-/18-/24-bit active matrix panel interface support (replicated or dithered encoded pixel values)
 - Remote frame buffer support through the RFBI module
 - Partial display through the RFBI module
 - Second 24-bit digital output
 - Multiple-cycle output format on 8-/9-/12-/16-bit interface time division multiplexing (TDM)
 - HDMI through external bridge
- Signal processing
 - Overlay support for graphics (ARGB, RGBA, RGB, or Color Look-Up Table (CLUT)) and video1 (YCbCr 4:2:2, or ARGB, RGBA, RGB), video2 (YCbCr 4:2:2, or ARGB, RGBA, RGB)
 - Programmable video resizer independent horizontal and vertical resampling: Upsampling (up to x8) and downsampling (down to 1/4), maximum input width of 1024 pixels in 5-tap mode, and 2048 pixels in 3-tap configurations; no limitation on input height
 - Rotation 90-, 180-, and 270-degrees
 - Transparency color key (source and destination)
 - Synchronized buffer update
 - Programmable video color space conversion YCbCr 4:2:2 into RGB
 - Hardware cursor
 - Gamma curve support on LCD output
 - Multiple-buffer support
 - Mirroring support
 - Programmable color phase rotation (CPR)
 - Alpha blending support (no rescaling in ARGB or RGBA formats)
- Advanced
 - Self-refresh using the DMA FIFO
 - Arbitration between high/low priority (graphics video1 and video2)
 - FIFO handcheck in STALL mode
- Power modes: Low-power saving modes

- RFBI (MIPI® DBI protocol)
 - Access to remote frame buffer (RFB) direct microprocessor unit (MPU) interface
 - Sends commands to the RFB panel through the L4 interconnect
 - Sends data, received from the display controller or from the MPU through the DISPC pixel data bus, to the RFB panel
 - Reads data/status from the RFB to the L4 interconnect
 - RFB interface
 - 8-/9-/12-/16-bit 8086-series parallel interface
 - Two programmable configurations for two devices connected to the RFBI module
 - Data formats
 - Programmable pixel modes (12-/16-/18-/24-BPP modes in RGB format)
 - Programmable output formats on one/multiple cycles per pixel (data from the display controller and from the L4 interconnect)
 - Interconnect/FIFO
 - One slave port with DMA request and interconnect FIFO of 24x32-bit depth (for write access to DSS.RFBI_DATA register only)
 - One video port FIFO of 8 × 24-bit depth receiving data from the display controller
- SDI
 - TI Flatlink™ 3G display interface support
 - Pin multiplexing allows simultaneous operation with a single 9-bit RFBI-driven display (no support for simultaneous dual RFBI panel and SDI)

NOTE: The SDI pins are multiplexed with LCD parallel outputs.

- MIPI DSI
 - Transfer pixels and data received on the video port or L4 interconnect to the display through the DSI DSI_PHY
 - The maximum resolution supported on the video port is XGA at 60 fps with 24-bit pixels (maximum pixel clock of 67 MHz) for low voltage.
 - Supports video mode and command mode
 - Bidirectional data link support (only one data lane is used in reverse direction in command mode)
 - Supports up to two data-configurable lanes, in addition to the clock signaling (minimum of one data link and maximum of two, depending on speed, signal integrity requirements, and number of displays)
 - Maximum data rate of 800 Mbps per data pair
 - Data splitter for 2-data lane configuration
 - Error-correction code (ECC) and check-sum generation
 - Burst support for the video mode
 - RGB16, RGB18 packed and nonpacked, and RGB24 formats supported for video mode
 - Serial configuration port (SCP) for the DSI_PHY complex I/O and DSI PLL
 - Connection to the DSI_PHY complex I/O through PPI
 - Data interleaving support for one synchronous stream (video mode) from the display controller and up to three interleaved asynchronous streams (command mode) from the interconnect concurrently
 - Data interleaving supports up to four interleaved asynchronous streams (command mode) from the interconnect or video port when there is no video mode
 - MIPI DCS support (transparent to the protocol engine, no decoding and interpretation of the information from and to the peripheral)
 - Supports selection between low-power state and HS mode between HS packet transfers
 - Generic data type (DT) support

NOTE: The DSI pins are multiplexed with LCD parallel outputs.

- Video encoder

- NTSC/PAL encoder outputs with the following standards:
 - NTSC-J, M
 - PAL-B, D, G, H, I
 - PAL-M
- CGMS-A as described in the CEA-608-x Standard.
- Input data interface compatible with the following protocols:
 - 24-bit input bus compatible with external sync
 - RGB 4:4:4
- Dual output data 10-bit interface for internal digital-to-analog converter (DAC) that supports:
 - Composite video (CVBS)
 - Separate video (S-video)
- TV output data supports ITU-R BT 470-7 recommendation standard for consumer market
- Master clock input 13.5 MHz, 27 MHz (supports ITU-R 601 sampling for NTSC/PAL), and 54 MHz
- Programmable horizontal sync, vertical timing, and waveforms
- Programmable subcarrier frequency and SCH
- Internal test pattern generation (color bar, flat field, color burst)
- 2x/4x oversampling
- Supports square pixel sampling (NTSC: 12.27 MHz, 24.54 MHz, 49.09 MHz PAL: 14.75 MHz, 29.5 MHz, 59 MHz)

CAUTION

In square pixel mode, an external clock generator is required to provide sampling frequencies.

- TV detection gating pulse generation

12.2 Display Subsystem Environment

This section describes the two main functions handled by the display subsystem:

- LCD support
- TV display support

12.2.1 LCD Support

LCD panels can be connected to the display subsystem of the device using parallel and/or serial interfaces.

12.2.1.1 Parallel Interface

In parallel interface, the paths of the display subsystem modules are the display controller and the RFBI.

The display controller provides the required control signals to interface the memory frame buffer (SDRAM or SRAM) directly to the external displays. The display controller is connected to the memory through the L3 interconnect and has its own DMA (with embedded FIFOs) to read data from the system memory. The L3 interconnect is the master port, while the L4 interconnect is the slave port of the display subsystem.

The display controller has two I/O pad modes at the module level:

- RFBI mode (RFBI enabled), which implements the MIPI DBI 2.0 protocol
- Bypass mode (RFBI disabled), which implements the MIPI DPI 1.0 protocol

The DSS.DISPC_CONTROL[16:15] GPOUT[1:0] bits control selection of the display subsystem modules (see [Table 12-1](#)).

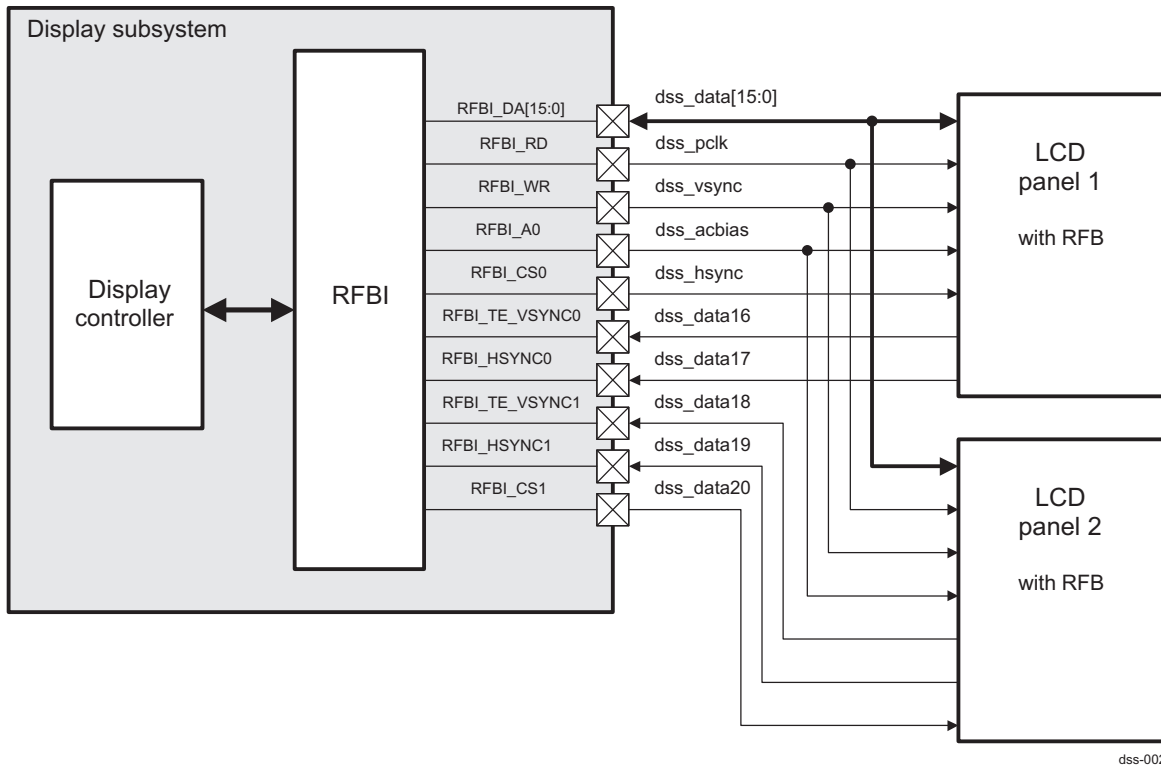

Table 12-1. I/O Pad Mode Selection

| DSS.DISPC_CONTROL[16] GPOUT1 Bit | DSS.DISPC_CONTROL[15] GPOUT0 Bit | |
|----------------------------------|----------------------------------|------------------|
| | 0 | 1 |
| 0 | 00 (reset) | 01 (RFBI mode) |
| 1 | 10 (invalid) | 11 (bypass mode) |

The RFB of the LCD panel is directly connected to the RFBI module of the device. The RFBI controls the reads/writes from/to the RFB. The RFBI receives the output from the DISPC (which takes data from the memory) and generates the signals to control the LCD panel. Through the RFBI, the MPU can send commands or parameter/display data to the LCD panel and directly set the DISPC registers to read/write the data from/to the memory in the LCD panel. The RFBI can manage up to two LCD panels when the serial interface is not used.

12.2.1.1.1 Parallel Interface in RFBI Mode (MIPI DBI Protocol)

[Figure 12-2](#) shows the LCD support parallel interface in RFBI mode (example for 16-bit data interface).

Figure 12-2. LCD Support Parallel Interface (RFBI Mode)

NOTE: If the SDI is used, the second display device connected to RFB#1 is limited to 9-bit data.

Configure the DSS.RFBI_CONTROL[3:2] CONFIGSELECT bit field to drive signals for LCD 1 only, LCD 2 only, or both LCD 1 and LCD 2.

Table 12-2 describes the interface signals to/from the LCD panel in RFBI mode.

Table 12-2. LCD Interface Signals (RFBI Mode)

| Signal Name | Type ⁽¹⁾ | Description |
|----------------|---------------------|--|
| RFBI_DA[15:0] | I/O | RFBI I/O data |
| RFBI_RD | O | Read access signal |
| RFBI_WR | O | Write access signal |
| RFBI_A0 | O | Command/data selection signal |
| RFBI_CS0 | O | Chip-select (CS) signal for LCD 1 |
| RFBI_CS1 | O | CS signal for LCD 2 |
| RFBI_TE_VSYNC0 | I | Tearing effect (TE) synchronization signal (TE or VSYNC for LCD panel 1) |
| RFBI_HSYNC0 | I | HSYNC from LCD panel 1 |
| RFBI_TE_VSYNC1 | I | TE synchronization signal (TE or VSYNC for LCD panel 2) |
| RFBI_HSYNC1 | I | HSYNC from LCD panel 2 |

⁽¹⁾ I = Input, O = Output

- RFBI_DA[15:0]: The pixel data comprises the RFBI pixel data (bits 15:0). A write/read command must be sent to the LCD panel to send/read the data.

Before any data access, the application must send commands and parameters when it is necessary to configure an LCD panel. The data is used as input in read operations during production test and also to read the status of the registers in the LCD panel and pixels from the embedded frame buffer in the LCD panel module. RFBI_DA is multiplexed at the chip-level boundary with dss_data [15:0].

- RFBI_RD: This is the read-enable signal used to indicate when a read from the embedded memory in

the LCD panel is ongoing. The RFBI registers describe the behavior of the read signal (off/on/cycle time). The polarity of the read-enable signal is programmable. This signal is multiplexed at the chip-level boundary with `dss_pclk`. The read is used to get status/data information from the LCD panel.

- **RFBI_WR:** The write-enable signal is used to indicate when a write is ongoing. The RFBI registers describe the behavior of the write signal (off/on/cycle time). The polarity of the write-enable signal is programmable. This signal is multiplexed at the chip-level boundary with `dss_vsync`.
- **RFBI_A0:** The signal is asserted to indicate its status: Command or data. The polarity is programmable and the status of the signal depends on the RFBI registers written by the application (CMD/READ/STATUS/PARAM/PIXEL). The register in use by the hardware defines the status of RFBI_A0. The order of the writes/reads to the RFBI registers CMD/READ/STATUS/PARAM/PIXEL defines the transitions of A0. This signal is multiplexed at the chip-level boundary with `dss_acbias`.
- **RFBI_CSx:** The signal is the chip-select (CSx) asserted to indicate which LCD panel is selected and must be ready to receive/transmit commands and data. When RE or WE is on, CSx must not be changed ($x = 0$ for LCD panel 1; $x = 1$ for LCD panel 2). CS0 is multiplexed at the chip-level boundary with `dss_hsync`, and CS1 is multiplexed at the chip-level boundary with `dss_data[20]`.
- **RFBI_TE_VSYNCx:** Based on the trigger mode selected, the signal is the TE pulse signal or the LCD panel VSYNC (vertical synchronization) pulse signal. RFBI_TE_VSYNCx is used by the TE logic as the synchronization signal to send the pixel to the LCD panel.

To select the trigger mode, configure the DSS.RFBI_CONFIG[3:2] TRIGGERMODE bit field (0x0: Internal trigger mode with the DSS.RFBI_CONTROL[4] ITE bit, 0x1: External trigger mode with the TE signal RFBI_TE_VSYNCx, 0x2: External trigger mode with the RFBI_TE_VSYNCx, and RFBI_HSYNCx signals with the programmable line counter).

These signals are multiplexed at the chip-level boundary with `dss_data[16]` (RFBI_TE_VSYNC0) and `dss_data[18]` (RFBI_TE_VSYNC1) (LCD panel 1: $x = 0$; LCD panel 2: $x = 1$).

- **RFBI_HSYNCx:** The HSYNC pulse signals indicate to the RFBI module when horizontal synchronization occurs. The polarity of the HSYNC signals is programmable. The minimum pulse width of the signal is two L4 cycles. RFBI_HSYNC is used by the TE logic as a synchronization signal to send the pixel to the LCD panel. These signals are multiplexed at the chip-level boundary with `dss_data[17]` (RFBI_HSYNC0) and `dss_data[19]` (RFBI_HSYNC1) (LCD panel 1: $x = 0$; LCD panel 2: $x = 1$).

12.2.1.1.1 Description of the TE Pulse Signal

The externally-generated TE synchronization signal is a logical OR or AND operation between the HSYNC and VSYNC signals (see Figure 12-3). The logical operation (OR or AND) depends on the HSYNC and VSYNC signals polarity. The VSYNC signal indicates to the RFBI module when vertical synchronization occurs; the HSYNC signal indicates to the RFBI module when horizontal synchronization occurs.

Figure 12-3. External Generation of TE Signal Based on Logical OR Operation Between HSYNC and VSYNC (Active-High)

The RFBI module detects the VSYNC and HSYNC pulses embedded in the received signal. VSYNC is detected based on the minimum pulse width defined by the DSS.RFBI_VSYNC_WIDTH register.

HSYNC is detected based on the minimum pulse width defined by the DSS.RFBI_HSYNC_WIDTH register.

The signal is generated from external logic based on the VSYNC/HSYNC of the LCD panel. The automatic trigger can be programmed based on the RFBI_TE signal or use a bit field in the RFBI registers to start data capture.

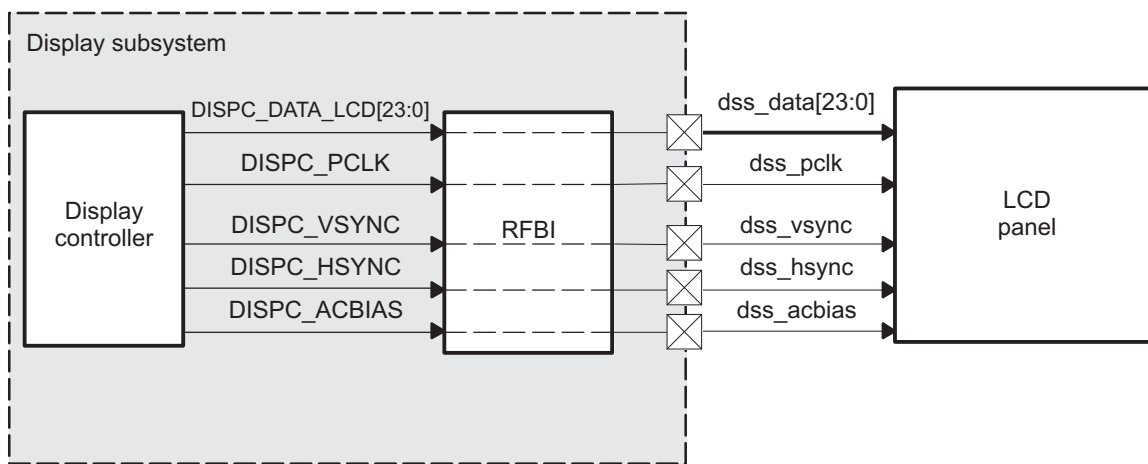

The polarity of the TE signal is programmable. The HSYNC and VSYNC pulses embedded in the TE signal have the same polarity, which is active high for an ORed signal and active low for an ANDED signal. The minimum pulse width of the signal is two L4 cycles. Hardware resets the line counter when the VSYNC occurs and increments it at every HSYNC. Transfer to the LCD panel begins when the line counter reaches the programmable line number.

12.2.1.1.2 Parallel Interface in Bypass Mode (MIPI DPI Protocol)

When bypass mode is enabled, the display controller must be set to use it.

Figure 12-4 shows the LCD support parallel interface in bypass mode.

Figure 12-4. LCD Support Parallel Interface (Bypass Mode)

dss-004

NOTE: In bypass mode, the SDI and the parallel interface cannot be used at the same time.

Table 12-3 describes the interface signals to/from the LCD panel in bypass mode.

Table 12-3. LCD Interface Signals (Bypass Mode)

| Signal Name | Type ⁽¹⁾ | Description |
|----------------------|---------------------|--|
| DISPC_DATA_LCD[23:0] | O | LCD data from the display controller module |
| DISPC_PCLK | O | Pixel CLK from the display controller module |
| DISPC_VSYNC | O | VSYNC from the display controller module |
| DISPC_HSYNC | O | HSYNC from the display controller module |
| DISPC_ACBIAS | O | ACBIAS from the display controller module |

⁽¹⁾ I = Input, O = Output, I/O = Input/Output

- DISPC_DATA_LCD[23:0]: The panel pixel data comes directly from the display controller module. DISPC_DATA_LCD is connected at the chip-level boundary with dss_data[23:0].
- DISPC_PCLK: This signal is the pixel clock that comes directly from the display controller. This signal is multiplexed at the chip-level boundary with dss_pclk.
- DISPC_VSYNC: Uses the vertical synchronization signal from the display controller. The LCD frame clock (VSYNC) toggles after all the lines in a frame are transmitted to the LCD panel and a programmable number of line clock cycles has elapsed both at the beginning and at the end of each frame. This signal is multiplexed with dss_vsync at the chip-level boundary.
- DISPC_HSYNC: Uses the horizontal synchronization signal from the display controller. The LCD line clock (HSYNC) toggles after all pixels in a line are transmitted to the LCD panel and a programmable number of pixel clock wait-states elapse, both at the beginning and at the end of each line. This signal

is multiplexed on the chip-level boundary with `dss_hsync`.

- DISPC_ACBIAS: Uses the ac-bias signal from the display controller.
 - In passive matrix technology, the ac-bias signal is configured to transition each time a programmable number of line clocks occurs. To prevent a dc charge within the screen pixels, the power and ground supplies of the panel are periodically switched. The DISPC signals the panel to switch the polarity by toggling the ac-bias pin.
 - In active matrix technology, the ac-bias signal acts as an output-enable signal to indicate when data must be latched using the pixel clock. This signal is multiplexed on the chip-level boundary with `dss_acbias`.

12.2.1.1.3 LCD Output and Data Format for the Parallel Interface

This section describes the pixel data bus and shows timing diagrams of transactions and synchronizations in both RFBI and bypass modes.

Figure 12-5 through Figure 12-11 show the pixel data bus for bypass mode, depending on the use of 4-, 8-, 12-, 16-, 18-, or 24-pixel data output pins. In RFBI mode, the pixel data bus is reformatted in accordance with the input and output data bus width.

Table 12-4 lists the number of displayed pixels per pixel clock cycle based on the type of display panel.

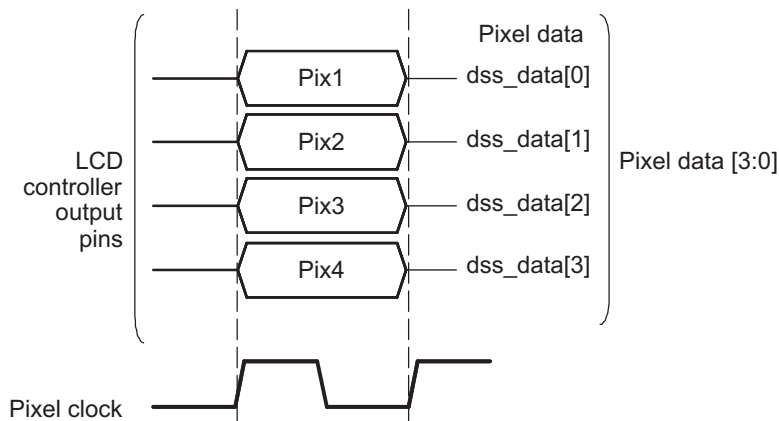

Table 12-4. Number of Displayed Pixels per Pixel Clock Cycle Based on Display Type

| Display Panel | Number of Displayed Pixels per Pixel Clock Cycle |
|----------------------|--|
| Monochrome 4-bit | 4 |
| Monochrome 8-bit | 8 |
| Passive matrix color | 8/3 |
| Active matrix | 1 |

- Passive matrix technology, Monochrome mode
 Monochrome displays use either a 4-bit or 8-bit interface. Each bit represents one pixel (on or off), which means that either 4 or 8 pixels are sent to the LCD at each pixel clock.

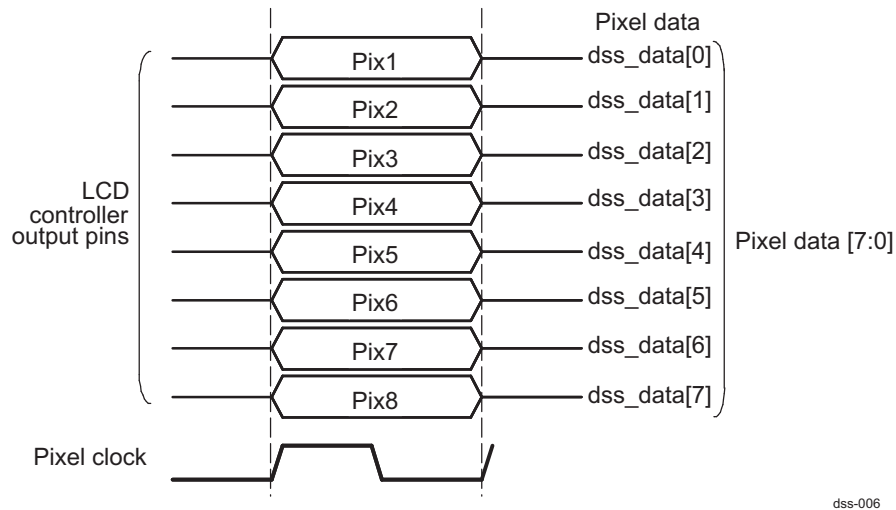

Figure 12-5 and Figure 12-6 show 4- and 8-bit monochrome displays, respectively.

Figure 12-5. LCD Pixel Data Monochrome4 Passive Matrix

dss-005

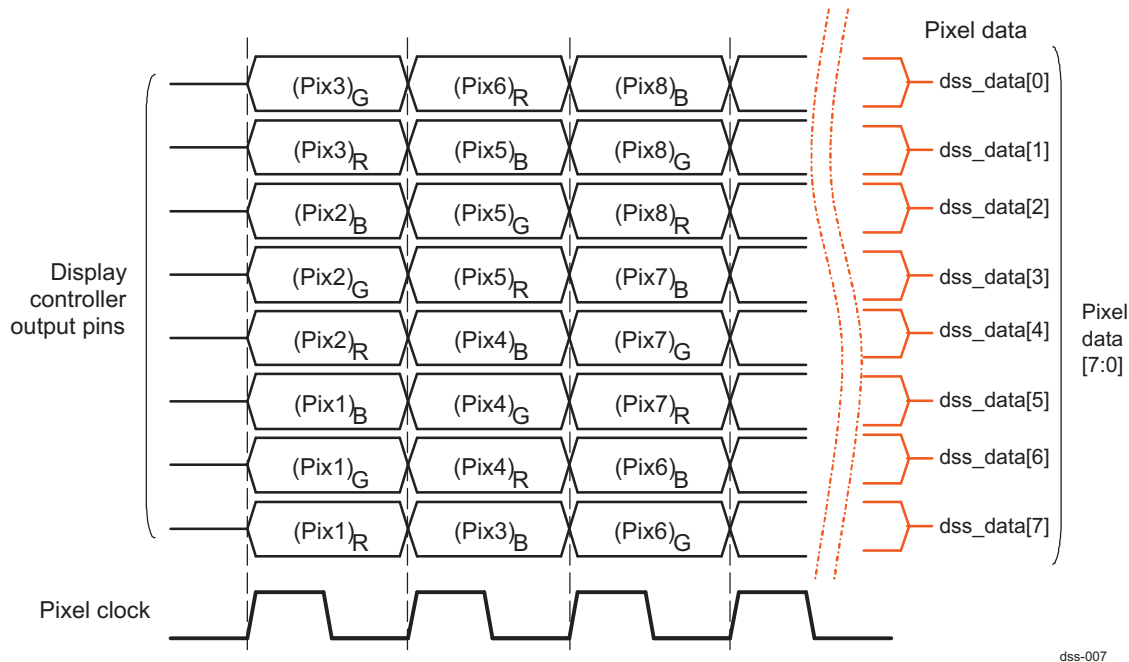

Figure 12-6. LCD Pixel Data Monochrome8 Passive Matrix

dss-006

- **Passive matrix technology, color mode**
Color passive displays use 8-bit data input lines. In a given pixel clock cycle, each line represents one color component (red, green, or blue).
[Figure 12-7](#) shows an 8-bit color passive matrix display.

Figure 12-7. LCD Pixel Data Color Passive Matrix

dss-007

- **Active matrix technology**
Active matrix displays bypass the STN dithering logic block and the output FIFO. Each line represents one pixel.
[Figure 12-8](#) through [Figure 12-11](#) show 12-, 16-, 18-, and 24-active matrix displays, respectively.

12.2.1.1.4 Transaction Timing Diagrams

- Timing diagrams in flow control mode
 - Stall signal

The stall signal is used in RFBI and DSI modes. In the case of RFBI mode, it is used to indicate when the display controller must stop sending data over the LCD output interface. The RFBI module asserts the stall signal to stop data output by the display controller. It is deasserted to indicate when new data must be outputted by the display controller.

Figure 12-12. RFBI Data Stall Signal Diagram

dss-134

To avoid underflow of the DMA FIFO, the FIFO handcheck feature can be enabled by setting the DSS.DISPC_CONFIG[16] FIFOHANDCHECK bit to 1. The fullness of the FIFOs associated with the pipelines used for the LCD output is checked when the STALL signal is inactive before providing data to the pipeline. This prevents emptying the FIFO when the RFBI module requests data and there is not enough data in the display controller DMA FIFO. This feature must be enabled only when the STALL mode is used (DSS.DISPC_CONTROL[11] STALLMODE bit set to 1). When the FIFO handcheck feature is activated, the pixel transfer to the RFBI module during STALL inactivity period can be stopped (no DISPC_PCLK pulse) and restarted when there is enough data in the FIFO. The FIFO handcheck ensures that underflow can not occur for the pipelines associated with the LCD output in RFBI mode. Figure 12-13 details the RFBI data stall with FIFO handcheck mode activated.

Figure 12-13. RFBI Data Stall Signal Diagram With Handcheck

dss-135

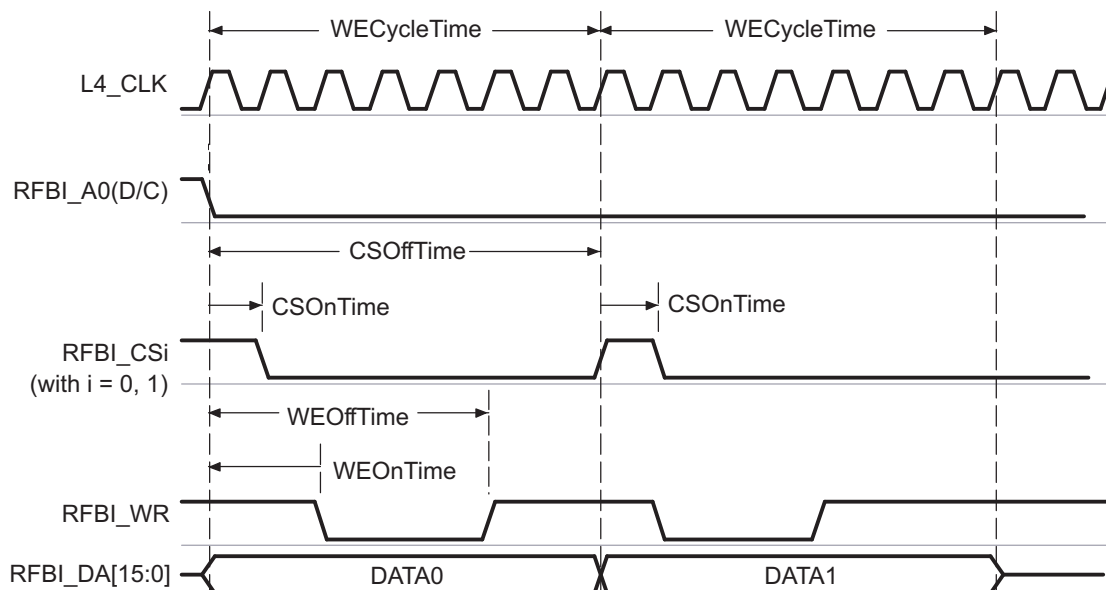

– RFBI timing diagrams

Table 12-5 lists the programmable timing fields. Figure 12-14 through Figure 12-16 show timing diagrams of read/write transactions to the LCD panel for the RFBI mode.

Table 12-5. Programmable Timing Fields in RFBI Mode

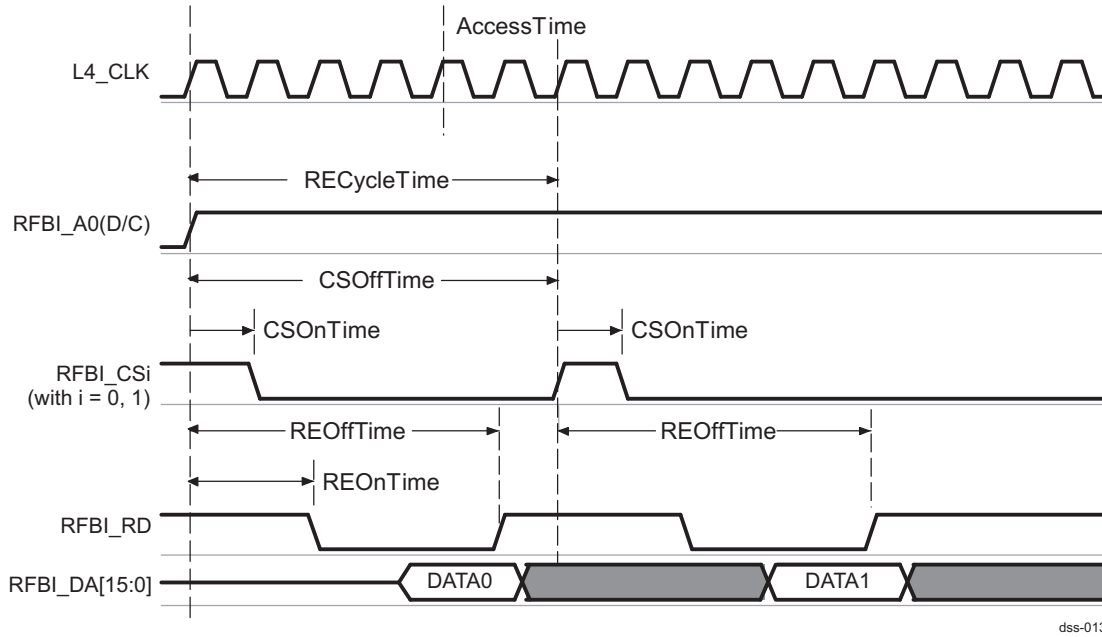

| Timing Name | Register Field | Description |
|--------------|---|---|
| CSONTime | DSS.RFBI_ONOFF_TIMEi[3:0] CSONTIME (with I = 0 or 1) | CS assertion time from start access time |
| CSoftime | DSS.RFBI_ONOFF_TIMEi[9:4] CSOFFTIME (with I = 0 or 1) | CS deassertion time from start access time |
| WeCycleTime | DSS.RFBI_CYCLE_TIMEi[5:0] WECYCLETIME (with I = 0 or 1) | The time when A0 becomes valid until write cycle completion |
| WEOnTime | DSS_RFBI_ONOFF_TIMEi[13:10] WEONTIME (with I = 0 or 1) | WE assertion delay time from start access time |
| WEOffTime | DSS_RFBI_ONOFF_TIMEi[19:14] WEOFFTIME (with I = 0 or 1) | WE deassertion delay time from start access time |
| RECycleTime | DSS.RFBI_CYCLE_TIMEi[11:6] RECYCLETIME (with I = 0 or 1) | The time when A0 becomes valid until read cycle completion |
| REOnTime | DSS_RFBI_ONOFF_TIMEi[23:20] REONTIME (with I = 0 or 1) | RE assertion delay time from start access time |
| REOffTime | DSS.RFBI_ONOFF_TIMEi[29:24] REOFFTIME (with I = 0 or 1) | RE assertion delay time from start access time |
| CSPulseWidth | DSS.RFBI_CYCLE_TIMEi[17:12] CSPULSEWIDTH (with I = 0 or 1) | The time when write cycle time or read cycle time completes |

- Timing diagrams in bypass mode

Figure 12-17 through Figure 12-32 show timing diagrams of synchronization signals and pixel clock in bypass mode for both passive matrix and active matrix panels. The display controller directly drives these signals, which are related to the programmable fields described in Table 12-6.

Table 12-6. Programmable Fields in Bypass Mode

| Name | Register | Description |
|-------|---|--|
| PPL | DSS.DISPC_SIZE_LCD[10:0] PPL bit field value + 1 | Pixels per line (PPL) |
| LPP | DSS.DISPC_SIZE_LCD[26:16] LPP bit field value + 1 | Lines per panel |
| HBP | DSS.DISPC_TIMING_H[31:20] HBP bit field value + 1 | Horizontal back porch |
| HFP | DSS.DISPC_TIMING_H[19:8] HFP bit field value + 1 | Horizontal front porch |
| HSW | DSS.DISPC_TIMING_H[7:0] HSW bit field value + 1 | Horizontal synchronization pulse width |
| VBP | DSS.DISPC_TIMING_V[31:20] VBP bit field value | Vertical back porch |
| VFP | DSS.DISPC_TIMING_V[19:8] VFP bit field value | Vertical front porch |
| VSW | DSS.DISPC_TIMING_V[7:0] VSW bit field value + 1 | Vertical synchronization pulse width |
| ONOFF | DSS.DISPC_POL_FREQ[17] ONOFF bit | DISPC_HSYNC and DISPC_VSYNC pixel clock control |
| RF | DSS.DISPC_POL_FREQ[16] RF bit | DISPC_HSYNC and DISPC_VSYNC pixel clock edge control |
| IEO | DSS.DISPC_POL_FREQ[15] IEO bit | Invert DISPC_ACBIAS |
| IPC | DSS.DISPC_POL_FREQ[14] IPC bit | Invert DISPC_PCLK |
| IHS | DSS.DISPC_POL_FREQ[13] IHS bit | Invert DISPC_HSYNC |
| IVS | DSS.DISPC_POL_FREQ[12] IVS bit | Invert DISPC_VSYNC |

- Active matrix timing configuration 1

- DSS.DISPC_POL_FREQ[17] ONOFF bit = 0
- DSS.DISPC_POL_FREQ[16] RF bit = 0
The DISPC_HSYNC and DISPC_VSYNC signals are driven on the opposite edge of DISPC_PCLK from the pixel data.
- DSS.DISPC_POL_FREQ[15] IEO = 0
The DISPC_ACBIAS signal is active high.
- DSS.DISPC_POL_FREQ[14] IPC = 0
The pixel data are driven on the rising edge of DISPC_PCLK.
- DSS.DISPC_POL_FREQ[13] IHS = 0
The DISPC_HSYNC signal is active high.

- DSS.DISPC_POL_FREQ[12] IVS = 0
The DISPC_VSYNC signal is active high.

12.2.1.2 SDI Serial Interface

In the serial interface, the modules in the display subsystem path are the display controller and the SDI with its associated PLL. The display controller provides the required control signals to interface the memory frame buffer (either SDRAM or SRAM) directly to the external displays. The display controller is connected to the memory through the L3 interconnect and has its own DMA to read the data from the system memory.

The SDI module is an additional display output mode that facilitates the connection of displays over relatively few conductors.

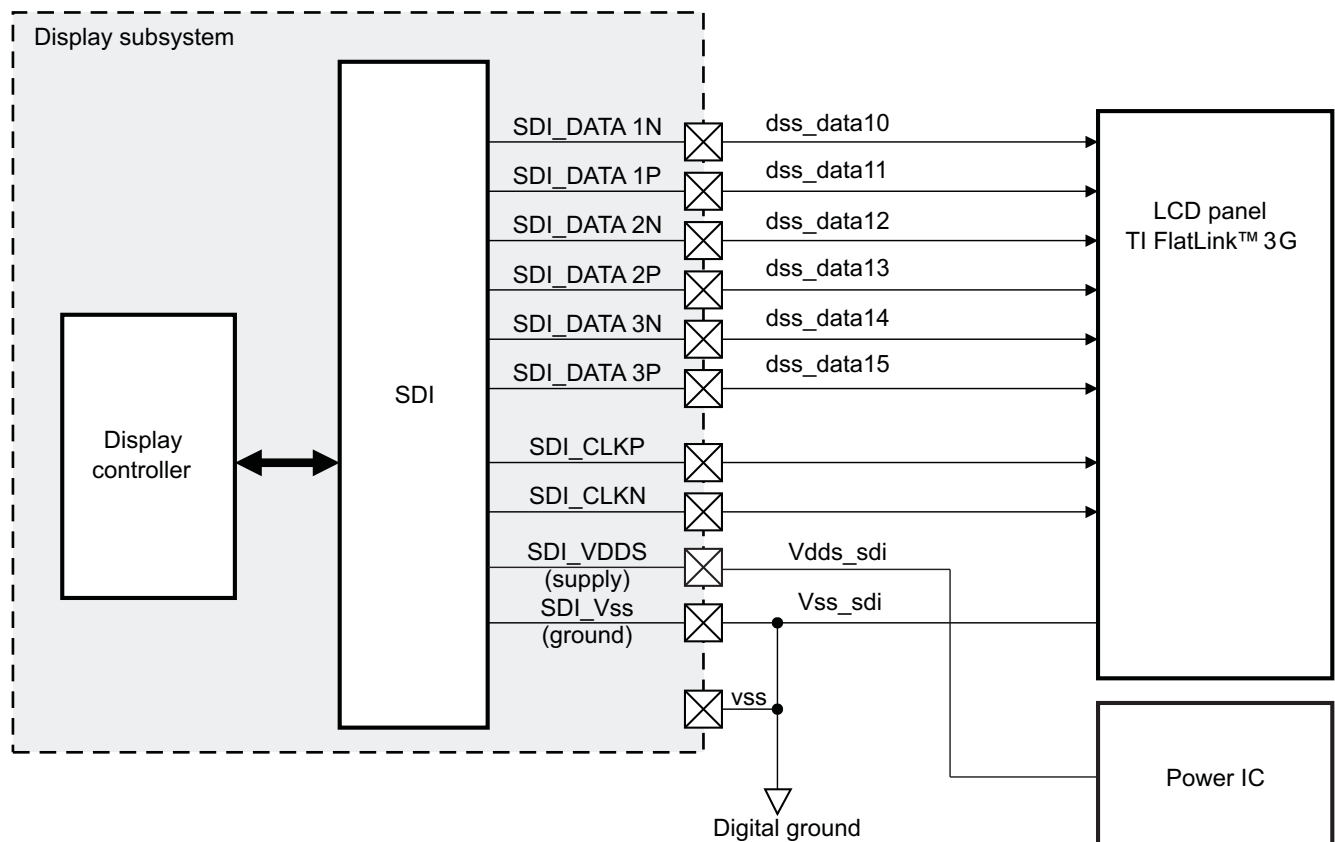

The SDI module implements the TI FlatLink3G protocol and converts the conventional parallel display signals (including pixel data) from the display controller to serial form. Texas Instruments provides a global solution with OMAP device associated to a programmable 27-bit serial display interface receiver - SN65LVDS302 receiver for 3-data pair, SN65LVDS304 receiver for 2-data pair, and SN65LVDS306 receiver for 1-data pair.

The SDI module contains a PLL to multiply the pixel clock by an appropriate factor. The resulting serialized data is then transmitted on 1 to 3 differential data pairs and an additional clock pair that has a reference transition at the boundary between pixels.

NOTE: Only one 9-bit RFBI driven display can be run at the same time as the SDI.

Figure 12-33 shows a typical connection between the SDI module and a compliant panel display.

Figure 12-33. Typical SDI Connection

dss_F98-002

CAUTION

When routing the PCB, ensure that the connections between the OMAP device and the LCD panel meet FlatLink3G specifications, which are available in the 27-bit serial display interface receiver data sheet.

NOTE:

- The SDI pins are multiplexed in mode 1 with some LCD parallel pins. See [Chapter 6, System Control Module](#), for more details on pad multiplexing.
- The connection from the vss_sdi pin of the device to the PCB digital ground must be as short as possible.
- The vdds_sdi dedicated power supply is provided by a power IC. Texas Instruments provides a global solution with the OMAP device associated with a power IC.

[Table 12-7](#) describes the interface signals between the SDI module of the OMAP device and the LCD panel.

Table 12-7. Interface Signals Between the SDI Module and LCD Panel

| Signal Name | Type ⁽¹⁾ | Description |
|-------------|---------------------|--|
| SDI_DATA1N | O | First pair of differential data signals |
| SDI_DATA1P | | |
| SDI_DATA2N | O | Second pair of differential data signals |
| SDI_DATA2P | | |
| SDI_DATA3N | O | Third pair of differential data signals |
| SDI_DATA3P | | |
| SDI_CLKN | O | Pair of differential clock signals |
| SDI_CLKP | | |
| VDDS_SDI | PWR | Dedicated vdds power supply for SDI module |
| VSS_SDI | PWR | Dedicated vss ground for SDI module |

⁽¹⁾ O=Output PWR=Power

12.2.1.3 DSI Serial Interface

Figure 12-34 shows a typical connection between the DSI modules and a compliant panel display.

Figure 12-34. Typical DSI Connection

dss-194

NOTE: The DSI pins are multiplexed in mode 1 with some LCD parallel pins. See [Chapter 6, System Control Module](#), for more details on pad multiplexing.

12.2.2 LCD Support With MIPI DSI 1.0 Protocol and Data Format

This section summarizes the MIPI DSI1.0 protocol and data format.

12.2.2.1 Physical Layer

Table 12-8 lists the DSI interface I/O.

Table 12-8. I/O Description for DSI Serial Interface

| Signal Name | I/O ⁽¹⁾ | Description | Value at Reset |
|-------------|--------------------|-------------|--------------------------------|
| dsi_dx0 | line 1 | I/O | Serial data/clock input/output |
| dsi_dy0 | | | |
| dsi_dx1 | line 2 | I/O | Serial data/clock input/output |
| dsi_dy1 | | | |
| dsi_dx2 | line 3 | I/O | Serial data/clock input/output |
| dsi_dy2 | | | |

⁽¹⁾ I/O = Input/Output

NOTE: Each serial line (line 1, line 2, and line 3) can be used as clock lane or data lane. All polarities are supported. The MIPI DSI 1.0 protocol requires at least one clock line and one data lane.

Lanes support four operating modes:

- HS mode: High-speed transmit mode
- LP mode: Low-power transmit mode (also called low-power state [LPS])
- ULPS: Ultra-low power state used between two transmissions
- Off mode: Lane is off.

12.2.2.1.1 Data/Clock Configuration

From the device point of view, the DSI interface consists of six input/output signals representing three differential signals: The serial clock and one or two serial data. The minimum configuration is one data pair and one clock pair.

- The data signal carries the bit-serial data. The DSI transmitter in the host sends the data in-quadrature with the DDR clock in high speed mode; otherwise, the clock is extracted from the received data in low-speed mode. The data is transmitted byte-wise least significant bit (LSB) first.
- The clock signal carries the DDR clock signal in high speed transmission.
- Software users must configure the order of the data lanes to indicate the byte order while splitting the byte stream for each DSI_PHY into bytes.

Table 12-9 details all the DSI lanes configuration.

Table 12-9. DSI Lane Configuration

| DSI DSI_PHY Lane Configuration | Data/Clock Lane Position | | | Description |
|--------------------------------|--------------------------|----------|----------|------------------|
| | 1 | 2 | 3 | |
| Mode CLK + DATA1 | CLK | DATA1 | Not used | Single data lane |
| | CLK | Not used | DATA1 | |
| | DATA1 | CLK | Not used | |
| | Not used | CLK | DATA1 | |
| | DATA1 | Not used | CLK | |
| | Not used | DATA1 | CLK | |
| Mode CLK + DATA1 + DATA2 | CLK | DATA1 | DATA2 | Two data lanes |
| | CLK | DATA2 | DATA1 | |
| | DATA1 | CLK | DATA2 | |
| | DATA2 | CLK | DATA1 | |
| | DATA1 | DATA2 | CLK | |
| | DATA2 | DATA1 | CLK | |

NOTE:

- The byte on Dn is sent before the byte on Dn+1, all the combinations of data and clock are supported through programming of the DSS.DSI_COMPLEXIO_CFG1 register. The CLOCK_POSITION and CLOCK_POL bit fields configure which lane transmits the clock and define its polarity. Four bit fields (DATA1_POSITION, DATA1_POL, DATA2_POSITION, and DATA2_POL) configure the data lanes and their polarity. The DATA2_POSITION bit field can be set to 0; in this case, only the data lane defined in the DATA1_POSITION bit field is used, and data is transmitted on only one clock lane and one data lane.
- The configuration of the DSI complex I/O (number of data lanes, position, differential order) should not be changed while DSS.DSI_CLK_CTRL[20] LP_CLK_ENABLE bit is set to 1. For the hardware to recognize a new configuration of the complex I/O (done in DSS.DSI_COMPLEXIO_CFG1 register), it is recommended to follow this sequence: First set the DSS.DSI_CTRL[0] IF_EN bit to 1, next reset the DSS.DSI_CTRL[0] IF_EN to 0, then set DSS.DSI_CLK_CTRL[20] LP_CLK_ENABLE to 1, and finally, set again the DSS.DSI_CTRL[0] IF_EN bit to 1. If the sequence is not followed, the DSI complex I/O configuration is undetermined.
- Only DATA1 is bidirectional in command mode. The low-power received information is always sent by the display panel using DATA1. Since any lane of the DSI complex I/O can be configured as data lane DATA1, all lanes of the complex I/O are bidirectional

12.2.2.1.2 ULPS

Each lane can be put in ultra-low power state (ULPS) by software configuration. The ULPS mode requires all the following conditions:

- The lane must be in stop state.
- For data lanes, no data must be pending in the DSI module.
- For data lane 1, no BTA should have been sent. The DSI module should have control of the bus.

The control of each lane is independently controlled by the DSS.DSI_COMPLEXIO_CFG2 register.

12.2.2.2 Video Port (VP) Interface

NOTE: The signals described in this section are internal and not bounded outside the device. This section aims at helping software users understand the internal connections between the display controller (DISPC) and the DSI protocol engine.

Table 12-10 summarizes the video interface signals. This interface is used to connect the display controller to the DSI protocol engine to send real time data streams. Note that only the active matrix timings are supported by DSI protocol engine. The HSYNC/VSYNC/DE/DATA signals are driven on the rising or falling edge of the pixel clock (VP_PCLK).

Table 12-10. Video Interface for DSI Protocol Engine

| Signal Name | Type ⁽¹⁾ | Description |
|---------------|---------------------|---|
| VP_HSYNC | I | Horizontal sync signal |
| VP_VSYNC | I | Vertical sync signal |
| VP_DATA[23:0] | I | Parallel output data: Bits 0 to 23 |
| VP_PCLK | I | Pixel clock. In case of STALL configuration, it is used to indicate when new data is on the data bus during the clock period of VP_CLK. |
| VP_DE | I | Data enable |
| VP_STALL | O | The stall signal must be deasserted to receive pixel and asserted to stop receiving pixel. (It can be used only while the display controller is configured in STALL mode; in that mode, HSYNC and VSYNC are not generated). |
| VP_CLK | I | Display controller internal clock. It is a free-running clock. The VP_CLK is a divided clock from VP_PCLK. |

⁽¹⁾ I = Input, O = Output

NOTE:

- The polarities of VP_HSYNC and VP_VSYNC are programmable by setting the DSS.DSI_CTRL register.
- The maximum frequency for VP_CLK is 173 MHz at nominal voltage, and 96 MHz at low voltage.
- Clocks VP_CLK and VP_PCLK can have the same frequency.
- The number of bits to be captured on the video port is defined in the DSS.DSI_CTRL[7:6] VP_DATA_BUS_WIDTH bit field.
- VP_DE is connected to the dss_acbias signal in the display controller, and its polarity can be controlled by setting the DISPC_POL_FREQ[15] IEO bit.

The data received on the video port can be stored into the line buffer memories or sent directly on the DSI interface in two cases:

- The line buffer size is too small compared to the line from the display controller.
- There is no line buffer instantiated. If there is no line buffer, the burst mode, defined as frequency burst mode, can not be used. Only the transparency burst mode is supported.

NOTE: The DSS.DSI_CTRL[13:12] LINE_BUFFER bit field defines the number of lines to be used for transferring data from the video port to the DSI link.

12.2.2.2.1 Video Port Used for Video Mode

If the video port is used for video mode, the VP_STALL is not used. [Table 12-11](#) lists the active signals on the video port.

Table 12-11. Video Interface in the Context of Video Mode

| Signal Name | Type ⁽¹⁾ | Description |
|---------------|---------------------|---|
| VP_HSYNC | I | Horizontal sync signal |
| VP_VSYNC | I | Vertical sync signal |
| VP_DATA[23:0] | I | Parallel output data: bits 0 to 23 |
| VP_PCLK | I | Pixel clock. |
| VP_DE | I | Data enable |
| VP_CLK | I | It is a free running clock used as the display controller functional clock. The maximum frequency is 173 MHz at nominal voltage, and 96 MHz at low voltage. |

⁽¹⁾ I = Input, O = Output

Three video modes are available:

- No line buffer: The data received on the video port are directly output of the DSI port without buffering. The ration of VP_CLK and the DSI high-speed (HS) clock period must ensure the same throughput on the two ports (the two clocks must be generated using the same PLL; the subsystem must provide such configuration).
- One line buffer:
 - The data are first stored in the line buffer; once all the data for one line are received, the DSI protocol engine sends the whole line. Software must adjust timings to allow for storing all line data into the line buffer before sending it to DSI outputs. The synchronization packets are never stored into the line buffer.
- Two line buffers:
 - One line is stored when the second line is output on the DSI port. It allows burst capability. While receiving the first line of the frame, there is no RGB packets sent because the line buffers are empty. To send the last line of the frame, a dummy line must be provided by the display controller to flush the line buffers. The synchronization packets are never stored into the line buffer.

NOTE: If more active lines are received on the video port than the number defined in the DSS.DSI_VM_TIMING3[15:0] VACT bit field, the extra lines are discarded by the DSI protocol engine. These lines are treated as blanking lines.

Figure 12-35 through Figure 12-37 show these three video modes.

NOTE:

- When HSync start and Hsync end short packets are not generated (HSA does not exist), HBP signal must be different than 0.
 - The software must ensure that VBP is always defined so that there is at least one HSYNC during VBP.
 - In blanking low-power mode (BL-LP), two options are possible:
 - The lane remains in ULPS, and the DSI_CTRL[20] BLANKING_MODE bit is set to 0x0.
 - Dummy bytes are sent during LP with the DSI_CTRL[20] BLANKING_MODE bit set to 0x1; the number of sent bytes is determined by the DSI_VM_TIMING6[15:0] BL_LP_INTERLEAVING bit field.
-

Figure 12-35. DSI Video Mode Without Burst (No-Line Buffer)

dss-136

Figure 12-36. DSI Video Mode Without Burst (One-Line Buffer)

If the VP_DE signal is asserted for too many VP_PCLK cycles, the module should stop capturing the data on the video port while the number of bytes to capture, as defined in the word count field of the header, is reached.

The HS must check that the received synchronization events on the video port (VSYNC and HSYNC) are within the synchronization window based on expected timings. If the timings (internal and received) are out of sync, the interrupt for out-of-sync should be generated and the interface must be disabled (DSS.DSI_CTRL[0] IF_EN bit is automatically reset by hardware). The unsynchronization window is defined by the DSS.DSI_VM_TIMING2[27:24] WINDOW_SYNC bit field.

12.2.2.2 Video Port Used on Command Mode

If the video port is used for command mode, the VP_HSYNC, VP_VSYNC, and VP_DE signals are not used. Table 12-12 describes the active signals on the video port.

Table 12-12. Video Interface in the Context of Command Mode

| Signal Name | Type ⁽¹⁾ | Description |
|---------------|---------------------|---|
| VP_DATA[23:0] | I | Parallel output data: bits 0 to 23 |
| VP_PCLK | I | One pulse is generated every time new data is output on the data bus |
| VP_STALL | O | The stall signal must be deasserted to receive pixel and asserted to stop receiving pixel. (It can be used only while the display controller is configured in STALL mode; in that mode, HSYNC and VSYNC are not generated). |
| VP_CLK | I | Display controller internal clock: It is a free running clock used as the display controller functional clock. The maximum frequency is 173 MHz at nominal voltage and 96 MHz at low voltage. |

⁽¹⁾ I = Input, O = Output

NOTE: The stall signal must be deasserted to receive pixels and asserted to stop receiving pixels.

Figure 12-38 and Figure 12-39 show the VP_STALL signal assertion and deassertion on rising and falling edges, respectively.

NOTE: In DSI command mode, the display controller must be configured in stall mode by setting the DSS.DISPC_CONTROL[11] STALLMODE bit to 1.

Figure 12-38. Stall Timing With Pixel on Rising Edge

dss-187

Figure 12-39. Stall Timing With Pixel on Falling Edge

dss-188

To stop the transfer, the VP_STALL signal must be asserted when the last data is output. The data can be output on the rising or falling edge of the VP_PCLK through registers in the display controller module. The case with data output on falling edge of VP_PCLK is supported by the DSI protocol engine.

The VP_PCLK clock is generated from VP_CLK; these two clocks are balanced. Assertion and deassertion of VP_PCLK is done on the rising edge of VP_CLK. The width of the VP_PCLK pulse depends on the configuration of the clock divisor in the display controller (DSS.DISPC_DIVISOR[7:0] PCD bit field). In the DSI protocol engine, the information is defined in the DSS.DSI_CTRL[4] VP_CLK_RATIO bit and should be aligned with the display controller configuration.

Deassertion of the VP_STALL signal should occur at least 4 VP_CLK cycles before assertion of VP_PCLK. Assertion of VP_STALL should occur one cycle VP_CLK after deassertion of VP_PCLK for the last pixel to be transferred. The VP_CLK clock is generated by the display controller under software control. It can be kept running between assertion and deassertion of VP_STALL.

The word count (WC) defined in the DSS.DSI_VcN_LONG_PACKET_HEADER register for the virtual channel (VC) associated with the video port, indicates the number of bytes to receive (one line or two lines can be used, depending on the WC and size of the line buffer). The total size defined in the WC of the header register can not exceed the size of the line buffer multiplied by the number of buffer lines.

The stall assertion/deassertion depends on the number of bytes to be received considering the size of the video port bus defined in the DSS.DSI_CTRL[7:6] VP_DATA_BUS_WIDTH bit field.

Figure 12-40 shows the data flow in command mode using the video port.

Figure 12-40. Data Flow in Command Mode Using the Video Port

dss-139

Two command modes are available:

- One line buffer: The data are stored in the line buffer before being sent.
- Two line buffers: The two lines are used if the word count defined in the DSS.DSI_VcN_LONG_PACKET_HEADER register is bigger than the line size; otherwise, one line buffer is used.

NOTE: In command mode, the video port can only be used in one or two line buffer configuration. The no-line buffer configuration is not allowed.

The packets can be sent using high-speed or low-speed.

NOTE: The DCS command in the payload can be inserted automatically using the DSI_CTRL[24] DCS_CMD_ENABLE bit. If TE is used, hardware automatically inserts the DCS Write Start command for the first packet of the frame transfer and the DCS Write Continue command for all subsequent packets.

12.2.2.2.3 Burst Mode

When the burst mode is enabled, the video port receives data from the display controller at the pixel clock. The DSI protocol engine buffers the data in its own line FIFO (double-line buffer of 1024 x 24-bit pixels maximum). The read speed of the line can be twice the pixel clock to increase the blanking time of the video mode and to allow command mode traffic to be interleaved during the blanking period. The burst mode uses a dual-line buffer.

The DSI port can output data from one line buffer while the second one is accessed by the video port. The two processes are concurrent but they do not access the same line at the same time. The DSI transfer can start only when the whole video port line is transferred into a line buffer. The switch is controlled by the VP_HS signal on the video port side and by internal signal on the DSI port indicating that the last data for the current line has been written into the line buffer.

NOTE: The line buffers are used to store the pixels only. The synchronization codes are not stored in the line buffers. They should be sent according to the video port timings.

12.2.2.3 Multilane Layer

Peripherals do not typically have high bandwidth requirements for returning data to the host processor. To keep designs simple and improve interoperability, all DSI-compliant systems should only use Lane 1 in LP mode for returning data from a peripheral to the host processor.

12.2.2.3.1 SoT and EoT in Multilane Configurations

Since a HS transmission is composed of an arbitrary number of bytes that may not be an integer multiple of the number of lanes, some lanes may run out of data before others. Therefore, the lane management layer, as it buffers up the final set of less-than-N bytes, deasserts its *valid data* signal into all lanes for which there is no further data. Although all lanes start simultaneously with parallel SoTs, each lane operates independently and may complete the HS transmission before the other lanes, sending an EoT one cycle (byte) earlier.

12.2.2.3.2 Lane Splitter

The lane splitter can split the byte stream into 2 lanes (for 1 lane, the splitter is bypassed). [Figure 12-41](#) and [Figure 12-42](#) show the byte position into each serial link for 1 and 2 data lane configurations. The byte stream always starts from lane 1. It finishes on one of the lanes, depending on the number of bytes to send and the number of lanes. The splitter module is only used when packets are sent using high-speed mode (HS). In low-power mode (LP), only one data lane is used (Lane 1).

Figure 12-41. Two Data Lane Configuration

dss-140

Figure 12-42. One Data Lane Configuration

dss-329

In case of back-to-back packets, the byte stream is considered as a single packet by the splitter module. Figure 12-43 shows the example of two packets sent back to back. N bytes for the first packet and M bytes for the second one.

Figure 12-43. Two Packets Using Two-Data Lane Configuration (Example)

dss-142

12.2.2.4 Protocol Layer

The low level protocol (LLP) is a byte-oriented protocol. It supports short and long packet formats. The DSI protocol layer defines how the display data is transported onto the physical layer. Packets can be sent using high-speed or low-speed mode. LLP is selected through DSI registers. The features of the DSI protocol layer are:

- Transport of arbitrary data (payload independent)
- 8-bit word size
- Support for up to four interleaved VCs on the same link
- Special packets for frame start, frame end, line start, and line end information
- Descriptor for the type, pixel depth, and format of application-specific payload data
- ECC for 1-bit or 2-bit error detection in the header
- 16-bit checksum code for error detection

Figure 12-44 shows the protocol layer with short and long packets.

Figure 12-44. Protocol Layer With Short and Long Packets

dss-143

12.2.2.4.1 Short Packet

Figure 12-45 shows the structure of the short packet. A short packet should contain an 8-bit data ID followed by two command or data bytes and an 8-bit ECC; a packet footer should not be present. Short packets should be four bytes in length. The ECC byte allows correction of single-bit errors and detection of 2-bit errors in the short packet.

Figure 12-45. Short Packet Structure

dss-144

NOTE: The short packets can be sent in low-power mode or in high-speed mode.

12.2.2.4.2 Long Packet

Figure 12-46 shows the structure of the low-level protocol long packet. A long packet must consist of three elements: A 32-bit packet header (PH), an application-specific data payload with a variable number of bytes, and a 16-bit packet footer (PF). The packet header is further composed of three elements: An 8-bit data identifier, a 16-bit word count, and 8-bit ECC. The packet footer has one element, a 16-bit checksum. Long packets can be from 6 to 65,541 bytes in length.

Figure 12-46. Long Packet Structure

dss-145

- The data identifier defines the VC for the data and the DT for the application-specific payload data.
- The word count defines the number of bytes in the data payload between the end of the packet header and the start of the packet footer. Neither the packet header nor the packet footer should be included in the word count.
- The ECC byte allows single-bit errors to be corrected and 2-bit errors to be detected in the packet header. This includes the data identifier and the word count fields.

After the end of the packet header, the receiver reads the next word count * bytes of the data payload. There are no limitations on the value of a data word within the data payload block, that is, no embedded codes are used. Once the receiver has read the data payload, it reads the checksum in the packet footer. The host processor should always calculate and transmit a checksum in the packet footer. Peripherals are not required to calculate a checksum. Also note the special case of zero-byte data payload: If the payload has length 0, then the checksum calculation results in (0xFFFF). If the checksum is not calculated, the packet footer should consist of two bytes of all zeros (0x0000). In the generic case, the length of the data payload should be a multiple of bytes. In addition, each data format may impose additional restrictions on the length of the payload data, that is, multiple of four bytes. Each byte is transmitted LSB first. Payload data may be transmitted in any byte order, restricted only by data format requirements. Multibyte elements such as word count and checksum should be transmitted least-significant byte first.

NOTE: The long packets can be sent in low-power mode or in high-speed mode.

12.2.2.4.3 Data Identifier

The data identifier byte contains the virtual VC ID value and the DT value as illustrated in Figure 12-47. The VC ID is contained in the two MS bits of the data identifier byte. The DT value is contained in the six LSBs of the data identifier byte. DI[7:6]: These two bits identify the data as directed to one of four VCs. DI[5:0]: These six bits specify the DT.

Figure 12-47. Data Identifier Structure

dss-146

12.2.2.4.4 Virtual Channel ID - VC Field, DI[7:6]

The host can service up to four peripherals with tagged commands or blocks of data using the VC ID field of the header for packets targeted at different peripherals. The VC ID enables one serial stream to service two or more virtual peripherals by multiplexing packets onto a common transmission channel. Note that each packet sent in a single transmission have its own VC assignment and can be directed to different peripherals. The VC ID is defined in the DSS.DSI_VcN_SHORT_PACKET_HEADER and DSS.DSI_VcN_LONG_PACKET_HEADER registers for short and long packets, respectively. It should not be modified by hardware. There is one set of registers for each VC. Each set of registers defines the characteristics of the traffic between the host and the display associated with the VC.

Figure 12-48 shows the VC controller.

Figure 12-48. Virtual Channel Controller

dss-147

12.2.2.4.5 Data Type Field DT[5:0]

The DT field specifies whether the packet is a long or short packet type and the packet format. The DT field, along with the word count field for long packets, informs the receiver on how many bytes to expect in the remainder of the packet. This is necessary because there are no special packet start/end sync codes to indicate the beginning and end of a packet. This permits packets to convey arbitrary data, but it also requires the packet header to explicitly specify the size of the packet.

12.2.2.4.6 Pixel Data Formats in Video Mode

The host can send different pixel formats in video mode. Table 12-13 summarizes the pixel formats supported by the DSI interface in video mode.

Table 12-13. Pixel Data Format in Video Mode

| Mode | Description |
|---------------------------------|-------------|
| RGB888 (using 24-bit container) | RGB888 |
| RGB666 (using 24-bit container) | RGB666 |

Table 12-13. Pixel Data Format in Video Mode (continued)

| Mode | Description |
|---|---------------|
| RGB666 (18-bit packet using 18-bit container) | RGB666_PACKET |
| RGB565 (using 16-bit container) | RGB565 |

12.2.2.4.7 Synchronization Codes

Each frame can be identified by two synchronization codes: One for the start of vertical synchronization pulse (VSSC) and one for the end of the vertical synchronization pulse (VSEC). Each line can be identified by two synchronization codes: One for the start of horizontal synchronization pulse (HSSC) and one for the end of the horizontal synchronization pulse (HSEC). The synchronization events may not be required by the display (peripheral): They are optional. Users can program which sync events are generated to the display from the timings received from the display controller in video mode. When data are received on the L4 interconnect slave port, the synchronization codes are not automatically generated by the protocol engine. They can be provided on the L4 interconnect port by writing to the registers with limited timing control. It is highly recommended to use the video port from the display controller to receive the synchronization events to automatically generate the short synchronization packets to the peripheral. When the DSI protocol engine detects that the VSYNC signal from the display controller transitions from inactive to active state, the VSSC short packet replaces the following HSSC corresponding to the following HSYNC synchronization short packet (if the generation is enabled). When the transition from active to inactive state is detected, the VSEC short packet is generated (if the generation is enabled) replacing the HSSC synchronization packet corresponding to the following HSYNC. When the DSI protocol engine detects that the HSYNC signal from the display controller transition from inactive to active state, the HSSC short packet is generated (if the generation is enabled). When the transition from active to inactive state is detected, the HSEC short packet is generated (if the generation is enabled). For the first frame, any HSYNC and data received on the video port prior to the first VSYNC should be ignored. Since the first VSYNC sent to the display is also recognized as a HSYNC for the first line, there should be no HSYNC sent for the first line. To send the synchronization codes, the DSI protocol engine uses the short packets. [Table 12-14](#) summarizes the 6-bit DT synchronization code values.

Table 12-14. Synchronization Codes

| Synchronization Code | Value | Comments |
|--------------------------|-------|----------|
| V sync start code (VSSC) | 0x1 | Optional |
| V sync end code (VSEC) | 0x11 | Optional |
| H sync start code (HSSC) | 0x21 | Optional |
| H sync end code (HSEC) | 0x31 | Optional |

12.2.2.4.8 Blanking

To keep the DSI link in HS state while using the video mode, during blanking periods, the long blanking packets are sent to the display. The DSS.DSI_VM_TIMINGi (I between 1 and 7) registers define the size of the long blanking packets after:

- Horizontal sync start code (short packet)
- Horizontal sync end code (short packet)
- Vertical sync start code (short packet)
- Vertical sync end code (short packet)
- Pixels (long packet)

[Table 12-15](#) defines the short packet values for the synchronization packets:

Table 12-15. Sync Short Packet Values

| Virtual Channel ID | Sync Code | Header (1st Byte) | Header (2nd Byte): Data Field LSB | Header (3rd Byte): Data Field MSB | Header (ECC) |
|--------------------|-----------|-------------------|-----------------------------------|-----------------------------------|-------------------------------|
| 0x0 | 0x1 | 0x1 | 0x0 | 0x0 | See note following this table |
| | 0x11 | 0x11 | | | |
| | 0x21 | 0x21 | | | |
| | 0x31 | 0x31 | | | |
| 0x1 | 0x1 | 0x41 | | | |
| | 0x11 | 0x51 | | | |
| | 0x21 | 0x61 | | | |
| | 0x31 | 0x91 | | | |
| 0x2 | 0x1 | 0x81 | | | |
| | 0x11 | 0x81 | | | |
| | 0x21 | 0xA1 | | | |
| | 0x31 | 0xB1 | | | |
| 0x3 | 0x1 | 0xC1 | | | |
| | 0x11 | 0xD1 | | | |
| | 0x21 | 0xC1 | | | |
| | 0x31 | 0xF1 | | | |

NOTE:

- If the ECC is enabled by setting the DSS.DSI_VCn_CTRL[8] ECC_TX_EN bit to 1 for the VC in video mode, the ECC value is calculated; otherwise, 0x00 is used for the blanking long packets and sync short packets. If the CRC is enabled by setting the DSS.DSI_VCn_CTRL[7] CS_TX_EN bit to 1 for the VC in video mode, the check-sum value is calculated; otherwise, 0x00 is used for the blanking long packets.
- In other cases, when the DSS.DSI_VCn_CTRL[7] CS_TX_EN bit is set to 0, the value 0x00 is always used for the CRC (long packets). When the DSS.DSI_VCn_CTRL[8] ECC_TX_EN bit is set to 0, the value 0x00 is used for the ECC for short and long packets, except when the header is provided by the register, since the ECC field is available in the register. It can be used to generate invalid ECC values when the header is provided by the register.

The link [lane(s) and clock separately] can be put in ULPS mode. While using the blanking values formerly defined, the packets (short and long) are considered in HS mode.

Timing parameters VSA, VBP, VFP, HSA, HBP, HFP, VACT, and t_L are defined in the DSS.DSI_VM_TIMINGx (x between 1 and 7) register. HSA, HBP, HFP, and t_L are defined using the byte clock unit (TxByteClkHS) and also in low-power clock cycles (TxClkEsc). VSA, VBP, VFP, and VACT are defined in term of number of lines. When the HS blanking packets are sent during the blanking periods, the parameters are used to determine the blanking packet payload size (taking into account the 4-byte header and the 2-byte check sum).

The configuration of the display controller timing generator must be used when the display controller timings are used to generate the DSI HS video mode transfer.

Special care must be taken in the case of the last line of the frame. The LPS transition is required when the link is in HS mode for the whole frame.

When BTA is sent for the data packets, the following blanking period can not be used for sending any data from the TX FIFO. When the blanking period starts with one HS packet from one VC, it can only be followed by another HS packet from the same VC, or by trigger (BTA for example). When there is no more HS data to send for this VC, the lane is in LPS. When the blanking period starts with one LP packet from one VC, it can only be followed by another LP packet from the same VC, by another VC, by trigger (BTA

for example), or by extra LP NULL packets. If the trigger has been sent, it is not possible to send any more data. When there is no more data from the TX FIFO to send in LP mode or the trigger has been sent, the lane is put into LPS. If the lanes must be kept in HS mode during blanking periods (except for the last blanking period of the frame), the HS blanking packets must be used. In case one trigger is sent at the beginning of the blanking period, the rest of the blanking period is in ULPS.

Figure 12-49 and Figure 12-50 show a nonburst transfer in DSI video mode with, and without VE and HE, respectively.

Figure 12-49. DSI Video Mode: Nonburst Transfer With VE and HE

dss-148

Figure 12-50. DSI Video Mode: Nonburst Transfer Without VE and HE

dss-149

NOTE: HSA timing is not used and does not have to be programmed when HE short packet is not generated.

Figure 12-51. DSI Video Mode: Burst Transfer Without VE and HE

dss-150

NOTE: HSA timing is not used and does not have to be programmed when HE short packet is not generated.

In [Figure 12-50](#) and [Figure 12-51](#), if HSync end short packet is not generated (HSA does not exist), HBP should be other than 0.

12.2.2.4.9 Frame Structures

[Figure 12-52](#) shows the general DSI frame structure.

dss-153

12.2.2.4.10 Virtual Channels

The DSI protocol layer transports VCs. The purpose of VCs is to separate different data flows, which are interleaved in a same data stream. Each VC is identified by a unique channel identification number in the packet header. The channel identification number is encoded in 2-bits. The DSI protocol engine determines the channel identifier number to be used for generating the packet header and multiplexes the interleaved data streams. The DSI protocol engine supports multiple concurrent VCs: Up to 4. [Table 12-16](#) summarizes the VC values used for each channel.

Table 12-16. Virtual Channel Values

| Virtual Channel Number | Value |
|------------------------|-------|
| Virtual channel 0 | 0x0 |
| Virtual channel 1 | 0x1 |
| Virtual channel 2 | 0x2 |
| Virtual channel 3 | 0x3 |

In the case of multiple displays connected to the single DSI port on the host, a hub may be used to root the data stream to the appropriate display based on the VC ID. Typically, VC ID 0x0 is used for the primary display and 0x1 for the secondary. The hub may have its own VC ID to provide communication capability between the host and the hub.

12.2.2.5 Pixel Data Formats

This section summarizes how the DSI supported pixel data formats in video mode are transmitted over the serial interface. For pixel formats in command mode. The DSI protocol engine can cope with all data formats given that the data line length sent through the DSI physical protocol is a multiple of a pixel. This condition is required for the DSI protocol engine to work properly.

12.2.2.5.1 24 Bits per Pixel - RGB Color Format, Long Packet

[Figure 12-55](#) shows the RGB888 format.

Figure 12-55. 24 Bits per Pixel RGB Color Format, Long Packet

dss-154

Packed pixel stream 24-bit format is a long packet used to transmit image data formatted as 24-bit pixels to a video mode display module. The packet consists of the DI byte, a two-byte WC, an ECC byte, a payload of length WC bytes, and a two-byte checksum. The pixel format is red (8 bits), green (8 bits), and blue (8 bits), in that order. Each color component occupies one byte in the pixel stream; no components are split across byte boundaries. Within a color component, the LSB is sent first, the MSB last.

12.2.2.5.2 18 Bits per Pixel (Loosely Packed) - RGB Color Format, Long Packet

Figure 12-56 details the RGB666 format.

Figure 12-56. 18 Bits per Pixel (Loosely Packed) RGB Color Format, Long Packet

dss-155

In the 18-bit pixel loosely-packed format, each R, G, or B color component is six bits but is shifted to the upper bits of the byte, such that the valid pixel bits occupy bits [7:2] of each byte. Bits [1:0] of each payload byte representing active pixels are ignored. As a result, each pixel requires three bytes as it is transmitted across the link. This requires more bandwidth than the packed format, but requires less shifting and multiplexing logic in the packing and unpacking functions on each end of the link. This format is used to transmit RGB image data formatted as pixels to a video mode display module that displays 18-bit pixels. The packet consists of the DI byte, a two-byte WC, an ECC byte, a payload of length WC bytes, and a two-byte checksum. The pixel format is red (6 bits), green (6 bits), and blue (6 bits) in that order. Within a color component, the LSB is sent first, the MSB last.

12.2.2.5.3 18 Bits per Pixel (Packed) - RGB Color Format, Long Packet

Figure 12-57 details the RGB666_PACKED format.

Figure 12-57. 18 Bits per Pixel (Packed) RGB Color Format, Long Packet

dss-156

Packed pixel stream 18-bit format (packed) is a long packet. It is used to transmit RGB image data formatted as pixels to a video mode display module that displays 18-bit pixels. The packet consists of the DI byte, a two-byte WC, an ECC byte, a payload of length WC bytes, and a two-byte checksum. Pixel format is red (6 bits), green (6 bits), and blue (6 bits), in that order. Within a color component, the LSB is sent first, the MSB last. With this format, it is strongly recommended that the total line width be a multiple of four pixels (nine bytes).

12.2.2.5.4 16 Bits per Pixel - RGB Color Format, Long Packet

Figure 12-58 details the RGB565 format.

Figure 12-58. 16 Bits per Pixel RGB Color Format, Long Packet

Packed pixel stream 16-bit format is a long packet used to transmit image data formatted as 16-bit pixels to a video mode display module. The packet consists of the DI byte, a two-byte WC, an ECC byte, a payload of length WC bytes, and a two-byte checksum. Pixel format is five bits red, six bits green, five bits blue, in that order. Note that the *green* component is split across two bytes. Within a color component, the LSB is sent first, the MSB last.

12.2.3 LCD Output With TI FlatLink3G Data Format for the SDI Module

The parallel-to-serial conversion of the 24-BPP pixel data depends on the number of data channels in use.

Figure 12-59 through Figure 12-61 summarize the pixel order for each data format of the TI FlatLink3G LCD panel.

The following apply to Figure 12-59 through Figure 12-61:

- VS: Vertical synchronization
- HS: Horizontal synchronizations
- DE: Data enable
- CP: Pixel parity. Parity of the whole 30-bit data is odd
- F1, F0: Reserved bits for the TI FlatLink3G protocol
- Clock channel: Differential clock signal between SDI_CLKP and SDI_CLKN

Figure 12-59. 24 Bits Per Pixel With One Data Channel

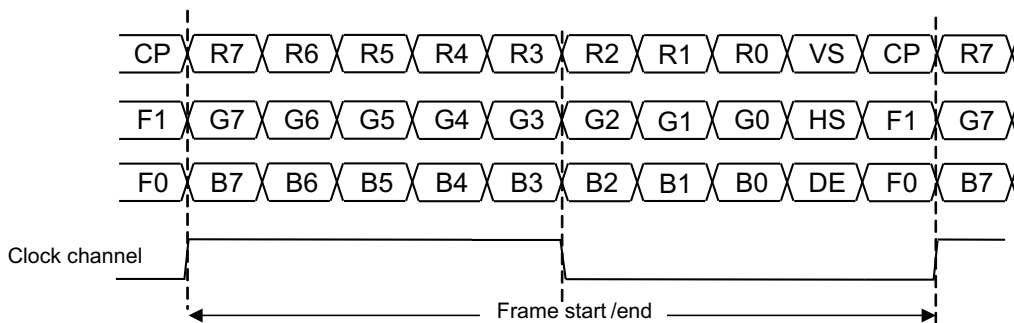

dss-032

Figure 12-60. 24 Bits Per Pixel With Two Data Channels

dss-033

Figure 12-61. 24 Bits Per Pixel With Three Data Channels

dss-034

NOTE: The range of the data rates permitted is 120 Mbps per pair minimum (4 MHz pixel clock, one data pair) to 650 Mbps per pair maximum (65 MHz pixel clock, three data pairs).

12.2.4 TV Display Support

The TV display path includes the following modules:

- Display controller
- Video encoder
- Dual 10-bit DAC with video amplifiers

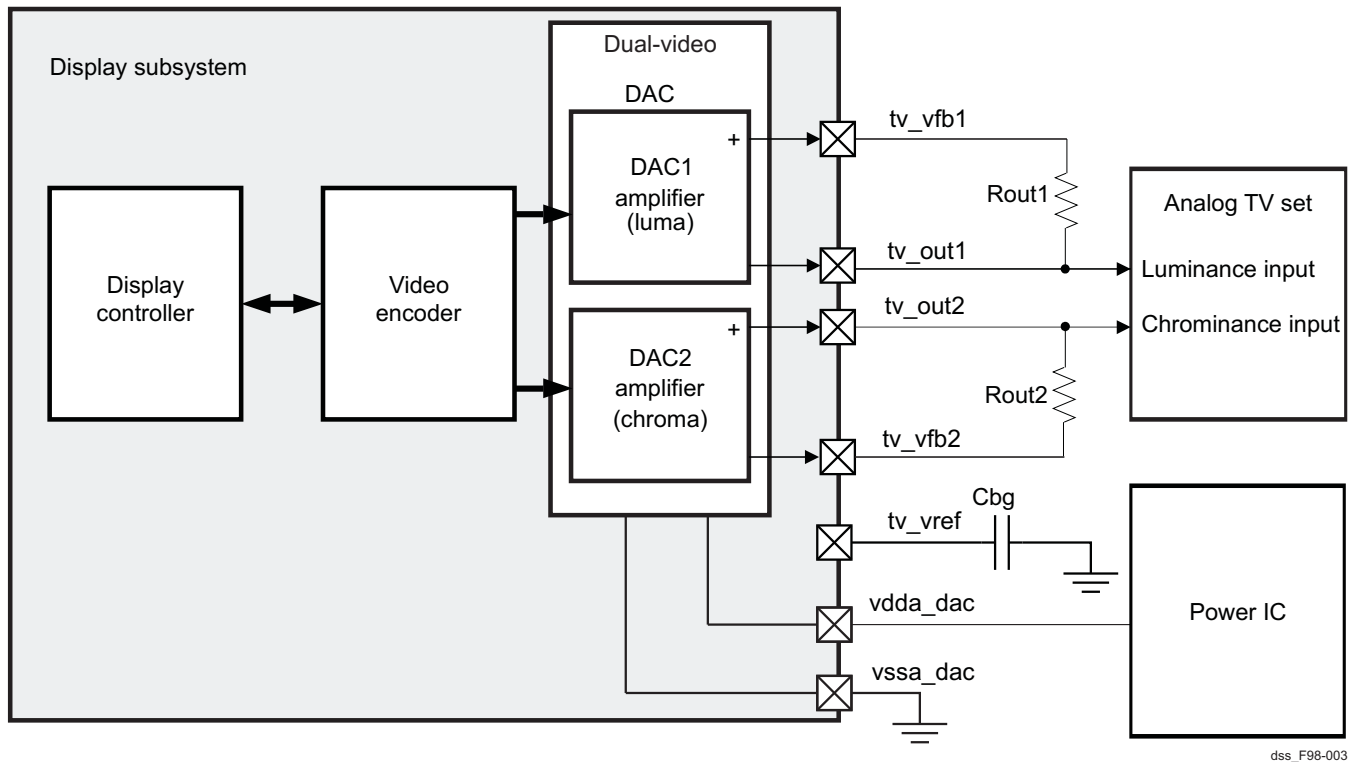

The display controller module receives synchronization signals from the video encoder and synchronously sends pixel data to the video encoder with these signals. The digital output of the display controller is always a 24-bit RGB value based on a pixel request from the video encoder.

The video encoder converts RGB video signals to conform to the NTSC/PAL standard analog video. The video encoder includes an integrated synchronization signal generator and a 2-channel video digital-to-analog converter (DAC) with video amplifiers, data manager, luma stage, chroma stage, modulator, and a control interface.

The video encoder also provides the synchronization signals to the display controller: VSYNC, active Video (AVID), and field ID (FID).

Figure 12-62 is a block diagram of the TV display interface (s-video mode).

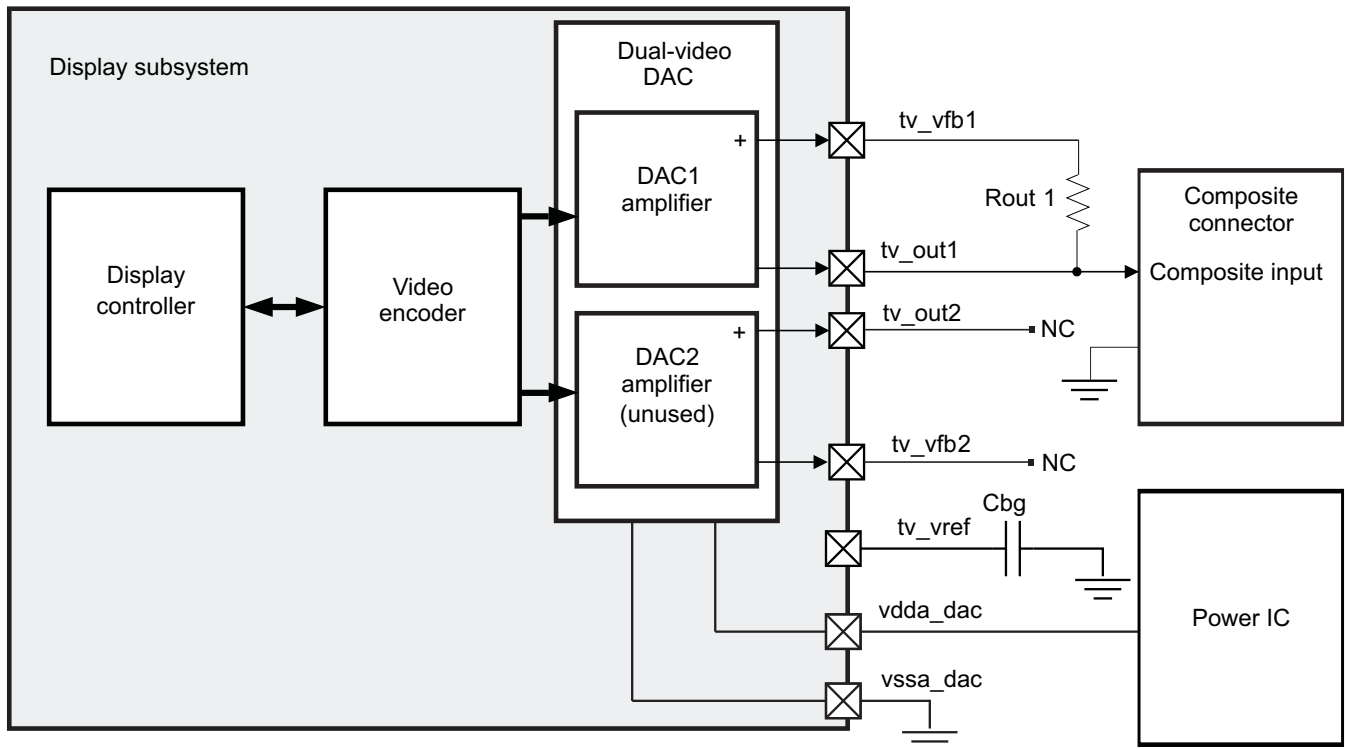

Figure 12-62. TV Display Interface (s-video mode)

dss_F98-003

Figure 12-63 is a block diagram of the TV display interface (composite mode).

Figure 12-63. TV Display Interface (Composite Mode)

dss-191

NOTE: In composite video mode, the video DAC2 chroma output must be disabled by setting the DSS.VENC_OUTPUT_CONTROL[2] CHROMA_ENABLE bit to 0.

Table 12-17 describes the interface signals to/from the TV set for TV display support.

Table 12-17. TV Display Interface Pins

| Pin Name | Type ⁽¹⁾ | Description |
|----------|---------------------|--|
| tv_out1 | O | Analog luma or composite video output. An external resistor is connected between this node and the tv_vfb1 pin. The nominal value of Rout1 is 1650 Ω. Note that this is the output node that drives the load (75 Ω). |
| tv_out2 | O | Analog chroma video output. An external resistor is connected between this node and the tv_vfb2 pin. The nominal value of Rout2 is 1650 Ω. This is the output node that drives the load (75 Ω). |
| tv_vfb1 | O | Amplifier feedback node. An external resistor is connected between this node and tv_out1. The nominal value of Rout1 is 1650 Ω. |
| tv_vfb2 | O | Amplifier feedback node. An external resistor is connected between this node and tv_out2. The nominal value of Rout2 is 1650 Ω. |
| tv_vref | O | Reference output voltage from internal bandgap. A decoupling capacitor must be connected for optimum performance. tv_vref is generated internally to the OMAP device. |
| vdda_dac | Power | Analog supply voltage for the dual video DAC |
| vssa_dac | Power | Analog ground for the dual video DAC |

⁽¹⁾ O = Output, Power = Power pin

CAUTION

- tv_out1 and tv_out2 are very high-frequency analog signals and must be routed with extreme care. As a result, the path of these signals must be as short as possible, and as isolated as possible from other interfering signals.
- During board design, the onboard traces and parasites must be matched for the two channels. tv_vfb1 and tv_vfb2 pins are the most sensitive pins in the TV out system. The onboard parasitic capacitance associated with these two pins should be less than 0.5 pF. Low onboard resistance is required for the traces that connect the Rout1/Rout2 to the tv_vfb1/tv_vfb2 and TV OUT pins (tv_out1 and tv_out2). The resistance on those trace affects output impedance matching. Therefore, Rout1 and Rout2 resistors are suggested to be placed as close as possible to the OMAP device pins. The onboard traces lead to the TV OUT pins must have a characteristic impedance of 75 Ω starting from the closest possible place to the OMAP device pin output. For typical values of Rout1, Rout2, Cout, and Cbg, see the device data manual.
- If the TV output is not used, the analog pins tv_ref and vdda_dac must be grounded. The tv_out1, tv_out2, tv_vfb1, and tv_vfb2 pins can be grounded or left unconnected. To avoid current leakage, the following bits must be set to 0:
 - DSS.DSS_CONTROL[5] DAC_POWERDN_BGZ
 - DSS.VENC_OUTPUT_CONTROL[2:0]
 - PRM.CM_FCLKEN_DSS[2] EN_TV
 - CONTROL.CONTROL_DEVCONF[18] TVOUTBYPASS

Texas Instruments provides a global solution with an OMAP device associated with a power IC. The power pin vdda_dac is software controlled by the power IC.

12.2.4.1 TV Output and Data Format

The output data to the TV set are the analog composite data from the DAC. The following video standards are supported:

- NTSC-J, M
- PAL-B, D, G, H, I
- PAL-M

12.2.4.2 Digital-to-Analog Converter

The DAC includes the following main features:

- 1.0-V-to-1.3-V digital power supply, 1.8-V analog power supply
- 10-bit resolution
- DNL within 1 LSB and INL within 1 LSB
- Sample rate of up to 60 megasamples per second (MSPS)
- Support composite/S-video dc or ac coupled output
- Full-scale voltage output: 0.88 V_{pp} with a 75- Ω load
- Internal TV detect feature
- Signal-to-noise ratio (SNR) is 54 dB (taking into account the ac coupling)
- Suitable for low-power wireless applications; total power: 10 mA (no load in dc-coupled mode)
- Power-down mode with less than 2.5- μ A standby current
- Differential gain error and differential phase error: 1.5% and 1%, respectively

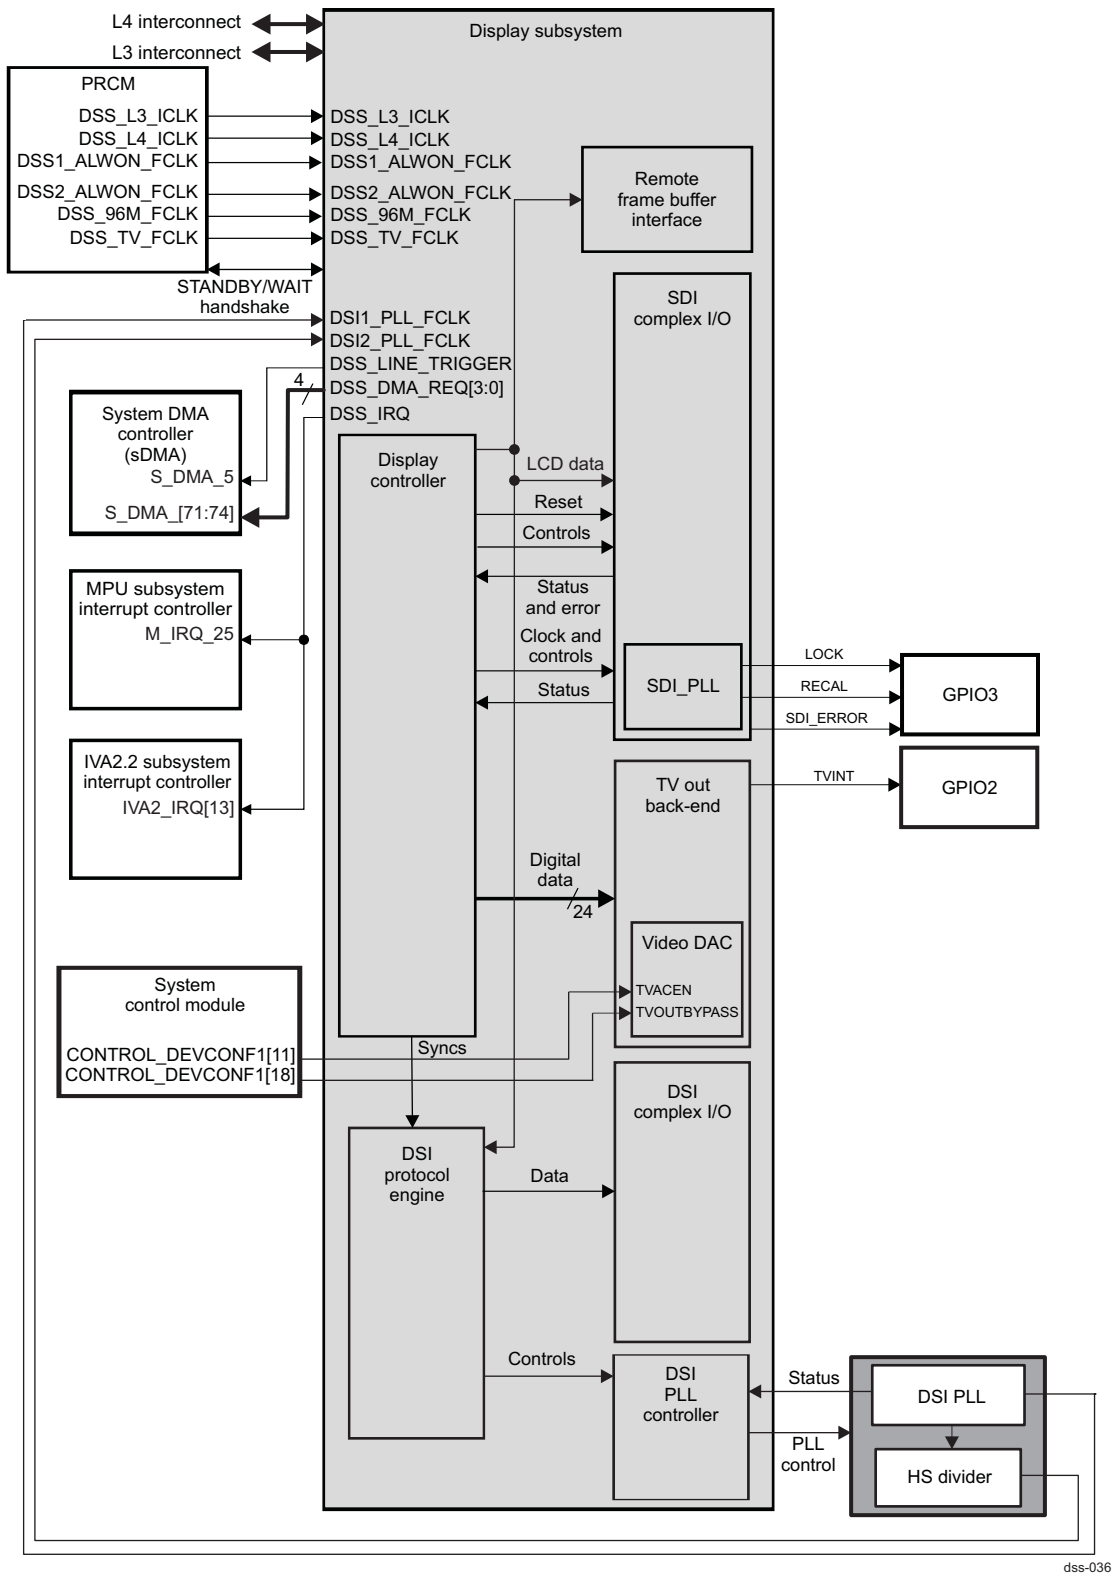

NOTE: To enhance the TV color display, it is highly recommended to set the DSS.DSS_CONTROL[4] DAC_DEMEN bit.

12.3 Display Subsystem Integration

This section describes the integration of the display subsystem and details clocks, resets, hardware requests, and power modes.

Figure 12-64 shows the integration of the display subsystem in the device.

Figure 12-64. Display Subsystem Integration

12.3.1 Clocking, Reset, and Power-Management Scheme

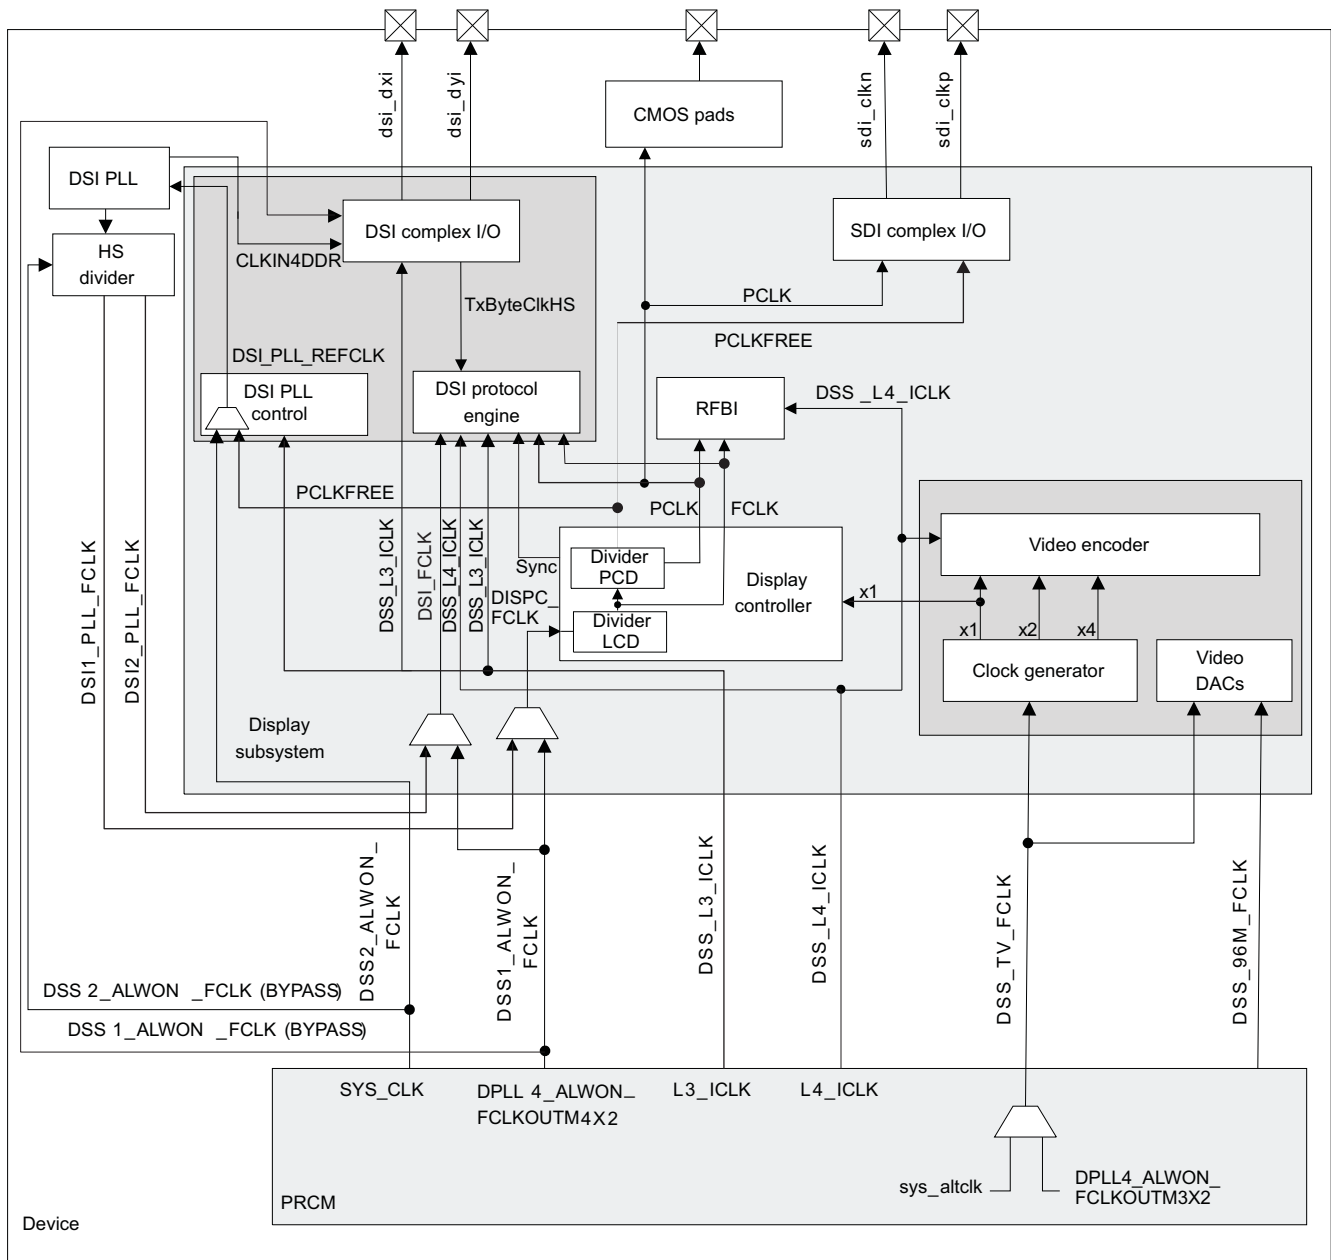

12.3.1.1 Clocks

The power, reset, and clock management (PRCM) module provides six clock signals to the display subsystem: The L3 interface clock (DSS_L3_ICLK) and the L4 interface clock (DSS_L4_ICLK), with frequencies equal to the L3 interconnect clock and the L4 interconnect clock, respectively; two configurable functional clocks (DSS1_ALWON_FCLK and DSS2_ALWON_FCLK); and two other functional clocks (DSS_TV_FCLK and DSS_96M_FCLK).

The DSI PLL provides two functional clock signals to the display subsystem: DSI1_PLL_FCLK and DSI2_PLL_FCLK.

Figure 12-65 details the clock tree for the display subsystem.

Figure 12-65. Display Subsystem Clock Tree

dss-158

NOTE: A synchronization signal is sent by the display controller (DISPC) to the DSI protocol engine. This signal, named DISPC_UPDATE_SYNC, is used to inform the DSI protocol engine that it must be unsynchronized with the display controller.

Table 12-18 describes the different clocks with their possible frequency values.

Table 12-18. Display Subsystem Clocks

| Clock Signal | Attribute | Module | Frequency | Comment |
|-----------------|--------------------|----------------------------|---|---|
| DSS_L3_ICLK | L3 interface clock | DSS | (See , PRCM) | L3 interface clock from PRCM |
| DSS_L4_ICLK | L4 interface clock | DSS | (See , PRCM) | L4 interface clock from PRCM |
| DSS1_ALWON_FCLK | Functional clock | DISPC, DSI protocol engine | Up to 173 MHz at nominal voltage | From PRCM: DPLL4 (source: DPLL4_ALWON_FCLK) |
| DSS2_ALWON_FCLK | Functional clock | DSI PLL | 12/13/16.8/19.2/26/38.4 MHz | From PRCM: SYS_CLK |
| DSI1_PLL_FCLK | Functional clock | DISPC | Up to 173 MHz at nominal voltage | From DSI PLL and HS divider |
| DSI2_PLL_FCLK | Functional clock | DSI protocol engine | Up to 173 MHz at nominal voltage | From DSI PLL and HS divider |
| DSS_TV_FCLK | Functional clock | DSS, video mode DAC | 54 MHz or sys_alt_clk (up to 59 MHz) | From PRCM: DPLL4 (source: DPLL4_ALWON_FCLK) or External input clock (See , PRCM) |
| DSS_96M_FCLK | Functional clock | Video DAC | 96 MHz | From PRCM: 96M_FCLK |

To enable or disable each functional clock, set the following bit (1: Enable, 0: Disable):

- PRCM.CM_FCLKEN_DSS[0] EN_DSS1 bit to enable DSS1_ALWON_FCLK
- PRCM.CM_FCLKEN_DSS[1] EN_DSS2 bit to enable DSS2_ALWON_FCLK
- PRCM.CM_FCLKEN_DSS[2] EN_TV bit to enable DSS_TV_FCLK and DSS_96M_FCLK

To enable or disable the DSS_L3_ICLK and DSS_L4_ICLK interface clocks, write (1: Enable, 0: Disable) to the PRCM.CM_ICLKEN_DSS[0] EN_DSS bit.

NOTE: Note that it is not possible to gate/stop L3 clock and keep L4 clock running.

- L3 and L4 interface clock

The DSS_L3_ICLK clock is only used by the display controller interface to fetch the pixel data. The DSS_L4_ICLK is used to access the L4 interconnect for configuring all the display subsystem registers.

NOTE: A clock generated internally from the L3 interface clock allows the submodules to be configured and is the functional clock for the RFBI. The SDI module and all the display subsystem registers are configured through the display subsystem register.

- Display controller functional clocks

The display controller can use either the DSS1_ALWON_FCLK or the DSI1_PLL_FCLK functional clock.

To select the DSS1_ALWON_FCLK functional clock (the default clock selected after reset), write 0 in the DSS.DSS_CONTROL[0] DISPC_CLK_SWITCH bit; to select the DSI1_PLL_FCLK functional clock, write 1 in the DSS.DSS_CONTROL[0] DISPC_CLK_SWITCH bit.

NOTE: The DSS1_ALWON_FCLK and DSI1_PLL_FCLK functional clocks must be active (the PRCM.CM_FCLKEN_DSS[0] EN_DSS1 and DSI PLL programmed correctly) to switch from one functional clock to another. The new functional clock is effective when the next vertical blanking interval occurs. This is true only if the DSS.DISPC_CONTROL[5] GOLCD bit is set to 1.

Depending on the DPPLL4 input clock frequency, the DSS1_ALWON_FCLK can be adjusted by setting the PRCM.CM_CLKSEL_DSS[4:0] CLKSEL_DSS1 bit field.

- DSI PLL functional clock (DSI_PLL_REFCLK)
The DSI PLL controller module can use either the DSS2_ALWON_FCLK (from PRCM) or the PCLKFREE (from DISPC) functional clock. To select the DSS2_ALWON_FCLK functional clock (default clock selected after reset), write 0 in the DSS.DSI_PLL_CONFIGURATION2[11] DSI_PLL_CLKSEL bit; to select the PCLKFREE functional clock, write 1 in the DSS.DSI_PLL_CONFIGURATION2[11] DSI_PLL_CLKSEL bit.
- DSI protocol engine functional clocks (DSI_FCLK)
The DSI protocol engine can use either the DSS1_ALWON_FCLK (from PRCM) or the DSI2_PLL_FCLK (from DSI PLL) functional clock. To select the DSS1_ALWON_FCLK functional clock (default clock selected after reset), write 0 in the DSS.DSS_CONTROL[1] DSI_CLK_SWITCH bit; to select the DSI2_PLL_FCLK functional clock, write 1 in the DSS.DSS_CONTROL[1] DSI_CLK_SWITCH bit.

NOTE: It is possible to switch between these two clocks, even when both of them are not active.

- There are five clock domains in the DSI module:
 - Byte clock domain:
TxByteClkHS is generated from the bit clock and converted into a byte clock. The maximum frequency is 100 MHz (all OPPs). It is generated by the DSI complex I/O.
 - Functional clock domain
The DSI_FCLK is the functional clock for the DSI protocol engine module. The maximum frequency is 173 MHz (nominal voltage) and 124 MHz (low voltage). It should always be equal to or higher than the byte (TxByteClkHS), L4 interconnect (DSS_L4_ICLK), and video port (VP_CLK) clocks. The software must configure the clocks correctly.
 - L4 interface clock domain
The DSS_L4_ICLK is used in the L4 interconnect port domain. The maximum frequency is 166 MHz at nominal voltage and 83 MHz at low voltage.
 - The video port domain
The pixel clock (PCLK) on the video port is used by the video port domain to capture the pixels from the display controller. The maximum frequency of VP_CLK used as the functional clock for the video port domain is 173 MHz at nominal voltage and 96 MHz at low voltage.
 - Serial Configuration Port (SCP) and Power Control (PWR) interfaces
The DSS_L4_ICLK is the functional clock.

NOTE:

- There is no clock domain for RxClkEsc because it is used as an enable and not as a clock by the DSI protocol engine module
 - The clock domains are asynchronous (except for L4 interconnect port and SCP/PWR because both of them use DSS_L4_ICLK). The clocks used for the L4 interconnect port and SCP/PWR interface should be balanced.
 - If video mode is used, the display controller functional clock must be generated using a clock from the DSI PLL.
-

- Video encoder functional clock
The DSS_TV_FCLK is divided into three balanced clocks, depending on the clock mode selected (see [Table 12-19](#)).

Table 12-19. Possible Digital Clock Division for the Video Encoder

| Clock Output | Clock Mode | |
|------------------------|---------------|--------------------------|
| | Clock mode 0 | Clock mode 1 |
| Video encoder clock 4x | DSS_TV_FCLK | DSS_TV_FCLK or 0 (gated) |
| Video encoder clock 2x | DSS_TV_FCLK/2 | DSS_TV_FCLK |
| Video encoder clock 1x | DSS_TV_FCLK/4 | DSS_TV_FCLK/2 |

The clock mode is defined by the the [DSS_CONTROL\[2\]](#) VENC_CLOCK_MODE bit:

- In the case of clock mode 1, the [DSS_CONTROL\[3\]](#) VENC_CLOCK_4X_ENABLE bit is used to control clock gating.
- In the case of clock mode 0, the VENC_CLOCK_4X_ENABLE bit must be set to 0x1 by software.

NOTE: After reset, clock mode 0 is selected by default and the DSS_TV_CLK clock is disabled. The DSS_TV_CLK / 4 in mode 0, or the DSS_TV_CLK / 2 in mode 1, is used in the DISPC module to send data to the video encoder.

NOTE: Clock mode 1 can be used for power-saving purposes, or if a 27-MHz external clock is provided to the video encoder.

DSS_TV_FCLK can be adjusted depending on the DPLL4 input clock frequency by setting the PRCM.CM_CLKSEL_DSS[12:8] CLKSEL_TV bit field. If the DPLL4 is selected, the DSS_TV_FCLK is provided by the DPLL4_ALWON_FCLKOUTM3X2 clock.

NOTE: If the DSS_TV_FCLK is not provided by DPLL4 but rather by the sys_alt_clk pin, an external clock generator must be connected to this pin. In this case, a 54-MHz clock is needed for PAL or NTSC 601, a 49.09-MHz clock is needed for NTSC square pixel, and a 59-MHz clock is needed for PAL square pixel.

- Dual video DAC clocks
The dual video DAC uses two distinct clocks: The DSS_TV_FCLK and the DSS_96M_FCLK. The video data are latched on the positive edge of the DSS_TV_FCLK clock. On the other hand, the video DAC uses the DSS_96M_FCLK fixed-frequency clock internally as the clock input for the switch capacitor resistor.
- SDI functional clock
The display controller provides the functional clocks PCLK (pixel clock) and PCLKFREE (free-running pixel clock) of the SDI module, which is derived from the display controller functional clock. The SDI module functional clock drives the phase-locked loop SDI_PLL that multiplies and divides the PCLK frequency by two programmable factors for the serial connection.

NOTE: When using the SDI, configure the PCLK in the free-running mode by setting the [DSS.DISPC_CONTROL\[27\]](#) PCLKFREEENABLE bit to 1.

12.3.1.2 Resets

12.3.1.2.1 Hardware Reset

The display subsystem receives its reset signal DSS_RST (the reset signal of the display subsystem [DSS] power domain) from the PRCM module.

12.3.1.2.2 Software Reset

The display subsystem can receive a software reset propagated through all of the submodules and used to initialize the display subsystem. To apply the reset, write to the DSS.DSS_SYSCONFIG[1] SOFTRESET bit (1: Reset; 0: Normal). The DSS.DSS_SYSSTATUS[0] RESETDONE bit indicates that the software reset is complete when its value is 1.

NOTE: The display controller, the DSI protocol engine, and the RFBI modules also have their own software reset functionality. To access this reset, access the DSS.DISPC_SYSCONFIG[1] SOFTRESET bit for the display controller, the DSS.DSI_SYSCONFIG[1] SOFTRESET bit for the DSI protocol engine, and the DSS.RFBI_SYSCONFIG[1] SOFTRESET bit for the RFBI module.

To properly reset these modules, 0x2 is the only valid value to write to these registers.

CAUTION

All the interface and functional clocks, even for the TV output, must be provided to the display subsystem to update the RESETDONE status bit correctly.

12.3.1.3 Power Domain

The display subsystem modules are on the display subsystem (DSS) power domain and on the VDD2 voltage domain, except for the dual video DACs, which are on the analog vdda_dac voltage domain.

12.3.1.4 Power Management

12.3.1.4.1 Clock Activity Mode

The display controller clocks can be configured in one of the following clock activity modes:

- DSS.DISPC_SYSCONFIG[9:8] CLOCKACTIVITY bit field set to 0x0 (reset value): The interface and functional clocks can be switched off.
- DSS.DISPC_SYSCONFIG[9:8] CLOCKACTIVITY bit field set to 0x1: The functional clocks can be switched off and the interface clocks are maintained during the wake-up period.
- DSS.DISPC_SYSCONFIG[9:8] CLOCKACTIVITY bit field set to 0x2: The interface clocks can be switched off and the functional clocks are maintained during the wake-up period.
- DSS.DISPC_SYSCONFIG[9:8] CLOCKACTIVITY bit field set to 0x3: The interface and functional clocks are maintained during the wake-up period.

The DSI protocol engine clocks can be configured in one of the following clock activity modes:

- DSS.DSI_SYSCONFIG[9:8] CLOCKACTIVITY bit field set to 0x0 (reset value): The interface and functional clocks can be switched off.
- DSS.DSI_SYSCONFIG[9:8] CLOCKACTIVITY bit field set to 0x1: The functional clocks can be switched off and the interface clocks are maintained during the wake-up period.
- DSS.DSI_SYSCONFIG[9:8] CLOCKACTIVITY bit field set to 0x2: The interface clocks can be switched off and the functional clocks are maintained during the wake-up period.
- DSS.DSI_SYSCONFIG[9:8] CLOCKACTIVITY bit field set to 0x3: The interface and functional clocks are maintained during the wake-up period.

The DSS power domain clock activity status is logged in the PRCM.CM_CLKSTST_DSS[0] CLKACTIVITY_DSS status bit. When set to 0, there is no domain clock activity. When set to 1, the DSS power domain clock is active.

-
- NOTE:** The display subsystem interface clock can be dependent on the DSS power domain state. This is configured with PRCM.CM_AUTOIDLE_DSS[0] AUTO_DSS bit:
- When the AUTO_DSS bit is set to 0 (reset value): The display subsystem interface clock is not related to the DSS power domain state transition.
 - When the AUTO_DSS bit is set to 1: The display subsystem interface clock is automatically enabled or disabled along with the DSS power domain state transition.
-

12.3.1.4.2 Autoidle Mode

The RFBI, display controller, DSI protocol engine, and L4 interfaces can internally gate their clocks to decrease power consumption if no transaction is present on the related bus. The following bits must be set to enable this functionality:

- DSS.DSS_SYSCONFIG[0] AUTOIDLE bit (1: Autoidle; 0: Clock free-running) for the display subsystem
- DSS.RFBI_SYSCONFIG[0] AUTOIDLE bit (1: Autoidle; 0: Clock free-running) for the RFBI
- DSS.DISPC_SYSCONFIG[0] AUTOIDLE bit (1: Autoidle; 0: Clock free-running) for the display controller
- DSS.DSI_SYSCONFIG[0] AUTOIDLE bit (1: Autoidle; 0: Clock free-running) for the DSI protocol engine
- DSS.DISPC_CONFIG[9] FUNCGATED bit (1: Functional clocks gated enabled; 0: Functional clocks gated disabled) for the display controller

NOTE: All the bits listed above (except for the FUNCGATED bit) are set to 1 by default. It is highly recommended to set all the bits to 1 to save power.

12.3.1.4.3 Idle Mode

The display controller, DSI protocol engine, and RFBI can be configured into one of the following acknowledgment modes:

- Force-idle mode: The module immediately enters the idle state on receiving a low-power mode request from the PRCM module. In this mode, the software must ensure that there are no asserted output interrupts before requesting this mode to go into the idle state. Set the DSS.DISPC_SYSCONFIG[4:3] SIDLEMODE bit field to 0x0 (reset value) for display controller, set the DSS.DSI_SYSCONFIG[4:3] SIDLEMODE bit field to 0x0 (reset value) for DSI protocol engine, and, finally, the DSS.RFBI_SYSCONFIG[4:3] SIDLEMODE bit field to 0x0 (reset value) for RFBI.
- No-idle mode: The module never enters the idle state. Set the DSS.DISPC_SYSCONFIG[4:3] SIDLEMODE bit field to 0x1 for display controller, set the DSS.DSI_SYSCONFIG[4:3] SIDLEMODE bit field to 0x1 for DSI protocol engine, and, finally, the DSS.RFBI_SYSCONFIG[4:3] SIDLEMODE bit field to 0x1 for RFBI.
- Smart-idle mode:
 - Display controller: After receiving a low-power-mode request from the PRCM module, the display controller module enters the idle state when all the following conditions are satisfied:
 - All asserted output interrupts are acknowledged (no interrupt pending).
 - The display controller does not use anymore the L4 interface clock (DSS_L4_ICLK).
 - DSI protocol engine: After receiving a low-power-mode request from the PRCM module, the DSI protocol engine enters the idle state when all the following conditions are satisfied:
 - All asserted output interrupts are acknowledged (no interrupt pending).
 - The DSI protocol engine does not use the L4 interface clock (DSS_L4_ICLK) anymore.
 - The SCP and PWR transactions are complete.
 - No data remains in the TX FIFO (data waiting in the FIFO to be sent to the peripheral).

To configure the display subsystem in smart-idle mode, set the DSS.DISPC_SYSCONFIG[4:3] SIDLEMODE bit field to 0x2 for display controller, set the DSS.DSI_SYSCONFIG[4:3] SIDLEMODE bit field to 0x2 for DSI protocol engine, and, finally, the DSS.RFBI_SYSCONFIG[4:3] SIDLEMODE bit field to 0x2 for RFBI.

Once the idle handshake protocol is over:

- The DSS L4 interface clock (DSS_L4_ICLK) can be shutdown at any time.
- Any transaction on the L4 configuration port is ignored.

12.3.1.4.4 SDI Idle Mode

To save power consumption, the PLL (SDI_PLL) of the SDI module can be configured in one of the operation modes shown in [Table 12-20](#) when not locked.

Table 12-20. SDI PLL Operation Modes

| SDI_PLL Operation Mode | Stop mode Low power (1) | Stop mode Low power (1) | Idle bypass Low power | Idle bypass Fast relock | Limp |
|--|--|---|---|--|-------------------------|
| | Output clock stopped Lowest power standby | Output clock stopped Fastest start-up time | Output clock at PCLK rate Lowest power standby | Output clock at PCLK rate Fastest start-up time | Output at full speed |
| DSS.DSS_PLL_CONTROL[0] SDI_PLL_IDLE | 0 | 0 | 1 | 1 | 1 or PCLK stops |
| DSS.DSS_PLL_CONTROL[20] SDI_PLL_LOWCURRSTBY | 1 | 0 | 1 | 0 | X |
| DSS.DSS_PLL_CONTROL[17] SDI_PLL_STOPMODE | 1 | 1 | 1 | 1 | 0 |

(1) Recommended

12.3.1.4.5 Wake-Up Mode

The Display Controller (DISPC) supports the wake-up protocol. The mode is selected by programming the appropriate value in the DSS.DISPC_SYSCONFIG[2] ENWAKEUP bit. The wake-up signal is asserted when the DISPC is in idle mode and when anyone of the following events occur:

- Graphics pipe is enabled and data fetch is not completed for graphics window, and the number of data bytes in FIFO is less than the low threshold programmed value.
- Video1 pipe is enabled and data fetch is not completed for video1 window, and the number of data bytes in FIFO is less than the low threshold programmed value.
- Video2 pipe is enabled and data fetch is not completed for video2 window, and the number of data bytes in FIFO is less than the low threshold programmed value.
- The current pixel is the last pixel displayed on the LCD panel if it is not the last frame.
- The current pixel is the last pixel displayed on the digital panel if it is not the last frame.

If software users set the DSS.DISPC_CONFIG[17] FIFOFILLING bit, when one of the active pipe reaches the low threshold and should refill the FIFO for the current frame, the other pipes also refill their own FIFOs, even if the low threshold has not been reached. This is used to improve the probability of increasing the time when there is no access to the L3 interconnect (MStandby asserted, affects power savings).

Once the wake-up signal is asserted, the WAKEUP interrupt request is generated. The wake-up signal is deasserted when the idle request is no longer activated.

12.3.1.4.6 Standby Mode

As part of the system-wide power-management scheme, the display controller can enter standby mode. To configure the display controller, write the DSS.DISPC_SYSCONFIG[13:12] MIDDLEMODE bit field (00: Forced standby; 01: No standby; 10: Smart standby) in one of the following standby modes:

- Forced standby mode (default mode): The module enters standby mode when the module is disabled.
- No standby mode: The module never enters standby mode.
- Smart standby mode: The module enters standby state when the DISPC module is disabled or when all the three following events occur:
 - Graphics pipe is disabled or graphics pipe is enabled but data fetch completed for graphics window,

or graphics pipe is enabled and data fetch is not completed and number of data bytes in FIFO is greater than the high threshold programmed value.

- Video1 pipe is disabled or video1 pipe is enabled but data fetch completed for video1 window, or video1 pipe is enabled and data fetch is not completed and number of data bytes in FIFO is greater than the high threshold programmed value.
- Video2 pipe is disabled or video2 pipe is enabled but data fetch completed for video2 window, or video2 pipe is enabled and data fetch is not completed and number of data bytes in FIFO is greater than the high threshold programmed value.

When in standby mode, the display controller does not generate transactions on the L3 master port. Standby is active when the PRCM module confirms this mode.

The display subsystem standby mode activity can be monitored with the PRCM.CM_IDLEST_DSS[0] ST_DSS status register. When this register is read to 0, the display subsystem is accessible and the interface clock running; when it is read to 1, the display subsystem is in standby mode.

12.3.1.4.6.1 Conditions to Exit Standby Mode

The following conditions allow the subsystem to exit standby mode:

- Forced standby mode: Standby mode is exited when the display controller is enabled.
- Smart standby mode: Standby mode is exited when any one of the following events occurs:
 - Graphics pipe is enabled and data fetch is not completed for graphics window, and number of data bytes in FIFO is less than the low threshold programmed value.
 - Video1 pipe is enabled and data fetch is not completed for video1 window, and number of data bytes in FIFO is less than the low threshold programmed value.
 - Video2 pipe is enabled and data fetch is not completed for video2 window, and number of data bytes in FIFO is less than the low threshold programmed value.

12.3.1.4.6.2 Standby Transition Dependency

The sleep transition of the DSS power domain can be dependent or not with respect to MPU domain. This is configured by PRCM.CM_SLEEPDEP_DSS[1] EN_MPU bit:

- When the EN_MPU bit is set to 0 (reset value): The DSS power domain sleep dependency with the MPU power domain is disabled. The DSS power domain will not enter idle unless the MPU power has previously entered idle.
- When the EN_MPU bit is set to 1: The DSS power domain sleep dependency with the MPU power domain is enabled. The DSS power domain will enter idle regardless of the power domain state of the MPU.

The sleep transition of the DSS power domain may, or may not depend on the IVA2.2 domain, depending on the configuration of the PRCM.CM_SLEEPDEP_DSS[2] EN_IVA2 bit:

- When the EN_IVA2 bit is set to 0 (reset value): The DSS power domain sleep dependency on the IVA2.2 power domain is disabled.
- When the EN_IVA2 bit is set to 1: The DSS power domain sleep dependency on the IVA2.2 power domain is enabled.

12.3.1.4.6.3 Standby Procedure Description

When the display subsystem initiates a standby procedure, it also initiates an standby/wait handshake protocol with the PRCM module that lets the PRCM cut the display subsystem clocks. Depending on the PRCM setting, two modes are available:

- Manual mode
 - DSS1_ALWON_FCLK is shut down when the PRCM.CM_FCLKEN_DSS[0] EN_DSS1 bit is set to 0 and the display subsystem is in standby mode.
 - DSS2_ALWON_FCLK is shut down when the PRCM.CM_FCLKEN_DSS[1] EN_DSS2 bit is set to 0 and the display subsystem is in standby mode.
 - DSS_L3_ICLK and DSS_L4_ICLK are controlled together. They are shut down when the PRCM.CM_ICLKEN_DSS[0] EN_DSS bit is set to 0 and the display subsystem is in standby mode.

CAUTION

Do not stop DSS1_ALWON_FCLK, or DSS2_ALWON_FCLK clock (if used) if the display subsystem is not disabled.

CAUTION

DSS_TV_FCLK does not depend on the display subsystem standby state. Ensure correct clock management for DSS_TV_FCLK.

The clocks are reactivated when the related bits are set to 1 and the display subsystem exits from standby. For more information, see , *Power, Reset, and Clock Management*.

- Hardware- or software-supervised mode

The DSS-power state-transition between active and inactive states can be either hardware or software supervised. This is programmed with the PRCM.CM_CLKSTCTRL_DSS[1:0] CLKTRCTRL_DSS bit field:

- When the CLKTRCTRL_DSS bit field is set to 0x0 (reset value), the automatic transition is disabled
- When the CLKTRCTRL_DSS bit field is set to 0x1, the software-supervised sleep transition is started on the DSS power domain.
- When the CLKTRCTRL_DSS bit field is set to 0x2, the software-supervised wake-up transition is started on the DSS power domain.
- When the CLKTRCTRL_DSS bit field is set to 0x3, the automatic transition is enabled. Any transition on the DSS power domain is supervised by the hardware.

12.3.1.4.6.4 Display Subsystem Standby Mode, Power-Saving Use Cases

- Setup
 - Set the display subsystem in smart standby mode.
 - Manually enable DSS_L3_ICLK and DSS_L4_ICLK.
 - Manually enable DSS1_ALWON_FCLK or DSS2_ALWON_FCLK.
 - Manually enable DSS_TV_FCLK if the video encoder is used.
 - Set the PRCM.CM_CLKSTCTRL_DSS[1:0] CLKTRCTRL_DSS bit field to 0x3 (autocontrol mode supervised by hardware).
- Shut down the display subsystem.
 - Disable the display subsystem.
 - Manually disable DSS1_ALWON_FCLK, DSS2_ALWON_FCLK, DSS_TV_FCLK, DSS_L3_ICLK, and DSS_L4_ICLK.

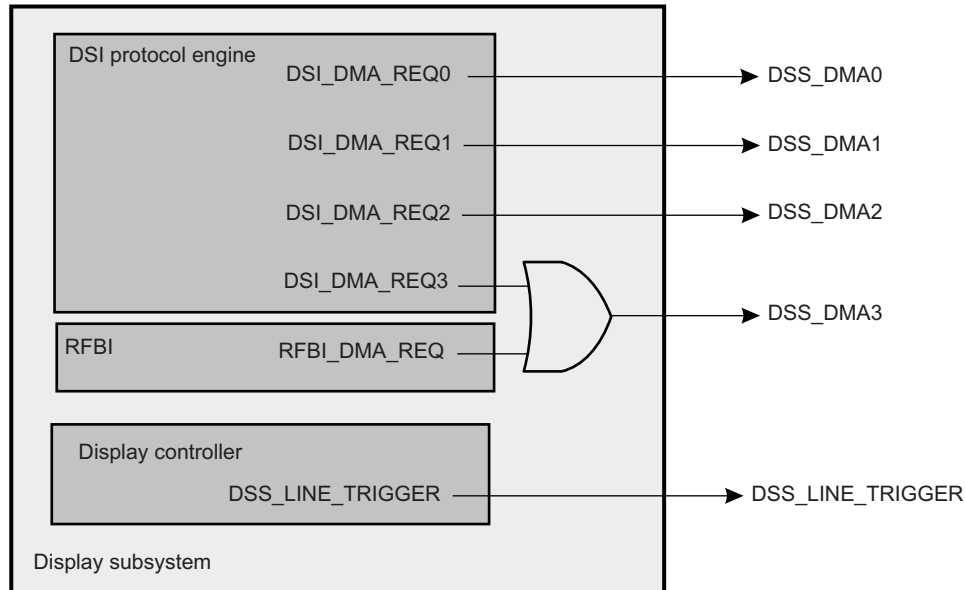

For more details on low-power programming settings, see [Section 12.6.2](#).

12.3.2 Hardware Requests

12.3.2.1 DMA Requests

The display controller, the DSI protocol engine, and the RFBI generate some DMA requests to the sDMA. [Figure 12-66](#) details the DMA tree.

Figure 12-66. Display Subsystem DMA Tree

dss-159

Table 12-21. DSS DMA Requests Description

| DMA Request Name | DSS Module | Mapping | Description |
|------------------|---------------------|----------|--|
| DSS_LINE_TRIGGER | DISPC | S_DMA_5 | See Section 12.3.2.1.1 |
| DSI_DMA_REQ0 | DSI protocol engine | S_DMA_71 | See Section 12.3.2.1.2 |
| DSI_DMA_REQ1 | DSI protocol engine | S_DMA_72 | See Section 12.3.2.1.2 |
| DSI_DMA_REQ2 | DSI protocol engine | S_DMA_73 | See Section 12.3.2.1.2 |
| DSI_DMA_REQ3 | DSI protocol engine | S_DMA_74 | See Section 12.3.2.1.2 |
| RFBI_DMA_REQ | RFBI | S_DMA_74 | See Section 12.3.2.1.3 |

NOTE: The DMA requests from the RFBI module (RFBI_DMA_REQ) and the DSI protocol engine (DSI_DMA_REQ3) are merged on line DSS_DMA3. The software must only use DSS_DMA3 on one module at a time (RFBI or DSI protocol engine).

12.3.2.1.1 Display Controller DMA Request (Line Trigger)

One DMA synchronization line (DSS_LINE_TRIGGER) is connected to the sDMA by the sDMA controller (S_DMA_5) input line. This DMA request is not a classical one but a synchronization signal from the display subsystem to the sDMA informing the sDMA that a programmable number of lines are output to the LCD, and that the system memory can be updated. This request is related to an interrupt event described in [Section 12.3.2.2, Interrupt Requests](#). This allows the sDMA channel to be synchronized with the display subsystem internal DMA controller. In other words, it allows to synchronize a memory to memory frame buffer update based on the scan line of the frame buffer in system memory (SDRAM or SRAM) by the display controller. The DSS_LINE_TRIGGER DMA request is generated at a programmable line number defined in DSS.DISPC_LINE_NUMBER[10:0] LINENUMBER bit field.

12.3.2.1.2 DSI Protocol Engine DMA Request

The DSI DMA requests are used to allow automatic transfer by the sDMA or MPU (with less efficiency and through-put capability) from the DSI RX FIFO to the system memory and from the system memory to the DSI TX FIFO. Two independent DMA requests for RX FIFO and TX FIFO for the same VC are supported.

12.3.2.1.3 RFBI DMA Request

The RFBI_DMA_REQ is used to receive data into the RFBI FIFO. The DMA request is always generated when there is enough room in the FIFO to accept the full burst.

12.3.2.2 Interrupt Requests

The DSI protocol engine, the DSI complex I/O (DSI_IRQ), and the display controller (DISPC_IRQ) generate one interrupt request each. The DSI_IRQ and DISPC_IRQ lines are merged together in a single interrupt line.

One interrupt line (DSS_IRQ) is connected to two interrupt controllers:

- MPU interrupt controller (M_IRQ_25 input line)
- IVA interrupt handler (IVA2_IRQ[13] input line)

Figure 12-67 shows the interrupt tree for the DSI protocol engine and DSI complex I/O in detail.

Figure 12-67. DSI Interrupt Tree

dss-160

Figure 12-68 details the interrupt tree for the DISPC and the display subsystem.

Figure 12-68. DISPC and DSS Interrupts Tree

dss-161

12.3.2.2.1 DISPC Interrupt Request

The interrupt line indicates when one or more events are detected by the hardware. Each event is independently maskable by setting the `DSS.DISPC_IRQENABLE` register.

To check when a particular interrupt event occurs and to reset a particular event, the `DSS.DISPC_IRQSTATUS` register must be accessed. This register regroups all the status of the module internal events that generate an interrupt (read 0: No interrupt occurred; read 1: Interrupt occurred; write 1: Status bit reset). See [Section 12.7, Display Subsystem Register Manual](#), for more information on checking and clearing interrupt events.

[Table 12-22](#) lists the display subsystem interrupt events.

Table 12-22. Display Subsystem Interrupts

| Interrupt Name | Description |
|----------------------------|--|
| FRAMEDONE | Active frame is complete and LCD output is disabled. |
| VSYNC | VSYNC interrupt occurred at the end of the frame. |
| EVSYNC_EVEN ⁽¹⁾ | EVSYNC_EVEN interrupt occurred at the end of the frame. (EVSYNC is received and the field polarity is even.) |
| EVSYNC_ODD ⁽¹⁾ | EVSYNC_ODD interrupt occurred at the end of the frame. (EVSYNC is received and the field polarity is odd.) |
| ACBIASCOUNTSTATUS | The ac-bias transition counter decremented to 0. |
| PROGRAMMEDLINENUMBER | The LCD reached the user-programmed line number. |
| GFXFIFOUNDERFLOW | The input graphics FIFO goes underflow. |
| GFXENDWINDOW | The screen reached the end of the graphics window. All data for the graphics window are fetched from memory and displayed on the screen. |
| PALETTEGAMMALOADING | The palette/gamma table is loaded. |
| OCPERROR | L3 interconnect sent SResp = ERR. |
| VID1FIFOUNDERFLOW | The input video1 FIFO goes underflow. |
| VID1ENDWINDOW | The screen reached the end of video1 window. All data for the video window are fetched from the memory and displayed on the screen. |

⁽¹⁾ EVYNC interrupts (EVSYNC_EVEN and EVSYNC_ODD) are external interrupts received by the display controller and generated by the video encoder (VENC) module.

Table 12-22. Display Subsystem Interrupts (continued)

| Interrupt Name | Description |
|-------------------|--|
| VID2FIFOUNDERFLOW | The input video2 FIFO goes underflow. |
| VID2ENDWINDOW | The screen reached the end of video2 window. All data for the video window are fetched from the memory and displayed on the screen. |
| SYNCLOST | Interrupt occurs when VSYNC width/front or back porches are not wide enough to load the pipelines with data (LCD output). |
| SYNCLOSTDIGITAL | Interrupt occurs when the display controller is not ready to output data when a digital request occurs. This interrupt informs that the timings of the NTSC/PAL video encoder are not set correctly. |
| WAKEUP | Occurs when the wakeup signal is asserted |

NOTE: To clear a synchronization lost interrupt, follow this sequence:

1. Clear the DSS.DISPC_CONTROL[0] LCDENABLE (LCD: SYNCLOST interrupt) or DSS.DISPC_CONTROL[1] DIGITALENABLE (TV: SYNCLOSTDIGITAL interrupt) bits. Check the interrupts.
LCD: Verify that a FRAMEDONE interrupt occurs.
TV : Verify that EVSYNC_EVEN or EVSYNC_ODD interrupts occur.
2. Set the DSS.DSS_SYSCONFIG[1] SOFTRESET bit to reset the display subsystem.
3. Set the display subsystem registers again.

NOTE: The SYNCLOSTDIGITAL interrupts, which occur before the first VSYNC pulse signal (from the video encoder), should not be considered.

After the first VSYNC pulse signal, the SYNCLOSTDIGITAL interrupt status bit must be cleared by writing 1 in the DSS.DISPC_IRQSTATUS[15] SYNCLOSTDIGITAL bit; then the SYNCLOSTDIGITAL interrupt can be enabled by setting the DSS.DISPC_IRQENABLE[15] SYNCLOSTDIGITAL bit.

12.3.2.2 DSI Interrupt Request

The DSI protocol engine requires a single interrupt line, DSI_IRQ. The DSS.DSI_IRQSTATUS register indicates the general interrupt events. Refer to [Table 12-23](#). Each VC and complex I/O has a dedicated interrupt register: DSS.DSI_VCn_IRQSTATUS and DSS.DSI_COMPLEXIO_IRQSTATUS respectively. Refer to [Table 12-24](#) and [Table 12-25](#).

[Table 12-23](#) indicates the DSI global interrupt events.

Table 12-23. DSI Global Interrupts

| Interrupt Name | Description |
|-----------------------|--|
| RESYNCHRONIZATION_IRQ | Resynchronization in video mode |
| TA_TO_IRQ | Turn-around timer expired |
| LDO_POWER_GOOD_IRQ | Signal LDOPWRGOOD from the DSI_PHY changes its state for the supply VDDALDODSIPLL from up to down or down to up. |
| SYNC_LOST_IRQ | Synchronization with video mode port is lost (video mode only) |
| ACK_TRIGGER_IRQ | Acknowledge trigger is received |
| TE_TRIGGER_IRQ | Tearing effect trigger is received |
| WAKEUP_IRQ | Occurs when the SWakeup signal is asserted |
| HS_TX_TO_IRQ | High speed TX Time-out Interrupt |
| LP_RX_TO_IRQ | Low speed RX Time-out Interrupt |
| COMPLEXIO_ERR_IRQ | Error signaling from complex I/O: The interrupt is triggered when any error is received from the complex I/O (events are defined in DSI_COMPLEXIO_IRQSTATUS). |

Table 12-23. DSI Global Interrupts (continued)

| Interrupt Name | Description |
|----------------------|--|
| PLL_RECAL_IRQ | PLL recal event (assertion of DSISRecal signal from the DSI PLL Control module) |
| PLL_UNLOCK_IRQ | PLL unlock event (deassertion of DSISLock signal from the DSI PLL Control module) |
| PLL_LOCK_IRQ | PLL lock event (assertion of DSISLock signal from the DSI PLL Control module) |
| VIRTUAL_CHANNEL3_IRQ | Virtual channel #3 Error signaling from DSI Virtual Channel3: The interrupt is triggered when an error is received from DSI Virtual Channel3 (events are defined in DSI_VC3_IRQENABLE). |
| VIRTUAL_CHANNEL2_IRQ | Virtual channel #2 Error signaling from DSI Virtual Channel2: The interrupt is triggered when an error is received from DSI Virtual Channel2 (events are defined in DSI_VC2_IRQENABLE). |
| VIRTUAL_CHANNEL1_IRQ | Virtual channel #1 Error signaling from DSI Virtual Channel1: The interrupt is triggered when an error is received from DSI Virtual Channel1 (events are defined in DSI_VC1_IRQENABLE). |
| VIRTUAL_CHANNEL0_IRQ | Virtual channel #0 Error signaling from DSI Virtual Channel0: The interrupt is triggered when an error is received from DSI Virtual Channel0 (events are defined in DSI_VC0_IRQENABLE). |

Table 12-24 indicates the DSI complex I/O interrupt events.

Table 12-24. DSI Complex I/O Interrupts

| Interrupt Name | Description |
|------------------------|--|
| ULPSActiveNot_ALL0_IRQ | All signals ULPSActiveNOT are 0 |
| ULPSActiveNot_ALL1_IRQ | All the ULPSActiveNOT signals corresponding to the lanes with TXULPSExit being high are high |
| STATEULPS3_IRQ | Lane #3 in ultralow-power state |
| STATEULPS2_IRQ | Lane #2 in ultralow-power state |
| STATEULPS1_IRQ | Lane #1 in ultralow-power state |
| ERRCONTROL3_IRQ | Control error for lane #3 |
| ERRCONTROL2_IRQ | Control error for lane #2 |
| ERRCONTROL1_IRQ | Control error for lane #1 |
| ERRESC3_IRQ | Escape entry error for lane #3(edge trigger interrupt) |
| ERRESC2_IRQ | Escape entry error for lane #2 (edge trigger interrupt) |
| ERRESC1_IRQ | Escape entry error for lane #1 (edge trigger interrupt) |
| ERRCONTENTIONLP1_1_IRQ | Contention LP1 error for lane #1 |
| ERRCONTENTIONLP0_1_IRQ | Contention LP0 error for lane #1 |
| ERRCONTENTIONLP1_2_IRQ | Contention LP1 error for lane #2 |
| ERRCONTENTIONLP0_2_IRQ | Contention LP0 error for lane #2 |
| ERRCONTENTIONLP1_3_IRQ | Contention LP1 error for lane #3 |
| ERRCONTENTIONLP0_3_IRQ | Contention LP0 error for lane #3 |
| ERRSYNCESC3_IRQ | Low power Data transmission synchronization error for lane #3 |
| ERRSYNCESC2_IRQ | Low power Data transmission synchronization error for lane #2 |
| ERRSYNCESC1_IRQ | Low power Data transmission synchronization error for lane #1 |

NOTE: The error contention signals for DX and DY signals of each lane are ORed together.

Table 12-25 indicates the DSI VCs interrupt events

Table 12-25. DSI Virtual Channel Interrupts

| Interrupt Name | Description |
|-----------------------|---|
| ECC_CORRECTION_IRQ | Virtual channel - ECC has been used to correct a 1-bit error (short and long packet only). Indicates whether a 1-bit error correction occurred using the ECC. |
| PACKET_SENT_IRQ | Indicates that a packet has been sent. It is used when BTA manual mode is used |
| CS_IRQ | Virtual channel - Check-Sum of the payload mismatch detection |
| FIFO_RX_OVF_IRQ | RX FIFO overflow. The FIFO used on the L4 interconnect slave port for buffering the data received on the DSI link has overflowed |
| FIFO_TX_OVF_IRQ | TX FIFO overflow. The FIFO used on the L4 interconnect slave port for buffering the data received on the L4 interconnect slave port has overflowed |
| BTA_IRQ | Bus turnaround is received from the peripheral (the VC ID used for the last BTA request transfer to the peripheral is used to determine which VC is used to flag the interrupt) |
| ECC_NO_CORRECTION_IRQ | ECC error (short and long packets). No correction of the header because of more than 1-bit error |
| FIFO_TX_UDF_IRQ | TX FIFO underflow. The FIFO used on the slave port for buffering the data received on the L4 interconnect port has under-flowed in the middle of a packet transfer |

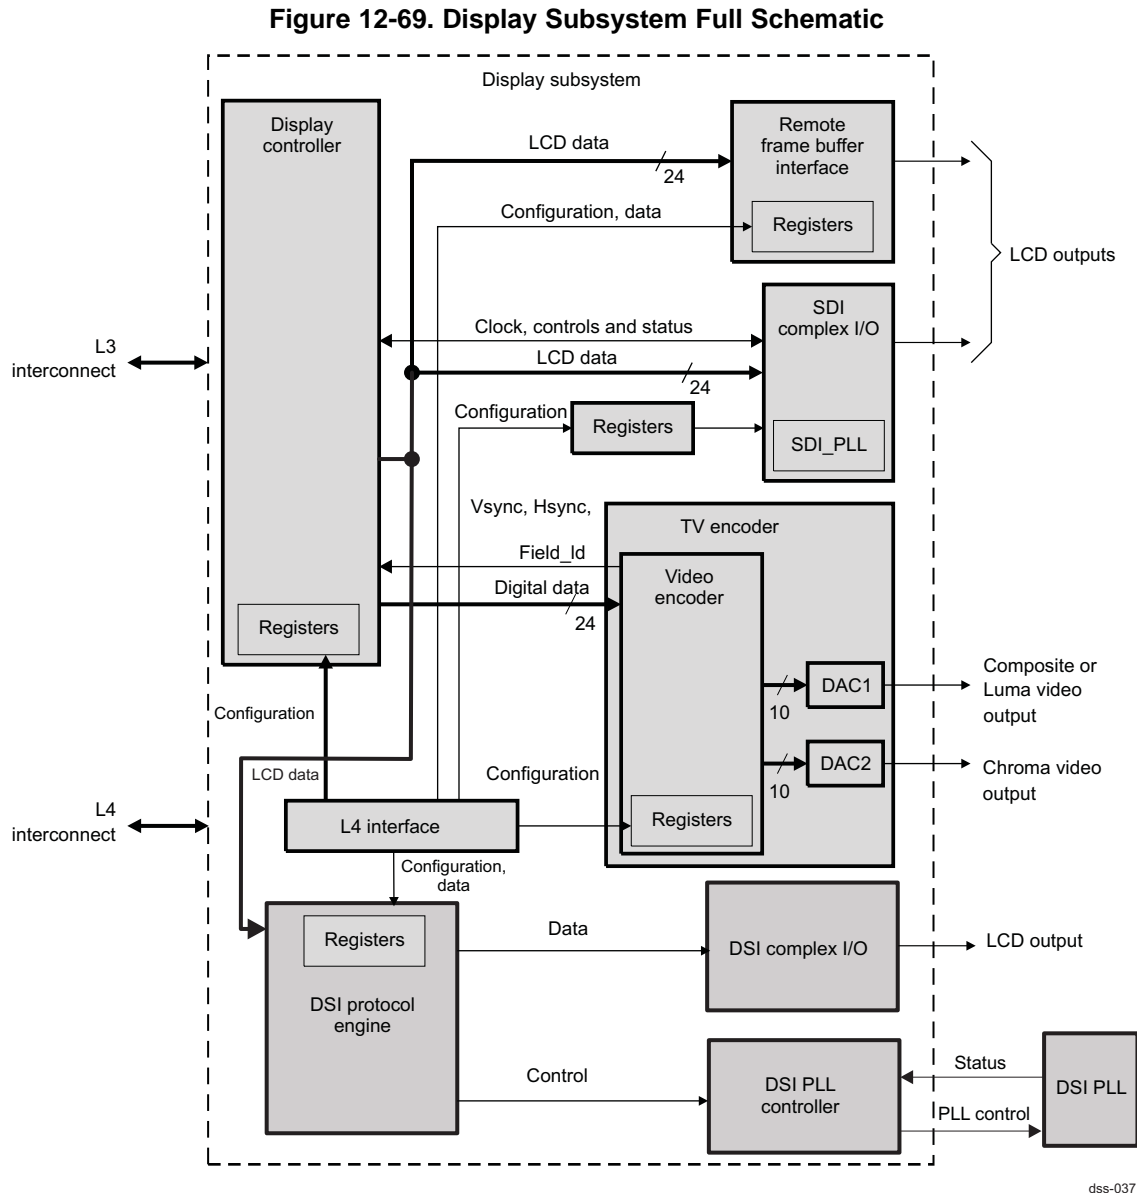

12.4 Display Subsystem Functional Description

This section describes the functionalities of the LCD and TV display supports by describing the following modules: Display controller, DSI protocol engine, DSI PLL controller, DSI complex I/O, RFBI, SDI, and video encoder.

The functionalities of the display controller are common to both LCD and TV data paths; the RFBI and SDI functionalities are LCD-specific; and the video encoder functionalities are specific to the TV set.

12.4.1 Block Diagram

Figure 12-69 is a schematic of the display subsystem.

12.4.2 Display Controller Functionalities

The display controller can read and display the encoded pixel data stored in memory (see Figure 12-70).

Figure 12-70. Display Controller Architecture Overview

dss-038

Several processes can be configured to manage the graphics pipeline (palette, gamma table correction) and video pipeline (color space conversion, upsampling, downsampling, overlay, and transparency features).

The internal timing generator logic generates the LCD input signals. The external timing generator generates the appropriated signals to drive the digital output. The data from the two overlay managers are sent on the two concurrent 24-bit buses outside the display controller module. The memory accessed by the display controller is either the SDRAM memory or the SRAM memory.

12.4.2.1 Display Modes

12.4.2.1.1 LCD Output

The display subsystem supports two types of display technologies (both monochrome and color modes):

- Passive matrix displays
- Active matrix displays

The passive matrix display mode supports 3375 possible colors, allowing 16, 256, or 3375 colors to be displayed in each frame, depending on the color depth. The monochrome LCD has 15 grayscale levels available.

In active matrix display mode, the configuration of colors depends on the color depth:

- 24 BPP supports 16,777,216 colors.
- 18 BPP supports 262,144 colors.
- 16 BPP supports 65,536 colors.
- 12 BPP supports 4096 colors.

12.4.2.1.2 Digital Output

The digital output is always a 24-bit RGB value based on an external pixel request.

12.4.2.2 Graphics Pipeline

The graphics pipeline is connected to the graphics FIFO controller for the input port and to the two overlay managers (LCD and digital). It consists of one 256-entry palette and some programmable replication logic. The replication logic is used to convert the RGB pixels, excluding the RGB24 format, into RGB24 format based on user programming (replication of the most-significant bits [MSBs] for the RGB24 LSBs or use of 0s). The first unit connected to the input port of the graphics pipeline is the replication logic used for RGB pixels, then the second unit is the palette for concerned pixels.

12.4.2.2.1 Graphics Memory Format

The supported formats for the graphics layer are CLUT bitmaps (1-, 2-, 4-, and 8-BPP) and true color bitmaps in RGB formats (12-, 16-, and 24-BPP [packet and nonpacket RGB24]) and in ARGB or RGBA formats (ARGB 16-, and 32-BPP, and RGBA 32-BPP) as follows:

- BITMAP 1-BPP data memory organization (CLUT) (little endian)

- BITMAP 1-BPP data memory organization (CLUT) (little endian + nibble mode)

- BITMAP 1-BPP data memory organization (CLUT) (big endian)

- BITMAP 1-BPP data memory organization (CLUT) (big endian + nibble mode)

- BITMAP 2-BPP data memory organization (CLUT) (little endian)

12.4.2.2.2 Color Look-Up Table/Gamma Table

The graphics path supports the palette/gamma table. [Figure 12-71](#) shows the internal architecture of the color look-up/gamma table.

The palette is split into three memories of 256-bit x 8-bit entries. For bitmap (CLUT) indexes, the same value (1-, 2-, 4-, or 8-BPP) indexes the three memories. For gamma curve correction, each R, G, and B component indexes the corresponding memory to combine the three gamma curve values into a 24-bit value. The table can be reloaded every frame, once or never (at the beginning of the frame before fetching the pixels for the graphics and/or video windows).

Figure 12-71. Palette/Gamma Correction Architecture

12.4.2.2.1 Color Look-Up Table

The palette mode uses the encoded pixel values from the input graphics FIFO as pointers to index the 24-bit-wide palette: 1-BPP pixels address 2 palette entries, 2-BPP pixels address 4 palette entries, 4-BPP pixels address 16 palette entries, and 8-BPP pixels address 256 palette entries.

When a palette entry is selected by the encoded pixel value, the content of the entry is sent to the color/grayscale space/time base passive matrix dithering circuit, or to the color time base active matrix dithering circuit.

In the color mode, the value within the palette is made up of three 8-bit fields, one for each color component (red, green, and blue). For color operation, an individual frame is limited to a selection of 256 colors (the number of palette entries). In the monochrome mode, only one 8-bit value is present.

After passing through the palette, 256 gray scales and 16,777,216 colors are numbers obtained. A redundancy introduced in the dithering logic step reduces these numbers when displaying. For passive matrix panels, the colors are limited to 15 gray scales and 3375 colors.

- Passive matrix technology
The palette is bypassed in 12, 16, and 24 BPP. The palette is not used.
- Active matrix technology
The palette is bypassed in 12, 16, and 24 BPP, allowing up to $2^{24} = 16,777,216$ colors to be displayed.

12.4.2.2.2 Gamma Table

In the gamma curve mode, the selected encoded pixel values based on the color keys from the video or graphics paths are sent to the gamma curve table. The mode is available only if the color look-up palette is not used for graphics. The output of the gamma curve processing is always sent to the LCD output. It is not available on digital output.

Each component of encoded pixel value is used as a pointer to index 1 out of 256 24-bit gamma curve entries in the table. Each 8-bit component is replaced with the 8-bit table value corresponding to an R, G, or B component.

12.4.2.2.2.1 Replication Logic

The replication logic increases the color depth of the graphics and video encoded pixels (from true color RGB 12-, and 16-BPP to 24-BPP). The encoded value is shifted to the 24-bit alignment. The MSB bits are copied to the LSB missing ones. Then the graphics are merged with the video data based on the transparency color keys. When the replication logic is not selected, the encoded pixel values are shifted to the MSB boundary of the 24-bit format. The missing bit values are filled up with 0s.

This is an example for RGB16 extension:

- Original 16-BPP data:

- If replication logic is ON:

- If replication logic is OFF:

12.4.2.3 Video Pipeline

The video pipeline is connected to the video FIFO controller for the input port and to the two overlay managers (LCD and digital). It consists of the Re-Sampling unit, the Color Space Conversion Unit, and some programmable replication logic. The replication logic is used to convert the RGB pixels, excluding the RGB24 format, into RGB24 format based on user programming (replication of the MSBs for the RGB24 LSBs or use of 0s). The first unit connected to the input port of the video pipeline is the Re-Sampling Unit, then the replication logic used for RGB pixels, then the Color Space Conversion Unit for YUV422 pixels.

12.4.2.3.1 Video Memory Formats

The display subsystem supports the following formats for the video layer: YUV2, UYVY, RGB12, RGB16, RGB24 (non-packed and packed formats), ARGB16 (video channel 2 only), ARGB32 (video channel 2 only), and RGBA32 (video channel 2 only).

- RGB 12-BPP data memory organization (little endian)

- RGB 12-BPP data memory organization (big endian)

- RGB 16-BPP data memory organization (little endian)

- RGB 16-BPP data memory organization (big endian)

- ARGB 16-BPP data memory organization (little endian + video 2 channel only)

- ARGB 16-BPP data memory organization (big endian + video 2 channel only)

- RGB 24-BPP data memory organization (little or big endian)

- RGB 24-BPP packet data memory organization (little or big endian)

- ARGB 32-BPP data memory organization (little or big endian + video 2 channel only)

- RGBA 32-BPP data memory organization (little or big endian + video 2 channel only)

- UYVY 4:2:2 data memory organization (little endian)

- UYVY 4:2:2 data memory organization (big endian)

- YUV2 4:2:2 data memory organization (little endian)

- YUV2 4:2:2 data memory organization (big endian)

12.4.2.3.2 Color Space Conversion

The color space conversion module converts the video-encoded pixel values from YCbCr 4:2:2 format into RGB24. [Figure 12-72](#) and [Figure 12-73](#) detail the YCbCr 4:2:2 conversion to YCbCr 4:4:4 depending on the rotation parameters.

Figure 12-72. YCbCr 4:2:2 to YCbCr 4:4:4 (0- or 180-Degree Rotation)

dss-061

Figure 12-73. YCbCr 4:2:2 to YCbCr 4:4:4 (90- or 270-Degree Rotation)

dss-060

The interpolation of the missing chrominance component is given by the equation in [Figure 12-74](#).

Figure 12-74. Interpolation of the Missing Chrominance Component

$$Cb_n(YCbCr\ 444) = \frac{Cb_{n-1}(YCbCr\ 422) + Cb_{n+1}(YCbCr\ 422)}{2} \text{ (n odd)}$$

$$Cr_n(YCbCr\ 444) = \frac{Cr_{n-1}(YCbCr\ 422) + Cr_{n+1}(YCbCr\ 422)}{2} \text{ (n odd)}$$

dss-E062

First, to convert the YCbCr 4:2:2 encoded pixel values into YCbCr 4:4:4 format, the missing chrominance samples (Cb and Cr) are interpolated using the average values of the two closest values on the same line (1/2, 1/2) or are repeated from the second pixel in the same 32-bit container.

- In case of rotation 0-degree, for the last pixel, the chrominance samples are duplicated using the values from the previous pixel; otherwise, the chrominance samples are averaged using the two adjacent values.
- In case of 180-degree rotation, for the first pixel the chrominance samples missing are duplicated from the adjacent pixel; otherwise, the chrominance samples are averaged using the two adjacent values.
- In case of rotation 90- and 270-degree, the missing chrominance components are duplicated from the adjacent pixel in the same 32-bit container.

In case of 5-tap configuration for the vertical filtering, the missing chrominance samples are always duplicated using the second chrominance samples in the same 32-bit value.

Then the pixels are converted from YCbCr color space into the RGB color space, because the output format of the color space conversion is RGB24 (8-bit value per component: Red, green, and blue). The following matrices show the 11-bit coefficients registers used to convert from YCbCr 4:4:4 into RGB24. Users set the coefficients according to the standard used to encode the pixel data in YCbCr color space.

In case of resampling, the YUV422 format is converted into YUV444. The YUV422-to-YUV444 processing is bypassed in the color space conversion unit.

If the active range for the luminance samples (Y) is [16235] and [16240] for the chrominance samples (Cb and Cr), the values of R, G, and B output components are clipped to the range [0:255]. The equation shown in [Figure 12-75](#) gives the 11-bit coefficients of the YCbCr to RGB color space conversion.

Figure 12-75. YCbCr to RGB Registers (VIDFULLRANGE=0)

$$\begin{bmatrix} R \\ G \\ B \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} RY & RCr & RCb \\ GY & GCr & GCb \\ BY & BCr & BCb \end{bmatrix} * \begin{bmatrix} Y - 16 \\ Cr - 128 \\ Cb - 128 \end{bmatrix}$$

dss-E063

If the active range for the luminance samples (Y) and chrominance samples (Cb and Cr) is [0:255], the values of R, G, and B output components are clipped to the range [0:255]. The equation shown in [Figure 12-76](#) gives the 11-bit coefficients of the YCbCr-to-RGB color space conversion.

Figure 12-76. YCbCr to RGB Registers (VIDFULLRANGE=1)

$$\begin{bmatrix} R \\ G \\ B \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} RY & RCr & RCb \\ GY & GCr & GCb \\ BY & BCr & BCb \end{bmatrix} * \begin{bmatrix} Y \\ Cr - 128 \\ Cb - 128 \end{bmatrix}$$

dss-E064

[Figure 12-77](#) describes the computation for the calculation of the R component. The same computation applies for the G and B components:

Figure 12-77. Color Space Conversion Macro-Architecture

dss-065

12.4.2.3.3 Hardware Cursor

The video layer can be used to display the hardware cursor. The encoded pixel data for the cursor image are in RGB12, RGB16 or RGB24 formats and the color space conversion block is bypassed. The transparency color key can be used when a non rectangle shape is used.

The alpha blending can be used to show a partial transparent cursor. When the alpha blender is enabled, the graphics layer is on top of the video layers. The cursor uses the graphics layer. The pixel alpha blending or the transparency color key can be used.

12.4.2.3.4 Up-/Down-Sampling

The video layer has a dedicated resizing block to upsample and downsample the video-encoded pixels. The supported input formats from memory are RGB24, RGB16, and YUV422

(RGB12 and all the alpha formats like ARGB and RGBA are not supported)

Users must set the right size and position of the original video before resizing for the upsampled/downsampled video to be inside the display screen boundaries.

The filtering applies on each component independently (R, G, and B).

For the horizontal up-/downsampling, the equation is R component with five taps):

$$R_{out}(n) = \left(\sum_{i=-2}^{i=2} C_i(\Phi) \times R_{in}(n+i) \right) \gg 7$$

dss-E066

(2)

For the vertical up-/downsampling, the equation is R component with three taps):

$$Rout(n) = \left(\sum_{i=-1}^{i=1} Ci(\Phi) \times Rin(n+i) \right) \gg 7 \tag{3}$$

dss-E067

For the vertical up-/downsampling, the equation is R component with five taps):

$$Rout(n) = \left(\sum_{i=-2}^{i=2} Ci(\Phi) \times Rin(n+i) \right) \gg 7 \tag{4}$$

dss-E068

Rout: R component output

$Ci(\Phi)$
dss-E069 : FIR filter coefficients

Rin: R component input

The pixel (n + 1) is older than pixel (n). The line (n + 1) is older than line (n).

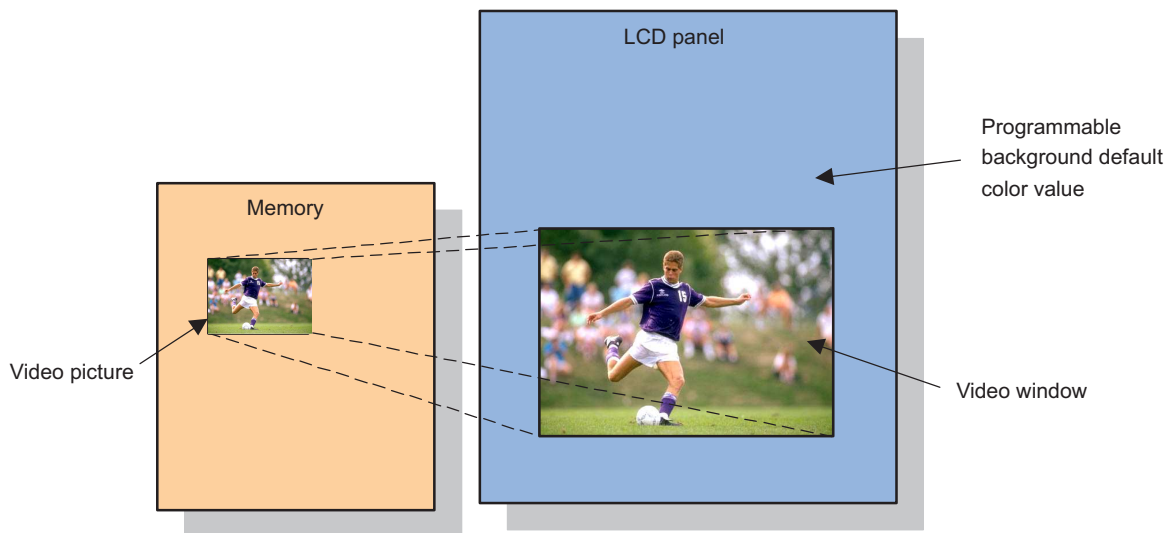

NOTE: The coefficients $Ci()$ depend on the phase between input and output pixels.

NOTE: If the 5-tap resizer is used for RGB16 and YUV422 picture formats, the width of the input picture must be a multiple of 2 pixels and more than 5 pixels.

`DISPC_VIDn_ATTRIBUTES[21] VIDVERTICALTAPS == 1`
`DISPC_VIDn_PICTURE_SIZE[10:0] VIDORGSIZEX > 4 and even`

Figure 12-78 shows an example of video upsampling.

Figure 12-78. Video Upsampling

dss-070

Filter Description

The up/downsampling filter is a poly-phase filter with five taps and eight phases for the horizontal filter and a programmable number of taps (three or five) and eight phases for vertical filter. The upsampling ratio is up to x8. The downsampling ratio using 3-tap configuration is $1/2$. The downsampling ratio using 5-tap configuration is $1/4$. The vertical filter is first applied to the encoded input pixel data; and then the horizontal filter is applied on the resulting pixel values to generate the output pixel values. Figure 12-79 shows the computation for the R component in the case of three coefficients (vertical filtering). The same computation applies to the G and B components.

Figure 12-79. Resampling Macro-Architecture (3-Coefficient Processing)

To determine if the minimum functional clock matches the down sampling ratio and the desired Pixel clock, the following formula must be used in conjunction with [Table 12-26](#) and [Table 12-27](#).

Ratio V when performing a vertical down-sampling only

$$h_ratio = \frac{DISPC_SIZE_LCD.PPL}{DISPC_VID_SIZE.VidSizeX}$$

$$v_ratio = \frac{DISPC_VID_PICTURE_SIZE.VidOrgSizeY}{DISPC_VID_SIZE.VidSizeY}$$

$$Ratio = \frac{v_ratio}{2 \times h_ratio} \quad \text{If } 1 < v_ratio \leq 2$$

$$Ratio = \max\left(\frac{v_ratio}{2 \times h_ratio}, \frac{v_ratio - 2}{2 \times (h_ratio - 1)}\right) \quad \text{If } 2 < v_ratio \leq 4$$

dss_swpu108-E135

NOTE: For frequency ratio calculation on the TV output, it is correct to replace [DISPC_SIZE_LCD](#) with [DISPC_SIZE_DIG](#).

When the down-sampling ratio is below 0.5, it is not possible to use a video in full screen.

Ratio H when performing a horizontal down-sampling only

$$Ratio = \frac{DISPC_VID_PICTURE_SIZE.VidOrgSizeX}{DISPC_VID_SIZE.VidSizeX}$$

dss_swpu108-E136

Ratio H+V when performing a horizontal and vertical down-sampling

Ratio = max (horizontal Ratio, vertical Ratio) as previously defined.

Table 12-26. Functional Clock Frequency Requirement in RGB16 & YUV422—Active Matrix Display

| Minimum Functional Clock (MHz) | | Horizontal Resampling | | | | |
|--------------------------------|------------------|-----------------------|------------|------------|------------|------------|
| | | Off | Up | 1:1 – 1:2 | 1:2 – 1:3 | 1:3 – 1:4 |
| Vertical Resampling | Off | AxPCLK | AxPCLK | 2xPCLK | 3xPCLK | 4xPCLK |
| | Up | AxPCLK | AxPCLK | 2xPCLK | 3xPCLK | 4xPCLK |
| | 3-tap 1:1 to 1:2 | 2xPCLK | 2xPCLK | 4xPCLK | 6xPCLK | 8xPCLK |
| | 5-tap 1:1 to 1:4 | RatioxPCLK | RatioxPCLK | RatioxPCLK | RatioxPCLK | RatioxPCLK |

With A = 1 in case all the data and synchronization signals are asserted and deasserted on the rising edge of the PCLK; otherwise, A = 2.

Table 12-27. Functional Clock Frequency Requirement in RGB24—Active Matrix Display

| Minimum Functional Clock (MHz) | | Horizontal Resampling | | | | |
|--------------------------------|------------------|-----------------------|------------|--------------|--------------|--------------|
| | | Off | Up | 1:1 – 1:2 | 1:2 – 1:3 | 1:3 – 1:4 |
| Vertical Resampling | Off | AxPCLK | AxPCLK | 2xPCLK | 3xPCLK | 4xPCLK |
| | Up | AxPCLK | AxPCLK | 2xPCLK | 3xPCLK | 4xPCLK |
| | 3-tap 1:1 to 1:2 | 2xPCLK | 2xPCLK | 4xPCLK | 6xPCLK | 8xPCLK |
| | 5-tap 1:1 to 1:4 | RatioxPCLK | RatioxPCLK | 2xRatioxPCLK | 2xRatioxPCLK | 2xRatioxPCLK |

With A = 1 in case all the data and synchronization signals are asserted and deasserted on the rising edge of the PCLK; otherwise, A = 2.

Use case example:

An input picture of 1024*768 is scaled to an output picture of size of 800*600 and displayed onto a LCD of resolution 1280*768 at a PCLK of 74.25 MHz with a DSS functional clock of 133 MHz.

In this example, a H+V down-sampling is done on the input picture. Firstly the Ratio V and H are determined and the resulting maximum value is taken to calculate the functional clock frequency required.

Ratio V: $h_ratio = 1.6$ and $v_ratio = 1.28$ then Ratio = 0.4

Ratio H: Ratio = 1.28

Ratio H+V: Ratio = $\max(1.28, 0.4) = 1.28$

In this use case, the horizontal and vertical down sampling range are 1:1–1:2. The 3-tap or 5-tap configuration can be taken into consideration. Therefore, from [Table 12-26](#) and [Table 12-27](#), If in RGB16-YUV422:

- 3-taps → DSS functional clock = 4 * PCLK = 297 MHz
- 5-taps → DSS functional clock = Ratio * PCLK = 95.36 MHz

If in RGB24,

- 3-taps → DSS functional clock = 4 * PCLK = 297 MHz
- 5-taps → DSS functional clock = 2 * Ratio * PCLK = 190.72 MHz

In this use case, the pixel format supported is RGB16-YUV422 in a 5-tap configuration.

12.4.2.4 Overlay Support**CAUTION**

Enabling overlay optimization (setting the `DSS.DISPC_CONTROL` [12] `OVERLAYOPTIMIZATION` bit) if no overlay region effectively exists (the `DSS.DISPC_VIDn_ATTRIBUTES` [0] `VIDENABLE` bit is cleared, with $n = 1, 2$) leads to unpredictable behavior. The overlay optimization feature must be enabled only when an overlay area exists. Before enabling the overlay optimization, the `DSS.DISPC_GFX_WINDOW_SKIP`[31:0] `GFXWINDOWSKIP` bit field must be first set according to the video1 and graphics windows overlap.

The overlay mechanism consists of displaying more than one layer (graphics and video layers) using rules based on priority and transparency color keys.

When the pixel format is ARGB or RGBA, the color key match logic uses only the RGB value defined by ARGB or RGBA. The alpha blending factor is ignored.

The overlay managers are based on the same rules for priority and transparency color keys (see [Figure 12-82](#)).

Each data pipeline is assigned a single overlay related to a single display controller output.

The overlay manager is connected to all three outputs of the pipelines (graphics, video1 and video2). The output of the LCD overlay manger is connected to the Spatial/Temporal Dithering, and Passive Matrix units and back to the palette unit in the case of Gamma correction.

12.4.2.4.1 Priority Rule

The overlay manager can be configured in two distinct modes:

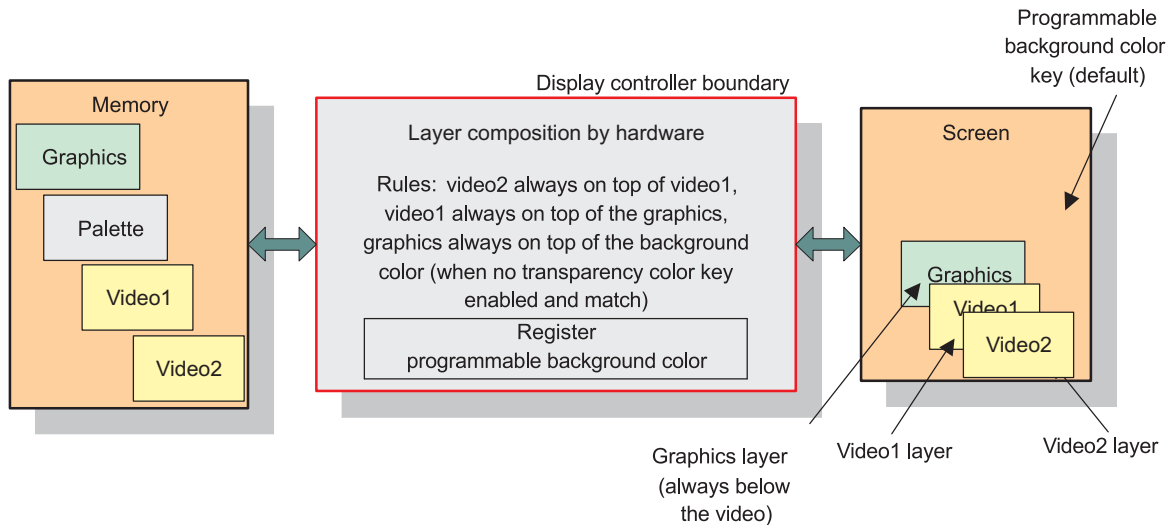

- Alpha mode (only source color key with the graphics layer)
- Normal mode (no alpha support)

The following rules apply in normal mode:

The video1 layer is always on top of the graphics layer. The video2 layer is always on top of the video1 and graphics. The display controller reads the data for each buffer from the system memory and, depending on the transparency color key values, displays either the pixels in the video layer, the pixels in the graphics layer, or the solid background color.

Each layer can have any size up to full-display screen. If there are no graphics or video-encoded pixels at a specific position, the programmable, solid background color appears (see [Figure 12-84](#)).

Figure 12-80. Overlay Manager in Normal Mode

dss-072

Figure 12-81. Display Attributes in Normal Mode

dss-073

The following rules apply in alpha mode:

The video2 layer is always on top of the video1 layer. The graphics layer is always on top of the video1 and video2. The display controller reads the data for each buffer from the system memory and, depending on the transparency color key values, displays either the pixels in the video layer, the pixels in the graphics layer, or the solid background color.

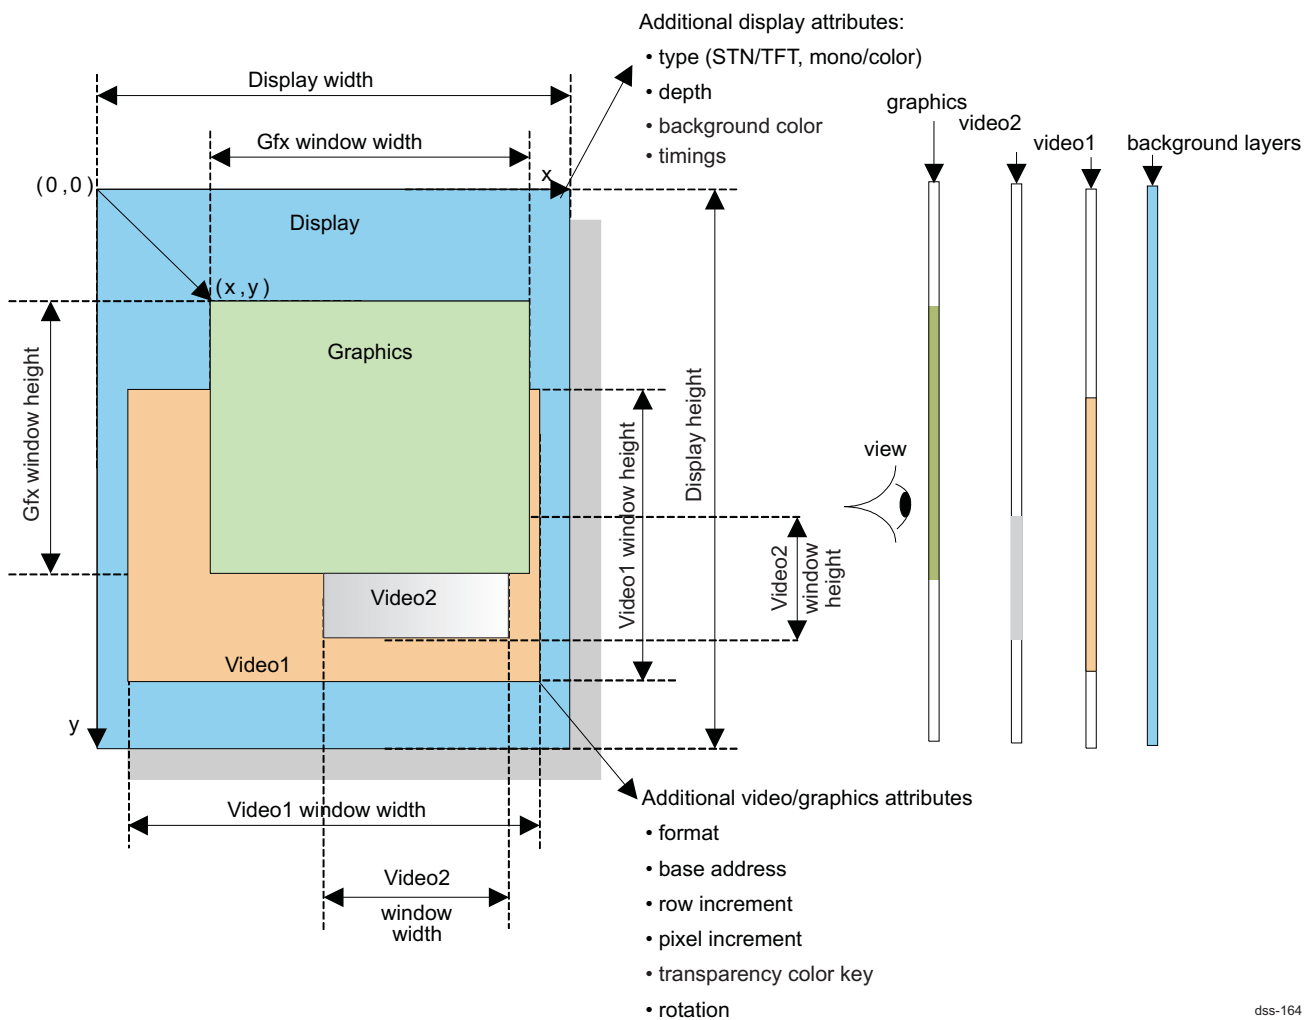

Each layer can have any size up to full-display screen. If there are no graphics or video-encoded pixels at a specific position, the programmable, solid background color appears (see [Figure 12-84](#)).

Figure 12-82. Overlay Manager in Alpha Mode

dss-163

Figure 12-83. Display Attributes in Alpha Mode

dss-164

Figure 12-84 shows the alpha blending processing in detail.

Figure 12-84. Alpha Blending Macro Architecture

dss-165

NOTE: "1-alpha" operator corresponds to the basic 1's complement operation.

The alpha blending value is defined by the pixel value (ARGB or RGBA formats). A global alpha blending value can be defined and used in combination with the pixel alpha blending value. If the pixel format contains no alpha blending value, the pixel alpha value is considered to be 0xFF.

In case of ARGB-444, the alpha blending is defined using a 4-bit value. It is converted into an 8-bit value by duplicating the 4-bit value. Table 12-28 details the alpha blending 4-bit values and the corresponding blending percentage.

Table 12-28. Alpha Blending 4-Bit Values

| Alpha Blending 4-Bit Value (ARGB-444) | Alpha Blending 8-Bit Value (Converted Value) | % Blending |
|---------------------------------------|--|--------------------|
| 0x0 | 0x00 | 100% (transparent) |
| 0x1 | 0x11 | 93.33% |
| 0x2 | 0x22 | 86.6% |
| ... | ... | ... |
| 0xE | 0xEE | 6.6% |
| 0xF | 0xFF | 0% (opaque) |

12.4.2.4.2 Transparency Color Keys

12.4.2.4.2.1 Normal Mode

This section describes the features available in normal mode.

The two transparency color keys are the video source transparency color key and the graphics destination transparency color key. The encoded pixel color value is compared to the transparency color key. For CLUT bitmaps, the palette index is compared to the transparency color key and not to the palette value pointed out by the palette index.

NOTE: The video source transparency color key and graphics destination transparency color key cannot be active at the same time.

- Video source transparency color key value:

The video source transparency color key value defines the encoded pixel data considered as the transparent pixel. The encoded pixel values with the source color key value are pixels not visible on the screen, and the underlayer encoded pixel values or solid background color are visible.

The video source transparency color key can be used only if the color space conversion and the up-/down-scaling modules are disabled. The format of the data is RGB 16. (This feature handles the hardware cursor displayed by one of the video layers.)

To enable the video source transparency color key, set to 0x1 the DSS.DISPC_CONFIG[11] TCKLCDSELECTION bit for LCD output or the DSS.DISPC_CONFIG[13] TCKDIGSELECTION bit for digital output. Program the DSS.DISPC_CONFIG[10] TCKLCDENABLE bit (LCD output) or the DSS.DISPC_CONFIG[12] TCKDIGENABLE bit (digital output) to enable or disable the transparency color key.

An example is shown in [Figure 12-85](#): The video source transparency is applied on video1 (VID1) and video2 (VID2) layers. The pixels with the transparency color key are not displayed; instead, underlying layers are shown.

Figure 12-85. Video Source Transparency Example

dss-074

- Graphics destination transparency color key value:

The graphics destination transparency color key value defines the encoded pixels in the video layers to be displayed. The encoded pixel values with the destination color key value are pixels not visible on the screen and the pixels different from the transparency color key are displayed over the video layers. The destination transparency color key is applicable only in the graphics region when graphics and video overlap; otherwise, the destination transparency color key is ignored.

To enable the graphics destination transparency color key, set to 0x0 the DSS.DISPC_CONFIG[11] TCKLCDSELECTION bit for LCD output or the DSS.DISPC_CONFIG[13] TCKDIGSELECTION bit for digital output. Program the DSS.DISPC_CONFIG[10] TCKLCDENABLE bit (LCD output) or the DSS.DISPC_CONFIG[12] TCKDIGENABLE bit (digital output) to enable or disable the transparency color key.

An example is shown in [Figure 12-86](#): The destination transparency is applied on graphics (GFX) layer and the pixels without the transparency color key are displayed over the overlying layers.

Figure 12-86. Graphics Destination Transparency Example

dss-075

12.4.2.4.2 Alpha Mode

This section describes the features available in alpha mode.

Only the graphics source transparency color key is available. The encoded graphics pixel color value is compared to the transparency color key. The encoded pixel values with the source transparency key are not visible and the under-layer encoded pixel values or solid background color are visible. To enable the graphics source transparency color key, set to 0x0 the DSS.DISPC_CONFIG[11] TCKLCDSELECTION bit for LCD output or the DSS.DISPC_CONFIG[13] TCKDIGSELECTION bit for digital output. Program the DSS.DISPC_CONFIG[10] TCKLCDENABLE bit (LCD output) or the DSS.DISPC_CONFIG[12] TCKDIGENABLE bit (digital output) to enable or disable the transparency color key. In the case of CLUT bit maps, the palette index is compared to the transparency color key and not the palette value pointed out by the palette index.

12.4.2.4.3 Overlay Optimization (Only Available in Normal Mode)

The display controller can be configured to take advantage of the fact that the graphics pixels under video window 1 are not visible when the transparency color key is not used. The optimization can be selected to reduce the bandwidth used to fetch the pixels for graphics. The color key must be disabled. The graphics pixels under the video window 1 are not fetched from system memory. At least the video window 1 and the graphics window must be enabled. The following graphic formats are supported: RGB (RGB16 and RGB24 packed and unpacked), YUV422, and BITMAP 8. The formats BITMAP 1, 2, and 4 are not supported. The video format can be RGB (RGB16, RGB24 packed and unpacked, and YUV422 formats). The DMA engine does not fetch the unnecessary graphics pixels to avoid extra bandwidth use. Only visible pixels from graphics and video buffers in system memory are fetched and displayed by the display controller.

12.4.2.5 Active/Passive Matrix Display Data Path

For active matrix display data path, the following blocks are serial and each of them can be bypassed:

- Color phase rotation
- Spatial/temporal dithering
- Multiple cycle data format

For passive matrix display data path, the following blocks are serial and each of them can be bypassed:

- Color phase rotation

- Spatial/temporal dithering
- Passive matrix technology

12.4.2.5.1 Color Phase Rotation

The Color Phase Rotation (CPR) can be used to correct the LCD output colorimetry in case of non pure white backlight.

The color phase rotation can be selected for passive matrix and active matrix panel. The logic is integrated after the LCD overlay manager or the palette while using the gamma correction and before the spatial/temporal dithering. The color phase rotation can be selected to correct the nonpure white backlight of the LCD module by using a programmable matrix to convert the 24-bit RGB pixel value into a new 24-bit RGB pixel value. The matrix is programmed through a set of nine 10-bit signed coefficients. The output of the calculation is clipped to [0:255]. The color phase rotation is processed by the equation shown in Figure 12-87.

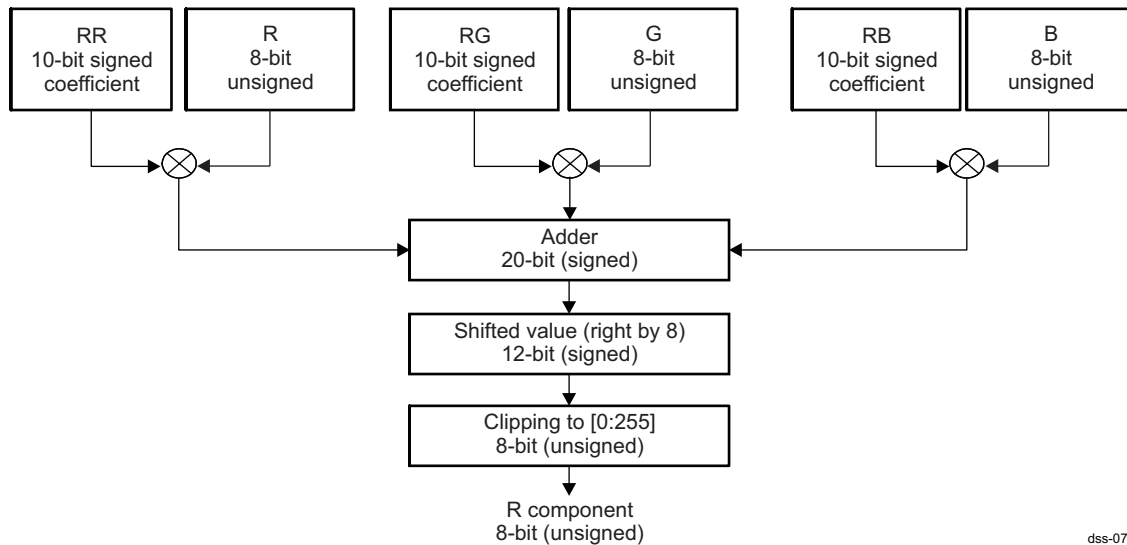

Figure 12-87. Color Phase Rotation Matrix

$$\begin{bmatrix} R_{out} \\ G_{out} \\ B_{out} \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} RR & RG & RB \\ GR & GG & GB \\ BR & BG & BB \end{bmatrix} * \begin{bmatrix} R_{in} \\ G_{in} \\ B_{in} \end{bmatrix}$$

dss-E076

Figure 12-88 shows the color phase rotation macro-architecture.

Figure 12-88. Color Phase Rotation Macro Architecture

12.4.2.5.1.1 Spatial/Temporal Dithering

The spatial/temporal dithering logic can be selected for passive matrix and active matrix panel. The dithering logic is integrated after the color phase rotation and before the TDM and passive matrix units. The spatial/temporal dithering logic can be selected to enhance the quality of the passive matrix and active matrix outputs. The dithering logic can process the pixels over a single frame, two frames, or four frames. In the case of a single frame, only spatial processing is applied. In the case of multiple frames, spatial and temporal processing is applied to the pixels.

- **Passive Matrix Technology:** The passive matrix display dithering logic path is used. The spatial/temporal dithering logic can be selected. When selected, the pixels are preprocessed by the spatial/temporal dithering logic before the passive matrix display dithering logic. The output format of the spatial/temporal dithering logic is RGB 12-bit (not configurable).

- **Active Matrix Technology:** The encoded pixel values are used by spatial/temporal dithering logic to display the data in a lower color depth on the LCD panel. The spatial/temporal dithering algorithm is based on the (x,y) pixel position, the value of removed bits and the frame number. The picture quality is improved when enabling the spatial/temporal dithering logic. When spatial/temporal dithering is not enabled, the three MSBs of the pixel color components are output on the interface data bus if the interface data bus is smaller than the pixel format size. If the interface data bus is wider than the pixel format size, by programming the pixel components replication active/inactive, the MSB is replicated to the LSB of the interface data bus or the LSB is filled with 0s.

12.4.2.5.2 **Passive Matrix Display Dithering Logic**

- **Passive matrix technology**
After the graphics data are merged with the video data from the video layers depending on the transparency status, the result is sent to the color/grayscale space-/time-based dither generator. The monochrome data and each RGB color component are encoded on 4 bits, which are the 4 MSBs of the pixel-encoded component 8-bit value defined by the merge of the graphics data and the video data. These 4-bit values are used to select on the 16 intensity levels. The gray/color intensity is controlled by turning individual pixels on and off at varying period rates, making the average time the pixel is off longer than the average time the pixel is on, thus producing more intense grays/colors. The dithering generator also uses the intensity of adjacent pixels in the calculation to give the screen image a smooth appearance. The proprietary dither algorithm is optimized to provide a range of intensity values that matches the visual perception of color/gray graduations.
- **Active matrix technology**
The passive matrix dithering logic is always bypassed in active displays.

NOTE: If the interface data bus is smaller than the pixel format size, dithering logic can be enabled. If the interface data bus is wider than the pixel format size, the dithering logic cannot be enabled and replication feature can be used.

12.4.2.5.3 **Passive Matrix Display Output FIFO**

- **Passive matrix technology**
The display controller contains a 2-entry by 8-bit-wide output FIFO used to store pixel data before it is driven out to the LCD pins. Each time a modulated pixel value is output from the dither generator, it is placed into a serial shifter. The shifter can be configured to be 4 or 8 bits wide. Single-panel monochrome screens use either four or eight data lines; single-panel color screens use eight data pins.
- **Active matrix technology**
The output FIFO is bypassed in active matrix mode.

12.4.2.5.4 **Multiple Cycle Output Format**

The pixels after the active matrix display processing are formatted on one or multiple cycles (from one to three cycles). The interface width can be 8-, 9-, 12-, or 16-bit. On three cycles, two pixels can concatenate and send to the panel. When the TDM is disabled, the display controller outputs the pixels using the conventional formats: Passive matrix display/active matrix display monochrome/color.

The following example shows an output configuration based on the interface width (8-bit) and the pixel format output (24-bit) (also see [Table 12-29](#)):

- The DSS.DISPC_CONTROL[24:23] TDMCYCLEFORMAT bit field is set to 0x2 (three cycles for one pixel).
- The DSS.DISPC_DATA_CYCLEk (k=0) register is set to 0x00000008 (8 bits from pixel 1 for the first cycle).
- The DSS.DISPC_DATA_CYCLEk (k=1) register is set to 0x00000008 (8 bits from pixel 1 for the second cycle).
- The DSS.DISPC_DATA_CYCLEk (k=2) register is set to 0x00000008 (8 bits from pixel 1 for the third cycle).

Table 12-29. 8-Bit Interface Configuration/24-Bit Mode

| | 24-Bit Mode | | |
|---------|-------------|-----------|-----------|
| | 1st Cycle | 2nd Cycle | 3rd Cycle |
| Data[7] | R0[7] | G0[7] | B0[7] |
| Data[6] | R0[6] | G0[6] | B0[6] |
| Data[5] | R0[5] | G0[5] | B0[5] |
| Data[4] | R0[4] | G0[4] | B0[4] |
| Data[3] | R0[3] | G0[3] | B0[3] |
| Data[2] | R0[2] | G0[2] | B0[2] |
| Data[1] | R0[1] | G0[1] | B0[1] |
| Data[0] | R0[0] | G0[0] | B0[0] |

12.4.2.6 Video Line Buffer

The line buffer size is 1024 x 24-bit. There are six line buffers (1024 x 24-bit) that can be merged into three lines (2048 x 24-bit). [Table 12-30](#) lists the maximum width depending on the TAP configuration and the pixel format.

Table 12-30. Maximum Width Allowed

| Vertical Tap | Pixel Format | Maximum Width (Pixels) |
|--------------|--------------|------------------------|
| 3 | RGB16 | 2048 |
| | RGB24 | |
| | YUV422 | |
| 5 | RGB16 | 1024 |
| | RGB24 | |
| | YUV422 | |

12.4.2.7 Synchronized Buffer Update

A synchronization mismatch between the frame buffer and the display refreshes, named tearing effect, can lead to images that appear to be stretched on the screen. To avoid this, a synchronization mechanism is needed between the display controller and the process that updates the buffer. An interrupt is generated when the display reaches a predefined line number. This PROGRAMMEDLINENUMBER interrupt is a level signal and stays active during the programmed line of the display.

12.4.2.8 Rotation

In case of SDRAM buffer, the display controller accesses the encoded pixels in burst, always considering the consecutive data in memory. The rotation engine (VRFB) in the SDRAM scheduler (SDRC) is in charge of translating the addresses from virtual to physical SDRAM addresses (see , *Memory Subsystem*).

NOTE: It is highly recommended to use the VRFB Rotation engine when possible and not the display subsystem DMA engine for rotating frame buffer to have a good performance in the L3 interconnect and SDRAM memory efficiency.

The rotation using the SMS-VRFB rotation engine is supported for BITMAP8, RGB12 (16-bit container) and ARGB16, RGB16, ARGB16, RGB24 (using 32-bit container) and ARGB32 and RGBA32 and YUV422 (YUV2 and YUYV). The formats not supported are BITMAP1, BITMAP2, BITMAP4 and RGB24 (using 24-bit container).

12.4.2.9 Multiple Buffer Support

Users update the base address of the buffer when the update of the working buffer has finished and is ready to be displayed. The register that contains the base address of the buffer is a shadow register that is read by the hardware at the next Vertical Front Porch (VFP).

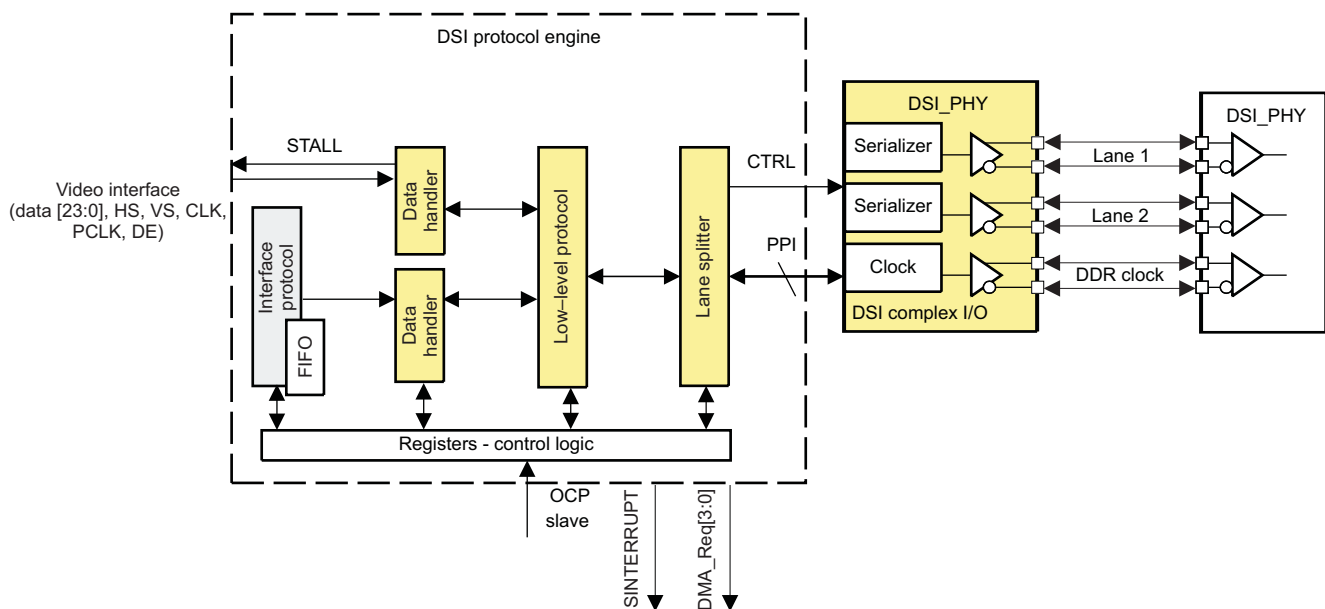

12.4.3 DSI Protocol Engine Functionalities

The DSI protocol engine integrates DSI interface to the display through the DSI DSI_PHY module, L4 interconnect interface and video interface from the display controller. The DSI DSI_PHY or complex I/O module is detailed in Section 12.4.5. The DSI Transmitter (Protocol Engine + PHY) port can be connected to multiple displays using a single DSI host port. The DSI protocol engine controls the DSI PLL Control module detailed in Section 12.4.4. The DSI Transmitter port can be used in video mode or/and command mode.

12.4.3.1 DSI Protocol Architecture

The DSI protocol engine receives data from the video port and/or the L4 interconnect slave port, encapsulates them with the VC ID, generates the ECC and check-sum, and splits the data into byte stream to the DSI_PHY to be sent using the low-speed (LS) or high-speed (HS) protocol. The DSI protocol engine receives data and acknowledge from the display using the same DSI link in case of bidirectional display. Multiple data streams can be interleaved to support multiple panels connected to the same host DSI port. Figure 12-89 details the DSI protocol engine architecture.

Figure 12-89. DSI Protocol Engine

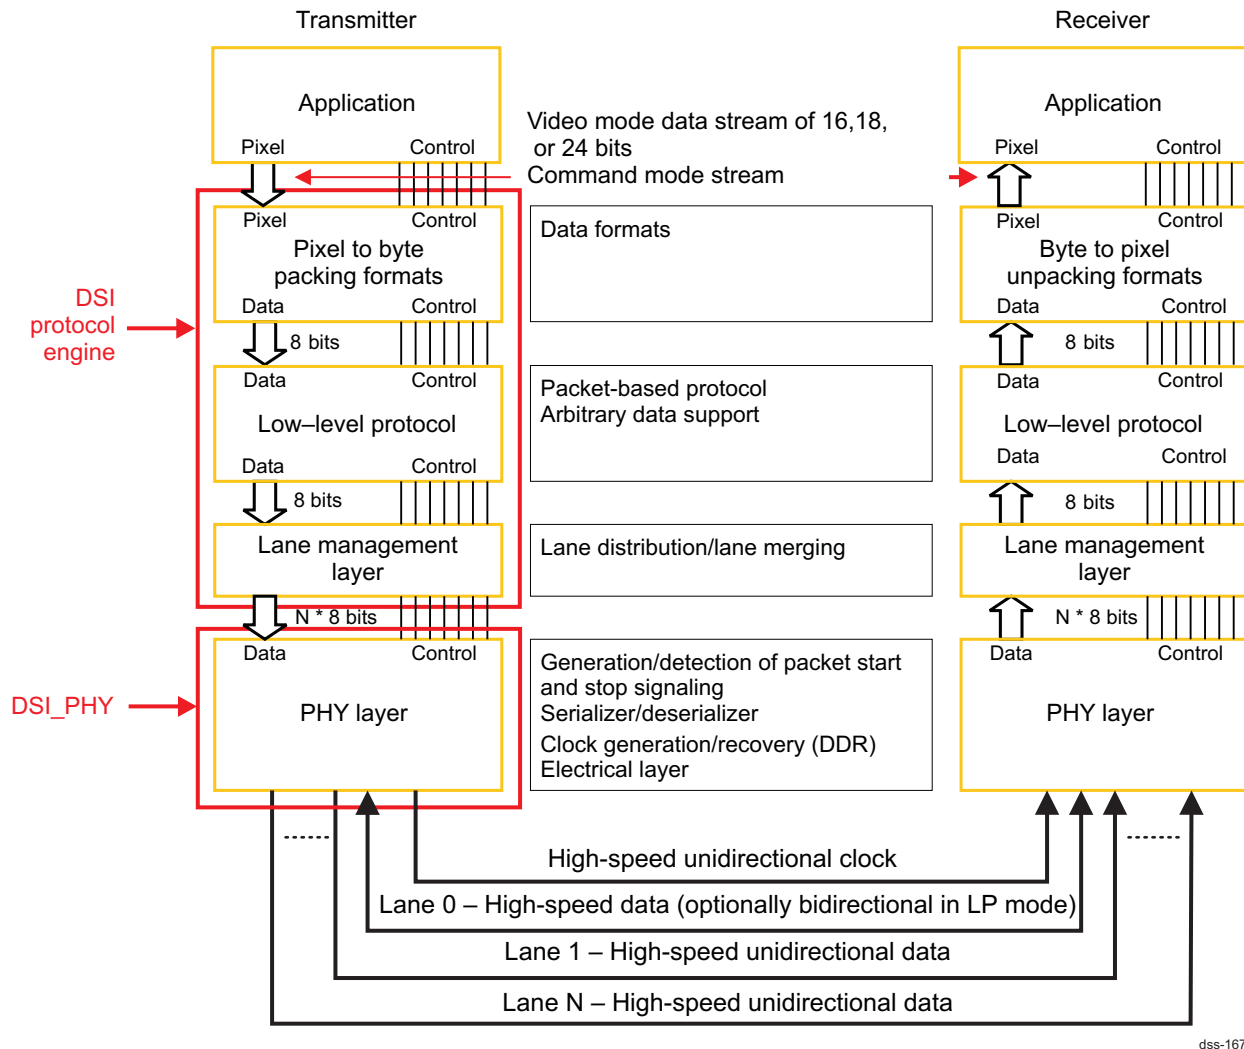

dss-166

NOTE: The order of the PHY pairs (clock and data lanes) is informative. Each PHY pair can be Clock or Data. The DSI complex I/O receives the configuration for pin order and the differential +/- in a pair from the settings in DSS.DSI_COMPLEXIO_CFG1 register.

The DSI serial interface is a bidirectional differential serial interface with data/clock for the physical layer (configured in unidirectional link in case the display module is only unidirectional). The maximum DSI data transfer capacity is 800 Mbps per channel. The speed of the link can be software configured only when the DSI_PHY is in stop state or in ULPS.

Figure 12-90 shows the DSI transmitter/receiver high-level data flow.

Figure 12-90. DSI Transmitter/Receiver Data Flow

dss-167

12.4.3.2 Clock Requirements

The serial clock generated by the DSI host and sent to the display can be a continuous clock. The clock lane supports clock transmission even there is no data to send for displays that require continuous clock. It is software programmed through the `DSS.DSI_CLK_CTRL[13] DDR_CLK_ALWAYS_ON` bit: This bit can be programmed only when the interface is disabled (that is, `DSS.DSI_CTRL[0] IF_EN` bit set to 0).

The peripheral can use two different kinds of clocks. The first one is the DDR clock provided on the clock lane. The second clock is some transitions on the data lane 1 even if there is no valid data to send using low power mode.

The LP clock (TxClkEsc) frequency provided to the DSI complex I/O is in the range of 67% to 150% of the peripheral Low-Power (LP) clock frequency. It is generated internally by the DSI protocol engine module using the DSI functional clock. The DSI functional clock is divided by 1, 2, 3, up to 8191 using the value programmed in the `DSS.DSI_CLK_CTRL[12:0] LP_CLK_DIVISOR` bit field. The LP clock generated from DSI functional clock should be in the range of 20 MHz down to 32 KHz. The duty cycle should be 50/50 (tolerance of 45/55 for maximum value). LP clock frequency visible on the pads (DP xor DN) is half the frequency of TxClkEsc.

The `DSS.DSI_CLK_CTRL[20] LP_CLK_ENABLE` bit is used to enable or disable the clock. When disabled, the value of `DSS.DSI_CLK_CTRL[12:0] LP_CLK_DIVISOR` bit field is ignored and does not have to be programmed by software users.

12.4.3.2.1 Timing Parameters for an LP to HS Transaction

Figure 12-91 shows the timing requirement when switching the data and clock lane state from LP to HS. Table 12-31 lists the LP to HS timing parameters.

Figure 12-91. LP to HS Timing

dss-325

Table 12-31. LP to HS Timing Parameters

| Timing | Description | Register |
|-------------------|--|--|
| T_{LPX} | Length of any low-power state period. The value set in DSI_PHY_CFG1[22:16] TLPX_HALF bit field is half of the T_{LPX} . | DSI_PHY_CFG1[22:16] TLPX_HALF |
| $T_{CLK-PREPARE}$ | Time to drive the CLK lane to LP-00 state, to prepare for HS clock transmission | DSI_PHY_CFG2[7:0] TCLK_PREPARE |
| $T_{CLK-ZERO}$ | Time to drive the CLK lane to HS-0 state before starting the clock | DSI_PHY_CFG1[7:0] TCLK_ZERO |
| $T_{CLK-PRE}$ | Time that the HS clock must be driven before any associated data lane begins the transition from LP to HS mode $T_{CLK-PRE} = DDR_CLK_PRE - T_{LPX} - T_{CLK-PREPARE} - T_{CLK-ZERO}$ | See the MIPI DSI_PHY specification. |
| $T_{HS-PREPARE}$ | Time to drive the data lane to LP-00 state, to prepare for HS packet transmission | DSI_PHY_CFG0[31:24] THS_PREPARE |
| $T_{HS-ZERO}$ | Time to drive the data lane to HS-0 state before the synchronous sequence. $T_{HS-ZERO} = DSI_PHY_CFG0[23:16]$ THS_PREPARE_THS_ZERO - $T_{HS-PREPARE}$ | DSI_PHY_CFG0[23:16] THS_PREPARE_THS_ZERO |

Table 12-31. LP to HS Timing Parameters (continued)

| Timing | Description | Register |
|-----------------------|--|--|
| DDR_CLK_PRE | Time between the CLK lane request assertion and the data request assertion to switch the data lanes to HS | DSI_CLK_TIMING[15:8] DDR_CLK_PRE |
| ENTER_HS_MODE_LATENCY | Time to enter into HS mode. It is critical that $ENTER_HS_MODE_LATENCY = 1 + DIVROUNDUP(2 * TLPX_HALF, 4) + DIVROUNDUP(THS_PREPARE, 4) + DIVROUNDUP(THS_PREPARE_THS_ZERO - THS_PREPARE + 3, 4)$ ⁽¹⁾ | DSI_VM_TIMING7[31:16] ENTER_HS_MODE_LATENCY |

⁽¹⁾ The formula $DIVROUNDUP(value, div)$ is equivalent to $ROUNDUP(value/div)$.

12.4.3.2.2 Timing Parameters for an HS to LP Transaction

Figure 12-92 shows the timing requirement when switching the state of the data and clock lanes from HS to LP. Figure 12-92 lists the HS to LP timing parameters.

Figure 12-92. HS to LP Timing

dss-326

Table 12-32. HS to LP Timing Parameters

| Timing | Description | Register |
|--------------|--|----------|
| T_{HS-EOT} | If EoT is enabled, a delay is added to $EXIT_HS_MODE_LATENCY$ to send the EoT packet. The EoT period depends on the number of data lanes: | |

Table 12-32. HS to LP Timing Parameters (continued)

| Timing | Description | Register |
|----------------------|---|--|
| | 1 data lane = 4 DDR clocks 2 data lanes = 2 DDR clocks | |
| $T_{HS-TRAIL}$ | Time to drive flipped differential state after last payload data bit of a HS transmission burst | DSI_PHY_CFG0[15:8] THS_TRAIL |
| $T_{HS-EXIT}$ | Time to drive data lane to LP-11 state, after HS burst | DSI_PHY_CFG0[7:0] THS_EXIT |
| $T_{CLK-POST}$ | Time that the transmitter must continue sending HS clock after the last associated data lane has transitioned to LP mode | See the MIPI DSI-PHY specification. |
| $T_{CLK-TRAIL}$ | Time to drive HS differential state after last payload clock bit of a HS transmission burst | DSI_PHY_CFG1[15:8]TCLK_T RAIL |
| DDR_CLK_POST | Time between the data lane request deassertion and the CLK request deassertion to switch the data lanes into LP mode. The DDR_CLK_POST value must follow the rule: $DDR_CLK_POST \geq T_{HS-TRAIL} + T_{HS-EOT} + T_{CLK-POST}$ | DSI_CLK_TIMING[7:0] DDR_CLK_POST |
| EXIT_HS_MODE_LATENCY | Time to exit in HS mode. It is critical that $EXIT_HS_MODE_LATENCY = DIVROUNDUP((T_{HS-TRAIL} + T_{HS-EXIT}), 4) + 1 + T_{HS-EOT}$ ⁽¹⁾ | DSI_VM_TIMING7[15:0] EXIT_HS_MODE_LATENCY |

⁽¹⁾ The formula $DIVROUNDUP(value, div)$ is equivalent to $ROUNDUP(value/div)$.

12.4.3.2.3 Extra LP Transitions

Some DSI receivers require extra clock cycles in LP mode to process the data. The DSI protocol engine can be programmed to send automatically one NULL long packet. It applies only when no more data are ready to be sent from the internal FIFO to the peripheral on the last low speed transfer. The same value is used for all the VCs sending packets in low speed mode.

The size of the payload is defined by the DSS.DSI_CLK_CTRL[17:16] LP_CLK_NULL_PACKET_SIZE bit field. The header value depends on the VC ID and the size of the payload as detailed in Table 12-33 and Table 12-34.

Table 12-33. Extra NULL Packet Header

| Virtual Channel ID | Payload size (DSI_CLK_CTRL[17:16] LP_CLK_NULL_PACKET_SIZE) | Header (1st Byte) | Header (2nd Byte): WC LSB | Header (3rd Byte): WC MSB | Header (ECC) |
|--------------------|--|-------------------|---------------------------|---------------------------|--------------|
| 0x0 | 0 | 0x9 | 0x0 | 0x0 | 0x9 |
| | 1 | | 0x1 | | 0x13 |
| | 2 | | 0x2 | | 0x2F |
| | 3 | | 0x3 | | 0x35 |
| 0x1 | 0 | 0x49 | 0x0 | | 0x1F |
| | 1 | | 0x1 | | 0x05 |
| | 2 | | 0x2 | | 0x39 |
| | 3 | | 0x3 | | 0x23 |
| 0x2 | 0 | 0x89 | 0x0 | | 0x10 |
| | 1 | | 0x1 | | 0x0A |
| | 2 | | 0x2 | | 0x36 |
| | 3 | | 0x3 | | 0x2C |
| 0x3 | 0 | 0xC9 | 0x0 | | 0x06 |
| | 1 | | 0x1 | | 0x1C |
| | 2 | | 0x2 | | 0x20 |
| | 3 | | 0x3 | | 0x3A |

Table 12-34. Extra NULL Packet Payload

| Payload size (DSI_CLK_CTRL[17:16] LP_CLK_NULL_PACKET_ SIZE) | Payload (1st byte) | Payload (2nd byte) | Payload (3rd byte) | Payload (CRC) LSB | Payload (CRC) MSB |
|--|-----------------------|-----------------------|--------------------|----------------------|----------------------|
| 0 | NA | NA | NA | 0xFF | 0xFF |
| 1 | 0 | NA | NA | 0x87 | 0x0F |
| 2 | 0 | 0 | NA | 0xB8 | 0xF0 |
| 3 | 0 | 0 | 0 | 0x33 | 0x39 |

NOTE:

- In [Table 12-33](#) and [Table 12-34](#), both ECC and checksum are enabled.
- NA means not available.

12.4.3.3 DSI Transfer Modes

There are two transfer modes supported by the DSI module:

- Video mode (VM): Pixels are received from the video port, there are some real time constraints (pixels must be sent at the pixel frequency required by the display module) for sending the data to the display;
- Command mode (CM): Pixels can be received from the video port or from the L4 interconnect, there are no real time constraints except that TE should be avoided by starting the transfer at the right time during scan of the display and should be fast enough.

12.4.3.3.1 Video Mode

The video mode refers to the MIPI DPI 1.0 standard. The sync events and pixels should be sent according to the display mode timings. Data are received from the video port. The display controller is in charge of fetching the data from the system memory and providing the data to the DSI protocol engine using the video port. The short packets used for the sync event are using precalculated 32-bit values. The long packets are constructed using the header defined in [DSS.DSI_VCn_LONG_PACKET_HEADER](#) registers.

12.4.3.3.2 Command Mode

The command mode refers to the MIPI DCS standard. The commands, parameters and pixels are sent to the display module with limited real time constraints (as defined in [Section 12.4.3.3.1](#)). The pixels can be provided on the video port by the display controller or on the L4 interconnect port.

NOTE: In DSI command mode, the display controller must be configured in stall mode by setting the [DSS.DISPC_CONTROL\[11\]](#) STALLMODE bit to 1.

The [DSS.DSI_VCn_LONG_PACKET_HEADER](#) registers are used for the header of long packets, the [DSS.DSI_VCn_SHORT_PACKET_HEADER](#) registers are used for the short packets.

The error correction code (ECC) can be provided while writing the ECC value directly into the [DSS.DSI_VCn_LONG_PACKET_HEADER](#) and [DSS.DSI_VCn_SHORT_PACKET_HEADER](#) registers. The [DSS.DSI_VCn_CTRL\[8\]](#) ECC_TX_EN bit indicates if the ECC value should be calculated or if the value written in the register should be used instead for command and video modes. In case of synchronization short packets for video mode, since the hardware generates the short packets without using [DSS.DSI_VCn_SHORT_PACKET_HEADER](#) registers, if the [DSS.DSI_VCn_CTRL\[8\]](#) ECC_TX_EN bit is set to 1, the ECC is calculated otherwise the value zero is used. The feature is used to generate incorrect ECC for debug purpose and to ease the check for the link and peripheral error detection and correction.

For the payload, the [DSS.DSI_VCn_LONG_PACKET_PAYLOAD](#) registers are used. Each 32-bit PAYLOAD data is written into the [DSS.DSI_VCn_LONG_PACKET_PAYLOAD](#) register from the MPU subsystem or system DMA. It is buffered to be able to send packets with higher rate than the L4 interconnect frequency can provide. The word count defined in the [DSS.DSI_VCn_LONG_PACKET_HEADER](#) registers is used to determine the number of bytes to be sent

using the DSS.DSI_VCn_LONG_PACKET_PAYLOAD registers. The write into the DSS.DSI_VCn_LONG_PACKET_HEADER registers is required before accessing the DSS.DSI_VCn_LONG_PACKET_PAYLOAD register. The hardware should be able to extract the length of the payload and be able to discard extra data sent using the DSS.DSI_VCn_LONG_PACKET_PAYLOAD register. The hardware takes into account the write into the DSS.DSI_VCn_LONG_PACKET_HEADER register only if the VC is enabled otherwise the write is ignored by hardware.

In the case of pixels received on the video port, only the DSS.DSI_VCn_LONG_PACKET_HEADER register is used. The video port pixels are used for the payload. When the pixel data is coming from the display controller video port, the DSI protocol can add a DCS command byte between the packet header and pixel data by setting the DSS.DSI_CTRL[24] DCS_CMD_ENABLE bit to 0x1. The value will be either 0x2c (write_memory_start) by setting the DSS.DSI_CTRL[25] DCS_CMD_CODE bit to 0x1, or 0x3c (write_memory_continue) by setting the DSS.DSI_CTRL[25] DCS_CMD_CODE bit to 0x0.

When transmitting RGB 16-BPP data, the DSS.DSI_CTRL[26] RGB565_ORDER bit must be set to 0x1 to maintain the pixel byte order as in video mode.

A 2-line ping-pong buffer is implemented to allow the DSI protocol engine to store incoming pixels from the display controller through the video port while sending the DSI formatted frame to the DSI_PHY. The ping-pong buffer is supported in command mode, provided the size of the packet defined in the header register is less than the size of each line buffer (768 *32 bits). If the size of the packet is greater than the size of the line buffer, the ping-pong mechanism cannot be used (both lines are used as a single line).

The ping-pong buffer status can be checked by the DSI_VCn_CTRL[14] PP_BUSY bit.

- When PP_BUSY equals 1, the ping-pong buffer is active and the line buffers are not ready to receive data; therefore, the user cannot update a new header.
- When PP_BUSY equals 0, at least one line buffer is empty; therefore, the user can update a new header. PP_BUSY is then set to 0x1. If both line buffers are empty, the user can write two headers, one following the other. PP_BUSY remains at 0x0 after the first header is written, and is set to 0x1 after second header is written.

An IRQ is available to allow software to update header on events. The IRQ is enabled by setting the DSI_VCn_IRQENABLE[8] PP_BUSY_CHANGE_IRQ bit to 0x1, and its status is accessible on the DSI_VCn_IRQSTATUS[8] PP_BUSY_CHANGE_IRQ bit.

12.4.3.3.3 Video + Command Modes

The two modes can be interlaced to send two DSI streams to two types of panels: Video or command types. The number of concurrent video stream is limited to a single one. The number of concurrent command mode streams is limited to 4 when there is no video stream and 3 otherwise. In case there is one DSI stream using video mode, the command mode pixels should be provided on the L4 interconnect only.

12.4.3.3.4 Burst Modes

- Frequency-burst mode The frequency-burst mode is used to reduce the high-speed (HS) period by increasing the clock frequency on the DSI link. It allows in some case, the power consumption reduction of the link. The non-HS period used typically to drive the main panel can be used to send data to the secondary panel or to allow feedback (acknowledge) from the primary and secondary panels. The DSI protocol engine needs to buffer a full line before sending the HS packets for the line. A double buffering mechanism is required to be able to send a line while the following one is being received on the video port.
- Transparent-burst mode The transparent-burst mode is used by increasing the pixel clock frequency generated by the display controller with in addition an increase of the horizontal blanking period.

12.4.3.3.5 Interleaving Mode

Video mode can output command mode packets, which are provided to DSI through the L4 interconnect, during the blanking periods of the video stream sequence on the PPI link. These command mode packets can be programmed as high-speed packets or low-power packets.

During a video stream sequence on the PPI link, four types of gap exist:

- BLLP gap: Blanking period during VSA, VBP, and VFP lines
- HSA gap: Blanking period during VACT lines; always between HS and HE short packet
- HBP gap: Blanking period during VACT lines; always between HS/HE short packet and data pixel long packet
- HFP gap: Blanking period during VACT lines; always between data pixel long packet and the end of the current VACT line

To perform interleaving in a particular gap, video mode must be set to go into low-power state during the blanking gap. Each type of gap has separate configurable register bits that determine whether a blanking long packet will be sent or the link will go into low-power state during the gap on the PPI link. If low-power state is set during a gap, the DSI module performs interleaving during that period.

Two set of registers are available for:

- High-speed interleaving (when high-speed command mode packets must be sent during a video stream on the PPI link)
- Low-power interleaving (when low-power command mode packets must be sent during a video stream on the PPI link)

12.4.3.3.5.1 HS Command Mode Interleaving Programming Model

Figure 12-93 shows the various HS mode scenarios in interleaving mode during a blanking gap. For each type of blanking gap, a dedicated bit field determines the number of TxByteClkHS clock cycles used for interleaving in HS command mode packets.

- The BL_HS_INTERLEAVING[31:16] [DSI_VM_TIMING6](#) bit field defines the number of TxByteClkHS clock cycles used to interleave HS command mode packets during a BLLP gap.
- The HBP_HS_INTERLEAVING[7:0] [DSI_VM_TIMING4](#) bit field defines the number of TxByteClkHS clock cycles used to interleave HS command mode packets during an HBP gap.
- The HFP_HS_INTERLEAVING[15:8] [DSI_VM_TIMING4](#) bit field defines the number of TxByteClkHS clock cycles used to interleave HS command mode packets during an HFP gap.
- The HSA_HS_INTERLEAVING[23:16] [DSI_VM_TIMING4](#) bit field defines the number of TxByteClkHS clock cycles used to interleave HS command mode packets during an HSA gap.

These programmable values must be programmed to satisfy the timings for the clock and data lane to enter and exit HS mode latency. According to the scenario, different equations must be considered when calculating the register values.

Figure 12-93. HS Command Mode Interleaving

dss-327

NOTE: For calculations and equations, the following abbreviations are used: EXIT_CLK_HS_MODE represents the exit HS mode latency for the clock lane. There is no dedicated register for this value but the programmer must know this value for further calculations.

$$\text{EXIT_CLK_HS_MODE} = T_{\text{CLK-TRAIL}} + T_{\text{S-EXIT}}$$

For the following equations, BLANKING_PERIOD represents the BLLP, HSA, HBP, or HFP blanking periods. The HS_INTERLEAVING period represents the maximal period HS command mode packets. Its value is set in the BL_HS_INTERLEAVING, HSA_HS_INTERLEAVING, HBP_HS_INTERLEAVING, or HFP_HS_INTERLEAVING registers, depending on the blanking type.

In each scenario, two calculations are present, depending on the value of ddr_clk_always_on.

- ddr_clk_always_on = 1: Clock lane is always active.
- ddr_clk_always_on = 0: Clock lane is activated only when there are HS packets to be sent on the PPI link.
- Scenario 1: The gap for interleaving starts and ends with a regular video stream HS packet.
 - ddr_clk_always_on = 1
 $\text{HS_INTERLEAVING} = \text{BLANKING_PERIOD} - (\text{EXIT_HS_MODE_LATENCY} + \max\{\text{ENTER_HS_MODE_LATENCY}, 2\} + 1)$
 - ddr_clk_always_on = 0
 $\text{HS_INTER1} = \text{BLANKING_PERIOD} - (\text{EXIT_HS_MODE_LATENCY} + \max\{\text{ENTER_HS_MODE_LATENCY}, 2\} + 1)$

$$\text{HS_INTER2} = \text{BLANKING_PERIOD} - (\text{DDR_CLK_POST} + \text{EXIT_CLK_HS_MODE} + \text{DDR_CLK_PRE} + \text{ENTER_HS_MODE_LATENCY} + 1)$$

$$\text{HS_INTERLEAVING} = \min\{\text{HS_INTER1}, \text{HS_INTER2}\}$$

- Scenario 2: The gap for interleaving starts with a regular video stream HS packet and ends in LP state.
 - ddr_clk_always_on = 1

$$\text{HS_INTERLEAVING} = \text{BLANKING_PERIOD} - (\text{EXIT_HS_MODE_LATENCY} + 3)$$
 - ddr_clk_always_on = 0

$$\text{HS_INTER1} = \text{BLANKING_PERIOD} - (\text{EXIT_HS_MODE_LATENCY} + 3)$$

$$\text{HS_INTER1} = \text{BLANKING_PERIOD} - (\text{DDR_CLK_POST} + \text{EXIT_CLK_HS_MODE} + 3)$$

$$\text{HS_INTERLEAVING} = \min\{\text{HS_INTER1}, \text{HS_INTER2}\}$$
- Scenario 3: The gap for interleaving starts with the LP state and ends with a regular video stream HS packet.
 - ddr_clk_always_on = 1

$$\text{HS_INTERLEAVING} = \text{BLANKING_PERIOD} - (\text{ENTER_HS_MODE_LATENCY} + \text{EXIT_HS_MODE_LATENCY} + \max\{\text{ENTER_HS_MODE_LATENCY}, 2\} + 1)$$
 - ddr_clk_always_on = 0

$$\text{HS_INTER1} = \text{BLANKING_PERIOD} - (\text{DDR_CLK_PRE} + \text{ENTER_HS_MODE_LATENCY} + \text{EXIT_HS_MODE_LATENCY} + \max\{\text{ENTER_HS_MODE_LATENCY}, 2\} + 1)$$

$$\text{HS_INTER2} = \text{BLANKING_PERIOD} - (\text{DDR_CLK_PRE} + \text{ENTER_HS_MODE_LATENCY} + \text{DDR_CLK_POST} + \text{EXIT_CLK_HS_MODE} + \text{DDR_CLK_PRE} + \text{ENTER_HS_MODE_LATENCY} + 1)$$

$$\text{HS_INTERLEAVING} = \min\{\text{HS_INTER1}, \text{HS_INTER2}\}$$
- Scenario 4: The gap for interleaving starts with the LP state and ends with a regular video stream HS packet.
 - ddr_clk_always_on = 1

$$\text{HS_INTERLEAVING} = \text{BLANKING_PERIOD} - (\text{ENTER_HS_MODE_LATENCY} + \text{EXIT_HS_MODE_LATENCY} + 3)$$
 - ddr_clk_always_on = 0

$$\text{HS_INTER1} = \text{BLANKING_PERIOD} - (\text{DDR_CLK_PRE} + \text{ENTER_HS_MODE_LATENCY} + \text{EXIT_HS_MODE_LATENCY} + 3)$$

$$\text{HS_INTER2} = \text{BLANKING_PERIOD} - (\text{DDR_CLK_PRE} + \text{ENTER_HS_MODE_LATENCY} + \text{DDR_CLK_POST} + \text{EXIT_CLK_HS_MODE} + 1)$$

$$\text{HS_INTERLEAVING} = \min\{\text{HS_INTER1}, \text{HS_INTER2}\}$$

12.4.3.3.5.2 LP Command Mode Interleaving Programming Model

Figure 12-94 shows the various LP mode scenarios in interleaving mode during a blanking gap. For each type of blanking gap, a dedicated bit field determines the number of TxByteClkHS clock cycles used for interleaving in LP command mode packets.

- BL_LP_INTERLEAVING bit field [DSI_VM_TIMING6\[15:0\]](#) defines the number of TxByteClkHS clock cycles used to interleave the HS command mode packets during a BLLP gap.
- HBP_LP_INTERLEAVING bit field [DSI_VM_TIMING5\[7:0\]](#) defines the number of TxByteClkHS clock cycles used to interleave the HS command mode packets during an HBP gap.
- HFP_LP_INTERLEAVING bit field [DSI_VM_TIMING5\[15:8\]](#) defines the number of TxByteClkHS clock cycles used to interleave HS command mode packets during an HFP gap.
- HSA_LP_INTERLEAVING bit field [DSI_VM_TIMING5\[23:16\]](#) defines the number of TxByteClkHS clock cycles used to interleave HS command mode packets during an HSA gap.

These programmable values must be programmed to satisfy the timings for clock and data lane enter and exit LP mode latency. Clock lane timings do not affect LP command mode interleaving, because the clock lane can be controlled separately, compared with the data lane high-speed and low-power mutually exclusive control. Clock lanes can be in high-speed mode while the data lanes are in high-speed data transfer mode, low-power data transfer mode, or in low-power state.

According to this scenario, different equations must be considered for calculating register values.

Figure 12-94. LP Command Mode Interleaving

dss-328

For the following equations, **BLANKING_PERIOD** represents the BLLP, HSA, HBP, or HFP blanking periods. The **LP_INTERLEAVING** period represents the maximal period in LP command mode packets. Its value is set in the **BL_LP_INTERLEAVING**, **HSA_LP_INTERLEAVING**, **HBP_LP_INTERLEAVING**, or **HFP_LP_INTERLEAVING** registers, depending on the blanking type.

ALLOWED_HSBYTE_CLOCKS_FOR_LP represents the number of TxByteClkHS clock cycles during which LP interleaving can appear.

To calculate the **LP_INTERLEAVING** value:

1. Calculate how many TxByteClkHS clock cycles can be reserved for LP interleaving during the appropriate blanking video mode gap.
2. Calculate the **LP_INTERLEAVING** value according to the results of Step 1.

Step 1:

- Scenario 1: The gap for interleaving starts and ends with a regular video stream HS packet.

$$\text{ALLOWED_HSBYTE_CLOCKS_FOR_LP} = \text{BLANKING_PERIOD} - (\text{EXIT_HS_MODE_LATENCY} + \max\{\text{ENTER_HS_MODE_LATENCY}, 2\} + 1)$$
- Scenario 2: The gap for interleaving starts with a regular video stream HS packet and ends in LP state.

$$\text{ALLOWED_HSBYTE_CLOCKS_FOR_LP} = \text{BLANKING_PERIOD} - (\text{EXIT_HS_MODE_LATENCY} + 1)$$
- Scenario 3: The gap for interleaving starts with the LP state and ends with a regular video stream HS packet.

$$\text{ALLOWED_HSBYTE_CLOCKS_FOR_LP} = \text{BLANKING_PERIOD} - (\max\{\text{ENTER_HS_MODE_LATENCY}, 2\} + 1)$$

- Scenario 4: The gap for interleaving starts with the LP state and ends with a regular video stream HS packet.

$$\text{ALLOWED_HSBYTE_CLOCKS_FOR_LP} = \text{BLANKING_PERIOD} - 1$$

After finishing Step 1, the time period available for LP interleaving is known:

$$T_{lp_available} = \text{ALLOWED_HSBYTE_CLOCKS_FOR_LP} * T_{TxByteClkHS}$$

Step 2:

The resulting value must be programmed in the appropriate video mode register for LP interleaving.

$$\text{LP_INTERLEAVING} < \left[\frac{T_{lp_available} - 8 * T_{hsbyte_clk} - 5 * T_{dsif_clk} - 26}{T_{txclkesc}} \right]_{16}$$

dss-E124

TxByteClkHS: Period of HS byte clock of DSI_PHY module

Tdsif_clk: Period of DSI functional clock

Ttxclkesc: Period of LP transmit escape clock

12.4.3.4 Power Management

The DSI protocol engine implements an handshake protocol on its L4 interconnect port with the PRCM. The DSI protocol engine provides a clock gating signal CIO_CLK_ICG to gate the L3 interface clock (L3_ICLK) provided by the PRCM to the DSI complex I/O. It allows reduction of the power consumption of the DSI complex I/O while the DSI link is not in used. To gate the L3_ICLK clock at DSI complex I/O level, set the DSS.DSI_CLK_CTRL[14] CIO_CLK_ICG bit to 1.

12.4.3.5 Serial Configuration Port (SCP) Interface

The SCP interface is used to transfer register values from the DSI protocol engine to the DSI PLL Control module and to the DSI complex I/O. It spends several cycles to serialize the data to be sent. Software users should take into account the delay in processing the transfer of the data from/to the slave port to/from the module.

12.4.3.5.1 Shadowing Register

The two first SCP registers for the DSI complex I/O address map should be implemented as shadow registers. The shadowing mechanism is enabled/disabled using the DSS.DSI_COMPLEXIO_CFG1[31] SHADOWING bit:

- When setting the DSS.DSI_COMPLEXIO_CFG1[31] SHADOWING bit to 1, the transfer of the values from the two first L4 interconnect port registers into the two first registers of the DSI complex I/O (DSS.DSI_PHY_CFG0 and DSS.DSI_PHY_CFG1) is done only when the DISPC_UPDATE_SYNC signal from the display controller is active and the DSS.DSI_COMPLEXIO_CFG1[30] GOBIT is set to 1. If there is no pending update for the two registers, when the DISPC_UPDATE_SYNC signal is asserted, the DSS.DSI_COMPLEXIO_CFG1[30] GObit is reset by hardware and there is no SCP transfer.
 - If there is only one register to update, only the corresponding new value is transferred. The second register in the DSI complex I/O is not updated. When the transfer is completed, the DSS.DSI_COMPLEXIO_CFG1[30] GOBIT is reset by hardware.
 - If the two registers need to be updated, the order of the transfer is first the register with lower address and then the second one. When the transfers are completed, the DSS.DSI_COMPLEXIO_CFG1[30] GOBIT is reset by hardware.

When there is an on-going transfer (read or write) to any SCP register, the transfer should complete prior to start the update of shadowing registers.

- When unsetting the DSS.DSI_COMPLEXIO_CFG1[31] SHADOWING bit to 0, if the transfer into the

two first DSI complex I/O registers has already started, it should be finished

NOTE: When reading the shadow registers, the local value stored in the DSI protocol engine is returned if the update is pending; otherwise, the values stored in the DSI complex I/O are returned.

12.4.3.5.2 *Busy Signal*

The signal SCPBusy indicates that there is still some activity using the SCPClk provided by the PRCM. The SCPClk clock is the DSS_L3_ICLK clock.

12.4.3.6 *Power Control*

The DSI protocol engine can control and send power commands for both DSI complex I/O and DSI PLL controller modules.

12.4.3.6.1 Complex I/O Power Control Commands

12.4.3.6.1.1 Complex I/O Power Control Commands

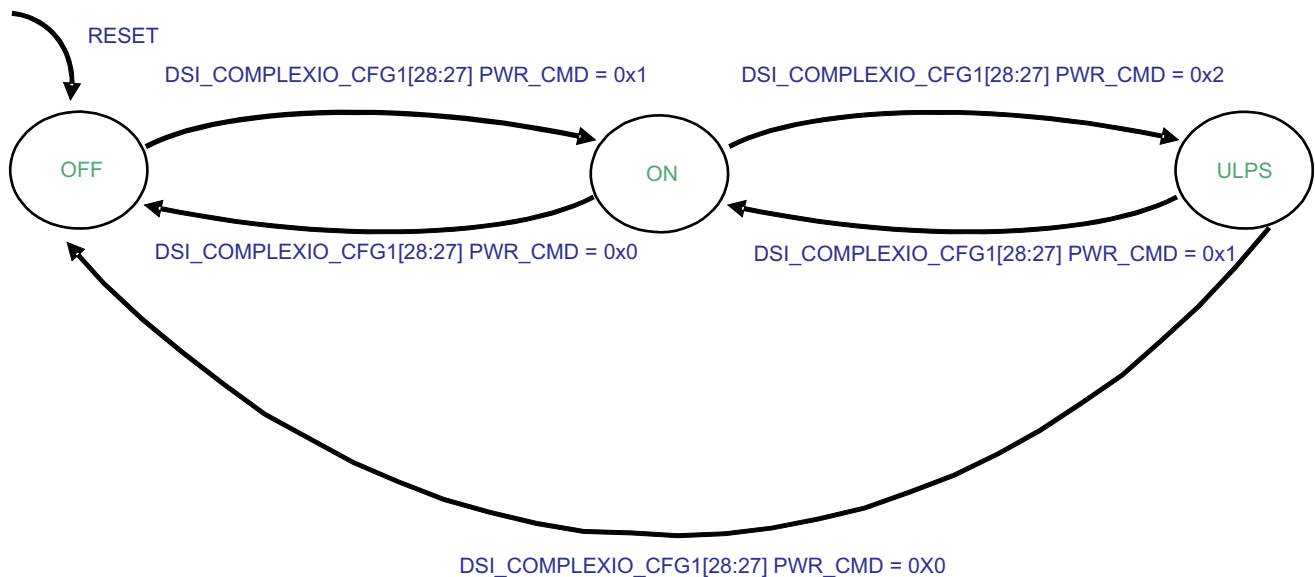

The DSI complex I/O can be set into three modes:

- OFF: In this power state, the complete DSI_PHY circuit is powered down. The internal LDO is OFF.
- ON: In this power state, the complete DSI_PHY circuit is powered on and functional.
- ULPS: In this power state, the ULPS exit detection circuit power switch is ON for the lanes which are in receive ULPS mode. For the lanes which are in transmit ULPS mode, the circuitry for weak pull-down is ON. The ultralow-power state should only be used when all the three lanes are in ULPS (transmit or receive).

12.4.3.6.1.2 Complex I/O Power FSM

Figure 12-95 describes the power control FSM to control the power state of the complex I/O.

Figure 12-95. Complex I/O Power FSM

dss-169

The PwrCmdOff, PwrCmdUlp and PwrCmdOn commands control the state transition of the DSI complex I/O. Software users should set the DSS.DSI_COMPLEXIO_CFG1[28:27] PWR_CMD bit field to ask for a state change. The allowed transitions are: OFF -> ON and ON -> ULP and ULP -> OFF. The DSS.DSI_COMPLEXIO_CFG1[26:25] PWR_STATUS bit field gives a status on the current state of the DSI complex I/O.

CAUTION

- In automatic mode, the software should ensure that the DSI complex I/O in the ON mode (that is, ON command already sent) before sending requests to the complex I/O.
- In a command request to change to a state which is the current one (acknowledge has been received), the command is ignored (nothing is sent to the DSI complex I/O).
- To change state to ULP state, users should ensure that all the three ULPSActiveNot signals are low. The ULPSActiveNot_ALL0_IRQ interrupt can be used by software users to determine the state of the ULPSActiveNot signals. The change from ULP to ON state is required before starting the ULP status exit sequence (refer to Section 12.4.3.7.1 for details).

12.4.3.6.2 DSI PLL Power Control Commands

The DSI PLL controller module can be set into four modes:

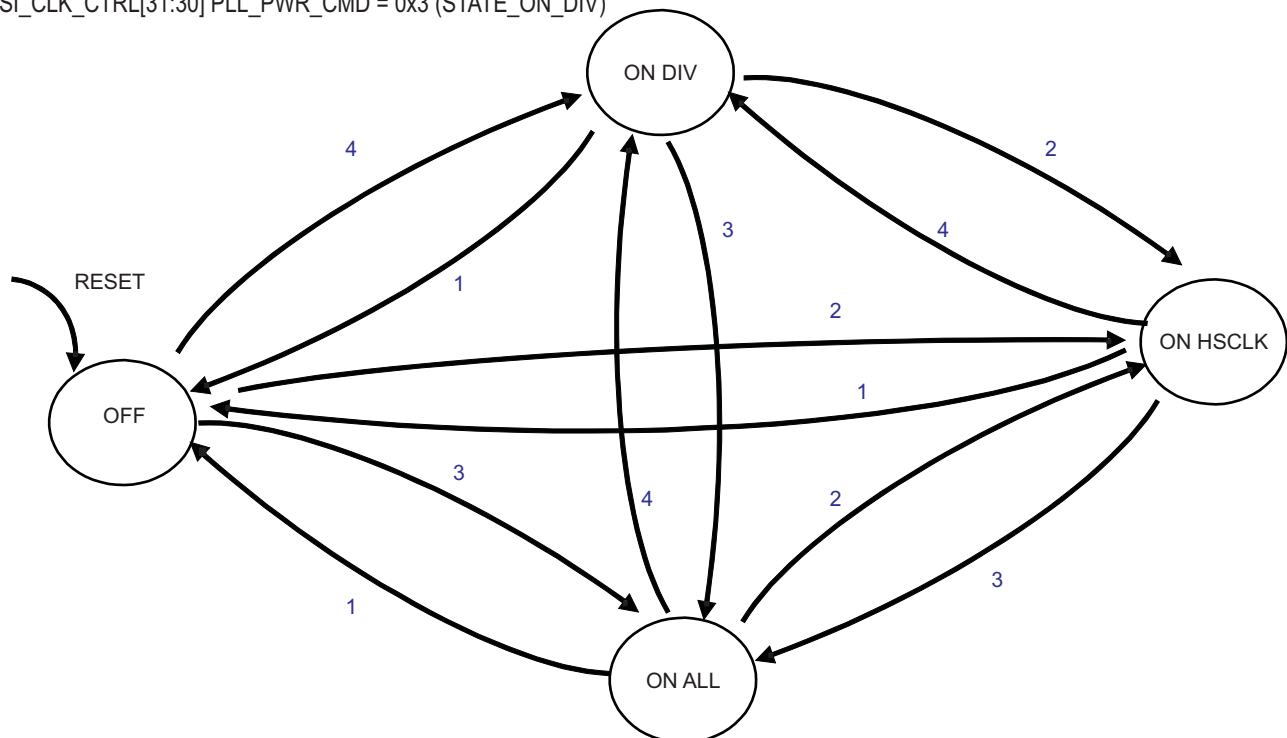

- OFF: The DSI PLL and HSDIVIDER are OFF.
- ON ALL: Both DSI PLL and HSDIVIDER are ON. The HS_CLK clock is provided to the DSI complex I/O and the second clock output is provided to the HSDIVIDER.
- ON HSCLK: The DSI PLL is ON. The HSDIVIDER is OFF. The HS_CLK clock is provided to the DSI complex I/O but the second clock output is not provided to the HSDIVIDER.
- ON DIV: Both DSI PLL and HSDIVIDER are ON. The HS_CLK clock is not provided to the DSI complex I/O but the second clock output is provided to the HSDIVIDER.

12.4.3.6.2.1 DSI-PLL Power FSM

Figure 12-96 shows the DSI PLL power FSM.

Figure 12-96. DSI PLL Power FSM

- 1 = DSI_CLK_CTRL[31:30] PLL_PWR_CMD = 0x0 (STATE_OFF)
- 2 = DSI_CLK_CTRL[31:30] PLL_PWR_CMD = 0x1 (STATE_ON_HSCLK)
- 3 = DSI_CLK_CTRL[31:30] PLL_PWR_CMD = 0x2 (STATE_ON_ALL)
- 4 = DSI_CLK_CTRL[31:30] PLL_PWR_CMD = 0x3 (STATE_ON_DIV)

dss-170

The commands PLLPwrCmdOff, PLLPwrCmdOnAll, PLLPwrCmdOnDIV and PLLPwrCmdOnHSClk controls the state transition of the DSI PLL control module. Software users should set the **DSS.DSI_CLK_CTRL[31:30] PLL_PWR_CMD** bit field to ask for a state change. The **DSS.DSI_CLK_CTRL[29:28] PLL_PWR_STATUS** bit field gives a status on the current state of the DSI PLL controller.

NOTE: In a command requests to change to a state which is the current one (acknowledge has been received), the command is ignored (nothing is sent to the DSI PLL Control module).

All the DSI PLL power is controlled by the DSI protocol engine except the LDO power of the PLL and HSDIVIDER that can be controlled by the DSI PLL controller module. Indeed, the HSDIVIDER and PLL

SYSRESET signals can be forced by the DSI PLL controller module by setting DSS.DSI_PLL_CONTROL[4] DSI_HSDIV_SYSRESET and DSS.DSI_PLL_CONTROL[3] DSI_PLL_SYSRESET bits, respectively. By setting these bits to 1, the SYSRESET signal is forced active (module is forced to reset state). When these bits are set to 0 (reset value), the SYSRESET signals are controlled by the DSI PLL power FSM.

12.4.3.6.2.1.1 DSI-PLL HS Clock Signals

The DSIStopClk signal is provided to the DSI PLL control module. It indicates when the DSI Protocol engine does not need to use the high-speed transfer mode (HS mode) and PLL HS output (HS_CLK clock) can be stopped. The following conditions must also be met when DISPC_UPDATE_SYNC may be generated by the display controller, as that may also result in the PLL HS output being stopped.

When the interface is disabled (that is, DSS.DSI_CTRL[0] IF_EN bit set to 0), the signal DSIStopClk is asserted.

The assertion of the DSIStopClk depends on the following conditions:

- Clock lane TxRequestHS is deasserted (the DDR clock on the clock lane is not required anymore). The get TxRequestHS deassertion, all of the following conditions are required:
 - The DSS.DSI_CLK_CTRL[13] DDR_CLK_ALWAYS_ON bit must be reset to 0 and no HS data transfer should be on going or already scheduled
 - No VC active in video mode. No VC using the video mode is enabled; if the VC is enabled, the mode is command mode only (that is, DSS.DSI_VCn_CTRL[0] VC_EN bit set to 1 and DSS.DSI_VCn_CTRL[4] MODE bit set to 0)
 - No command mode requiring high-speed transfer (one or more VCs using command mode can be active)
 - Or DSS.DSI_CTRL[0] IF_EN bit reset to 0 (if all previous conditions are not required)

The deassertion of the DSIStopClk depends on one of the following conditions (the DSI interface is enabled by setting the DSS.DSI_CTRL[0] IF_EN bit to 1):

- Clock lane TxRequestHS must be asserted (the DDR clock on the clock lane is required anymore).
- One video mode VC active
- At least one VC in command mode requiring high-speed transfer
- The DSS.DSI_CLK_CTRL[13] DDR_CLK_ALWAYS_ON bit is set to 1 by software users (the DSS.DSI_CTRL[0] IF_EN bit should be reset to 0 for updating the DDR_CLK_ALWAYS_ON bit value)

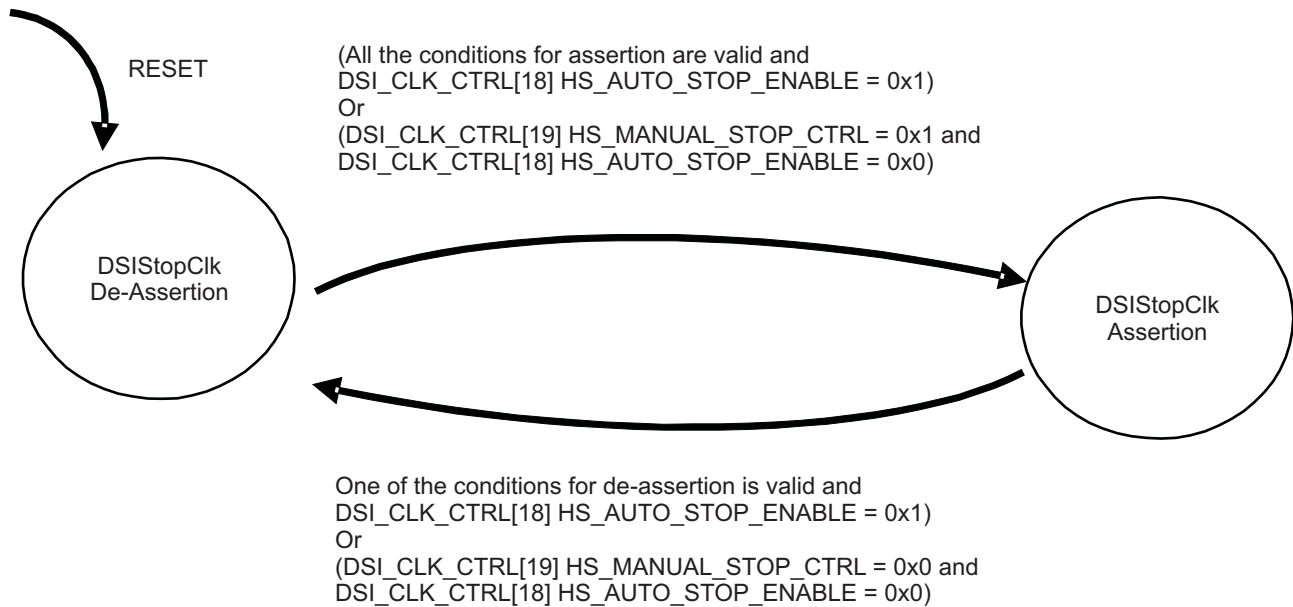

The automatic assertion/deassertion is enabled by using the DSS.DSI_CLK_CTRL[18] HS_AUTO_STOP_ENABLE bit.

The manual mode can be used by setting/resetting the DSS.DSI_CLK_CTRL[19] HS_MANUAL_STOP_CTRL bit to assert/deassert the DSIStopClk signal.

12.4.3.6.2.1.2 DSI-PLL HS Clock FSM

Figure 12-97 shows the DSI PLL HS clock FSM.

Figure 12-97. DSI PLL HS Clock FSM

dss-171

When DSIStopClk is used there is a latency through other modules (DSI PLL controller and DSI_PHY) before TxByteClkHS is stopped. This latency must be accounted for to prevent any issue when DSIStopClk is deasserted soon after being asserted. This is done using a hardware timer programmed using the DSS.DSI_STOPCLK_TIMING[7:0] DSI_STOPCLK_LATENCY bit field. This timer is programmed in number of periods of the DSI Protocol functional clock (DSI_FCLK). At reset value, the timer is programmed with 0x80 (128) value.

CAUTION

The programmed value in the DSS.DSI_STOPCLK_TIMING[7:0] DSI_STOPCLK_LATENCY bit field must be greater than ((3 x L3_ICLK period) + (5 x CLKIN4DDR period))/(DSI_FCLK period).

12.4.3.7 Timers

NOTE: Among the timers described in this section, only the HS TX, LP RX and turnRequests timers generates interrupts immediately when the timer value is null. For ForceTxStopMode timer, it ends counting instantly and ForceTxStopMode is not asserted.

12.4.3.7.1 Twakeup Timer

The T_{WakeUp} timer is not implemented in the DSI protocol engine. The software must use a general-purpose (GP) timer to handle this. This timer is used for existing ULP status mode for the active lanes (clock and/or data lanes). The sequence to exit ULP state is:

1. Change the state of TxULPSExit for each lane to ACTIVE.
2. Wait for the interrupt indicating that all lanes with TxULPSExit active have acknowledged by asserting ULPSActiveNot. This is done by reading the DSS.DSI_COMPLEXIO_IRQSTATUS ULPSACTIVENOT_ALLi_IRQ bit fields (i = 0, 1).
3. Start the application wake-up timer (GP timer).
4. Wait for the time-out.
5. Change the TxUlpsClk signals to INACTIVE state for the clock lane and/or TxRequestEsc INACTIVE state for the data lane(s).

NOTE: The minimum time for the wake-up period is 1 ms.

To enter ULPS mode for clock lane, TxUlpsClk state should be change to active state. To enter ULPS mode for data lane, TxRequestEsc state should be changed to active state (TxUlpsEsc as well if it is not in active state already).

12.4.3.7.2 ForceTxStopMode FSM

The signal ForceTxStopMode is used at initialization time (DSI complex I/O). Figure 12-98 describes the ForceTxStopMode FSM to assert/deassert ForceTxStopMode signal.

dss-172

The DSI protocol engine asserts ForceTxStopMode by setting the DSS.DSI_TIMING1[15] FORCE_TX_STOP_MODE_IO bit to 1. Asserting the FORCE_TX_STOP_MODE_IO bit allows to initialize the lanes. The lanes are in the Stop State when ForceTxStopMode signal is high.

No data can be sent before the ForceTxStopMode signal is deasserted. The deassertion time is defined by the STOP_STATE_COUNTER_IO, Stop_State_x4_IO, Stop_State_x16_IO field DSI_TIMING1[15:0]. The FORCE_TX_STOP_MODE_IO bit is reset by hardware when the time is reached.

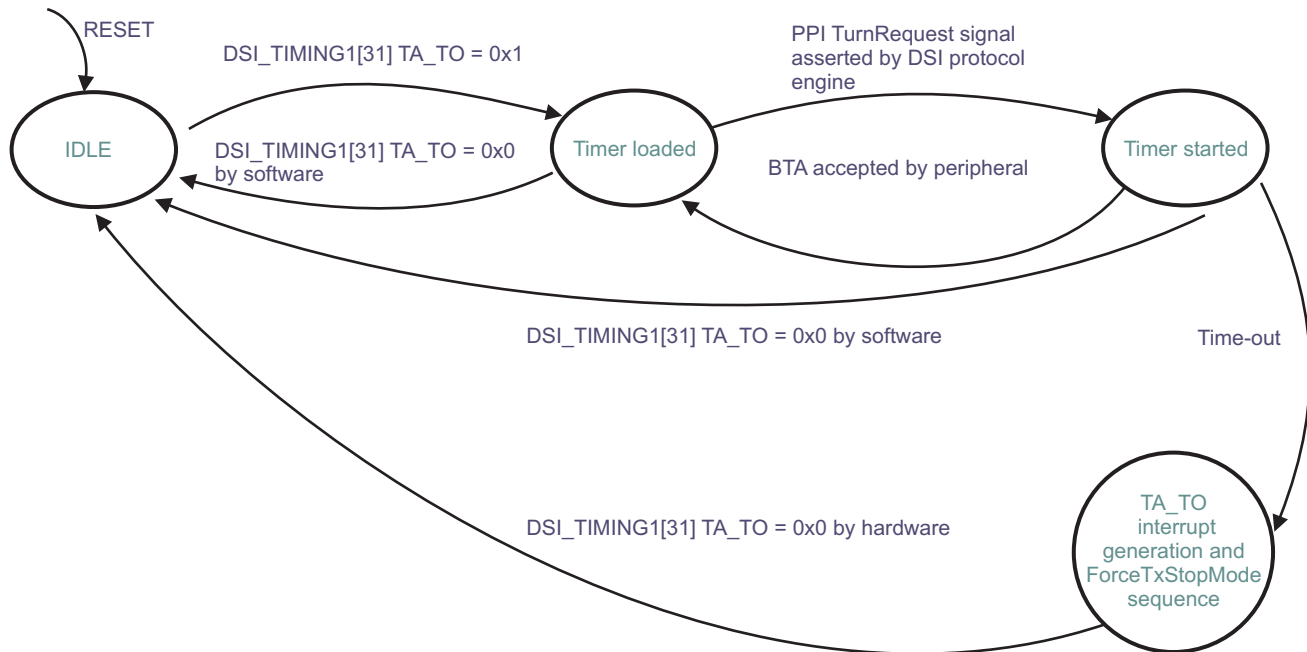

This bit can be reset by software.

The calculation of the number of DSI_FCLK cycles assertion period is defined by:

$$\text{Total period in DSI_FCLK cycles} = \text{DSI_TIMING1}[12:0] \text{ STOP_STATE_COUNTER_IO} \times ((\text{DSI_TIMING1}[14] \text{ STOP_STATE_X16_IO} \times 15) + 1) \times ((\text{DSI_TIMING1}[13] \text{ STOP_STATE_X4_IO} \times 3) + 1)$$

12.4.3.7.3 TurnRequest FSM

The signal TurnRequest is used to request turnaround. It is only valid for the data lane #1 since the other data lanes can not be used in the reverse direction to receive data from the DSI receiver. Figure 12-99 describes the TurnRequest FSM to assert/deassert TurnRequest signal.

Figure 12-99. TurnRequest FSM

dss-173

The DSI protocol engine asserts TurnRequest signal during one TxClkEsc cycle when the turn-around is enabled. The DSS.DSI_TIMING1[31] TA_TO bit is set/reset by software to respectively enable/disable the timer for turnaround procedure failure. It can be reset by software or automatically by hardware when the time out occurs.

The timer is loaded with the value in number of DSI_FCLK cycles:

$$\text{DSI_TIMING1}[28:16] \text{ TA_TO_COUNTER} \times ((\text{DSI_TIMING1}[30] \text{ TA_TO_X16} \times 15) + 1) \times ((\text{DSI_TIMING1}[29] \text{ TA_TO_X8} \times 7) + 1).$$

When the interrupt is generated, the hardware should automatically assert ForceTXStopMode in order for the DSI_PHY to drive LP-11 stop state. The ForceTXStopMode timer is used to define the minimum duration of LP-11 state. The Stop State can be longer if there is no activity.

The hardware resets the ForceTXStopMode bit, followed by an internal logic reset except all register values and TX FIFO content, then resets the DSS.DSI_CTRL[0] IF_EN bit. The software should take action to recover by resetting the peripheral, for example, if it is not responding. It should wait for DSS.DSI_TIMING1[15] FORCE_TX_STOP_MODE_IO and DSS.DSI_CTRL[0] IF_EN bits to be reset to 0 before starting the recovery sequence.

12.4.3.7.4 Peripheral Reset Timer

The peripheral reset timer is not implemented in the DSI protocol engine module. Such as the Twakeup timer, a general-purpose timer (GPTimer) should be used in case of reset of the peripheral to determine when the peripheral is ready again for operation.

12.4.3.7.5 HS TX Timer

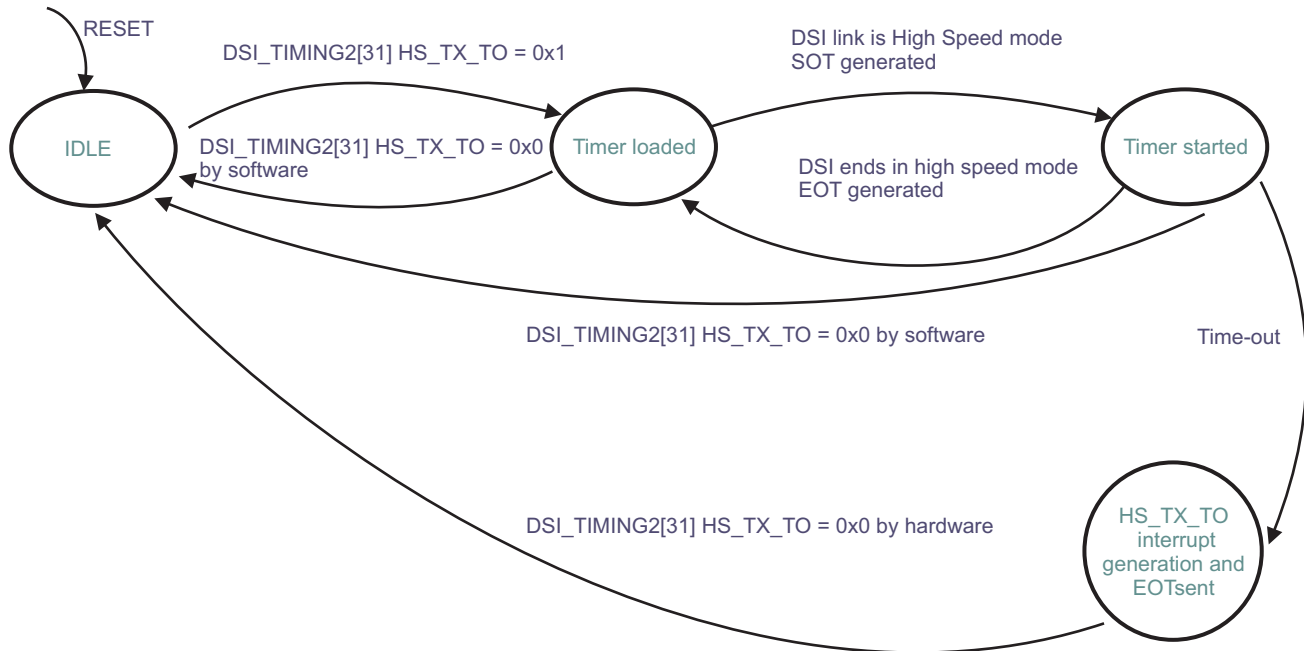

The HS TX timer is used to detect when the host has been in TX mode for too long. When time-out occurs, the EOT is forced. The timer is reloaded when a start of high speed transmission occurs. It is enabled/disabled by software through the DSS.DSI_TIMING2[31] HS_TX_TO bit. The interrupt HS_TX_TO_IRQ is generated when the timer expires. The DSS.DSI_IRQSTATUS[14] HS_TX_TO_IRQ bit is set to 1 when the HS TX time-out occurs.

The maximum time to be supported is 20 ms. It can be used to determine that at least once a frame in video mode, the HS mode is stopped to enter ULPS. Since the refresh rate can be up to 50 frames per second in video mode, the maximum time in HS is 20 ms.

The timer is loaded with the value in number of TxByteClkHS:

$$\text{DSI_TIMING2}[28:16] \text{ HS_TX_TO_COUNTER} \times ((\text{DSI_TIMING2}[30] \text{ HS_TX_TO_X16} \times 15) + 1) \times ((\text{DSI_TIMING2}[29] \text{ HS_TX_TO_X8} \times 7) + 1)$$

Figure 12-100. High-Speed TX Timer FSM

dss-174

When the time-out occurs, the hardware should send EOT request in order for the DSI complex I/O to drive LP-11 stop state. This is followed by the generation of the interrupt. The hardware will perform an internal logic reset including the TX FIFO content, but excluding the register values and then resets the DSS.DSI_CTRL[0] IF_EN bit.

The software should wait for the DSS.DSI_CTRL[0] IF_EN bit to be reset to 0 before taking any recovery action by resetting for example the peripheral if it is not responding.

12.4.3.7.6 LP RX Timer

When the host is in Low power Receive mode after a bus turn-around, the LP RX timer is loaded. When the timer expires, the host requests the DSI complex I/O to drive LP-11. The interrupt LP_RX_TO_IRQ is generated when the timer expires. The DSS.DSI_IRQSTATUS[15] LP_RX_TO_IRQ bit is set to 1 when the LP RX time-out occurs.

The DSS.DSI_TIMING2[15] LP_RX_TO bit is set/reset by the software to respectively enable/disable the timer.

The timer is loaded with the value in number of DSI_FCLK cycles:

$$\text{DSI_TIMING2}[12:0] \text{ LP_RX_TO_COUNTER} \times ((\text{DSI_TIMING2}[14] \text{ LP_RX_TO_X16} \times 15) + 1) \times ((\text{DSI_TIMING2}[13] \text{ LP_RX_TO_X4} \times 3) + 1)$$

Figure 12-101. Low-Power RX Timer FSM

dss-175

When the interrupt is generated, the hardware should automatically reset the DSS.DSI_TIMING2[15] LP_RX_TO bit and then assert ForceTXStopMode in order for the DSI complex I/O to drive LP-11 stop state. The ForceTXStopMode timer is used to define the minimum duration of LP-11 state. The Stop State can be longer if there is no activity.

The hardware resets the ForceTXStopMode bit, followed by an internal logic reset except all register values and TX FIFO content, then resets the DSS.DSI_CTRL[0] IF_EN bit. The software should take action to recover by resetting the peripheral, for example, if it is not responding. It should wait for the DSS.DSI_TIMING1[15] FORCE_TX_STOP_MODE_IO and DSS.DSI_CTRL[0] IF_EN bits to be reset before starting the recovery sequence. The TX FIFO is not flushed (the FIFO is flushed only when DSS.DSI_VcN_CTRL[0] VC_EN is set to 1).

12.4.3.8 Bus Turnaround

The bus turn-around (BTA) is not automatically sent by default after each packet sent to the display(s). It is programmable independently for each VC ID. The VC can be enabled when DSS.DSI_VcN_CTRL[6] BTA_EN bit is set to 1 by software. The software should ensure that, when the BTA is sent to the peripheral, there is enough time allocated for the response and the BTA from the peripheral to host. When setting the DSS.DSI_VcN_CTRL[6] BTA_EN bit to 1, one BTA is sent manually to the peripheral. This manual mode can be used for packets in command or video mode.

CAUTION

The BTA should not be sent when the RX FIFO is not empty. Users should take care of emptying the RX FIFO before sending BTA to the peripheral. It is to ensure that when receiving new data from peripheral, all the allocated spaces for all the VCs are empty.

In automatic mode, the BTA is sent automatically at the end of short or long packets when respectively the DSS.DSI_VcN_CTRL[2] BTA_SHORT_EN or the DSS.DSI_VcN_CTRL[3] BTA_LONG_EN bits are set to 1.

NOTE: If the DSS.DSI_VCn_CTRL[2] BTA_SHORT_EN bit is enabled, users can still set the DSS.DSI_VCn_CTRL[6] BTA_EN bit. Only one BTA is sent to the peripheral and the DSS.DSI_VCn_CTRL[6] BTA_EN bit is reset by hardware.

If the DSS.DSI_VCn_CTRL[3] BTA_LONG_EN bit is enabled, users can still set the DSS.DSI_VCn_CTRL[6] BTA_EN bit. Only one BTA is sent to the peripheral and the DSS.DSI_VCn_CTRL[6] BTA_EN bit is reset by hardware.

If the DSS.DSI_VCn_CTRL[2] BTA_SHORT_EN and DSS.DSI_VCn_CTRL[3] BTA_LONG_EN bits are both enabled, users can still set the DSS.DSI_VCn_CTRL[6] BTA_EN bit to send a BTA. Only one BTA is sent and the DSS.DSI_VCn_CTRL[6] BTA_EN bit is reset by hardware.

As explained previously, two modes can be used for each VC ID:

- **Automatic:** After each packet, a bus turn-around is sent. To determine the size of the long packet, the protocol engine on the host side should read the word count defined in the header (in DSS.DSI_VCn_LONG_PACKET_HEADER register) and use it to determine the last data to be sent on the DSI link. For short packets, the size is always 4 bytes. Then the bus turn-around is sent to the peripheral. The word count is also used to determine how many bytes should be transferred from the 32-bit writes access to the payload register (DSS.DSI_VCn_LONG_PACKET_PAYLOAD register).
- **Manual:** In case of data transfer using the L4 interconnect port, while all data have been provided to the DSI protocol engine, users can select bus turn-around for the last packet provided to the L4 interconnect port only by setting the bus turn-around enable bit (DSS.DSI_VCn_CTRL[6] BTA_EN) or for last packets and following ones by setting the automatic mode; in case of data transfer using the video port, the bus turnaround enable bit (DSS.DSI_VCn_CTRL[6] BTA_EN) can be selected at any time during the transfer of the packet. In case of video mode packets (data and synchronization events) users can not determine when the BTA is sent relatively the video mode packets, so it is highly recommended to use manual BTA mode only for packets generated in command mode but it is possible to use BTA when for a VC in video mode. In case of data provided on the video port, an interrupt for end of packet transfer (PACKET_SENT_IRQ) is provided to indicate users when the packet has been completely sent by the DSI complex I/O. The PACKET_SENT_IRQ can be monitored in DSI_VCn_IRQSTATUS[2] PACKET_SENT_IRQ status bit. Users can request BTA even if the space allocated in the TX FIFO for the corresponding VC is empty. It can be sent later on even if there was no packet sent before BTA request. The DSS.DSI_VCn_CTRL[6] BTA_EN bit should be reset by hardware if the BTA request has been sent even if the automatic mode for this specific type of packets is enabled.

The bus turnaround is supported for video mode packets and for command mode packets. It is not possible to send BTA during the blanking periods of the video mode when HS blanking packets should be sent, that is, when one of the following bits is set to 1:

- DSS.DSI_CTRL[20] BLANKING_MODE
- DSS.DSI_CTRL[21] HFP_BLANKING_MODE
- DSS.DSI_CTRL[22] HBP_BLANKING_MODE
- DSS.DSI_CTRL[23] HSA_BLANKING_MODE

Therefore, in video mode, the BTA request is delayed until there is a blanking period without HS blanking packets.

TA Timer

When TurnRequest signal is asserted (always only for data lane #1), the TA_TO timer is started. If the direction signal is no changed according to the turn-around request, the TA_TO interrupt is generated. When the Direction signal is in output mode, any data on the input data bus should be ignored since the DSI is in transmission mode (data and triggers should be ignored). Refer to [Section 12.4.3.7.3](#) for more details on the TA_TO timer.

12.4.3.9 PHY Triggers

The DSI protocol engine uses three triggers:

- Reset from host to display
- TE from display to host

- Acknowledge

These triggers are supported only for data lane #1. The reset trigger is associated with the signal TxTriggerEsc1[3]. The TE trigger is associated with the signal RxTriggerEsc1[2]. The acknowledge trigger is associated with the signal RxTriggerEsc1[1].

NOTE: The TX signals - TxTriggerEsc1[2], TxTriggerEsc1[1], and TxTriggerEsc1[0] - and the RX signals - RxTriggerEsc1[3], and RxTriggerEsc1[0] - are not used by DSI protocol engine.

12.4.3.9.1 Reset

The DSI protocol engine can use one of the triggers of the DSI_PHY to send a reset to the display. The DSS.DSI_CTRL[5] TRIGGER_RESET bit is set to 1 to send the trigger reset. When the software requires the trigger reset to be sent to the peripheral, the DSI protocol engine should reset its own logic but not the registers. The software can select between two reset modes:

- Immediate reset: All pending requests in TX FIFO not already taken into account for transfer scheduling, the RX FIFO requests, and the data from video port are ignored. Only the current transfer on DSI link and already scheduled ones are transmitted. All the other transfers are discarded.
- Synchronized reset: The mode is only valid if there is VC using the video mode and if it is active. The principle is to wait for the current video frame to be transferred on the link. Any data on VP after the current frame are ignored.

To select the reset mode, software users must program the DSS.DSI_CTRL[14] TRIGGER_RESET_MODE.

CAUTION

For both reset modes, the hardware should flush the FIFOs, synchronization buffers, and line buffers before resetting the DSS.DSI_CTRL[0] IF_EN bit.

12.4.3.9.2 Tearing Effect

The TE on the display is avoided by having synchronization information from the display. It is used only in command mode. In case of video mode, it is not functional. Users are responsible for selecting the command mode for the VC using the TE feature.

The software must set and send the appropriate sequence to receive the TE trigger from the peripheral. When receiving the TE trigger, the DSI protocol engine should generate the TE_TRIGGER_IRQ interrupt with TE event if the interrupt is enabled. To enable the interrupt, set to 1 the DSS.DSI_IRQENABLE[16] TE_TRIGGER_IRQ_EN bit. The DSS.DSI_IRQSTATUS[16] TE_TRIGGER_IRQ status bit indicates if the interrupt event has been generated.

One or multiple VCs can be synchronized using the same TE trigger. The DSS.DSI_VCn_TE[30] TE_EN bit should be set to indicate that the hardware should use the following TE trigger to start the transfer of the data from the related VC. This bit is reset when all the data have been sent to the peripheral. The DSS.DSI_VCn_TE[31] TE_START bit should be used when the automatic mode enabled by setting the DSS.DSI_VCn_TE[30] TE_EN bit is not used. It allows users to start the transfer manually based on application events or based on the TE trigger interrupt (TE_TRIGGER_IRQ).

The number of bytes to be transferred is defined by using the DSS.DSI_VCn_TE[15:0] TE_SIZE bit field. The TE_SIZE bit field is decremented for each payload byte (it does not include Check-sum) sent on the DSI link. The register content should not be modified by software during a transfer. The DSS.DSI_VCn_TE[15:0] TE_SIZE bit field should be set first to indicate that the following accesses to DSS.DSI_VCn_LONG_PACKET_HEADER register should be used for TE transfer.

The data can be provided from two sources (selection by setting the DSS.DSI_VCn_CTRL[1] SOURCE bit):

- L4 interconnect port using DMA request: The DMA request DSI_DMA_REQ_i (where i = 0 to 3) to should be asserted only when TE trigger is received or when the DSS.DSI_VCn_TE[31] TE_START bit is set by user and should not be asserted anymore when all the bytes defined in DSS.DSI_VCn_TE[15:0] TE_SIZE bit field have been sent on the DSI link. The VC is associated with a DMA request (from DSI_DMA_REQ0 to DSI_DMA_REQ3) by programming the number in the DSS.DSI_VCn_CTRL[23:21] DMA_TX_REQ_NB bit field. The DSS.DSI_VCn_LONG_PACKET_PAYLOAD register is used to provide the number of bytes defined by the DSS.DSI_VCn_TE[15:0] TE_SIZE bit field (the check-sum value is not provided in the DSS.DSI_VCn_LONG_PACKET_PAYLOAD register). The size of the header is not taken into account in the number of bytes to transfer. The DSS.DSI_VCn_SHORT_PACKET_HEADER register is not used.
- Video port: The DMA request is not asserted. The data are captured in the line buffer using the STALL mechanism. In case there is no line buffer instantiated (that is, DSS.DSI_CTRL[13:12] LINE_BUFFER bit field set to 0), it is not possible to use the video port to provide data. The line buffer should be filled up according to the word count defined in the DSS.DSI_VCn_LONG_PACKET_HEADER register header. The value should be written before the TE trigger event is received or before the DSS.DSI_VCn_TE[31] TE_START bit is set to 1 by software. In case the total number of bytes defined by the DSS.DSI_VCn_TE[15:0] TE_SIZE bit field is not a multiple of the word count defined in the DSS.DSI_VCn_LONG_PACKET_HEADER register, all the packets have the same size defined by the WC of the header except the last transfer. The size of the last transfer is defined by the remaining bytes to send. Since the DSS.DSI_VCn_TE[15:0] TE_SIZE bit field is modified after each packet transfer, the size of the last packet is equal to the value of DSS.DSI_VCn_TE[15:0] TE_SIZE bit field just before the last transfer (the header and the payload check-sum sizes are not included in DSS.DSI_VCn_TE[15:0] TE_SIZE bit field).

When the transfer is completed, the value of the DSS.DSI_VCn_TE[15:0] TE_SIZE bit field is equal to 0. The software must ensure that the pending data in the TX FIFO for the corresponding VC using TE are related to TE transfer. Any data in the TX FIFO that should be sent before reception of TE trigger should be sent before TE. This is done by not enabling TE trigger until all data for the corresponding VC have been sent to the peripheral. The software can check that the space allocated for the VC in the TX FIFO is empty by reading the DSS.DSI_VCn_CTRL[5] TX_FIFO_NOT_EMPTY status bit.

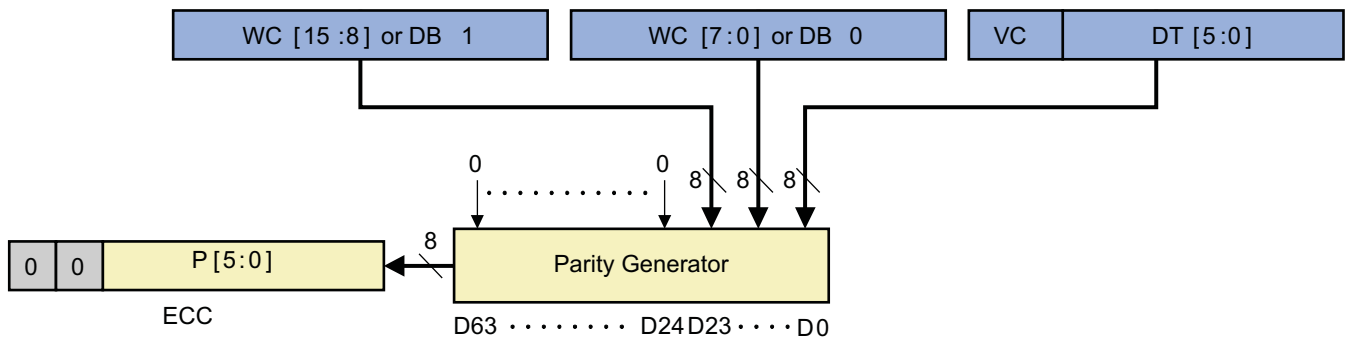

12.4.3.9.3 Acknowledge

The corresponding Acknowledge interrupt (ACK_TRIGGER_IRQ) should be generated upon reception of the acknowledge trigger. To enable the acknowledge interrupt, set the DSS.DSI_IRQENABLE[17] ACK_TRIGGER_IRQ_EN bit to 1. When the interrupt is generated, the DSS.DSI_IRQSTATUS[17] ACK_TRIGGER_IRQ status bit is set to 1.

12.4.3.10 ECC Generation

Note that the DSI protocol uses a four-byte packet header. Since ECC generation requires a fixed word length of 64-bits, the packet headers should be padded with additional bits to form a full eight-byte value for ECC generation and checking. The packet header less the ECC byte should occupy bits D[23:0] and the pad bits should occupy bits D[63:24]. All padding bits should be zero for the purpose of generating the ECC byte. ECC can be generated using a parallel approach as illustrated in Figure 12-102.

Figure 12-102. 64-Bit ECC Generation on TX Side

dss-176

The ECC generation/check can be enabled and disabled by software. It is defined by a common bit for all the VCs:

- The DSS.DSI_CTRL[2] ECC_RX_EN bit enables/disables the ECC generation in the receive direction.
- The DSS.DSI_VCn_CTRL[8] ECC_TX_EN bit enables/disables the ECC generation in the transmit direction

12.4.3.11 Checksum Generation for Long Packet Payloads

Long packets are comprised of a packet header protected by an ECC byte and a payload of 0 to $2^{16} - 1$ bytes. To detect the errors during the transmission of long packets, a checksum is calculated over the payload portion of the data packet. Note that, for the special case of a zero-length payload, the 2-byte checksum is set to 0xFFFF. The checksum can only indicate the presence of one or more errors in the payload. Unlike ECC, the checksum does not enable error correction. For this reason, checksum calculation is not useful for some unidirectional DSI implementations since the peripheral has no way for reporting errors to the host processor. Checksum generation and transmission is mandatory for host processors sending long packets to peripherals. It is optional for peripherals transmitting long packets to the host processor. However, the format of long packets is fixed; the peripherals that do not support checksum generation should transmit two bytes having value 0x0000 in place of the checksum bytes when sending long packets to the host processor. The host processor should disable checksum checking for received long packets from peripherals that do not support checksum generation.

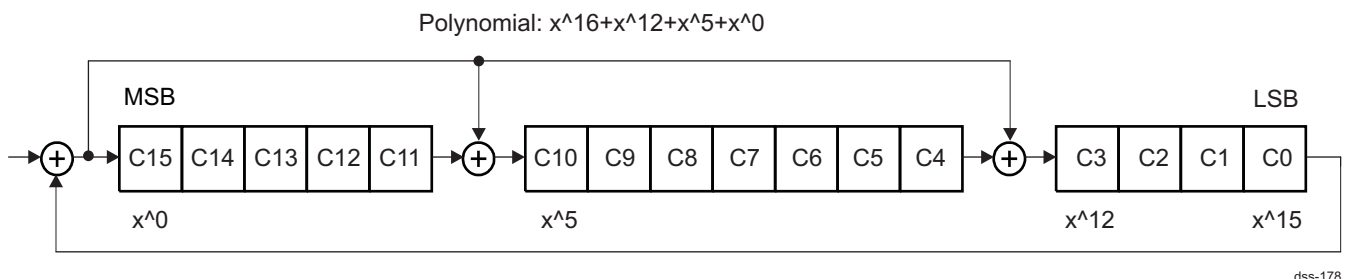

The checksum should be realized as a 16-bit CRC with a generator polynomial of $x^{16}+x^{12}+x^5+x^0$. The LS byte is sent first, followed by the MS byte. Note that within the byte, the LS bit is sent first.

Figure 12-103. Checksum Transmission

The CRC implementation is presented in Figure 12-104. The CRC shift register is initialized to 0xFFFF before packet data enters. Packet data not including the packet header then enters as a bitwise data stream from the left, LS bit first. Each bit is fed through the CRC shift register before it is passed to the output for transmission to the peripheral. After all bytes in the packet payload have passed through the CRC shift register, the shift register contains the checksum. C15 contains the checksums MSB and C0 the LSB of the 16-bit checksum. The checksum is then appended to the data stream and sent to the receiver.

Figure 12-104. 16 Bit CRC Generation Using a Shift Register

The check-sum generation/check can be enabled and disabled by software. It is defined by a common bit for all the VCs:

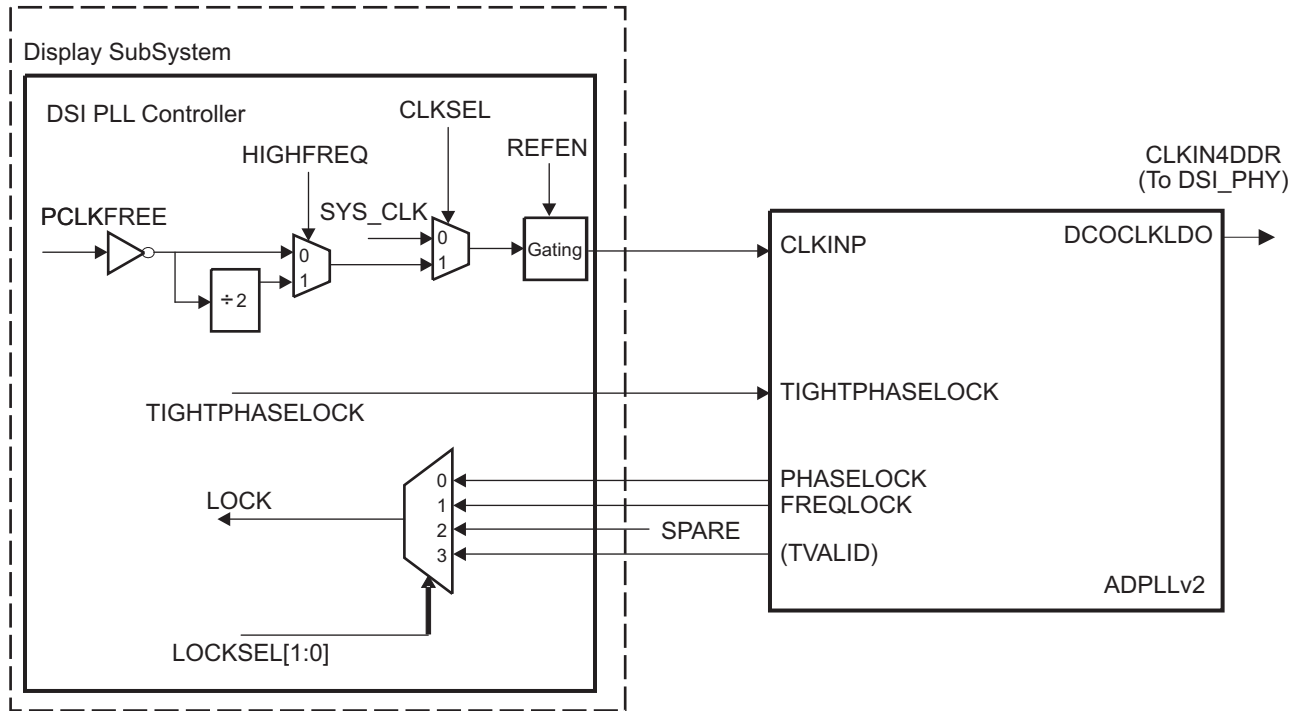

- The DSS.DSI_CTRL[1] CS_RX_EN bit enables/disables the check-sum generation in the receive direction.
- The DSS.DSI_VCn_CTRL[7] CS_TX_EN bit enables/disables the check-sum generation in the transmit direction

12.4.4.2 DSI PLL Controller Architecture

The DSI PLL is an ADPLLv2 module. The pixel clock (PCLK) frequency range is 2 to 65 MHz. This may be divided by 2. This is performed by setting the DSS.DSI_PLL_CONFIGURATION2[12] DSI_PLL_HIGHFREQ bit to 1.

Figure 12-106 shows the internal DSI PLL reference diagram.

Figure 12-106. DSI PLL Reference Diagram

Note: PCLK is inverted as the falling edge is the reference edge and ADPLLv2 uses positive edge as reference (F/F should be positive edge clock also)

dss-180

The DSI PLL clock output corresponds to the CLKIN4DDR clock of the DSI complex I/O module.

The DSI PLL reference clock is the DSI_PLL_REFCLK clock. Depending on the setting in DSS.DSI_PLL_CONFIGURATION2[11] DSI_PLL_CLKSEL bit, the reference clock can be either the DSS2_ALWON_FCLK provided by the PRCM or the PCLKFREE provided by the DISPC module.

12.4.4.3 DSI PLL Operations

The DSI PLL configuration signals operate according to Table 12-35. Table 12-35 indicates the operation when the PLL is not locked.

Table 12-35. DSI PLL Operation Modes When Not Locked

| DSI PLL Operation Mode | Stop mode Low power ⁽¹⁾ | Stop mode Fast Relock ⁽¹⁾ | Idle bypass |
|---|--|---|---|
| Mode Description | Output clocks stopped Lowest power standby | Output clocks stopped Fastest start-up time | Selects when PLL and HSDIVIDER bypass clocks are used |
| DSS.DSI_PLL_CONFIGURATION2[0] DSI_PLL_IDLE | 0 | 0 | 1 |
| DSS.DSI_PLL_CONFIGURATION2[6] DSI_PLL_LOWCURRSTBY | 1 | 0 | 1 |
| DSS.DSI_PLL_CONFIGURATION1[0] DSI_PLL_STOPMODE | 1 | 1 | X |

⁽¹⁾ Recommended

When locked, the PLL output frequency is: $[(2 \times \text{REGM}) / (\text{REGN} + 1)] \times [\text{CLKin}(\text{MHz}) / (\text{HIGHFREQ} + 1)]$
where:

- M multiplier is programmed in DSS.DSI_PLL_CONFIGURATION1[18:8] DSI_PLL_REGM bit field.
- N divider is programmed in DSS.DSI_PLL_CONFIGURATION1[7:1] DSI_PLL_REGN bit field.
- HIGHFREQ divider by 2 is enabled by setting the DSS.DSI_PLL_CONFIGURATION2[12] DSI_PLL_HIGHFREQ bit to 1.

12.4.4.4 DSI PLL Controller Shadowing Mechanism

The configuration registers are accessed through the DSI protocol engine register space using SCP port. This includes all the configuration signals and the returning status signals.

CAUTION

All writes must be 32-bit operations as the SCP always transfers 32 bits. Any 16-bit or 8-bit operations may lead to unpredictable errors.

A shadow mechanism is implemented for appropriate register values so that configurations may optionally be updated in synchronism with the display controller (DISPC) and DSI protocol engine. The front porch time from the DISPC indicates the time when making the update of the value. All the required updated values must have been written before this signal is asserted. Refer to [Section 12.4.3.5.1](#) for more details.

12.4.4.5 Error Handling

The PLL lock and recalibration signals may be monitored to detect loss of lock or requirement to recalibrate (due to large temperature change since the last lock request):

- The DSS.DSI_PLL_STATUS[1] DSI_PLL_LOCK status bit gives the DSI PLL lock state.
- The DSS.DSI_PLL_STATUS[2] DSI_PLL_RECAL status bit informs if the PLL must be uncalibrated

These signals can also generate interrupts at DSI protocol engine level:

- The PLL_LOCK_IRQ interrupt indicates that the DSI PLL control module has sent a lock request to the DSI PLL. To monitor this event, read the DSS.DSI_IRQSTATUS[7] PLL_LOCK_IRQ bit. Set this bit to 1 to clear the status bit.
- The PLL_UNLOCK_IRQ interrupt indicates that the DSI PLL control module has sent an unlock request to the DSI PLL. To monitor this event, read the DSS.DSI_IRQSTATUS[8] PLL_UNLOCK_IRQ bit. Set this bit to 1 to clear the status bit.
- The PLL_RECAL_IRQ interrupt indicates that the DSI PLL control module has sent a recalibration request to the DSI PLL. To monitor this event, read the DSS.DSI_IRQSTATUS[9] PLL_RECAL_IRQ bit. Set this bit to 1 to clear the status bit.

12.4.5 DSI Complex I/O Functionalities

12.4.5.1 DSI Complex I/O Overview

DSI_PHY is a complex I/O with 3 unidirectional (HS) Lane Modules. This includes 2 data lane modules and 1 clock lane module. Each lane module has 2 data pads (DX, DY). These data pads are connected with a complementary lane module on the DSI receiver device using point to point interconnect.

Lane modules support high-speed burst mode. Forward direction and reverse direction escape modes are also supported. Escape modes maybe used for Low Power Data Transmission, among other things.

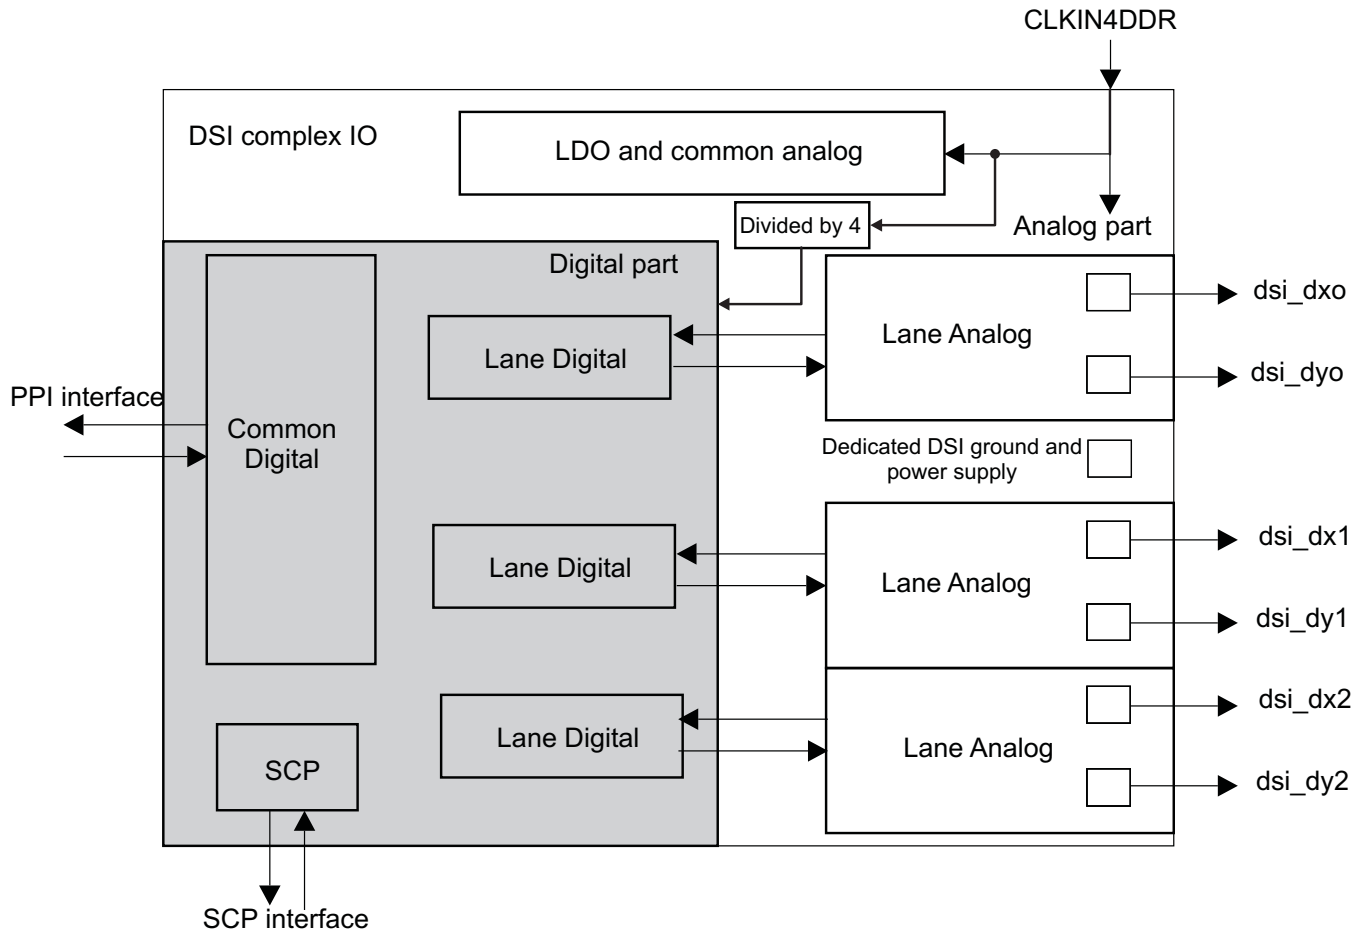

The maximum data rate supported in high-speed Mode is 800Mbps per data lane. The lane module function and position is configurable, that is, any lane module can be chosen as clock lane module, and DX/DY data pad for each lane module can be configured as either DP or DN pins defined by DSI_PHY spec.

DSI_PHY interacts with the higher layers of the DSI link through the PHY-Protocol Interface (PPI). DSI_PHY does not include a PLL; a high frequency clock input is expected in HS mode (CLKIN4DDR). DSI_PHY supports also Serial Configuration Protocol (SCP) to set various configuration and control registers. The DSI_PHY supports GPIO operation on each of the six data pins.

12.4.5.2 DSI Complex I/O Architecture

Figure 12-107 shows the top-level block diagram of DSI_PHY. It has 3 lane module functions, and some common analog and digital functions. Each lane module has an analog and a digital part. The digital lane circuitry implements the protocol interface of MIPI DSI_PHY. It interacts with the DSI protocol engine.

Figure 12-107. DSI Complex I/O Architecture

dss-189

The lane module analog circuit converts the digital levels to the LP and HS level signals for the link. It also converts the analog state of the link into digital levels.

For high-speed signals, the lane module analog also does the last stage untiming of HS data to obtain optimum quadrature with the HS clock.

DSI_PHY has an internal LDO to generate 1.2V supply. This LDO requires an off-chip decoupling capacitor and hence a dedicated pin. DSI_PHY expects a high frequency clock input in HS mode.

The clock input is required to have four times the frequency of the DDR clock, that is, twice the HS data rate. GPIO functions are supported on each dsi_dxi and dsi_dyi.

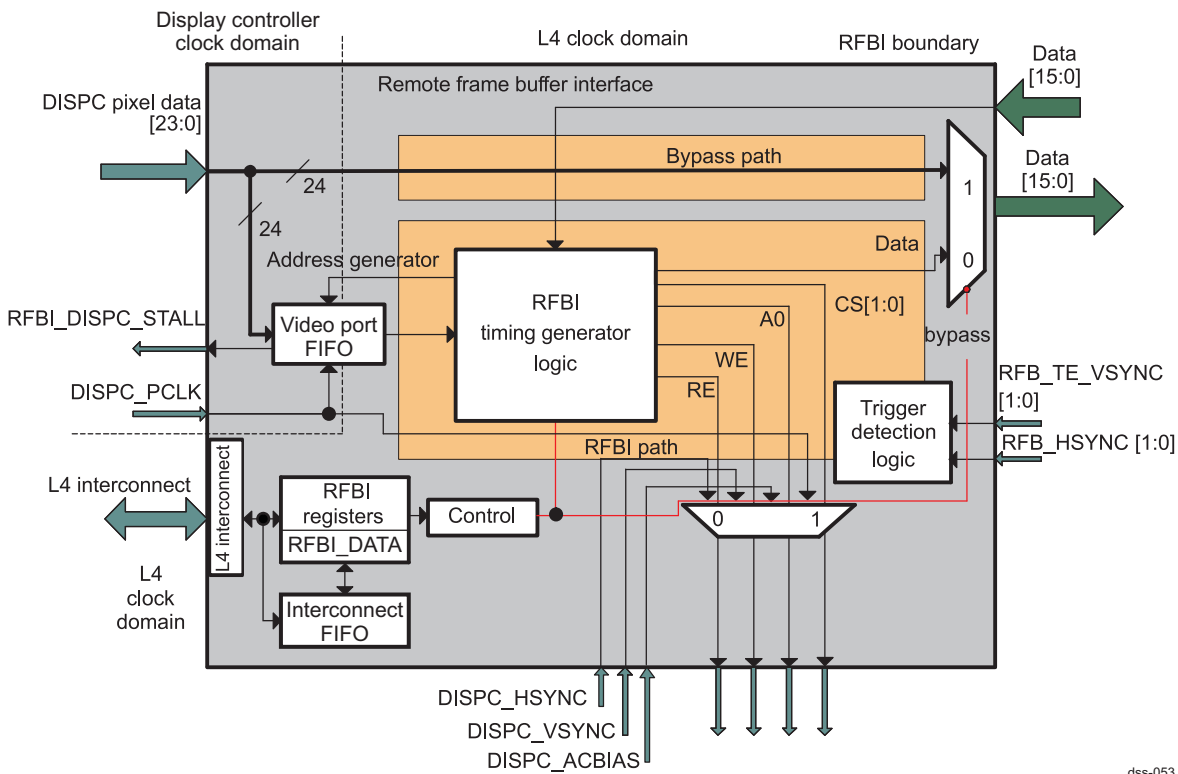

12.4.6 RFBI Functionalities

The RFBI module can capture the output pixel from the display controller and send the data to the RFB in the LCD panel. The application configures the RFBI module, sends commands, reads data, and configures the display controller to send data fetched from the system memory by the display controller DMA engine. The commands/data are sent using an 8-, 9-, 12-, or 16-bit parallel interface.

The display controller is configured to send the data in 12-, 16-, 18-, or 24-BPP format. In the video port FIFO, the encoded pixel values are in an LSB alignment independently of the endianness in system memory.

Figure 12-108 shows an overview of the RFBI architecture.

Figure 12-108. RFBI Architecture Overview

dss-053

12.4.6.1 RFBI FIFO

The input video port FIFO receives data from the display controller at the pixel clock. The data in the video port FIFO are read by the RFBI and are sent to the LCD panel. The video port FIFO is 24 bits wide and each pixel in 12-, 16-, 18-, and 24-BPP format is stored in the video port FIFO using one 24-bit value aligned on the 24-bit LSB. Section 12.4.6.4, *Output Parallel Modes*, shows an example of an output configuration based on the interface width (16 bits) and the pixel format output (24 bits).

12.4.6.2 RFBI Interconnect FIFO

The interconnect FIFO receives the data from RFBI_DATA write requests to the L4 interconnect slave port. The data in the interconnect FIFO are read by the RFBI and sent to the LCD panel. The width of the interconnect FIFO is 32 bits. The size of the interconnect FIFO is 24 words of 32 bits (that is, 24 words of RFBI_DATA).

12.4.6.3 Input Pixel Formats

The supported pixel formats in the RFBI module are: RGB24-888, RGB18-666, RGB16-565, and RGB12-444 as output from the display controller and from the L4 (for writing parameters). In both cases, the pixels are formatted in accordance with the configuration of the output interfaces (multiple cycles).

12.4.6.4 Output Parallel Modes

The RFBI output modes are 8-, 9-, 12-, and 16-bit interfaces. Any mode can be selected regardless of the pixel format. Set the right configuration in the cycle registers to define a valid configuration for each output cycle.

The following example is an output configuration based on the 16-bit interface width and the 24-bit pixel format ($i = 0$ or 1) (see also [Table 12-36](#)):

- The DSS.RFBI_CONFIG_i[10:9] CYCLEFORMAT bit field is set to 0x3 (three cycles for two pixels).
- The DSS.RFBI_DATA_CYCLE1_i register is set to 0x00000010 (16 bits from pixel 1 for the first cycle).
- The DSS.RFBI_DATA_CYCLE2_i register is set to 0x00080808 (8 bits from pixel 1 and pixel 2 and alignment of 8 bits from pixel 2 for the second cycle).
- The DSS.RFBI_DATA_CYCLE3_i register is set to 0x00100000 (16 bits from pixel 2 for the third cycle).

Table 12-36. 16-Bit Interface Configuration/24-Bit Mode

| | 24-Bit Mode | | |
|----------|-------------|-----------|-----------|
| | 1st Cycle | 2nd Cycle | 3rd Cycle |
| Data[15] | R0[7] | B0[7] | G1[7] |
| Data[14] | R0[6] | B0[6] | G1[6] |
| Data[13] | R0[5] | B0[5] | G1[5] |
| Data[12] | R0[4] | B0[4] | G1[4] |
| Data[11] | R0[3] | B0[3] | G1[3] |
| Data[10] | R0[2] | B0[2] | G1[2] |
| Data[9] | R0[1] | B0[1] | G1[1] |
| Data[8] | R0[0] | B0[0] | G1[0] |
| Data[7] | G0[7] | R1[7] | B1[7] |
| Data[6] | G0[6] | R1[6] | B1[6] |
| Data[5] | G0[5] | R1[5] | B1[5] |
| Data[4] | G0[4] | R1[4] | B1[4] |
| Data[3] | G0[3] | R1[3] | B1[3] |
| Data[2] | G0[2] | R1[2] | B1[2] |
| Data[1] | G0[1] | R1[1] | B1[1] |
| Data[0] | G0[0] | R1[0] | B1[0] |

12.4.6.5 Unmodified Bits

In a cycle, if every bit in the interface does not have a pixel value, the status of the unused bits can be programmed to be 0, 1, or the previous value (I/O power consumption optimization).

12.4.6.6 Bypass Mode

In bypass mode, the RFBI path is bypassed and the display controller data and signals are sent directly to the output interface of the RFBI.

12.4.6.7 Send Commands

The commands are written through the L4 interconnect and into the DSS.RFBI_CMD register. After a command is sent, another one can be accepted by the module and set. If the processing of a command is not complete, the MPU access to change the command stalls.

12.4.6.8 Read/Write

Depending on the status of A0, WE, and RE, the commands and display/parameter data are written to the panel (handled by the state-machine for the commands/parameter data and stored in memory for the display data), or the display data/status values are read from the LCD panel (status and display data in the LCD panel memory). The polarity of A0 (RFBI_A0 signal), WE (RFBI_WR signal), RE (RFBI_RD signal), and CSx (RFBI_CSx signal, with x = 0, 1) is programmable.

Table 12-37 describes the read/write function.

Table 12-37. Read/Write Function Description

| A0 (RFBI_A0) | WE (RFBI_WR) | RE (RFBI_RD) | Function Description |
|--------------|--------------|--------------|--|
| 1 | 0 | 1 | Display data write, parameter data write |
| 1 | 1 | 0 | Display data read |
| 0 | 1 | 0 | Status read |
| 0 | 0 | 1 | Command data write |

A minimum of RFBI_Cs cycle time, as defined in Table 12-38, is required to keep the RFBI_CSx signal asserted between write transfers of multiple pixels.

Table 12-38 indicates the minimum cycle time for RFBI_CSx, depending on the source of pixels (display controller or L4 interconnect slave port) and the cycle format (1 pixel/cycle, 1 pixel/2 cycles, 1 pixel/3 cycles, or 2 pixels/3 cycles).

Table 12-38. Minimum Cycle Time for CSx/WE Always Asserted

| RFBI Performance | RFBI_CONFIGi[10:9] CYCLEFORMAT | RFBI_CONFIGi[8:7] L4FORMAT | Minimum Cycle Time (in Number of L4 Cycles) |
|--------------------|-----------------------------------|-------------------------------|---|
| L4 interconnect | 1 pixel/cycle | 1 pixel | 5 |
| | 1 pixel/2 cycles | 1 pixel | 4 |
| | 1 pixel/3 cycles | 1 pixel | 4 |
| | 2 pixels/3 cycles | 1 pixel | 6 |
| | 1 pixel/cycle | 2 pixels | 4 |
| | 1 pixel/2 cycles | 2 pixels | 4 |
| | 1 pixel/3 cycles | 2 pixels | 4 |
| | 2 pixels/3 cycles | 2 pixels | 6 |
| Display Controller | 1 pixel/cycle | N/A | 4 |
| | 1 pixel/2 cycles | N/A | 3 |
| | 1 pixel/3 cycles | N/A | 3 |
| | 2 pixels/3 cycles | N/A | 6 |

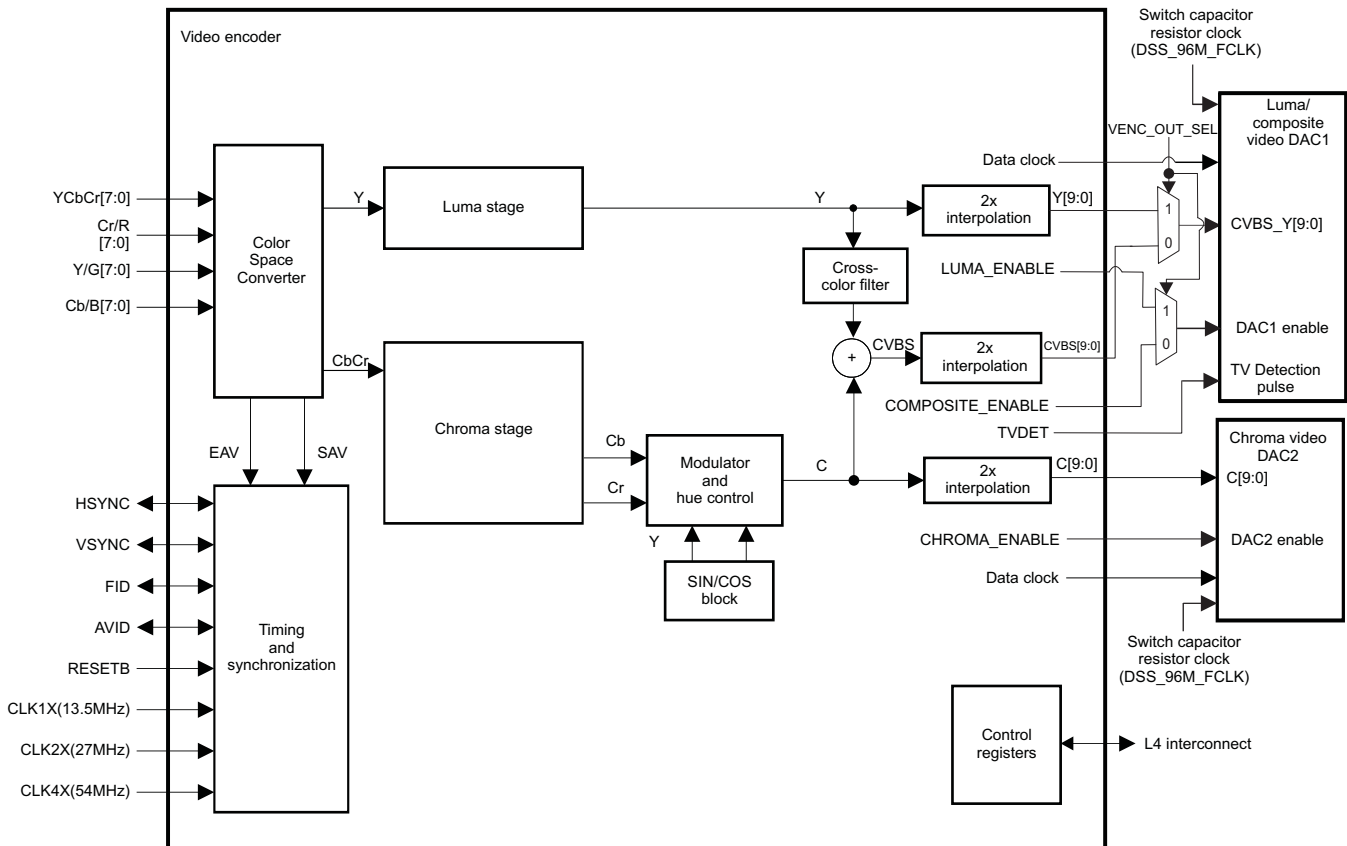

12.4.7 Video Encoder Functionalities

The input formats supported by the encoders are 24-bit 4:4:4 RGB. The encoder output is the DAC (for more information, see Section 12.2, *Display Subsystem Environment*). In the display subsystem, the input format from the display controller is always 24-bit RGB. The RGB-to-YCbCr color space converter converts the 24-bit RGB pixel data to 24-bit YCbCr data.

The remaining Cb and Cr color components enter the 2-to-1 chrominance decimation, which reduces by half the chrominance bandwidth and the amount of chrominance data. After the data manager, the encoder processes in 4:2:2 data path up to the 2x interpolation. A luma delay synchronizes luma to chrominance data.

Figure 12-109 shows an overview of the video encoder architecture.

Figure 12-109. Video Encoder Architecture Overview

dss-079

NOTE: Output video mode can be either composite video (CVBS output) or Separate video (s-video: Luma and chroma outputs):

- Composite video: DAC1 is used
 - Separate video (luma/chroma): Both DAC1 (luma) and DAC2 (chroma) are used
- The selection is programmed with DSS.DSS_CONTROL[6] VENC_OUT_SEL bit. Composite video is the default selection.

12.4.7.1 Test Pattern Generation

For diagnostic purposes, the data manager can be forced to output 100/100 color bar RGB/YCbCr data by setting the SVDS field VENC_F_CONTROL[7:6] register to 0x1.

Table 12-39. 100/100 Color Bar Table

| COLOR | R | G | B | Y | Cb | Cr |
|---------|-----|-----|-----|-----|-----|-----|
| White | 255 | 255 | 255 | 235 | 128 | 128 |
| Yellow | 255 | 255 | 0 | 210 | 16 | 146 |
| Cyan | 0 | 255 | 255 | 170 | 166 | 16 |
| Green | 0 | 255 | 0 | 145 | 54 | 34 |
| Magenta | 255 | 0 | 255 | 106 | 202 | 222 |
| Red | 255 | 0 | 0 | 81 | 90 | 240 |
| Blue | 0 | 0 | 255 | 41 | 240 | 110 |
| Black | 0 | 0 | 0 | 16 | 128 | 128 |

12.4.7.2 Luma Stage

The luma stage includes a luma pipeline delay, luma shaping, 2x interpolation filter, and luma variable delay. The luma pipeline delay block is used to match luma path length to chroma path length. In the luma gain shaper, a programmable gain is first applied to the luminance data output. The luminance gain is defined by the DSS.VENC_GAIN_Y register. Horizontal sync, vertical sync, and setup insertion are then performed.

Black level and blank level are programmable through the DSS.VENC_BLACK_LEVEL and DSS.VENC_BLANK_LEVEL registers. All the transition edges of the luminance signal, such as sync edges and active video edges, are properly shaped and filtered to keep the bandwidth within the standards.

After all required components of the luminance signal are added, the resulting signal is low-passed and interpolated to 2x-pixel rate. This 2x interpolation simplifies the external analog reconstruction filter design and improves the signal-to-noise ratio.

12.4.7.3 Chroma Stage

The chroma stage includes a low-pass filter, first-stage 2x interpolation, chroma gain shaper, and second-stage 2x interpolation. A pair of programmable gains adjusts the time-multiplexed U/V signal. The gains for U and V are independently controlled by the DSS.VENC_GAIN_U and DSS.VENC_GAIN_V register bits.

12.4.7.4 Subcarrier and Burst Generation

The encoder uses a 32-bit subcarrier increment to synthesize the subcarrier. The value of the subcarrier increments required to generate the desired subcarrier frequency for NTSC and PAL format is found by:

$$S_CARR = \text{ROUND} ([F_{sc}/F_{clkenc}] \times 2^{32})$$

where:

F_{sc} = Frequency of the subcarrier

F_{clkenc} = Frequency of the internal video encoder

The DSS.VENC_S_CARR register controls the subcarrier frequency. The DSS.VENC_C_PHASE register controls the phase of the subcarrier. The phase of the color subcarrier is reset to DSS.VENC_C_PHASE. Table 12-40 presents the VENC_S_CARR register values depending the standard and pixel type used.

Table 12-40. VENC_S_CARR Register Recommended Values

| Standard | Pixel Type | Subcarrier Frequency (Fsc) (MHz) | Fclkenc (MHz) | VENC_S_CARR register value (hexa) |
|-------------------|--------------|----------------------------------|---------------|-----------------------------------|
| NTSC-M, J | ITU-R601 | 3.579545 | 27 | 0x21F07C1F |
| PAL-M | ITU-R601 | 3.5756083125 | 27 | 0x21E6EFE3 |
| PAL-B, D, G, H, I | ITU-R601 | 4.43361875 | 27 | 0x2A098ACB |
| NTSC-M, J | Square pixel | 3.579545 | 24.5454 | 0x25555555 |
| PAL-M | Square pixel | 3.579561149 | 24.5454 | 0x1F15C01E |
| PAL-B, D, G, H, I | Square pixel | 4.43361875 | 29.50 | 0x26798C0C |

CAUTION

In square pixel mode, an external clock generator is needed to provide sampling frequencies (49.09 MHz for NTSC square pixel or 59 MHz for PAL square pixel).

The color subcarrier reset has four modes:

- No reset

- Reset every two lines
- Reset every two fields
- Reset every eight fields

The DSS.VENC_C_PHASE register can be used to adjust the SCH (subcarrier to horizontal sync phase). The DSS.VENC_BSTAMP_WSS_DATA[6:0] BSTAP bit field sets the amplitude of the color burst. The DSS.VENC_M_CONTROL[1] PAL bit enables phase alternation line encoding.

A phase switching subcarrier is generated to encode the chrominance signal when the DSS.VENC_M_CONTROL[1] PAL bit is set to 1. Otherwise, a normal subcarrier is generated. Phase alternation line refers to the encoding scheme in which the subcarrier alternates between two phases every scan line. Two possible alternation sequences are possible, and the DSS.VENC_M_CONTROL[5] PALPHS bit selects one of these sequences.

12.4.7.5 Closed Caption Encoding

The encoder can be programmed to encode closed-caption data and extended data in the selected line. The closed-caption data are sent to the encoder through the L4 interconnect. The data stream consists of 7-bit US-ASCII code and 1 odd-parity bit (see Table 12-41).

Table 12-41. Closed-Caption Data Format

| MSB | | | | | | LSB | |
|-------|-------|-------|-------|-------|-------|-------|------------|
| Bit 6 | Bit 5 | Bit 4 | Bit 3 | Bit 2 | Bit 1 | Bit 0 | Odd parity |

The standard service encodes closed caption in both fields; the extended service encodes closed caption in even fields. When set to 1, the DSS.VENC_L21_WC_CTL L21EN[0] bit enables closed-caption encoding in odd fields. When set to 1, the DSS.VENC_L21_WC_CTL L21EN[1] bit enables closed-caption encoding in even fields.

To select the scan line where the CC data are encoded, program the VENC_LN_SEL[4:0] SLINE bit field.

CAUTION

The setting of the value of the SLINE[4:0] bit field depends on the video standard:

- PAL mode: Because there is a one-line offset, program the desired line number – 1. To activate the closed caption on line 21 (0x15), program the value $0x15 - 1 = 0x14$. The default value is $0x15 + 1 = 0x16$ (line 22).
- NTSC mode: Because there is a four-line offset, program the desired line number – 4. To activate the closed caption on line 21 (0x15), program the value $0x15 - 4 = 0x11$. The default value is $0x15 + 4 = 0x19$ (line 25).

The DSS.VENC_LN_SEL[25:16] LN21_RUNIN bit field should be kept at reset value (0x10B). Four closed-caption data registers contain the data to be encoded. The DSS.VENC_LINE21[15:8] L21O and DSS.VENC_LINE21[7:0] L21O bit fields contain the first and the second bytes, respectively, of closed-caption data to be encoded in the odd field. The DSS.VENC_LINE21[31:24] L21E and DSS.VENC_LINE21[23:16] L21E bit fields contain the first and the second bytes, respectively, of data to be encoded in the even field.

Immediately after the closed-caption data is written to the registers, in either the odd field or even field, the corresponding closed-caption status bit (DSS.VENC_STATUS[4] CCE or DSS.VENC_STATUS[3] CCO) is reset to 0 to indicate that the closed-caption data is available in the closed-caption data registers and yet to be encoded.

Immediately after the closed-caption data is encoded, the DSS.VENC_STATUS[4] CCE bit or the DSS.VENC_STATUS[3] CCO bit is set to 1 to indicate that the closed-caption data has been encoded and is ready to accept new data. As seen in Figure 12-110, a null character is automatically inserted if the closed-caption data is not written to the closed-caption data registers in time for encoding.

The running clock frequency is controlled by the DSS.VENC_CC_CARR_WSS_CARR[15:0] FCC bit field which should be kept at reset value (0x2631) to get 5034960.5Hz (32xfline) for NTSC-601. The closed-caption running clock common frequencies are detailed in Table 12-42.

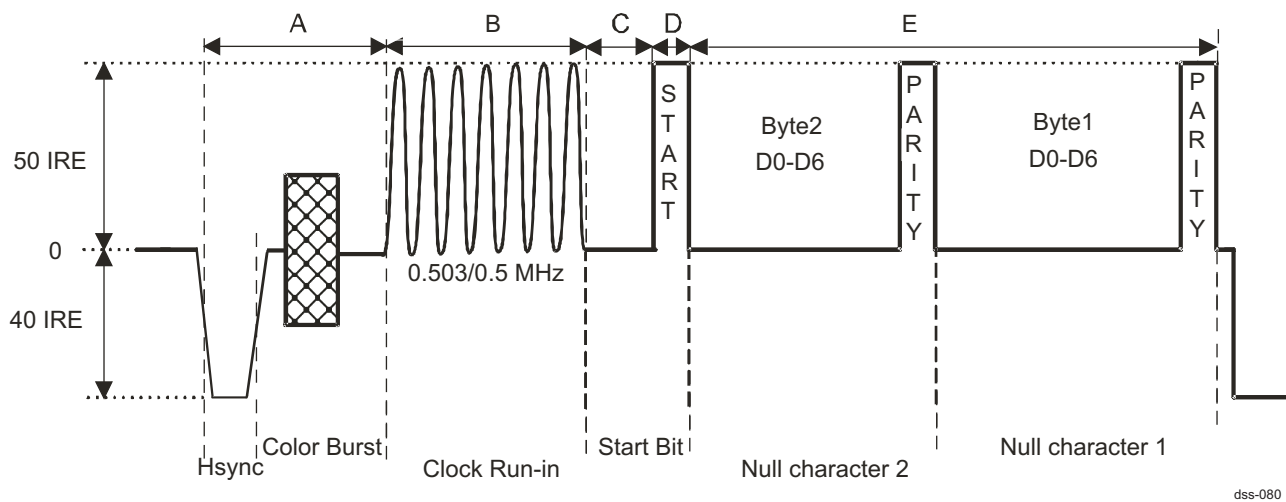

Table 12-42. Closed-Caption Run Clock Frequency Settings

| | NTSC-601 | PAL-601 | NTSC Square Pixel | PAL Square Pixel |
|---|----------|---------|-------------------|------------------|
| VENC_CC_CARR_WSS_CARR[15:0] FCC bit field value | 0x2631 | 0x25ED | 0x2A03 | 0x22B6 |

The closed-caption data is encoded in nonreturn-to-zero (NRZ) format. Additionally, the data translates to the IRE scale as follows: 0 = 0 IRE; 1 = 50 IRE.

Figure 12-110 shows the parameters of closed-caption line data implemented in different standards.

Figure 12-110. Closed Captioning Timing

NOTE:

- The interval A is controlled by the DSS.VENC_LN_SEL[25:16] LN21_RUNIN bit field.
- The interval B is controlled by DSS.VENC_CC_CARR_WSS_CARR[15:0] FCC bit field.

Table 12-43. Closed-Caption Standard Timing Values

| Intervals | Description | Timing Values for Encoding | | | Timing Values for Decoding | | |
|-----------|----------------------------------|----------------------------|-----------|-----------|----------------------------|-----------|-------------|
| | | Minimal | Nominal | Maximal | Lower Bound | Nominal | Upper Bound |
| A | HSYNC to clock running | 10.250 μs | 10.500 μs | 10.750 μs | 10.000 μs | 10.500 μs | 11.000 μs |
| B | Clock running | | 12.910 μs | | | 12.910 μs | |
| C | Clock running to third start bit | | 3.972 μs | | | 3.972 μs | |
| D | Start bit | | 1.986 μs | | | 1.986 μs | |
| E | Data characters | | 31.778 μs | | | 31.778 μs | |

NOTE: All timing values listed in Table 12-43 are measured from the mid-point (half amplitude) on all edges.

For a complete description of copy protection including CGMS-A, please refer to CEA-608-x standard

12.4.7.6 Wide-Screen Signaling (WSS) Encoding

The encoder can embed data, encoded in accordance with the IEC61880 and ITU-R 1119 data insertion standard, within the vertical blanking interval.

The encoder supports WSS data insertion on line 20 of every frame in the NTSC format. WSS data insertion is enabled by activating the DSS.VENC_L21_WC_CTL[14:13] EVEN_ODD_EN bit and by programming the VENC_BSTAMP_WSS_DATA[27:8] WSS_DATA bit field.

The running clock frequency is controlled by the DSS.VENC_CC_CARR_WSS_CARR[31:16] FWSS bit field. The wide-screen signaling running clock common frequencies are detailed in [Table 12-44](#)

Table 12-44. Wide-Screen Signaling Run Clock Frequency Settings

| | NTSC-601 | PAL-601 | NTSC Square Pixel | PAL Square Pixel |
|---|----------|---------|-------------------|------------------|
| VENC_CC_CARR_WSS_CARR[31:16] FWSS bit field value | 0x043F | 0x2F72 | 0x04AC | 0x2B6D |

To select the line where the WSS data are encoded, program the DSS.VENC_L21_WC_CTL[12:8] LINE bit field.

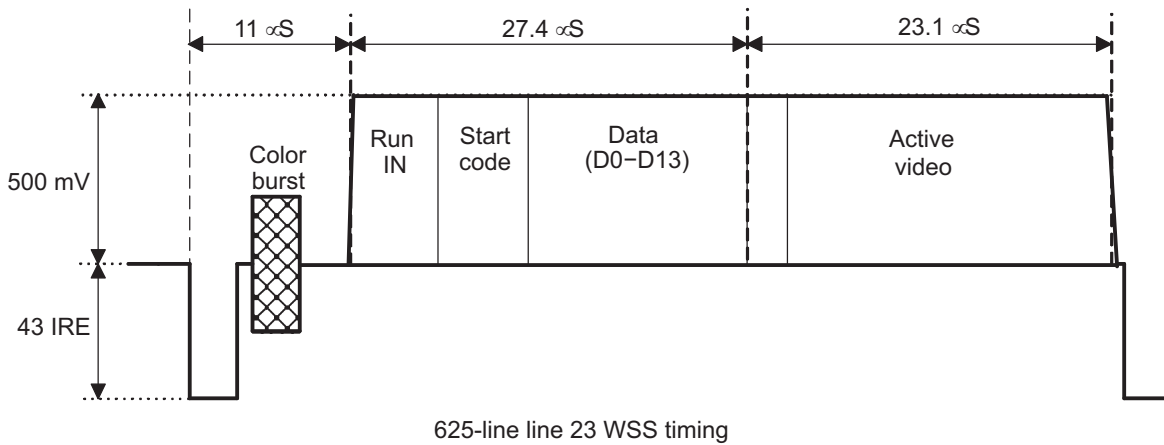

CAUTION

The setting of the LINE[12:8] bit field value depends on the video standard:

- PAL mode: There is an one line offset, so program the wanted line number - 1. The recommended value is line $0x16 + 1 = 0x17$ (23rd line). Note that the default value is $0x14 + 1 = 0x15$ (21st line).
- NTSC mode: There is a four line offset, so program the wanted line number - 4. The recommended value is line $0x10 + 4 = 0x14$ (20th line). Note that the default value is $0x14 + 4 = 0x18$ (24th line).

The WSS encoding block assumes that a full 10-bit video range is used to determine the 70 percent of peak-white amplitude of a logic-1 bit. The encoder also supports WSS data insertion on line 23 in the PAL format. Both waveforms are shown in [Figure 12-111](#).

Figure 12-111. WSS Timing

dss-081

12.4.7.7 Video DAC Architecture

Figure 12-112 shows the architecture of the dual 10-bit video DAC.

Figure 12-112. Dual 10-Bit Video DAC Architecture

dss-082

The display subsystem provides the necessary control signals to interface the memory frame buffer directly to external displays (TV sets). Two (one per channel) 10-bit current steering DAC is used to generate the video analog signal. The video mode DAC 1 (luma/composite) also includes the TV detection/disconnection and power-down mode features.

12.4.7.8 Video DC/AC Coupled TV Load

The dual 10-bit video DAC supports both dc-coupled and ac-coupled TV loads. The CONTROL.CONTROL_DEVCONF1[11] TVACEN bit is used to define which output coupling is used (0: Dc coupling; 1: Ac coupling). This bit is the first one to be programmed according to the TV load on the PCB board.

NOTE: When dc coupling is used, note that there is a 385-mV dc offset at the TVOUT output (tv_out1 for DAC1 and tv_out2 for DAC2).

12.4.7.9 TV Detection/Disconnection Pulse Generation and Usage

12.4.7.9.1 TV Detection/Disconnection Pulse Generation

The TV detect block is an integral part of the dual video DAC module.

NOTE:

- The TV detection/disconnection feature is supported only for VDAC1.
- The TV disconnection feature is recommended for power saving purpose. The TV detection/disconnection is only operational when video out is active. Therefore to detect cable connection automatically, it is necessary to periodically activate the video out to test for cable presence.

This block compares the output (tv_out1) to reference (tv_vref) voltages, to sense the condition of the load. To operate, the TV detect requires two digital signals, TVACEN and TVDET. The TVACEN signal indicates to both TVOUT buffer and the TV detect circuit if the load is ac or dc coupling to adjust accordingly. TVDET is a digital pulse at the frequency of the TV sync pulses. The operation of the circuit is based on the difference in voltage levels in the output of the buffer depending of the load status. The TV detect block compares the output against a couple of references and the result is latched at the start of every sync pulse. The status is read later in with the TVDET pulse rising edge.

The following registers are used to set the TV detection/disconnection pulse:

- The DSS.VENC_TVDETGP_INT_START_STOP_X register defines which pixels are used to start and stop the pulse inside their respective line.
- The DSS.VENC_TVDETGP_INT_START_STOP_Y register defines which lines are used to start and stop the pulse.
- The DSS.VENC_GEN_CTRL[0] EN bit enables or disables the TVDET pulse (0: Disable; 1: Enable).
- The DSS.VENC_GEN_CTRL[16] TVDP bit sets the TVDET pulse polarity (0: Active low; 1: Active high).

12.4.7.9.2 TV Detection Procedure

The TV detection procedure is the following:

1. Initial setup:
 - Program the DSS.VENC_TVDETGP_INT_START_STOP_X and DSS.VENC_TVDETGP_INT_START_STOP_Y registers to define on which pixels and lines, respectively, the TVDET pulse will start and stop.
 - Set the DSS.VENC_GEN_CTRL[16] TVDP bit to 1 (reset value) for a TVDET pulse active high polarity.
 - Set the DSS.VENC_GEN_CTRL[0] EN bit to 1 to enable the TVDET pulse generation.
2. The TVDET signal is set to low by hardware according to the settings in the DSS.VENC_TVDETGP_INT_START_STOP_X and DSS.VENC_TVDETGP_INT_START_STOP_Y registers.
3. Set the VENC_OUTPUT_CONTROL[0] LUMA_ENABLE bit (in s-video mode) or the VENC_OUTPUT_CONTROL[1] COMPOSITE_ENABLE (in composite video mode) to 1 to enable the video DAC1 output.
4. Power up the vdda_dac voltage for VDAC and the TVOUT buffer (repeat every TV field during the horizontal synchronization). This is software controlled through an I²C interface connected to the power IC .
5. The TVDET pulse is set high by hardware according to the settings in the DSS.VENC_TVDETGP_INT_START_STOP_X and DSS.VENC_TVDETGP_INT_START_STOP_Y registers.
6. Check the TVINT output signal: When TVINT is set to 1, the load is connected.

CAUTION

- If ac coupling is selected, two TVDET pulses are required to set high the TVINT signal. Due to the internal logic of the video DAC1, the TVINT signal is generated after the next positive edge of the TVDET signal that happens during the next VSYNC timing.
- If dc coupling is selected, only one TVDET pulse is required to set high the TVINT signal.

12.4.7.9.3 TV Disconnection Procedure

The TV disconnection procedure is the following:

1. Initial setup:
 - Program the DSS.VENC_TVDETGP_INT_START_STOP_X and DSS.VENC_TVDETGP_INT_START_STOP_Y registers to define on which pixels and lines, respectively, the TVDET pulse will start and stop.
 - Set the DSS.VENC_GEN_CTRL[16] TVDP bit to 1 (reset value) for a TVDET pulse active high polarity.
 - Set the DSS.VENC_GEN_CTRL[0] EN bit to 1 to enable the TVDET pulse generation.
2. The TVDET signal is set to low by hardware according to the settings in the DSS.VENC_TVDETGP_INT_START_STOP_X and DSS.VENC_TVDETGP_INT_START_STOP_Y registers.
3. The TVDET pulse is set high by hardware according to the settings in the DSS.VENC_TVDETGP_INT_START_STOP_X and DSS.VENC_TVDETGP_INT_START_STOP_Y registers.
4. Check the TVINT output signal: When TVINT is reset to 0, the load is disconnected.
5. Reset the VENC_OUTPUT_CONTROL[0] LUMA_ENABLE bit (in s-video mode) or the VENC_OUTPUT_CONTROL[1] COMPOSITE_ENABLE (in composite video mode) to 0 to disable the video DAC1 output.
6. Power-down the vdda_dac voltage for VDAC and the TVOUT buffer (repeat every TV field during the horizontal synchronization). This is software controlled through an I²C interface connected to the power IC.

CAUTION

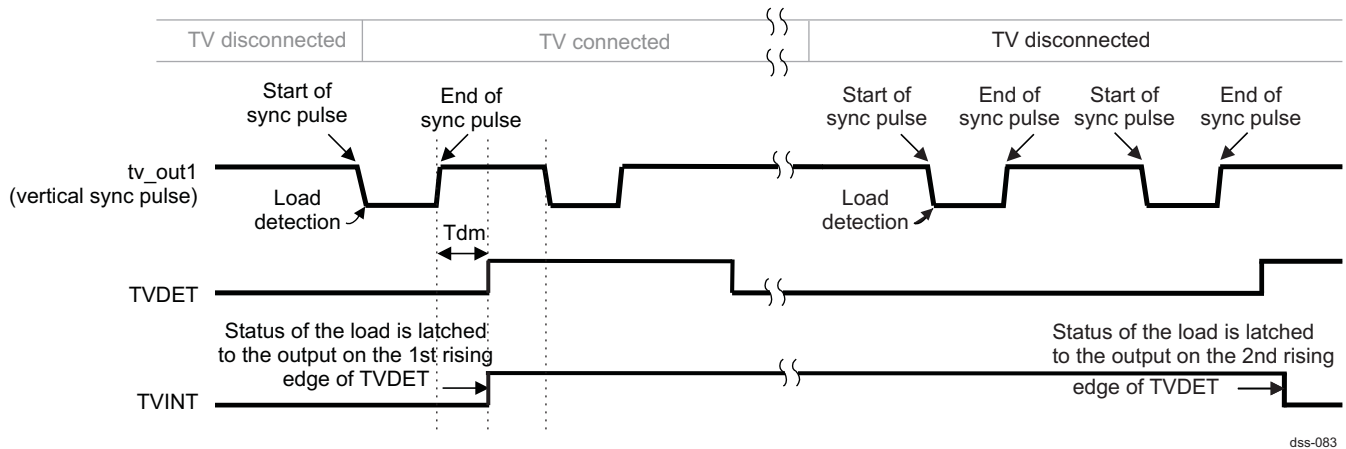

- If dc coupling is selected, two TVDET pulses are required to set low the TVINT signal. Due to the internal logic of the video DAC1, the TVINT signal is generated after the next positive edge of the TVDET signal that happens during the next VSYNC timing.
- If ac coupling is selected, only one TVDET pulse is required to set low the TVINT signal.

12.4.7.9.4 Recommended TV Detection/Disconnection Pulse Waveform

To enable the detection/disconnection of the load, the circuit requires that the TVDET pulse resembles the following waveform. As explained in [Section 12.4.7.9.2, TV Detection Procedure](#), and in [Section 12.4.7.9.3, TV Disconnection Procedure](#) by using the video encoder registers, the TVDET pulse polarity, start and stop is programmable. The only critical parameter is T_{dm}, which should be longer than the delay through the DAC and TVOUT buffer, which is at least 750 ns.

If dc-coupling is selected, the TVINT output signal for TV detection is latched at the rising edge of the first TVDET signal but the TVINT output signal for TV disconnection is latched after the next rising edge of the TVDET signal that happens during the next VSYNC timing. [Figure 12-113](#) shows the waveforms for the dc-coupling TV detect pulse (TVDET) when load is connected and disconnected.

Figure 12-113. DC-Coupling TV Detect Waveforms for TV Connected and Disconnected

If ac-coupling is selected, the TVINT output signal for TV detection is latched after the next rising edge of the TVDET signal that happens during the next VSYNC timing but the TVINT output signal for TV disconnection is latched at the rising edge of the first TVDET signal. Figure 12-114 shows the waveforms for the ac-coupling TV detect pulse (TVDET) when load is connected and disconnected.

Figure 12-114. AC-Coupling TV Detect Waveforms for TV Connected and Disconnected

NOTE:

- When setting the DSS.VENC_TVDETGP_INT_START_STOP_X register, software users must ensure that the TVDET signal is in the active area. To avoid any problem, the TVDET signal must not be longer than one line.
- The activation of the TVDET signal will not have a visual impact on the tv_out1 output signal.

12.4.7.9.5 TV Detection/Disconnection Usage

The TV-detection/TV-disconnection is based on the difference in voltage levels in the output of the TV buffer depending on the load status. The operation is slightly different for ac and for dc operation. For dc operation, the tv_out1 voltage is compared against a voltage reference (tv_vref) that makes the comparator trigger in each sync pulse while the load is connected. For ac operation, the tv_out1 voltage is compared against a voltage reference (tv_vref) that makes the comparator trigger in each sync pulse while the load is disconnected. In both cases, the TVINT output signal produces a logic 1 when a load is connected and a logic 0 when a load is disconnected.

For dc-coupling mode, see Figure 12-115 and for ac-coupling mode, see Figure 12-116

NOTE: Because the video DAC and the video encoder must be awake for connection detection, consider that the video DAC can take up to 10 μ s to wake up.

Figure 12-115. GPIO Signal Waveform Proposal for TV Detection/Disconnection in DC-Coupling Mode

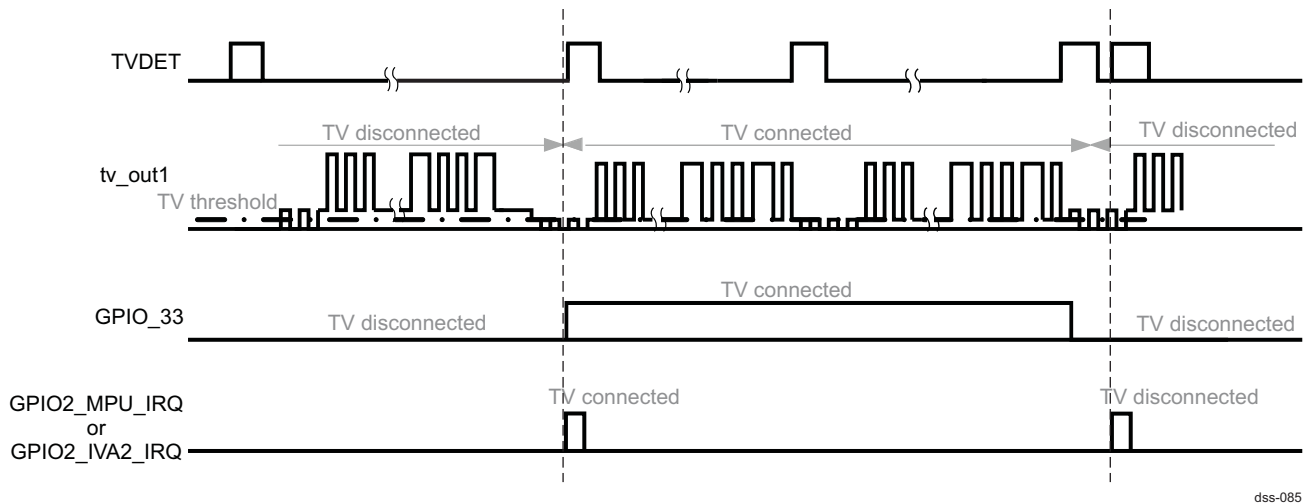

Figure 12-116. GPIO Signal Waveform Proposal for TV Detection/Disconnection in AC-Coupling Mode

12.4.7.10 Video DAC Bypass Mode

The dual 10-bit video DAC has a TVOUT buffer bypass mode that turns off the TVOUT buffer and redirects directly the DAC output to the VFB pins (tv_vfb1 for DAC1 and tv_vfb2 for DAC2).

This bypass mode is activated by setting the CONTROL.CONTROL_DEVCONF1[18] TVOUTBYPASS bit to 1. The reset value of the CONTROL.CONTROL_DEVCONF1[18] TVOUTBYPASS bit is 0 (that is, the TVOUT buffer is not bypassed).

NOTE: In bypass mode:

- the tv_out1 pin requires a RSET resistor connected to the ground. The typical value of the RSET resistor is 3.92 K.
- both tv_vfb1 and tv_vfb2 pins require a RLOAD resistor connected to the ground. The typical value of the RLOAD resistor is 976.

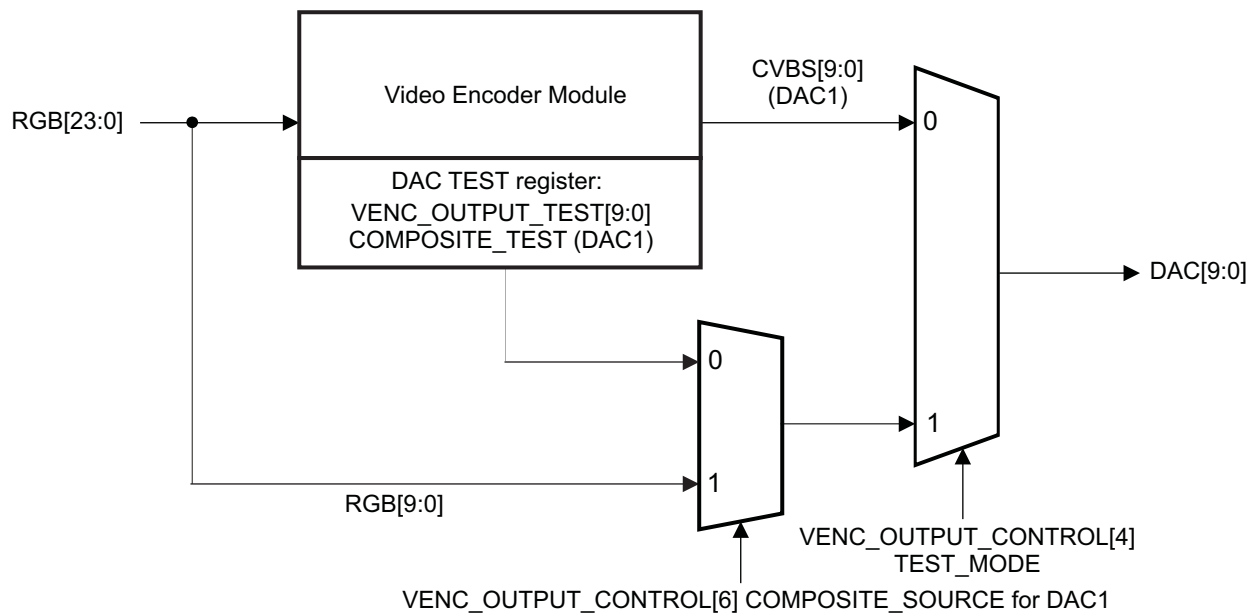

CAUTION

- The TV detect feature is not available in bypass mode.
- In bypass mode, an external amplifier is needed on the tv_vfb1 and tv_vfb2 pins.

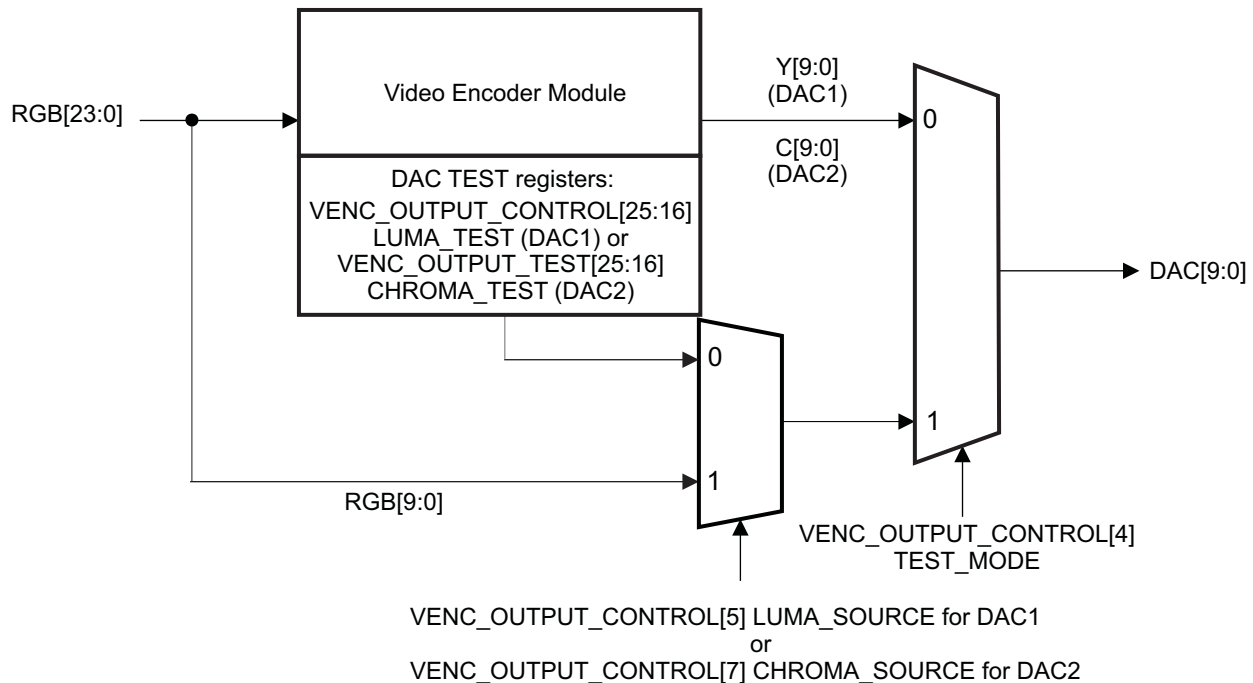

12.4.7.11 Video Dual-DAC Test Mode

The DAC can be tested for debug using either 10-bit external data or 10-bit internal register values directly connected to the DAC. See [Figure 12-117](#) for video DAC test in composite video mode, and see [Figure 12-118](#) for video DAC test in separate video mode.

Figure 12-117. DAC Test Mode in Composite Video Mode

dss-087

Figure 12-118. DAC Test Mode in Separate video Mode

dss-088

- Use the DSS.VENC_OUTPUT_CONTROL[4] TEST_MODE bit to select between DAC normal mode (0x0) and DAC test mode (0x1).
- Use the DSS.VENC_OUTPUT_CONTROL[7] CHROMA_SOURCE bit for DAC2 and either the DSS.VENC_OUTPUT_CONTROL[6] COMPOSITE_SOURCE bit (in composite video mode) or the DSS.VENC_OUTPUT_CONTROL[5] LUMA_SOURCE bit (in s-video mode) for DAC1 to select the test mode:
 - 0x0: From the internal register DSS.VENC_OUTPUT_TEST[25:16] CHROMA_TEST bit field for DAC2 and either DSS.VENC_OUTPUT_TEST[9:0] COMPOSITE_TEST bit field (composite video) or DSS.VENC_OUTPUT_CONTROL[25:16] LUMA_TEST (s-video mode) for DAC1
 - 0x1: From the video port G[1:0], B[7:0]

NOTE: In the external data test mode (bypass mode), the display controller must provide the data (G[1:0], B[7:0]) externally. To do this, configure the video encoder to generate correct timing signals, without which the display controller cannot operate (even if the encoder core is bypassed from the data path perspective).

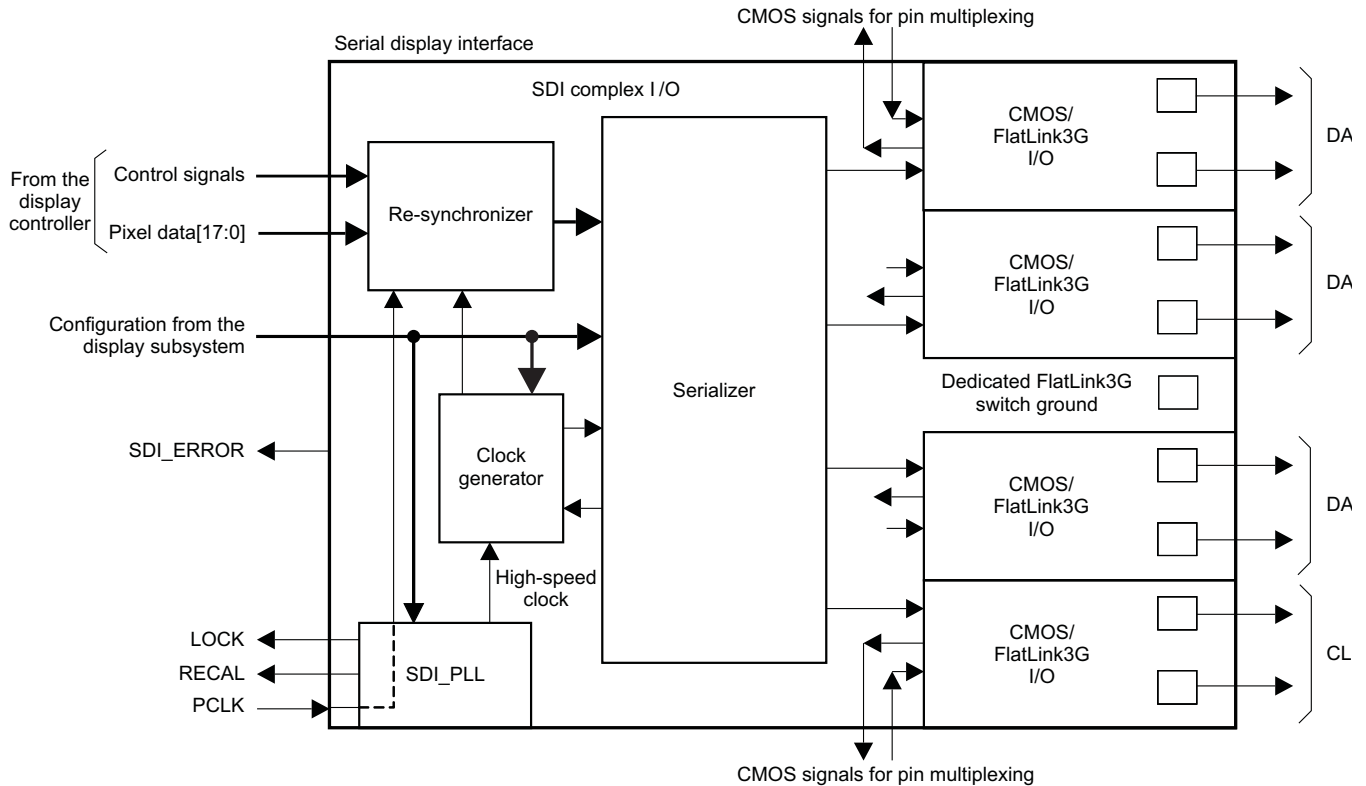

12.4.8 SDI Functionalities

The SDI interface has three main functions:

- A PLL (SDI_PLL) to multiply or divide the pixel clock frequency (PCLK) up to the required data rate. The pixel clock frequency range is 4-65 MHz. This clock may be divided by 2 above 32 MHz to meet the PLL input reference timing requirements.
- A specific IP block to output the data in the chosen serial format
- Output buffers to transmit the small swing differential signals

The last two functions are combined in the complex I/O module. [Figure 12-119](#) shows the SDI architecture.

Figure 12-119. SDI Architecture Overview

NOTE:

- The RECAL status indicates when the SDI_PLL must be recalibrated (0: No recalibration is required; 1: Recalibration is required). This status is connected to the GPIO_80 internal signal of the GPIO3 module. For additional information, see [Chapter 21, General-Purpose Interface](#).
 - The LOCK status indicates when the SDI_PLL is locked (0: PLL not locked; 1: PLL locked). This status is connected to the GPIO_81 internal signal of the GPIO3 module. For additional information, see [Chapter 21, General-Purpose Interface](#).
- For more information about lock and recalibration, see [Power, Reset, and Clock Management](#).
- The SDI_ERROR status indicated when the SDI module is in error mode (0: No error; 1: SDI in error). This status allows monitoring error conditions, such as inconsistent configuration or internal loss of synchronization. It is connected to the GPIO_82 internal signal of the GPIO3 module. For additional information, see [Chapter 21, General-Purpose Interface](#).

12.5 Display Subsystem Basic Programming Model

This section describes how to configure the display subsystem for the desired functionalities and also describes the programming models of the display controller, the RFBI, the SDI and the video encoder.

The main configuration scenarios are:

- LCD panel support (bypass or RFBI mode)
Configure the RFBI module (only if in RFBI mode; otherwise, the default values must remain), and then configure the display controller to the desired functionalities before the activities start.
- TV set support
Configure the video encoder and then the display controller.
- Both LCD panel support (bypass or RFBI mode) and TV set support
Configure the RFBI module (only if in RFBI mode; otherwise, leave the default values), configure the video encoder, and then configure the display controller.
- TI FlatLink 3G-compliant LCD panel support
Configure the SDI, configure the video encoder, and then configure the display controller.

12.5.1 Display Subsystem Reset

The display subsystem can receive a software reset that is propagated through all of the submodules to initialize the subsystem. The following procedure describes a possible sequence:

1. If the LCD is on, stop the LCD by setting the DSS.DISPC_CONTROL[0] LCDENABLE bit to 0.
 - (a) Reset the frame done status bit by writing 1 in the DSS.DISPC_IRQSTATUS[0] FRAMEDONE bit.
 - (b) Wait until the DSS.DISPC_IRQSTATUS[0] FRAMEDONE bit is set to 1. This shows that the end of frame has taken place and the LCD stop is complete.
2. To take the display subsystem out of reset, all clocks related to the display subsystem must be enabled and the DPLL4 must be enabled. The following clocks must be enabled to take the display subsystem out of reset:
 - PRCM.CM_FCLKEN_DSS[0] EN_DSS1 bit set to 1
 - PRCM.CM_FCLKEN_DSS[1] EN_DSS2 bit set to 1
 - PRCM.CM_FCLKEN_DSS[2] EN_TV bit set to 1
 - PRCM.CM_ICLKEN_DSS[0] EN_DSS bit set to 1

Once the clocks are enabled as shown, the display subsystem can be taken out of reset.
3. Write 1 in the DSS.DSS_SYSCONFIG[1] SOFTRESET bit to apply the soft reset to the subsystem.
4. Read the DSS.DSS_SYSSTATUS[0] RESETDONE bit. If this bit is 1, the reset sequence is complete; otherwise, read this bit again (the reset sequence is not completed).

12.5.2 Display Subsystem Configuration Phase

The display subsystem configuration phase is important to configure the data flow for using the LCD panel or the TV set. Use the following flow:

1. To configure the top level of the functional clock of the display controller clock, set the DSS.DSS_CONTROL[0] DSS_CLK_SWITCH bit.
2. To configure the top level of the video encoder, set the DSS.DSS_CONTROL[2] VENC_CLOCK_MODE bit and the DSS.DSS_CONTROL[3] VENC_CLOCK_X4 bit for TV set support.
3. To configure the top level of the DAC, set the DSS.DSS_CONTROL[4] DAC_DEMEN bit for TV set support (if required).
4. Configure the TI FlatLink 3G-compliant LCD panel through the SPI interface to use the serial interface display.
5. Configure the RFBI module and/or the SDI module and/or the video encoder as needed.
6. Configure the display controller.

12.5.3 Display Controller Basic Programming Model

Some display controller registers are termed *shadow registers*, which are associated with the digital output and/or the LCD output. A shadow register change has no direct effect on the configuration of the display controller unless the DSS.DISPC_CONTROL[5] GOLCD bit is set for the LCD output and/or the DSS.DISPC_CONTROL[6] GODIGITAL bit is set for the digital output.

In the case of the digital output, after programming the shadow registers, the DSS.DISPC_CONTROL[6] GODIGITAL bit must be set to 1. If this bit is not set, the configuration of the display controller will have no effect. This setting indicates that all display controller shadow registers are programmed and that hardware can update the internal registers at the external EVSYNC.

In the case of the LCD output, after programming the shadow registers, the DSS.DISPC_CONTROL[5] GOLCD bit must be set to 1. If this bit is not set, the configuration of the display controller will have no effect. This setting indicates that all display controller shadow registers are programmed and that hardware can update the internal registers at the VFP start period.

Before setting either the DSS.DISPC_CONTROL[5] GOLCD or DSS.DISPC_CONTROL[6] GODIGITAL bit, ensure that the bit is cleared.

Table 12-45 lists the shadow registers.

Table 12-45. Shadow Registers

| Shadow Register Name | Updated on VFP Start Period (LCD output) | Updated on External VSYNC (Digital output) |
|--|--|--|
| DSS.DISPC_CONTROL | X ⁽¹⁾ | X ⁽¹⁾ |
| DSS.DISPC_CONFIG | X | X |
| DSS.DISPC_DEFAULT_COLOR_m (m = 0) | X | |
| DSS.DISPC_DEFAULT_COLOR_m (m = 1) | | X |
| DSS.DISPC_TRANS_COLOR_m (m = 0) | X | |
| DSS.DISPC_TRANS_COLOR_m (m = 1) | | X |
| DSS.DISPC_LINE_NUMBER | X | |
| DSS.DISPC_TIMING_H | X | |
| DSS.DISPC_TIMING_V | X | |
| DSS.DISPC_POL_FREQ | X | |
| DSS.DISPC_DIVISOR | X | |
| DSS.DISPC_SIZE_DIG | | X |
| DSS.DISPC_SIZE_LCD | X | |
| DSS.DISPC_GFX_BA _j (j = 0,1) | X | X |
| DSS.DISPC_GFX_POSITION | X | X |
| DSS.DISPC_GFX_SIZE | X | X |
| DSS.DISPC_GFX_ATTRIBUTES | X | X |
| DSS.DISPC_GFX_FIFO_THRESHOLD | X | X |
| DSS.DISPC_GFX_ROW_INC | X | X |
| DSS.DISPC_GFX_PIXEL_INC | X | X |
| DSS.DISPC_GFX_WINDOW_SKIP | X | X |
| DSS.DISPC_GFX_TABLE_BA | X | X |
| DSS.DISPC_GFX_PRELOAD | X | X |

| DSS.DISPC_VIDn_FIR_COEF_Hi (i = 0 to 7) | X | X |
| DSS.DISPC_VIDn_FIR_COEF_HVi (i = 0 to 7) | X | X |
| DSS.DISPC_VIDn_FIR_COEF_Vi (i = 0 to 7) | X | X |
| DSS.DISPC_VIDn_CONV_COEFi (i = 0 to 4) | X | X |
| DSS.DISPC_VIDn_PRELOAD | X | X |
| DSS.DISPC_DATA_CYCLEk (k = 0 to 3) | X | X |

12.5.3.1 Display Controller Configuration

The following registers define the display controller configuration:

- DSS.DISPC_SYSCONFIG
- DSS.DISPC_SYSSTATUS
- DSS.DISPC_IRQSTATUS
- DSS.DISPC_IRQENABLE

12.5.3.2 Graphics Layer Configuration

The graphics layer configuration is common to the LCD and the TV set.

12.5.3.2.1 Graphics DMA Registers

The following registers define the graphics DMA engine configuration:

- DSS.DISPC_CONTROL
- DSS.DISPC_GFX_BAj
- DSS.DISPC_GFX_ATTRIBUTES
- DSS.DISPC_GFX_ROW_INC
- DSS.DISPC_GFX_PIXEL_INC
- DSS.DISPC_GFX_FIFO_THRESHOLD
- DSS.DISPC_GFX_TABLE_BA

The following fields define the attributes of the graphics DMA engine:

- Graphics layer enable (DSS.DISPC_GFX_ATTRIBUTES[0] GFXENABLE bit): The default value of this bit at reset time is 0x0 (Disabled). The graphics DMA engine fetches encoded pixels from the system memory only when the graphics layer is enabled (a valid configuration is programmed for the graphics layer). The graphics window is present and the graphics pipeline is active.
- Burst size (DSS.DISPC_GFX_ATTRIBUTES[7:6] GFXBURSTSIZE field): The default burst size at reset time is 4 x 32 bytes. The possible values are 4 x 32, 8 x 32, and 16 x 32 bytes. The burst size is initialized at boot time by the software and never changes as long as the display controller is enabled. This field indicates the maximum burst size for the specific pipeline. In case of misalignment, the DMA engine may issue single and/or smaller burst requests because the burst size must be aligned to the burst boundary.
- Preload configuration (DSS.DISPC_GFX_ATTRIBUTES[11] GFXFIFOPRELOAD bit): The default preload configuration uses the DSS.DISPC_GFX_PRELOAD register value (the reset value is 256 bytes) to define the number of bytes to be fetched from system memory into the display controller graphics FIFO. By programming the DSS.DISPC_GFX_ATTRIBUTES[11] GFXFIFOPRELOAD bit,

software users select between preload register (with 256 bytes as the reset value) and the high threshold value for preload of the encoded pixels. For best performance, the configuration of thresholds is defined using the FIFO size (in bytes) minus 1 for the high threshold, and the FIFO size (in bytes) minus the burst size (in bytes) for the low threshold, which provides 960, 992, and 1008, respectively, for burst sizes 16x32, 8x32, and 4x32. Note also that the preload value is defined based on the following display types:

- Active matrix (TFT) display: DSS.DISPC_GFX_PRELOAD[11:0] PRELOAD = 0x60 (value is 96)
- Color passive matrix (STN) display: DSS.DISPC_GFX_PRELOAD[11:0] PRELOAD = 0x72 (value is 114)
- Monochrome passive matrix (STN) display: DSS.DISPC_GFX_PRELOAD[11:0] PRELOAD = 0xE0 (value is 224)
- Base address of the graphics buffer in system memory (DSS.DISPC_GFX_BA_j registers): The default value of these two registers at reset time is 0x0. The horizontal resolution is one pixel because the base address is aligned on a pixel size boundary. In case of 4 BPP, the resolution is two pixels; for 2 BPP, resolution is four pixels; for 1 BPP, resolution is eight pixels; and for RGB24 packed format, the resolution is four pixels. The vertical resolution is one line. The register DSS.DISPC_GFX_BA0 defines the base address of the even field; and DSS.DISPC_GFX_BA1 defines the base of the odd field in the case of an external synchronization and based on the value of the input signal DISPC_FID and the polarity. To improve system throughput, the base address should be aligned on the burst size boundary.
- Graphics FIFO threshold (DSS.DISPC_GFX_FIFO_THRESHOLD register): The low threshold (DSS.DISPC_GFX_FIFO_THRESHOLD[11:0] GFXFIFOLOWTHRESHOLD) and the high threshold (DSS.DISPC_GFX_FIFO_THRESHOLD[27:16] GFXFIFOHIGHTHRESHOLD) values define the FIFO DMA behavior. When the low level is reached, one or more requests are issued to the L3-based interconnect to fill up the FIFO to reach the high threshold. A request is issued as long as the FIFO has enough space available to accept a burst. The DMA engine then waits until the low level is reached to restart the requests. By setting the DSS.DISPC_CONFIG[14] FIFOMERGE bit to 1, users merge the three FIFOs (GFX, VID1, and VID2). In this case, the low threshold (the DSS.DISPC_GFX_FIFO_THRESHOLD[11:0] GFXFIFOLOWTHRESHOLD bit field) and the high threshold (DSS.DISPC_GFX_FIFO_THRESHOLD[27:16] GFXFIFOHIGHTHRESHOLD bit field) values must be programmed with a multiplier factor of three (3 x value). By default, the FIFOs are not merged (the DSS.DISPC_CONFIG[14] FIFOMERGE bit reset value is 0).
- Palette/gamma table used (DSS.DISPC_CONFIG[3] PALETTEGAMMATABL bit): The bit indicates if the palette must be loaded before the graphics data for the following frame. The bit is set by software and reset by hardware.
- Base address of the palette/gamma table buffer in system memory (DSS.DISPC_GFX_TABLE_BA register): The default value of this register at reset time is 0x0. The base address is aligned on a 32-bit address. Depending on the pixel size of graphics data (1, 2, 4, or 8 BPP), 16 (1, 2, or 4 BPP), or 256 (8 BPP) x 32-bit values are loaded from system memory into the internal table memory. To load the table when using the memory as a gamma table, the graphics pipeline is enabled and then disabled by the software when the palette loaded interrupt is generated. The overlay manager ignores the graphics pipe when the table is used as a gamma table.

NOTE: In case of RGB16 format and optimization enabled, the base address is aligned on a 32-bit boundary and the number of bytes to skip is a multiple of 4 bytes.

- Graphics Priority (DSS.DISPC_GFX_ATTRIBUTES[14] GFXARBITRATION): The default value at reset time is 0x0. It is used to change between normal priority (value of 0) to high priority (value of 1) to change priority for the graphics channel vs. video channels. It can be used to give higher priority to the pipelines with real time constraint vs. non real time pipelines. For that is, pipelines associated to the LCD output in RFBI mode should have lower priority than pipelines associated to TV output.
- Graphics Self-Refresh (DSS.DISPC_GFX_ATTRIBUTES[15] GFXSELFREFRESH): The default value at reset time is 0x0. It is used to use the DMA FIFO without accessing the interconnect for multiple frames. Once, the data have been loaded to the DMA FIFO for displaying the frame, they are used for the following frames.

The sequence to activate the self-refresh is the following:

- Frame t: The bit field should be set at anytime during frame

- Frame t+1: Fetch of the data in the DMA FIFO and display of the frame
 - Frame t+2: No access to the L3 interconnect, DMA FIFO uses to provide the pixels
- The sequence to deactivate the self-refresh is the following:
- Frame t: No access to the L3 interconnect, DMA FIFO uses to provide the pixels, bit field can be changed at any time during the frame
 - Frame t+1: Fetch of the data from system memory using the L3 interconnect

12.5.3.2.2 Graphics Layer Configuration Registers

The following registers define the graphics layer configuration:

- DSS.DISPC_CONFIG
- DSS.DISPC_GFX_POSITION
- DSS.DISPC_GFX_SIZE
- DSS.DISPC_GFX_ATTRIBUTES

The graphics layer is enabled/disabled by setting/resetting the DSS.DISPC_GFX_ATTRIBUTES[0] GFXENABLE bit. When the graphics layer is disabled, the graphics window does not exist on the screen and the graphics pipeline and DMA are inactive.

Set a valid configuration before enabling the graphics layer. After a register change, either the DSS.DISPC_CONTROL[6] GODIGITAL or DSS.DISPC_CONTROL[5] GOLCD bit must be set. The software must wait for the hardware to reset the bit before setting it. The software reset is not recommended because the application cannot ensure that the bit is reset before the hardware reset.

12.5.3.2.3 Graphics Window Attributes

The following fields define the attributes of the graphics window:

- Graphics format (DSS.DISPC_GFX_ATTRIBUTES[4:1] GFXFORMAT bit field): The default value of this bit field at reset time is 0x0 (BITMAP 1-BPP). The graphics format can be either: BITMAP1, BITMAP2, BITMAP4, or BITMAP8 (CLUT) or RGB12, RGB16, or RGB24 (true-color formats).
- Graphics window X-position (DSS.DISPC_GFX_POSITION[10:0] GFXPOSX bit field): The default value at reset time is 0x0. The window X-position is from 0 to 2047 columns. All integer values in the range [0:2047] are allowed.
- Graphics window Y-position (DSS.DISPC_GFX_POSITION[26:16] GFXPOSY bit field): The default value of this bit field at reset time is 0x0. The window Y-position is from 0 to 2047 rows. All integer values in the range [0:2047] are allowed.
- Graphics window width (DSS.DISPC_GFX_SIZE[10:0] GFXSIZEX bit field): The default value at reset time is 0x0 (1 pixel). The window width is from 1 to 2048 pixels. All integer values in the range [1:2048] are allowed for the following formats: 8 BPP, RGB12, RGB16, and RGB24. The width must be a multiple of eight pixels for 1 BPP, four pixels for 2 BPP, and two pixels for 4 BPP. The maximum bandwidth efficiency for accessing the pixels in system memory is reached when the width of the graphics window (in bytes) is a multiple of the graphics burst size defined in the DSS.DISPC_GFX_ATTRIBUTES[7:6] GFXBURSTSIZE bit field (in bytes).

NOTE: When the RGB24 packed format is selected, the width must be a multiple of 12 bytes when the DSS.DISPC_GFX_ROW_INC register is not 1. When DSS.DISPC_GFX_ROW_INC register is 1, the width can be any size from 1 to 2048 pixels.

The entire pixels of the graphics window must be inside the LCD screen. Depending on the width of the buffer to be displayed in the graphics layer and the position, the width should be adjusted by software to limit the right edge of the window inside the screen.

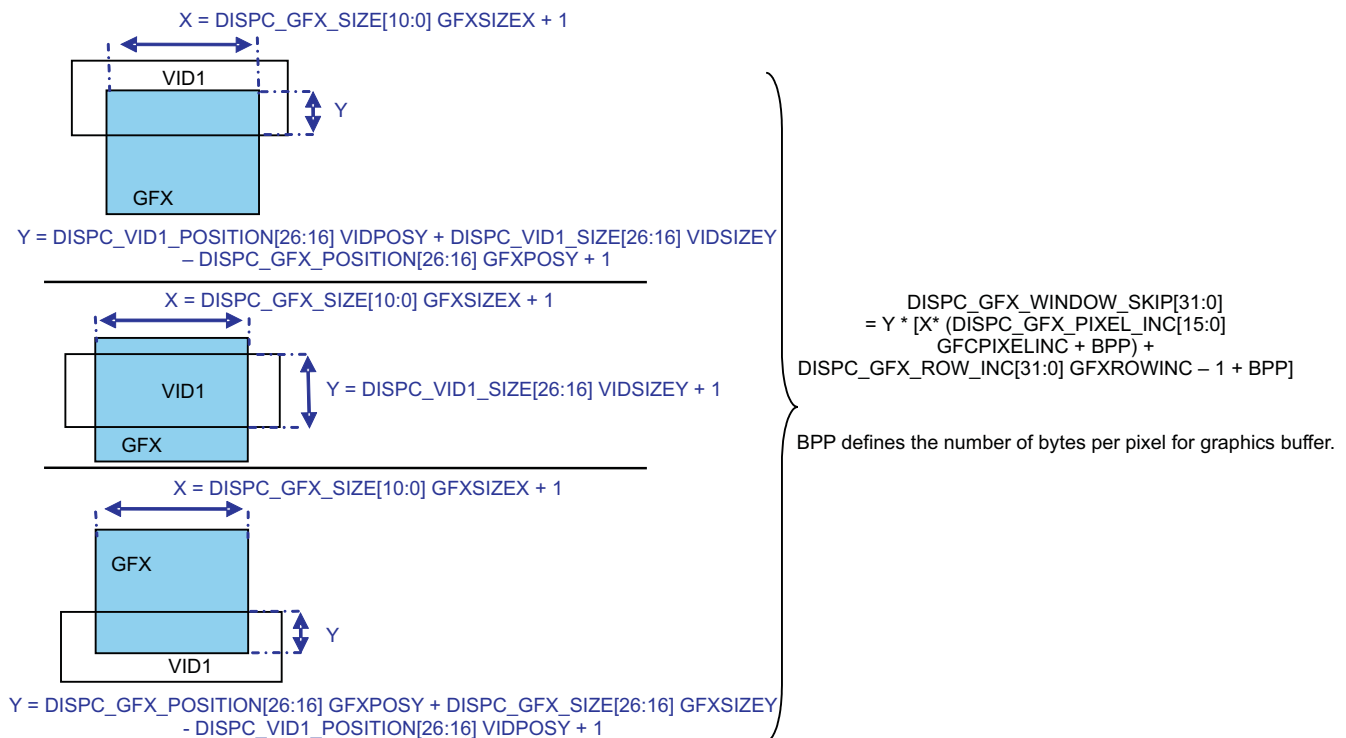

- Graphics window height (DSS.DISPC_GFX_SIZE[26:16] GFXSIZEY bit field): The default value at reset time is 0x0 (1 pixel). The window height is from 1 to 2048 pixels. All integer values in the range [1:2048] are allowed. The entire pixels of the graphics window must be inside the LCD screen. Depending on the height of the buffer to be displayed in the graphics layer and the position, the height should be adjusted by software to limit the bottom edge of the window inside the screen
- Graphics data endianness (DSS.DISPC_GFX_ATTRIBUTES[10] GFXENDIANNESS bit): This bit

indicates the endianness (little or big) of the graphics pixels. The default value at reset time is 0x0 (little endian).

- Graphics data nibble mode (DSS.DISPC_GFX_ATTRIBUTES[9] GFXNIBBLEMODE bit): This bit indicates the nibble mode of the graphics pixels. The default value at reset time is 0x0 (Disable).
- Graphics replication logic enable (DSS.DISPC_GFX_ATTRIBUTES[5] GFXREPLICATIONENABLE bit): The default value at reset time is 0x0 (Disable). The encoded pixel data in RGB format (RGB16) can be extended to 24-bit format with or without replication of the MSB part to fill up the LSB due to the 24-bit left alignment. If the replication logic is turned off, the LSB part is filled up with 0s.
- Graphics window skip enable (DSS.DISPC_CONTROL[12] OVERLAYOPTIMIZATION bit): By setting/resetting the bit, the overlay optimization is enabled or disabled. Before enabling the overlay optimization, the DSS.DISPC_GFX_WINDOW_SKIP[31:0] GFXWINDOWSKIP bit field must be set according to the video1 and graphics windows overlap. The default value at reset time is 0x0 (Disable). When video1 is not present, the DSS.DISPC_GFX_WINDOW_SKIP[31:0] GFXWINDOWSKIP bit field should be reset. When the color key is used, the DSS.DISPC_GFX_WINDOW_SKIP[31:0] GFXWINDOWSKIP bit field should be reset.
- Graphics window skip (DSS.DISPC_GFX_WINDOW_SKIP[31:0] GFXWINDOWSKIP bit field): The bit field represents the number of bytes to skip while fetching the graphics-encoded pixels when reaching the beginning of the video window. The optimization allows fetching only the visible graphics pixels. The color key cannot be selected because the graphics pixels under the video window are not present. The default value at reset time is 0x0 (0 byte).

Figure 12-120 through Figure 12-123 give examples of how to program the GFXWINDOWSKIP field for overlay optimization:

12.5.3.3 Video Layer Configuration

The video layer configuration is common to the LCD and the TV set.

12.5.3.3.1 Video DMA Registers

The following registers define the video DMA engine configuration:

- DSS.DISPC_CONTROL
- DSS.DISPC_VIDn_BA0
- DSS.DISPC_VIDn_ATTRIBUTES
- DSS.DISPC_VIDn_ROW_INC
- DSS.DISPC_VIDn_PIXEL_INC
- DSS.DISPC_VIDn_FIFO_THRESHOLD
- DSS.DISPC_VIDn_PICTURE_SIZE

The following fields define the attributes of the graphics DMA engine:

- Video layer enable (DSS.DISPC_VIDn_ATTRIBUTES[0] VIDENABLE bit): The default value of this bit at reset time is 0x0 (Disabled). The video DMA engine fetches encoded pixels from the system memory only when the video layer is enabled (a valid configuration is programmed for the video layer). The video window is present and the video pipeline is active.
- Burst size (DSS.DISPC_VIDn_ATTRIBUTES[15:14] VIDBURSTSIZE bit field): The default burst size at reset time is 4 x 32 bytes. The possible values are 4 x 32, 8 x 32, and 16 x 32 bytes. The burst size is initialized at boot time by the software and never changes as long as the display controller is enabled. This bit field indicates the maximum burst size for the specific pipeline. In case of misalignment, the DMA engine may issue single and/or smaller burst requests, because the burst size must be aligned to the burst boundary.
- Preload configuration (DSS.DISPC_VIDn_ATTRIBUTES[19] VIDFIFOPRELOAD bit): The default preload configuration uses the DSS.DISPC_VIDn_PRELOAD register value (the reset value is 256 bytes) to define the number of bytes to be fetched from system memory into the display controller graphics FIFO. By programming the DSS.DISPC_VIDn_ATTRIBUTES[19] VIDFIFOPRELOAD bit, software users select between preload register (with 256 bytes as the reset value) and the high threshold value for preload of the encoded pixels. For best performance, the configuration of thresholds is defined using the FIFO size (in bytes) minus 1 for the high threshold, and the FIFO size (in bytes) minus the burst size (in bytes) for the low threshold, which provides 960, 992, and 1008, respectively, for burst sizes 16x32, 8x32, and 4x32. Note also that the preload value is defined based on the following display types:
 - Active matrix (TFT) display: DSS.DISPC_VIDn_PRELOAD[11:0] PRELOAD = 0xB0 (value is 176)
 - Color passive matrix (STN) display: DSS.DISPC_VIDn_PRELOAD[11:0] PRELOAD = 0x110 (value is 272)
 - Monochrome passive matrix (STN) display: DSS.DISPC_VIDn_PRELOAD[11:0] PRELOAD = 0x1B0 (value is 432)
- Base address of the video buffer in system memory (DSS.DISPC_VIDn_BAj registers): The default

value at reset time is 0x0. The horizontal resolution is one pixel because the base address is aligned on pixel size boundary. In case of YCbCr 4:2:2 formats, the resolution is 2 pixels. In case of RGB24 packed format, the resolution is 4 pixels. The vertical resolution is one line. The register DSS.DISPC_VIDn_BA0 defines the base address of the even field, and DSS.DISPC_VIDn_BA1 defines the base of the odd field in the case of an external synchronization and based on the value of the input signal DISPC_FID and the polarity. To improve system throughput, the base address should be aligned on the burst size boundary.

- Video FIFO threshold (DSS.DISPC_VIDn_FIFO_THRESHOLD register): The low threshold (DSS.DISPC_VIDn_FIFO_THRESHOLD[11:0] VIDFIFOLOWTHRESHOLD) and the high threshold (DSS.DISPC_VIDn_FIFO_THRESHOLD[27:16] VIDFIFOHIGHTHRESHOLD) values define the FIFO DMA behavior. When the low level is reached, one or more requests are issued to the L3-based interconnect to fill up the FIFO to reach the high threshold. A request is issued as long as the FIFO has enough space available to accept a burst. The DMA engine then waits until the low level is reached to restart the requests. By setting the DSS.DISPC_CONFIG[14] FIFOMERGE bit to 1, users merge the three FIFOs (GFX, VID1, and VID2). In this case, the low threshold (the DSS.DISPC_VIDn_FIFO_THRESHOLD[11:0] VIDFIFOLOWTHRESHOLD bit field with n corresponding to the active video channel 1 or 2) and the high threshold (DSS.DISPC_VIDn_FIFO_THRESHOLD[27:16] VIDFIFOHIGHTHRESHOLD bit field with n corresponding to the active video channel 1 or 2) values must be programmed with a multiplier factor of three (3 x value). By default, the FIFOs are not merged (the DSS.DISPC_CONFIG[14] FIFOMERGE bit reset value is 0).
- Video buffer width (DSS.DISPC_PICTURE_SIZE[10:0] VIDORGSIZEX): The default value at reset time is 0x0 (1 pixel). The buffer width in system memory is from 1 up to 2048 pixels. All the integer values in the range [1:2048] are allowed. Software users must program this bit field to the value minus 1.
- Video buffer height (DSS.DISPC_PICTURE_SIZE[26:16] VIDORGSIZEY): The default value at reset time is 0x0 (1 pixel). The buffer height in system memory is from 1 up to 2048 pixels. All the integer values in the range [1:2048] are allowed. Software users must program this field to the value minus 1.
- Video data endianness (DSS.DISPC_VIDn_ATTRIBUTES[17] VIDENDIANNESS bit, with n=1 or 2): This bit indicates the endianness (little or big) of the video pixels. The default value at reset time is 0x0 (little endian).

12.5.3.3.2 Video Configuration Register

The following shadow registers define video layer n (with n = 1 or 2) configuration:

- DSS.DISPC_CONFIG
- DSS.DISPC_VIDn_POSITION
- DSS.DISPC_VIDn_SIZE
- DSS.DISPC_VIDn_ATTRIBUTES
- DSS.DISPC_VIDn_FIR
- DSS.DISPC_VIDn_PICTURE_SIZE
- DSS.DISPC_VIDn_FIR_COEF_Hi (with i = 0 to 7)
- DSS.DISPC_VIDn_FIR_COEF_HVi (with i = 0 to 7)
- DSS.DISPC_VIDn_CONV_COEFi (with i = 0 to 4)
- The video layer n (with n = 1 or 2) is enabled/disabled by setting/resetting the DSS.DISPC_VIDn_ATTRIBUTES[0] VIDENABLE field. If the video layer is disabled, the video window does not exist on the screen and the whole video pipeline and DMA are inactive. Before enabling the video layer, a valid configuration must be set. After a register change, either the DSS.DISPC_CONTROL[6] GODIGITAL or DSS.DISPC_CONTROL[5] GOLCD bit must be set. The software must wait for the hardware to reset the bit before setting this bit. The software reset is not recommended because the application cannot ensure that the bit is reset before the hardware reset.

12.5.3.3.3 Video Window Attributes

The following fields define the attributes of video window n:

- Video format (DSS.DISPC_VIDn_ATTRIBUTES[4:1] VIDFORMAT bit field, with n = 1 or 2): The default value at reset time is 0x0 (BITMAP 1 BPP, nonsupported format by the video pipeline). The video format can be RGB16, RGB24, YUV2 4:2:2 co-DSS sited, and UYVY 4:2:2 co-sited.
- Video window X-position (DSS.DISPC_VIDn_POSITION[10:0] VIDPOSX bit field, with n = 1 or 2): The default value at reset time is 0x0 (first column starting on the left edge of the screen). The window X-position is from 0 to 2047 columns. All integer values in the range [0:2047] are allowed.
- Video window Y-position (DSS.DISPC_VIDn_POSITION[26:16] VIDPOSY bit field, with n = 1 or 2): The default value at reset time is 0x0 (first row starting at the top of the screen). The window Y-position is from 0 to 2047 rows. All integer values in the range [0:2047] are allowed.
- Video window width (DSS.DISPC_VIDn_SIZE[10:0] VIDSIZEX bit field, with n = 1 or 2): The default value at reset time is 0x0 (1 pixel). The window width is from 1 to 2048 pixels. All integer values in the range [1:2048] are allowed. The maximum bandwidth efficiency for accessing the pixels in system memory is reached when the width (in bytes) of the video window is a multiple of the video burst size defined in the DSS.DISPC_VIDn_ATTRIBUTES[15:14] VIDBURSTSIZE bit field (in bytes).

NOTE: When the RGB24 packed format is selected, the width must be a multiple of 12 bytes when the DSS.DISPC_VIDn_ROW_INC register is not 1. When the DSS.DISPC_VIDn_ROW_INC register is 1, the width can be any size from 1 to 2048 pixels.

The entire pixels of the video window must be inside the LCD screen. Depending on the width of the buffer to be displayed in the video layer and the position, the width should be adjusted by software to limit the right edge of the window inside the screen.

- Video window height (DSS.DISPC_VIDn_SIZE[26:16] VIDSIZEY bit field, with n = 1 or 2): The default value at reset time is 0x0 (1 pixel). The window height is from 1 to 2048 pixels. All integer values in the range [1:2048] are allowed. The entire pixels of the video window must be inside the LCD screen. Depending on the height of the buffer to be displayed in the video layer and the position, the height should be adjusted by software to limit the bottom edge of the window inside the screen.
- Video picture width in system memory (DSS.DISPC_VIDn_PICTURE_SIZE[10:0] VIDORGSIZEX bit field, with n = 1 or 2): The default value at reset time is 0x0 (1 pixel). The window width is from 1 to 2048 pixels. All integer values in the range [1:2048] are allowed with RGB16 and RGB24 video data. For YUV2 4:2:2 and UYVY 4:2:2 formats, the width must be a multiple of two pixels. The maximum bandwidth efficiency for accessing the pixels in system memory is reached when the width (in bytes) of the video picture is a multiple of the video burst size defined in the DSS.DISPC_VIDn_ATTRIBUTES[15:14] VIDBURSTSIZE bit field (in bytes).
- Video picture height in system memory (the DSS.DISPC_VIDn_PICTURE_SIZE[26:16] VIDORGSIZEY bit field, with n = 1 or 2): The default value at reset time is 0x0 (1 pixel). The window width is from 1 to 2048 pixels. All integer values in the range [1:2048] are allowed.
- Video Priority (DSS.DISPC_VIDn_ATTRIBUTES[23] VIDARBITRATION): The default value at reset time is 0x0. It is used to change between normal priority (value of 0) to high priority (value of 1) to change priority for the video channel vs. other channels. It can be used to give higher priority to the pipelines with real time constraint vs. non real time pipelines. For that is, pipelines associated to the LCD output in RFBI mode should have lower priority than pipelines associated to TV output.
- Video Self-Refresh (DSS.DISPC_VIDn_ATTRIBUTES[24] VIDSELFREFRESH): The default value at reset time is 0x0. It is used to use the DMA FIFO without accessing the interconnect for multiple frames. Once, the data have been loaded to the DMA FIFO for displaying the frame, they are used for the following frames.

The sequence to activate the self-refresh is the following:

- Frame t: The bit field should be set at anytime during frame
- Frame t+1: Fetch of the data in the DMA FIFO and display of the frame
- Frame t+2: No access to the L3 interconnect, DMA FIFO uses to provide the pixels

The sequence to deactivate the self-refresh is the following:

- Frame t: No access to the L3 interconnect, DMA FIFO uses to provide the pixels, bit field can be changed at any time during the frame
- Frame t+1: Fetch of the data from system memory using the L3 interconnect

12.5.3.3.4 Video Up-/Down-Sampling Configuration

The video horizontal up-/downsampling block for video pipeline n (with n = 1 or 2) is enabled/disabled by setting/resetting the DSS.DISPC_VIDn_ATTRIBUTES[5] VIDRESIZEENABLE bit.

The video vertical up-/downsampling block for video pipeline n is enabled/disabled by setting/resetting the DSS.DISPC_VIDn_ATTRIBUTES[6] VIDRESIZEENABLE bit.

Set a valid configuration before enabling the video up-/downsampling block.

NOTE: Vertical and horizontal downsampling are limited to a 1/4 resize factor.

After a register change, either the DSS.DISPC_CONTROL[6] GODIGITAL or DSS.DISPC_CONTROL[5] GOLCD bit must be set. The software must wait until the hardware resets this bit before setting it. The software reset is not recommended because the application cannot ensure that the bit is reset before the hardware reset.

The following fields define the configuration of the video up-/downsampling block for video pipeline n:

- Vertical up-/downsampling increment value (DSS.DISPC_VIDn_FIR[27:16] VIDFIRVINC bit field, with n = 1 or 2): The unsigned integer value range is [1:4096]. The software calculates the value using the following equation:

$$VIDFIRVINC[12:0] = 1024 \times \left(\frac{VIDORGSIZEY[10:0]}{VIDSIZEY[10:0]} \right)$$

dss-E093

(5)

NOTE:

- If the VIDFIRVINC[11:0] bit field value is greater than 4096, it is clipped to 4096. If VIDSIZEY[10:0] equals 0x1, VIDSIZEY[10:0] is replaced by 0x2 in the previous equation.
 - The VIDORGSIZEY[10:0] and VIDSIZEY[10:0] bit field values must be programmed with the value desired minus 1.
-
- Horizontal up-/downsampling increment value (DSS.DISPC_VIDn_FIR[11:0] VIDFIRHINC bit field, with n = 1 or 2): The unsigned integer value range is [1:4096]. The software calculates the value using the following equation:

$$VIDFIRHINC[12:0] = 1024 \times \left(\frac{VIDORGSIZEX[10:0]}{VIDSIZEX[10:0]} \right)$$

dss-E094

(6)

NOTE:

- If the VIDFIRHINC[11:0] bit field value is greater than 4096, it is clipped to 4096. If VIDSIZEX[10:0] equals 1, VIDSIZEX[10:0] is replaced by 2 in the previous equation.
 - The VIDORGSIZEX[10:0] and VIDSIZEX[10:0] bit field values must be programmed with the value desired minus 1.
-
- Vertical up-/downsampling accumulator value (DSS.DISPC_VIDn_ACCUI[25:16] VIDVERTICALACCU bit field): The unsigned integer value range is [0:1023]. The accumulator value indicates in which phase the vertical filtering starts. The value 0 indicates that 0 is the first phase used by the hardware to generate the first data (see [Table 12-46](#)).
 - Vertical up-/downsampling line buffer configuration (DSS.DISPC_VIDn_ATTRIBUTES[22] VIDLINEBUFFERSPLIT bit): The default value at reset time is 0x0 (line buffers are not split). The backward compatibility is maintained versus OMAP2420 and OMAP2430 devices. When the bit field is set, each line buffer is split into two line buffers to be able to use six line buffers instead of three.
 - Vertical up-/downsampling line buffer configuration (DSS.DISPC_VIDn_ATTRIBUTES[21] VIDVERTICALTAPS bit): The default value at reset time is 0x0 (3-tap configuration is used). If the bit field is reset, the 3-tap configuration is used. The backward compatibility is maintained versus OMAP2420 and OMAP2430 devices. When the bit field is set, the 5-tap configuration is used and the

DSS.DISPC_VIDn_ATTRIBUTES[22] VIDLINEBUFFERSPLIT bit must be set to 1.

- Vertical up-/downsampling line buffer configuration (DSS.DISPC_VIDn_ATTRIBUTES[20] VIDDMAOPTIMIZATION bit): The default value at reset time is 0x0 (no optimization). If the bit is set, the DMA engine fetches two pixels for each 32-bit OCP request (RGB16 and YUV422) while doing 90- and 270-degree rotation. If the bit is clear, the DMA engine fetches one pixel for each 32-bit OCP request (RGB16 and YUV422) while doing 90- and 270-degree rotation. The width and height of picture should be even to use the optimization.

NOTE: If the 5-tap resizer is used for RGB16 and YUV422 picture formats, the width of the input picture must be a multiple of 2 pixels and more than 5 pixels. This leads to the following register configuration:

DISPC_VIDn_ATTRIBUTES[21] VIDVERTICALTAPS == 1
DISPC_VIDn_PICTURE_SIZE[10:0] VIDORGSIZEX > 4 and even

- Horizontal up-/downsampling accumulator value (DSS.DISPC_VIDn_ACCUI[9:0] VIDHORIZONTALACCU bit field): The unsigned integer value range is [0:1023]. The accumulator value indicates in which phase the horizontal filtering starts. The value 0 indicates that 0 is the first phase used by the hardware to generate the first data (see [Table 12-46](#)).

Table 12-46. Vertical/Horizontal Accumulator Phase

| Accumulator Value | Phases f |
|-------------------|----------|
| 0 | 0 |
| 128 | 1 |
| 256 | 2 |
| 384 | 3 |
| 512 | 4 |
| 640 | 5 |
| 768 | 6 |
| 896 | 7 |

- Vertical up-/downsampling coefficients (DSS.DISPC_VIDn_FIR_COEF_HVi registers, with n = 1 or 2, i = 0 to 7): The 3-tap vertical up-/downsampling coefficients are defined in these registers. There are eight registers for the eight phases with three coefficients for each, or a total of 24 programmable coefficients for the vertical up-/downsampling block. Each register contains two 8-bit signed coefficients and one 8-bit unsigned coefficient (the central one).

In addition, there are 2-tap vertical up-/downsampling coefficients defined in DSS.DISPC_VIDn_FIR_COEF_Vi registers. There are 8 registers for the 8 phases with 2 coefficients for each of them so a total of 16 programmable coefficients for the vertical up-/downsampling block used in addition of the 3-tap registers defined above. Each register contains two 8-bit signed coefficients. In case of 5-tap configuration, both sets of registers DSS.DISPC_VIDn_FIR_COEF_HVi and DSS.DISPC_VIDn_FIR_COEF_Vi are used. In case of 3-tap configuration, only one set of registers DSS.DISPC_VIDn_FIR_COEF_HVi is used.

- Horizontal up-/downsampling coefficients (DSS.DISPC_VIDn_FIR_COEF_Hi and DISPC_VIDn_FIR_COEF_HVi registers, with n = 1 or 2, i = 0 to 7): The DSS.DISPC_VIDn_FIR_COEF_Hi register and the DSS.DISPC_VIDn_FIR_COEF_HVi register define the 5-tap horizontal up-/downsampling coefficients. There are eight registers for the eight phases with five coefficients for each register, or a total of 40 programmable coefficients for the horizontal up-/downsampling block.

Each DSS.DISPC_VIDn_FIR_COEF_Hi register contains three 8-bit signed coefficients and one 8-bit unsigned coefficient (the central one). Each DSS.DISPC_VIDn_FIR_COEF_HVi register contains one 8-bit signed coefficient.

The programmable coefficient for the FIR up-/downsampling method must be adjusted based on application needs. For more details on scaling programming settings, see [Section 12.6.1](#).

12.5.3.3.5 Video Color Space Conversion Configuration

The DSS.DISPC_VIDn_CONV_COEFi registers (with i = 0 to 4) has nine 11-bit coefficients defined for the programmable color space conversion block for video pipeline n (with n = 1 or 2).

The standard register coefficients are:

YCbCr-to-RGB Registers (VidFullRange=0)

$$\begin{bmatrix} R \\ G \\ B \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} RY & RCr & RCb \\ GY & GCr & GCb \\ BY & BCr & BCb \end{bmatrix} * \begin{bmatrix} Y - 16 \\ Cr - 128 \\ Cb - 128 \end{bmatrix}$$

dssE095

(7)

YCbCr to RGB Registers (VidFullRange=1)

$$\begin{bmatrix} R \\ G \\ B \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} RY & RCr & RCb \\ GY & GCr & GCb \\ BY & BCr & BCb \end{bmatrix} * \begin{bmatrix} Y \\ Cr - 128 \\ Cb - 128 \end{bmatrix}$$

dss-E096

(8)

Table 12-47 lists the color space conversion register values.

Table 12-47. Color Space Conversion Register Values

| Coefficients | BT.601-5 | BT.601-5 Range [0:255] | BT.709 | BT.709 Range [0:255] |
|--------------|----------|---------------------------|--------|-------------------------|
| RY | 298 | 256 | 298 | 256 |
| RCr | 409 | 351 | 459 | 394 |

12.5.3.4 Rotation/Mirroring Display Subsystem Settings

This section describes rotation/mirroring settings. The device provides flexible mechanisms for an efficient implementation of rotation using the display-subsystem, its DMA engine, and the rotation engine of the SMS module. Depending on whether the image data is located in on-chip SRAM or external SDRAM, either a DMA rotation or a VRFB rotation is used. When configuring the rotation, the image data format (RGB or YUV) must also be taken into account. The video pipelines also perform the interpolation of YUV image data and the color conversion from YUV into RGB format for displaying the images on an LCD screen.

12.5.3.4.1 Image Data Formats

To understand the programming of the rotation mechanisms described underneath, the supported representations of the image data in memory must also be considered. Differences exist between the supported formats on the graphics and video pipelines. The graphics pipeline supports RGB and RGB with a color look-up table (CLUT), whereas the video pipelines support two versions of YUV 4:2:2 and RGB16. In the case of YUV, the interpolation and color conversion hardware in the video pipelines converts the image data to the RGB format suitable for the LCD screen.

The graphics pipeline supports:

- 1-, 2-, 4-, and 8-bits-per-pixel color look-up table
- 12-, 16-, and 24-bits-per-pixel RGB

The video pipelines support the following data formats (always 2 bytes/pixel):

- RGB16
- YUV2
- UYVY

For more information on the graphics data formats, please refer to [Section 12.4.2.2, Graphics Pipeline](#).

For more information on the video data formats, please refer to [Section 12.4.2.3, Video Pipeline](#).

In the video pipeline, the YUV 4:2:2 format is converted into a full YUV 4:4:4 format by interpolation of the chrominance values from neighboring pixels. After this interpolation is completed, the conversion to the RGB format (suitable for displaying the image on the LCD screen) is performed.

For more information on YUV 4:2:2 to RGB conversion, please refer to [Section 12.4.2.3.2, Color Space Conversion](#).

12.5.3.4.2 Image Data from On-Chip SRAM

For image data located in the on-chip SRAM, the DSS DMA is used to perform 90-degree, 180-degree, and 270-degree rotation. This is done by using the double-indexed addressing mode of the DMA. This addressing mode allows a pixel and a row increment to be specified. These address increments are used after each pixel or each row (line), respectively. [Figure 12-124](#) illustrates the principle steps for a 90-degree rotation.

Figure 12-124. 90° DMA Rotation Example

Table 12-48. 90-degree DMA Rotation Example Description

| Parameter | Description | Additional parameters for formulas |
|-----------|-------------------------------|------------------------------------|
| ba | Buffer Base Address in Memory | |
| IW | Image Width in pixels | $iw = IW - 1$ |
| IH | Image Height in pixels | $ih = IH - 1$ |
| ps | Pixel Size (in bytes) | |

Figure 12-124 shows how the image is stored in memory and how it is read out to achieve a 90-degree rotated orientation. The first pixel for the 0-degree orientation is located at the buffer base address (ba). If the image is to be shown on an LCD screen with a 90-degree rotation, the readout starts at the 90-degree base address (1). To proceed from one pixel to the next in the same line in the rotated orientation, the pixel increment (2) must be applied. At the end of each line of the rotated view, the row increment (3) is the offset to advance to the beginning of the next line in the memory buffer.

Hence, by setting the three DMA parameters (base address, pixel increment, and row increment), a 90-degree rotation can be achieved, as can 180-degree and 270-degree rotation. Each of the parameters can also be combined with an optional mirroring on the vertical axis.

Following there is a description the setup required to perform the rotation via the DSS DMA. This rotation mechanism is used when the image data is stored in internal SRAM.

12.5.3.4.2.1 Rotation/Mirroring Registers

To set up the rotation and/or mirroring, the following registers must be programmed:

- Graphics pipeline (GFX):
 - DSS.DISPC_GFX_BA_j
 - DSS.DISPC_GFX_PIXEL_INC
 - DSS.DISPC_GFX_ROW_INC
 - DSS.DISPC_GFX_ATTRIBUTES
 - DSS.DISPC_GFX_POSITION
 - DSS.DISPC_GFX_SIZE
 - DSS.DISPC_GFX_FIFO_THRESHOLD
- Video pipelines (VID) 1 and 2:
 - DSS.DISPC_VID_n_BA_j
 - DSS.DISPC_VID_n_PIXEL_INC
 - DSS.DISPC_VID_n_ROW_INC
 - DSS.DISPC_VID_n_ATTRIBUTES
 - DSS.DISPC_VID_n_POSITION
 - DSS.DISPC_VID_n_SIZE
 - DSS.DISPC_VID_n_CONV_COEF0 to DSS.DISPC_VID_n_CONV_COEF4
 - DSS.DISPC_VID_n_FIFO_THRESHOLD
- DSS.DISPC_XXX_BA_j: These registers contain the base address of the image data at which the DSS DMA transfer of the image starts. The register values depend on the rotation chosen (see Table 12-49 for the formulas). When using the LCD interface, the registers DISPC_XXX_BA0 are used. The registers DISPC_XXX_BA1 are only used for the TV output.
- DSS.DISPC_XXX_PIXEL_INC[15:0]: This bit field contains the DMA addressing increment after each pixel. This bit field is used to perform the DSS DMA rotation (see Table 12-49 for the formula).

NOTE: When the RGB24 packet format is selected, the only valid value is 1.

- DSS.DISPC_XXX_ROW_INC[31:0]: This bit field contains the DMA addressing increment after each row (line) of pixels. This bit field is used to perform the DSS DMA rotation (see Table 12-49 for the formula).

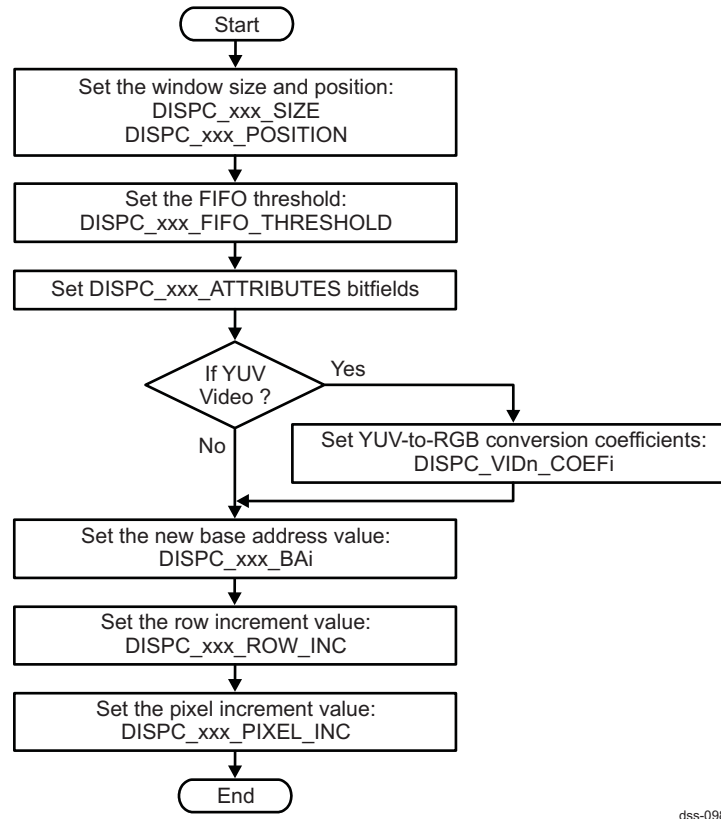

NOTE: When the RGB24 packet format is selected, the valid values are 1 and any value multiples of 12 bytes (4x32 bit). When the value is a multiple of 12 bytes, the width must be a multiple of 12 bytes. When the value is 1, the width can be any size from 1 to 2048 pixels.

- **DSS.DISPC_xxx_ATTRIBUTES:** These registers contain the main settings for the pipeline, such as the image data format, the rotation value, and the enable bit for the pipeline. The bit fields of these registers play a role in the rotation and in the image data format setup.
 - The following bit fields are used by the graphics pipeline to set up the image format:
 - **GFXENABLE:** Set this field to activate the hardware path in use.
 - **GFXFORMAT:** Use this field to specify the format of the graphic frame.
 - **GFXROTATION:** Set this field to the value corresponding to the rotation angle desired only if the frame contains RGB24 pixel data; otherwise, set it to 0x0 regardless of the degree of rotation.
 - **GFXREPLICATIONENABLE:** Use this bit to determine whether the encoded pixel data in RGB formats (RGB12 and RGB16) is extended to 24-bit format with or without replication of the MSB to fill the LSBs of each color component. If the replication logic is turned off, the LSB parts are filled with 0s. It is recommended to always enable this feature.
 - **GFXCHANNELOUT:** Set this field based on whether the frame is to be rendered on the LCD or on the TV set.
 - The following bit fields for the two video pipelines:
 - **VIDENABLE:** Set this field to activate the hardware path in use.
 - **VIDFORMAT:** Use this field to specify the format of the video frame (RGB16 or YUV422).
 - **VIDCOLORCONVENABLE:** If the video is in YUV422 format, set this field to enabled.
 - **VIDROTATION:** Set this field to the value corresponding to the rotation angle desired only if the frame contains non-RGB pixel data; otherwise, set it to 0x0 regardless of the degree of rotation. See [Section 12.5.3.4.4](#) for more information.
 - **VIDROWREPEATENABLE:** Set this field to enabled only if the frame contains YUV pixel data and the rotation is 90-degree or 270-degree so that the row pixel data are fetched twice to extract both Y components. See [Section 12.5.3.4.4](#) for more information.
 - **VIDCHANNELOUT:** Set this field based on whether the frame is to be rendered on the LCD or on the TV set.
- **DSS.DISPC_xxx_POSITION:** Use this register to configure the position of the window.
- **DSS.DISPC_xxx_SIZE:** Use this register to configure the size of the window.
- **DSS.DISPC_VIDn_CONV_COEF0**, **DSS.DISPC_VIDn_CONV_COEF1**, **DSS.DISPC_VIDn_CONV_COEF2**, **DSS.DISPC_VIDn_CONV_COEF3**, and **DSS.DISPC_VIDn_CONV_COEF4:** These registers contain the conversion coefficients required for YUV-to-RGB color conversion.
- **DSS.DISPC_xxx_FIFO_THRESHOLD:** Set the low threshold (**DSS.DISPC_GFX_FIFO_THRESHOLD**[11:0] **GFXFIFOWHLOWTHRESHOLD**) and the high threshold (**DSS.DISPC_GFX_FIFO_THRESHOLD**[27:16] **GFXFIFOWHIGHTHRESHOLD**) values to define the FIFO DMA behavior. When the low level is reached, one or more requests are issued to the L3-based interconnect to fill up the FIFO to reach the high threshold. The DMA engine then waits until the low level is reached to restart the requests.

12.5.3.4.2.2 DMA Register Settings

To configure the display controller for rotation and/or mirroring, use the following settings:

Figure 12-125. Rotation/Mirroring Settings

dss-098

NOTE: These registers are shadow registers. To take into account the new values, software users must set the DSS.DISPC_CONTROL[5] GOLCD bit to 1.

Table 12-49 details the base address, the row and pixel increment values to access the buffer in memory (contiguous pixels) except for the RGB24 packet format. Table 12-50 lists the rotation register settings for RGB24 packet format (only for the two video pipelines).

Table 12-49. DMA Rotation Register Settings

| Rotation | Registers | GFX/VIDx ⁽¹⁾ |
|-------------|---|---|
| 0 degree | DSS.DISPC_XXX_BAj DSS.DISPC_XXX_PIXEL_INC DSS.DISPC_XXX_ROW_INC | ba 1 1 |
| 90 degrees | DSS.DISPC_XXX_BAj DSS.DISPC_XXX_PIXEL_INC DSS.DISPC_XXX_ROW_INC | ba + (iw x (ih-1) x ps) -(iw x ps) - 1 (iw x (ih-1)) x ps + 1 |
| 180 degrees | DSS.DISPC_XXX_BAj DSS.DISPC_XXX_PIXEL_INC DSS.DISPC_XXX_ROW_INC | ba + (iw x ih-1) x ps -2 x ps -2 x ps |

(1)

- ba = start address of image buffer in memory
- iw = image width in pixels per row - 1 (for YUV: pixels per row divided by 2)
- ih = image height - 1 (number of rows)
- ps = pixel size in bytes (RGB: 2 bytes per pixel, YUV: 4 bytes per pixel)

See Table 12-48 for more information of these parameters.

Table 12-49. DMA Rotation Register Settings (continued)

| Rotation | Registers | GFX/VIDx ⁽¹⁾ |
|-------------|-------------------------|--|
| 270 degrees | DSS.DISPC_xxx_BAj | $ba + (iw - 1) \times ps$ |
| | DSS.DISPC_xxx_PIXEL_INC | $(iw - 1) \times ps + 1$ |
| | DSS.DISPC_xxx_ROW_INC | $-(iw \times (ih - 1)) \times ps - ps + 1$ |

NOTE: In case of RGB16 format and optimization enabled, the base address is aligned on a 32-bit boundary and the number of bytes to skip is a multiple of 4 bytes.

Table 12-50. Video Rotation Register Settings (With RGB24 Packet Format)

| Rotation | Registers (with n = 1 or 2) | SDRAM Direct Access ⁽¹⁾ |
|-------------|-----------------------------|------------------------------------|
| 0 degree | DSS.DISPC_VIDn_BAj | ba |
| | DSS.DISPC_VIDn_PIXEL_INC | 1 |
| | DSS.DISPC_VIDn_ROW_INC | 1 |
| 180 degrees | DSS.DISPC_VIDn_BAj | $ba + (iw * ih * 3) - 4$ |
| | DSS.DISPC_VIDn_PIXEL_INC | -7 |
| | DSS.DISPC_VIDn_ROW_INC | -7 |

⁽¹⁾

- ba = physical base address of the buffer in the system memory (top-left corner of the picture)
 - iw = number of pixels per row - 1 (original picture in system memory) for BITMAP and RGB formats and number of pixels per row divided by 2 for YUB422 formats
 - h = number of lines - 1 (original picture in system memory)
 - ps = pixel size in bytes (BITMAP8: 1 byte; RGB16: 2 bytes; YUV422: 4 bytes)
- See [Table 12-48](#) for more information of these parameters.

The DMA rotation described above can be also combined with an optional mirroring on the vertical axis (see [Figure 12-126](#)). The only settings that must be changed to achieve this mirroring are the registers described above: DISPC_xxx_BAj, DISPC_xxx_PIXEL_INC, and DISPC_xxx_ROW_INC. [Table 12-51](#) provides the DMA setup formulas for rotation with mirroring to access the buffer in memory (contiguous pixels) except for the RGB24 packet format.

Figure 12-126. 90° Rotation With Mirroring

dss-100

Table 12-51. Register Settings for DMA Rotation With Mirroring

| Rotation | Registers | GFX/VIDx ⁽¹⁾ |
|-------------|---|---|
| 0 degree | DSS.DISPC_xxx_BAj DSS.DISPC_xxx_PIXEL_INC DSS.DISPC_xxx_ROW_INC | ba + (iw-1) x ps -2 x ps + 1 2 x (iw-1) x ps + 1 |
| 90 degrees | DSS.DISPC_xxx_BAj DSS.DISPC_xxx_PIXEL_INC DSS.DISPC_xxx_ROW_INC | ba (iw-1) x ps (-iw x (ih-1)) x ps |
| 180 degrees | DSS.DISPC_xxx_BAj DSS.DISPC_xxx_PIXEL_INC DSS.DISPC_xxx_ROW_INC | ba + iw x (ih-1) x ps 1 -2 x iw x ps |
| 270 degrees | DSS.DISPC_xxx_BAj DSS.DISPC_xxx_PIXEL_INC DSS.DISPC_xxx_ROW_INC | ba + (iw x ih - 1) x ps (iw - 1) x ps + 1 - (iw x (ih-1)) x ps - ps + 1 |

(1)

- ba = start address of image buffer in memory
 - iw = image width in pixels per row - 1 (for YUV: pixels per row divided by 2)
 - ih = image height - 1 (number of rows)
 - ps = pixel size in bytes (RGB: 2 bytes per pixel, YUV: 4 bytes per pixel)
- See [Table 12-48](#) for more information of these parameters.

12.5.3.4.3 Image Data from External SRAM

The device offers a rotation engine in the SMS called the VRFB. This rotation method must be used for maximum efficiency when the image data is located in SDRAM. To use the VRFB rotation, both the SMS module and the DSS DMA must be configured.

In the DSS, the same registers must be set up as described for DMA rotation (see [Section 12.5.3.4.2, Image Data from On-Chip SRAM](#)). The differences are in the setup of the following registers:

- DISPC_xxx_ROW_INC: This field contains the DMA addressing increment after each row (line) of pixels. This field is used to add the remaining delta at the end of each line, to reach the 2048-pixel line size of the VRFB (see [Table 12-52](#) for the formula).
- DISPC_xxx_PIXEL_INC: This field contains the DMA addressing increment after each pixel. For VRFB rotation, this value is set always to 1 (see [Table 12-52](#)).

Table 12-52. VRFB Rotation - DMA Settings

| Rotation | Registers | GFX/VIDx ⁽¹⁾ |
|-------------|---|--|
| 0 degree | DSS.DISPC_xxx_BAj DSS.DISPC_xxx_PIXEL_INC DSS.DISPC_xxx_ROW_INC | VBA0 1 (2048 - iw) x ps + 1 |
| 90 degrees | DSS.DISPC_xxx_BAj DSS.DISPC_xxx_PIXEL_INC DSS.DISPC_xxx_ROW_INC | VBA90 + offset 1 (2048 - ih) x ps + 1 |
| 180 degrees | DSS.DISPC_xxx_BAj DSS.DISPC_xxx_PIXEL_INC DSS.DISPC_xxx_ROW_INC | VBA180 + offset 1 (2048 - iw) x ps + 1 |
| 270 degrees | DSS.DISPC_xxx_BAj DSS.DISPC_xxx_PIXEL_INC DSS.DISPC_xxx_ROW_INC | VBA270 + offset 1 (2048 - ih) x ps + 1 |

(1)

- VBAx = virtual address of the chosen VRFB context and orientation
- iw = image width (width in pixels for RGB, width in pixels divided by 2 for YUV)
- ih = image height
- ps = pixel size in bytes (2 bytes per pixel for RGB, 4 bytes per pixel for YUV)
- Offset = see below

Figure 12-127 provides the offset values that must be added to the virtual base addresses for 90-degree, 180-degree, and 270-degree rotation. This offset is applicable only when the defined image size in the VRFB module is greater than the actual image size, because it must be a multiple of the page width and height. In the example discussed above, the image height was set to 256 lines, instead of 240, because the page height was 32 lines. This offset must be added to the virtual base addresses, because the VRFB module is not aware of the actual image size. Figure 12-127 illustrates why this occurs and how the offset is calculated.

Figure 12-127. Offset for VRFB Rotation

dss-099

Δiw = Image width delta between the actual image width and the programmed image width because of the page width

Δih = Image height delta between the actual image height and the programmed image height because of the page height:

- Offset 90-degree: Δih pixels = $\Delta ih \times ps$ bytes
- Offset 180-degree: $2048 \times \Delta ih + \Delta iw$ pixels = $2048 \times \Delta ih \times ps + \Delta iw \times ps$ bytes
- Offset 270-degree: $2048 \times \Delta iw$ pixels = $2048 \times \Delta iw \times ps$ bytes

In the example given above, the delta in the image height is $256 - 240 = 16$ lines ($\Delta ih = 16$), whereas the exact value of the width can be programmed ($\Delta iw = 0$). In that case, the resulting offset values are:

- YUV:
 - Offset 90-degree: 16×4 bytes
 - Offset 180-degree: $2048 \times 16 \times 4$ bytes
 - Offset 270-degree: 0 bytes
- RGB:
 - Offset 90-degree: 16×2 bytes

- Offset 180-degree: 2048 x 16 x 2 bytes
- Offset 270-degree: 0 bytes

As with DMA rotation, mirroring along the vertical axis can be added on top of the rotation when using the VRFB. This mirroring is achieved by combining an appropriate VRFB rotation with a readout of the VRFB by the DSS DMA, going backwards from the last line to the first line of the rotated image. [Table 12-53](#) provides the DMA settings for VRFB rotation with mirroring.

Table 12-53. VRFB Rotation With Mirroring - DMA Settings

| Rotation | Registers | GFX/VIDx ⁽¹⁾ |
|-------------|---|--|
| 0 degree | DSS.DISPC_xxx_BAj DSS.DISPC_xxx_PIXEL_INC DSS.DISPC_xxx_ROW_INC | VBA180 + 2048 x (ih - 1) x ps + offset 1 -(2048 + iw) x ps + 1 |
| 90 degrees | DSS.DISPC_xxx_BAj DSS.DISPC_xxx_PIXEL_INC DSS.DISPC_xxx_ROW_INC | VBA270 + 2048 x (iw - 1) x ps + offset 1 -(2048 + ih) x ps + 1 |
| 180 degrees | DSS.DISPC_xxx_BAj DSS.DISPC_xxx_PIXEL_INC DSS.DISPC_xxx_ROW_INC | VBA0 + 2048 x (ih - 1) x ps 1 -(2048 + iw) x ps + 1 |
| 270 degrees | DSS.DISPC_xxx_BAj DSS.DISPC_xxx_PIXEL_INC DSS.DISPC_xxx_ROW_INC | VBA90 + 2048 x (iw - 1) x ps + offset 1 -(2048 + ih) x ps + 1 |

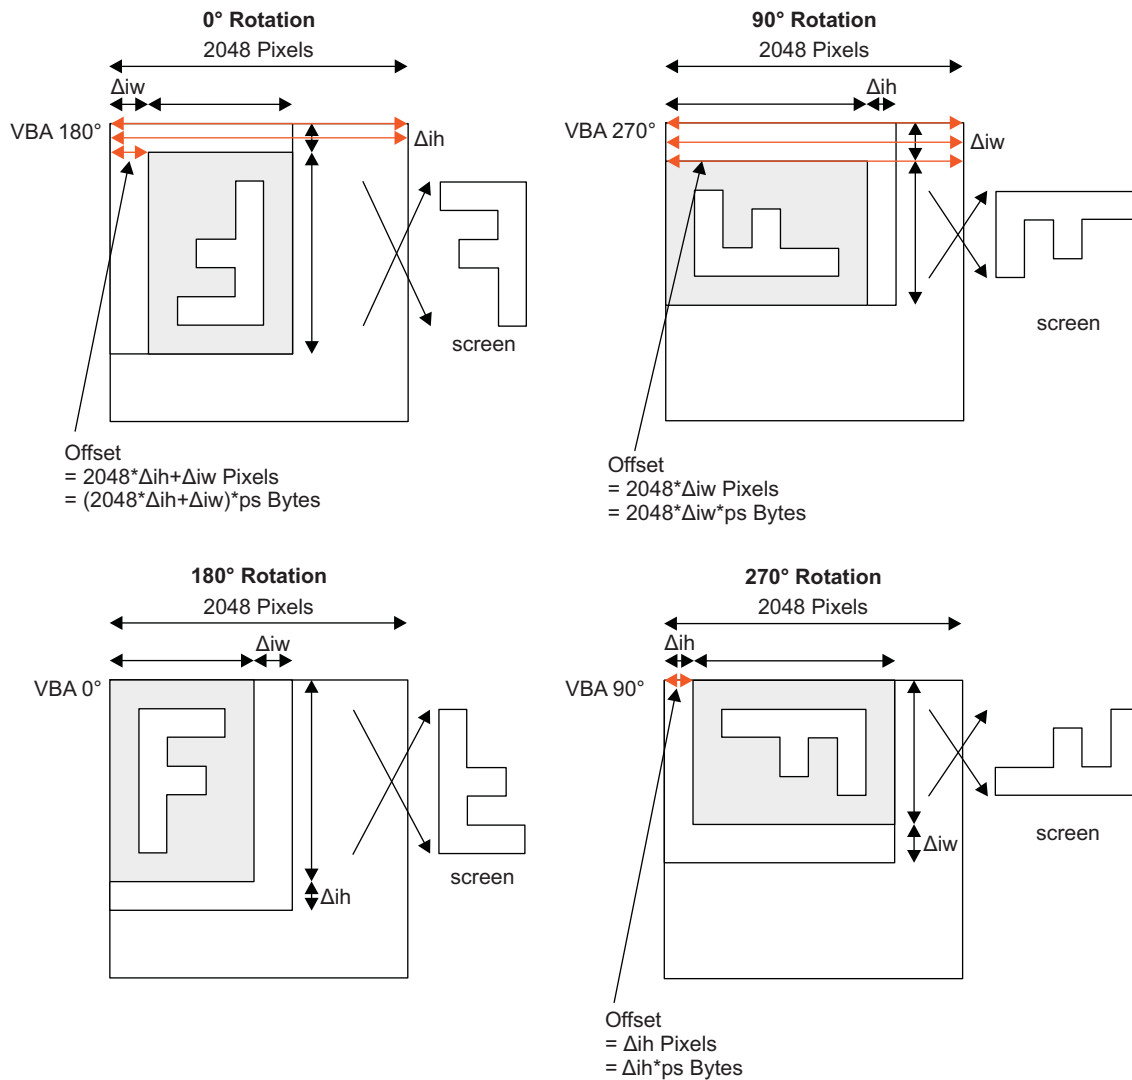

(1)

- VBAx = virtual address of the chosen VRFB context and orientation
- iw = image width (width in pixels for RGB, width in pixels divided by 2 for YUV)
- ih = image height
- ps = pixel size in bytes (2 bytes per pixel for RGB, 4 bytes per pixel for YUV)
- Offset = see below

Some offsets are required if there is a delta between the programmed image size in the VRFB and the actual image size. As shown in [Figure 12-128](#), this applies to 0-degree rotation with mirroring (using VBA 180°), 90° rotation with mirroring (VBA 270-degree), and 270-degree rotation with mirroring (VBA 90-degree). The offsets are calculated in this manner:

- Offset 0-degree (mirroring): 2048 x Δih + Δiw pixels = 2048 x Δih x ps + Δiw x ps bytes
- Offset 90-degree (mirroring): 2048 x Δiw pixels = 2048 x Δiw x ps bytes
- Offset 270-degree (mirroring): Δih pixels = Δih x ps bytes

Figure 12-128. Offset for VRFB Rotation With Mirroring

dss-101

12.5.3.4.4 Additional configuration when using YUV format

The rotation flag (DSS.DISPC_VIDn_ATTRIBUTES[13] VIDROTATION bit , with n = 1 or 2) and the repeat flag (DSS.DISPC_VIDn_ATTRIBUTES[18] VIDROWREPEATENABLE) indicate the rotation to apply to the video-encoded pixels from the SDRAM and SRAM. The 2D addressing mode is used, but even when accessing the SDRAM buffer, some post-processing must be performed on the YUV 4:2:2 data depending on the rotation. These bits are set only when the video format is not RGB; otherwise, the bit field is reset to 0. Table 12-54 and Table 12-55 describe the configuration of these registers.

Table 12-54. Video Rotation Register Settings (YUV Only)

| Rotation | Registers (with n = 1 or 2) | SDRAM + Rotation engine |
|-------------|--|-------------------------|
| 0 degree | DSS.DISPC_VIDn_ATTRIBUTES[13] VIDROTATION | 0x0 |
| | DSS.DISPC_VIDn_ATTRIBUTES[18] VIDROWREPEATENABLE | 0x0 |
| 90 degrees | DSS.DISPC_VIDn_ATTRIBUTES[13] VIDROTATION | 0x1 |
| | DSS.DISPC_VIDn_ATTRIBUTES[18] VIDROWREPEATENABLE | 0x1 |
| 180 degrees | DSS.DISPC_VIDn_ATTRIBUTES[13] VIDROTATION | 0x2 |
| | DSS.DISPC_VIDn_ATTRIBUTES[18] VIDROWREPEATENABLE | 0x0 |

Table 12-54. Video Rotation Register Settings (YUV Only) (continued)

| Rotation | Registers (with n = 1 or 2) | SDRAM + Rotation engine |
|------------|--|-------------------------|
| 270 degree | DSS.DISPC_VIDn_ATTRIBUTES[13] VIDROTATION | 0x3 |
| | DSS.DISPC_VIDn_ATTRIBUTES[18] VIDROWREPEATENABLE | 0x1 |

Table 12-55. Video Rotation With Mirroring Register Settings (YUV only)

| Rotation | Registers (with n = 1 or 2) | SDRAM + Rotation engine |
|-------------|--|-------------------------|
| 0 degree | DSS.DISPC_VIDn_ATTRIBUTES[13] VIDROTATION | 0x2 |
| | DSS.DISPC_VIDn_ATTRIBUTES[18] VIDROWREPEATENABLE | 0x0 |
| 90 degrees | DSS.DISPC_VIDn_ATTRIBUTES[13] VIDROTATION | 0x1 |
| | DSS.DISPC_VIDn_ATTRIBUTES[18] VIDROWREPEATENABLE | 0x1 |
| 180 degrees | DSS.DISPC_VIDn_ATTRIBUTES[13] VIDROTATION | 0x0 |
| | DSS.DISPC_VIDn_ATTRIBUTES[18] VIDROWREPEATENABLE | 0x0 |
| 270 degree | DSS.DISPC_VIDn_ATTRIBUTES[13] VIDROTATION | 0x3 |
| | DSS.DISPC_VIDn_ATTRIBUTES[18] VIDROWREPEATENABLE | 0x1 |

NOTE: For YUV 4:2:2 video-encoded pixels, the hardware must always fetch a 32-bit value from the system memory to generate a YUV 4:4:4 value before YUV-to-RGB conversion.

- For 90- and 270-degree rotation, the missing chrominance samples for the odd pixels are generated by duplicating the chrominance samples of the previous even pixels.
- For 0- and 180-degree rotation, the missing chrominance samples for the odd pixels are generated by averaging the contiguous chrominance samples.

12.5.3.5 LCD-Specific Control Registers

The following registers define the LCD output configuration:

- DSS.DISPC_CONTROL
- DSS.DISPC_CONFIG
- DSS.DISPC_DEFAULT_COLOR_m (m=0)
- DSS.DISPC_TRANS_COLOR_m (m=0)
- DSS.DISPC_TIMING_H
- DSS.DISPC_TIMING_V
- DSS.DISPC_POL_FREQ
- DSS.DISPC_DIVISOR
- DSS.DISPC_SIZE_LCD
- DSS.DISPC_DATA_CYCLEK
- DSS.DISPC_CPR_COEF_R, DSS.DISPC_CPR_COEF_G, DSS.DISPC_CPR_COEF_B

Setting/resetting the DSS.DISPC_CONTROL[0] LCDENABLE bit enables/disables the LCD output. A valid configuration must be set before enabling the LCD output.

12.5.3.5.1 LCD Attributes

The following fields define the attributes of the panel connected to the display controller:

- Monochrome or color panel (the DSS.DISPC_CONTROL[2]MONOCOLOR bit)
- Passive Matrix or active Matrix panel (the DSS.DISPC_CONTROL[3] STNTFT bit)
- Color depth (the DSS.DISPC_CONTROL[9:8] TFTDATALINES bit field)
- Number of lines per panel (the DSS.DISPC_SIZE_LCD[26:16] LPP bit field)
- Number of pixels per line (the DSS.DISPC_SIZE_LCD[10:0] PPL bit field)

- 4- or 8-bit interface for Passive Matrix monochrome panel (the DSS.DISPC_CONTROL[4] M8B bit)

12.5.3.5.2 LCD Timings

The following bit fields define the timing generation of HSYNC/VSYN:

- Horizontal front porch (the DSS.DISPC_TIMING_H[19:8] HFP bit field)
- Horizontal back porch (the DSS.DISPC_TIMING_H[31:20] HBP bit field)
- Horizontal synchronization pulse width (the DSS.DISPC_TIMING_H[7:0] HSW bit field)
- Vertical front porch (the DSS.DISPC_TIMING_V[19:8] VFP bit field)
- Vertical back porch (the DSS.DISPC_TIMING_V[31:20] VBP bit field)
- Vertical synchronization pulse width (the DSS.DISPC_TIMING_V[7:0] VSW bit field)
- On/Off control of HSYNC/VSYN pixel clock (the DSS.DISPC_POL_FREQ[17] ONOFF bit)
- Program HSYNC/VSYN rise or fall (the DSS.DISPC_POL_FREQ[16] RF bit)
- Invert HSYNC (the DSS.DISPC_POL_FREQ[13] IHS bit)
- Invert VSYNC (the DSS.DISPC_POL_FREQ[12] IVS bit)
- HSYNC gated (the DSS.DISPC_CONFIG[6] HSYNCGATED bit)
- VSYNC gated (the DSS.DISPC_CONFIG[7] VSYNCGATED bit)

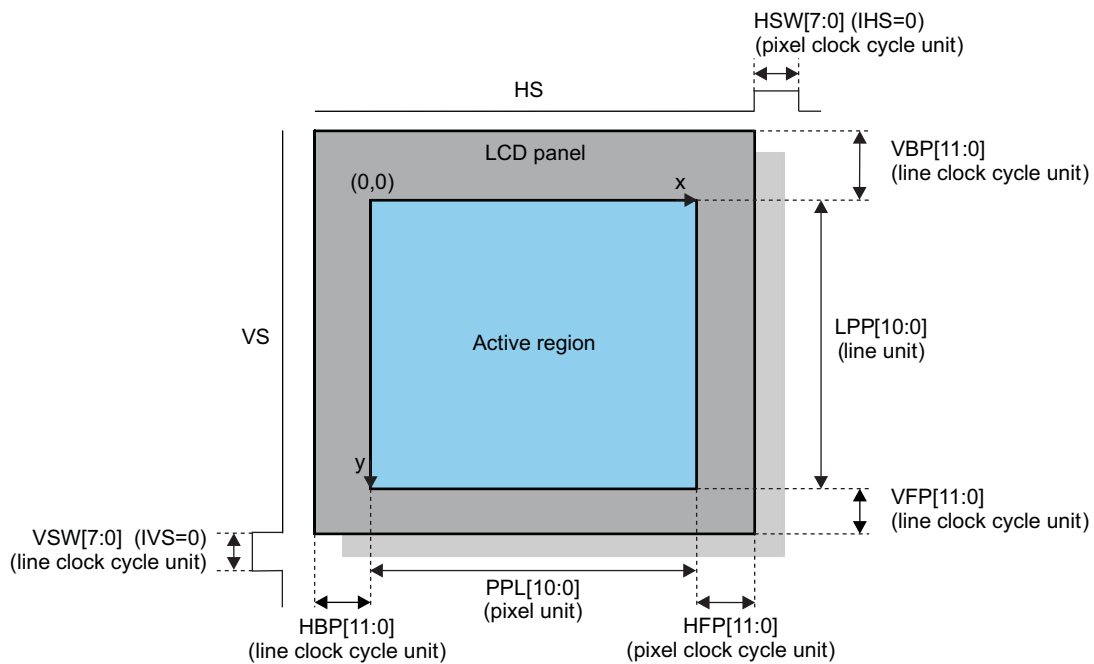

Table 12-56 describes the programming rules for LCD timing.

Table 12-56. Programming Rules

| | No Downsampling | Downsampling H or V | Downsampling H + V |
|---------------------------|-----------------|---------------------|--------------------|
| $(HBP + HSW + HFP) * PCD$ | > 8 | > 10 | > 20 |

Figure 12-129 shows the timing values description in the case of an active matrix display.

Figure 12-129. Timing Values Description (Active Matrix Display)

dss-102

The following bit fields define the timing generation of ac-bias (output enable in active matrix mode):

- Invert output enable (DSS.DISPC_POL_FREQ[15] IEO bit)
- ac-bias pin frequency (DSS.DISPC_POL_FREQ[7:0] ACB bit field)
- ac-bias pin transitions per interrupt (DSS.DISPC_POL_FREQ[11:8] ACBI bit field)

- ac-bias gated (DSS.DISPC_CONFIG[8] ACBIASGATED)

The following bit fields define the timing generation of the pixel clock:

- Pixel clock divisor (DSS.DISPC_DIVISOR[7:0] PCD bit field)
- Invert pixel clock (DSS.DISPC_POL_FREQ[14] IPC bit)
- Pixel clock gated (DSS.DISPC_CONFIG[5] PIXELCLOCKGATED bit)

The 8-bit pixel clock divider (the DSS.DISPC_DIVISOR[7:0] PCD bit field) selects the pixel clock frequency. This bit field generates a range of pixel clock frequencies from LC/1 to LC/255, where LC is the logic clock from the divided functional clock of the display controller by the DSS.DISPC_DIVISOR[23:16] LCD bit field.

The pixel clock is defined by the following equation:

$$\text{Pixel Clock} = (\text{FunctionalClock}/\text{LCD}[7:0])/\text{PCD}[7:0]$$

Table 12-57 through Table 12-60 show the pixel clock frequency limitations depending the panel type (active or passive matrix) and the mode (color or monochrome).

Table 12-57. Pixel Clock Frequency Limitations - RGB16 and YUV422 Active Matrix Display

| Min PCD Values | | Horizontal Resampling | | | | |
|---------------------|-------|-----------------------|----------------------|-----------|-----------|-----------|
| | | Off | Up | 1:1 - 1:2 | 1:2 - 1:3 | 1:3 - 1:4 |
| Vertical Resampling | Off | 2 (1) ⁽¹⁾ | 2 (1) | 2 | 3 | 4 |
| | Up | 2 (1) | 2 (1) ⁽¹⁾ | 2 | 3 | 4 |
| 1:1 - 1:2 | 3-tap | 2 | 2 | 4 | 6 | 8 |
| | 5-tap | PCDmin | PCDmin | PCDmin | PCDmin | PCDmin |
| 1:2 - 1:4 | | PCDmin | PCDmin | PCDmin | PCDmin | PCDmin |

⁽¹⁾ The PCD value can be 1 in case all the data and synchronization signals are asserted and deasserted on the rising edge of the pixel clock.

Table 12-58. Pixel Clock Frequency Limitations - RGB16 and YUV422 Passive Matrix Display - Mono4

| Min PCD Values | | Horizontal Resampling | | | | |
|---------------------|-------|-----------------------|----------|-----------|-----------|-----------|
| | | Off | Up | 1:1 - 1:2 | 1:2 - 1:3 | 1:3 - 1:4 |
| Vertical Resampling | Off | 4 | 4 | 8 | 12 | 16 |
| | Up | 4 | 4 | 8 | 12 | 16 |
| 1:1 - 1:2 | 3-tap | 8 | 8 | 16 | 24 | 32 |
| | 5-tap | 4xPCDmin | 4xPCDmin | 4xPCDmin | 4xPCDmin | 4xPCDmin |
| 1:2 - 1:4 | | 4xPCDmin | 4xPCDmin | 4xPCDmin | 4xPCDmin | 4xPCDmin |

Table 12-59. Pixel Clock Frequency Limitations - RGB16 and YUV422 Passive Matrix Display - Mono8

| Min PCD Values | | Horizontal Resampling | | | | |
|---------------------|-------|-----------------------|----------|-----------|-----------|-----------|
| | | Off | Up | 1:1 - 1:2 | 1:2 - 1:3 | 1:3 - 1:4 |
| Vertical Resampling | Off | 8 | 8 | 16 | 24 | 32 |
| | Up | 8 | 8 | 16 | 24 | 32 |
| 1:1 - 1:2 | 3-tap | 16 | 16 | 32 | 48 | 64 |
| | 5-tap | 8xPCDmin | 8xPCDmin | 4xPCDmin | 8xPCDmin | 8xPCDmin |
| 1:2 - 1:4 | | 8xPCDmin | 8xPCDmin | 4xPCDmin | 8xPCDmin | 8xPCDmin |

Table 12-60. Pixel Clock Frequency Limitations - RGB16 and YUV422 Passive Matrix Display - Color

| Min PCD Values | | Horizontal Resampling | | | | | |
|---------------------|-----------|-----------------------|----------|-----------|-----------|-----------|----------|
| | | Off | Up | 1:1 - 1:2 | 1:2 - 1:3 | 1:3 - 1:4 | |
| Vertical Resampling | Off | 3 | 3 | 6 | 9 | 12 | |
| | Up | 3 | 3 | 6 | 9 | 12 | |
| | 1:1 - 1:2 | 3-tap | 6 | 6 | 12 | 18 | 24 |
| | | 5-tap | 3xPCDmin | 3xPCDmin | 3xPCDmin | 3xPCDmin | 3xPCDmin |
| | 1:2 - 1:4 | 3xPCDmin | 3xPCDmin | 3xPCDmin | 3xPCDmin | 3xPCDmin | |

NOTE: In case of RGB24 format, [Figure 12-130](#) is still valid, except the PCDmin values which must be multiplied by two.

The PCDmin for vertical downsampling only is defined by the following equations:

Figure 12-130. PCDmin Formulas (V Down-Sampling Only)

$$h_ratio = \frac{DISPC_PPL_SIZE_LCD[10:0]PLL}{DISPC_VIDn_SIZE[10:0]VIDZSIZE}$$

$$v_ratio = \frac{DISPC_VIDn_PICTURE_SIZE[10:0]VIDORGSIZE}{DISPC_VIDn_SIZE[10:0]VIDSIZE}$$

$$PCD\ min = \frac{v_ratio}{2 \times h_ratio} \quad 1 < v_ratio \leq 2$$

$$PCD\ min = \max\left(\frac{v_ratio}{2 \times h_ratio}, \frac{v_ratio - 2}{2 \times (h_ratio - 1)}\right) \quad 2 < v_ratio \leq 4$$

dss-E103

The PCDmin for horizontal downsampling only is defined by the following formula:

While downsampling by n , $PCDmin = n$

For H+V downsampling, the formula is the following:

$PCDmin = \max(PCDmin\ H\ only, PCDmin\ V\ only)$ as defined above

The refresh rate depends on the following parameters:

- Horizontal front porch (the DSS.DISPC_TIMING_H[19:8] HFP bit field)
- Horizontal back porch (the DSS.DISPC_TIMING_H[31:20] HBP bit field)
- Horizontal synchronization pulse width (the DSS.DISPC_TIMING_H[7:0] HSW bit field)
- Vertical front porch (the DSS.DISPC_TIMING_V[19:8] VFP bit field)
- Vertical back porch (the DSS.DISPC_TIMING_V[31:20] VBP bit field)
- Vertical synchronization pulse width (the DSS.DISPC_TIMING_V[7:0] VSW bit field)
- Number of lines per panel (the DSS.DISPC_SIZE[26:16] LPP bit field)
- Number of pixels per line (the DSS.DISPC_SIZE[10:0] PPL bit field)
- 4- or 8-bit interface for the passive matrix monochrome panel (the DSS.DISPC_CONTROL[4] M8B bit)

The following bit fields define the behavior of the internal blocks:

- Spatial/temporal dithering logic enabled (DSS.DISPC_CONTROL[7] SPATIALTEMPORALDITHERENABLE bit)
- Spatial/temporal dithering logic number of frames (DSS.DISPC_CONTROL[31:30] SPATIALTEMPORALDITHERFRAMES bit field). The default value of this bit field at reset time is 0x0, which is 1 frame only (spatial processing without temporal dithering). The possible values are 0x0 (one frame), 0x1 (two frames), and 0x2 (four frames). The number of frames is initialized before enabling the spatial/temporal dithering unit. The software must not change this bit field value while the spatial/temporal unit is enabled.

The following bit field defines the clock gating strategy:

- In active matrix mode, the pixel clock is always gated or only when valid data are present (the DSS.DISPC_CONFIG[0] PIXELGATED bit).

12.5.3.5.3 LCD Overlay

The following bit fields define the overlay attributes of the LCD output:

- Transparency color key (the DSS.DISPC_TRANS_COLOR0i register (i = 0))
- Transparency color key enable (the DSS.DISPC_CONFIG[10] TCKLCDENABLE bit)
- Transparency color key selection between the destination graphics transparency color key and the source video transparency color key (the DSS.DISPC_CONFIG[11] TCKLCDSELECTION bit)
- The default solid background color is defined in the DSS.DISPC_DEFAULT_COLOR_m[23:0] DEFAULTCOLOR bit field (i=0).
- Alpha blender Enable (DSS.DISPC_CONFIG[18] LCDALPHABLENDERENABLE)
- Global alpha blending values (DSS.DISPC_GLOBAL_ALPHA[23:16] VID2GLOBALALPHA and DSS.DISPC_GLOBAL_ALPHA[7:0] GFXGLOBALALPHA). The value 0xFF corresponds to 100% opaque and 0 to 100% transparent

NOTE: The destination graphics transparency color key is available only to the overlay with which the graphics pipeline is connected. The software must set the correct configuration of the LCD and digital overlays.

NOTE: When the alpha blender is enabled, the destination transparency color key is not available and the source transparency color key applies to the graphics pixels and not the video pixels.

When all of these fields are set to the appropriate values, set the DSS.DISPC_CONTROL[5] GOLCD bit to indicate that all shadow registers of the pipelines connected to the LCD output are latched by the hardware (only if the DSS.DISPC_CONTROL[0] LCDENABLE bit is already set to 1). If the LCD output is disabled, the new values will be updated when the DSS.DISPC_CONTROL[0] LCDENABLE bit will be set to 1.

12.5.3.5.4 LCD TDM

The following fields define the multiple cycle output configuration:

- First cycle (the DSS.DISPC_DATA_CYCLEk (k=0) register)
- Second cycle (the DSS.DISPC_DATA_CYCLEk (k=1) register)
- Third cycle (the DSS.DISPC_DATA_CYCLEk (k=2) register)
- Enable (the DSS.DISPC_CONTROL[20] TDMENABLE bit)
- Parallel mode (the DSS.DISPC_CONTROL[22:21] TDMPARALLEMODE field)
- Cycle format (the DSS.DISPC_CONTROL[24:23] TDMCYCLEFORMAT field)
- Unused bits (the DSS.DISPC_CONTROL[26:25] TDMUNUSEDBITS field)

When all of these bit fields are set to the appropriate values, set the DSS.DISPC_CONTROL[5] GOLCD bit to indicate that all shadow registers of the pipelines connected to the LCD output are latched by the hardware (only if the DSS.DISPC_CONTROL[0] LCDENABLE bit is already set to 1). If the LCD output is disabled, the new values will be updated when the DSS.DISPC_CONTROL[0] LCDENABLE bit will be set to 1.

12.5.3.5.5 LCD Spatial/Temporal Dithering

The following bit fields define the LCD spatial/temporal dithering configuration:

- Number of frames (the DSS.DISPC_CONTROL[31:30] SPATIALTEMPORALDITHERINGFRAMES bit field) with:
 - 0x0 Spatial only (default value)
 - 0x1 Spatial + Temporal over two frames
 - 0x2 Spatial + Temporal over four frames

- 0x3 Reserved
- Enable (the DSS.DISPC_CONTROL[7] SPATIALTEMPORALDITHERENABLE bit)
 - 0x0 Disabled (default value)
 - 0x1 Enabled

When all of these bit fields are set to the appropriate values, set the DSS.DISPC_CONTROL[5] GOLCD bit to indicate that all shadow registers of the pipelines connected to the LCD output are latched by the hardware (only if the DSS.DISPC_CONTROL[0] LCDENABLE bit is already set to 1). If the LCD output is disabled, the new values will be updated when the DSS.DISPC_CONTROL[0] LCDENABLE bit will be set to 1.

12.5.3.5.6 LCD Color Phase Rotation

The following bit fields define the color phase rotation configuration:

- Enable (the DSS.DISPC_CONFIG[15] CPR bit)
 - 0x0 Disabled (default value)
 - 0x1 Enabled
- Red 10-bit signed coefficients used by the color phase rotation matrix (the DSS.DISPC_CPR_COEF_R register)
- Green 10-bit signed coefficients used by the color phase rotation matrix (the DSS.DISPC_CPR_COEF_G register)
- Blue 10-bit signed coefficients used by the color phase rotation matrix (the DSS.DISPC_CPR_COEF_B register)

The programmable color phase rotation block for the LCD output has nine 10-bit coefficients defined in the DSS.DISPC_CPR_COEF_R, DSS.DISPC_CPR_COEF_G, and DSS.DISPC_CPR_COEF_B, as described in Figure 12-131 through Figure 12-134.

Figure 12-131. Color Phase Rotation Matrix

$$\begin{bmatrix} R_{out} \\ G_{out} \\ B_{out} \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} RR & RG & RB \\ GR & GG & GB \\ BR & BG & BB \end{bmatrix} * \begin{bmatrix} R_{in} \\ G_{in} \\ B_{in} \end{bmatrix}$$

dss-E105

Figure 12-132. Color Phase Rotation Matrix (R Component Only)

$$R_{out} = \frac{1}{256} * (RR * R_{in} + RG * G_{in} + RB * B_{in})$$

dss-E106

Figure 12-133. Color Phase Rotation Matrix (G Component Only)

$$G_{out} = \frac{1}{256} * (GR * R_{in} + GG * G_{in} + GB * B_{in})$$

dss-E107

Figure 12-134. Color Phase Rotation Matrix (B Component Only)

$$B_{out} = \frac{1}{256} * (BR * R_{in} + BG * G_{in} + BB * B_{in})$$

dss-E104

When all of these bit fields are set to the appropriate values, set the DSS.DISPC_CONTROL[5] GOLCD bit to indicate that all shadow registers of the pipelines connected to the LCD output are latched by the hardware (only if the DSS.DISPC_CONTROL[0] LCDENABLE bit is already set to 1). If the LCD output is disabled, the new values will be updated when the DSS.DISPC_CONTROL[0] LCDENABLE bit will be set to 1.

12.5.3.5.6.1 Color Phase Rotation - Diagonal Matrix

The Color Phase Rotation feature is useful when using an LCD backlight that is not white. By using a correct configuration of the R, G and B coefficients of CPR, the color bias of the screen can be corrected. The following paragraphs give an example of configuration of the CPR feature.

The easiest example of CPR configuration is a diagonal matrix. This way, the output colors depends on one input color only. [Figure 12-135](#) gives the example of a diagonal matrix and the corresponding equation of the output components.

Figure 12-135. Diagonal Matrix Configuration

$$\begin{bmatrix} R_{out} \\ G_{out} \\ B_{out} \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} RR & 0 & 0 \\ 0 & GG & 0 \\ 0 & 0 & BB \end{bmatrix} * \begin{bmatrix} R_{in} \\ G_{in} \\ B_{in} \end{bmatrix}$$

$$\rightarrow R_{out} = \frac{1}{256} * (RR * R_{in})$$

$$\rightarrow G_{out} = \frac{1}{256} * (GG * G_{in})$$

$$\rightarrow B_{out} = \frac{1}{256} * (BB * B_{in})$$

dss-200

According to these 3 new equations, each output component only depends on the corresponding input color. The coefficients can easily be used to reduce the impact of a non-white backlight.

Let's take the example of a "blue" backlight. In this case, users have the feeling that a blue film has been added on the screen, and then each color seems to be "too much blue". The goal is then to reduce the "Blue" component and to keep the "Red" and "Green" ones unchanged. The following matrix can be used for a reduction by a half of the blue component. [Figure 12-136](#) gives the corresponding matrix and equations for each component.

Figure 12-136. Example - Diagonal Matrix Configuration

$$\begin{bmatrix} R_{out} \\ G_{out} \\ B_{out} \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} 256 & 0 & 0 \\ 0 & 256 & 0 \\ 0 & 0 & 128 \end{bmatrix} * \begin{bmatrix} R_{in} \\ G_{in} \\ B_{in} \end{bmatrix}$$

$$\rightarrow R_{out} = \frac{1}{256} * (256 * R_{in}) \Rightarrow R_{out} = R_{in}$$

$$\rightarrow G_{out} = \frac{1}{256} * (256 * G_{in}) \Rightarrow G_{out} = G_{in}$$

$$\rightarrow B_{out} = \frac{1}{256} * (128 * B_{in}) \Rightarrow B_{out} = 0.5 * B_{in}$$

dss-201

[Figure 12-137](#) shows the result of an image on a "blue" backlight screen with and without CPR.

Figure 12-137. Image With and Without CPR (Diagonal Matrix)

dss-202

A drawback of this diagonal matrix is that the color reduction is linear. The contrast is then different from the initial image. It is then necessary to use the 6 other coefficients of the CPR matrix to better correct a non-white backlight. The goal is to find the correct coefficients that remove the color offset added by the non-white backlight.

12.5.3.5.6.2 Color Phase Rotation - Standard Matrix

In the following example, the LCD backlight adds an offset of 128 (B_offset) to the Blue component. Figure 12-138 shows an example of matrix that reduces the offset of the screen, the corresponding equations and the resulting output colors.

Figure 12-138. Example - Image With and Without CPR (Standard Matrix)

$$\begin{bmatrix} R_{out} \\ G_{out} \\ B_{out} \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} 256 & 0 & 0 \\ 0 & 256 & 0 \\ -129 & -129 & 370 \end{bmatrix} * \begin{bmatrix} R_{in} \\ G_{in} \\ B_{in} \end{bmatrix}$$

$$\rightarrow R_{out} = \frac{1}{256} * (256 * R_{in})$$

$$\rightarrow G_{out} = \frac{1}{256} * (256 * G_{in})$$

$$\rightarrow B_{out} = \frac{1}{256} * (-129 * R_{in} + -129 * G_{in} + 370 * B_{in}) + B_{offset}$$

dss-203

This CPR matrix gives inputs and outputs very close. However, black can not be corrected because of its zero-components. No matter which coefficients are used in the matrix, the result will always be equal to the offset added by the LCD backlight.

12.5.3.6 TV Set-Specific Control Registers

The following registers define the digital output configuration:

- DSS.DISPC_CONTROL
- DSS.DISPC_CONFIG
- DSS.DISPC_DEFAULT_COLOR_m (m=1)
- DSS.DISPC_TRANS_COLOR_m (m=1)
- DSS.DISPC_SIZE_DIG

The digital output is enabled/disabled by setting/resetting the DSS.DISPC_CONTROL[1] DIGITALENABLE bit. A valid configuration must be set before the digital output can be enabled.

Perform the initialization sequence as follows:

1. Initialize the video encoder and the display controller configuration registers.
2. Set the DSS.DISPC_CONTROL[6] GODIGITAL bit and the DSS.DISPC_CONTROL[1] DIGITALENABLE bit to 1.
3. Wait for the first VSYNC pulse signal.
4. Clear the SYNCLOSTDIGITAL interrupt by setting the DSS.DISPC_IRQSTATUS[15] SYNCLOSTDIGITAL bit to 1.
5. Enable the SYNCLOSTDIGITAL interrupt by setting the DSS.DISPC_IRQENABLE[15] SYNCLOSTDIGITAL bit to 1.

12.5.3.6.1 Digital Timings

The following bit fields define the timing information:

- Data hold time (the DSS.DISPC_CONTROL[19:17] HT bit field)
- Logic clock divisor (the DSS.DISPC_DIVISOR[23:16] LCD bit field)

The 8-bit pixel clock divider (DSS.DISPC_DIVISOR[23:16]) bit field is used to select the logic clock frequency. The LCD generates a range of pixel clock frequencies from FCK/1 to FCK/255, where FCK is the input functional clock of the display controller.

12.5.3.6.2 Digital Frame/Field Size

The following bit fields define the field size (frame if progressive mode):

- Number of lines per panel (the DSS.DISPC_SIZE_DIG[26:16] LPP bit field)
- Number of pixels per line (the DSS.DISPC_SIZE_DIG[10:0] PPL bit field)

12.5.3.6.3 Digital Overlay

The following bit fields define the overlay attributes of the digital output:

- Transparency color key (the DSS.DISPC_TRANS_COLOR_m register (m=1))
- Transparency color key enable (the DSS.DISPC_CONFIG[12] TCKDIGENABLE bit)
- Transparency color key selection between the destination graphics transparency color key and the source video transparency color key (the DSS.DISPC_CONFIG[13] TCKDIGSELECTION bit)
- The default solid background color is defined in the DSS.DISPC_DEFAULT_COLOR_m[23:0] DEFAULTCOLOR bit field (i=1).
- Alpha blender Enable (DSS.DISPC_CONFIG[19] TVALPHABLENDERENABLE)
- Global alpha blending values (DSS.DISPC_GLOBAL_ALPHA[23:16] VID2GLOBALALPHA and DSS.DISPC_GLOBAL_ALPHA[7:0] GFXGLOBALALPHA). The value 0xFF corresponds to 100% opaque and 0 to 100% transparent

NOTE: The destination graphics transparency color key is available only to the overlay with which the graphics pipeline is connected. The software must set the correct configuration of the LCD and digital overlays.

NOTE: When the alpha blender is enabled, the destination transparency color key is not available and the source transparency color key applies to the graphics pixels and not the video pixels.

When this bit field is set to the appropriate values, set the DSS.DISPC_CONTROL[6] GODIGITAL bit to indicate that all shadow registers of the pipelines connected to the digital output are latched by the hardware (only if the DSS.DISPC_CONTROL[1] DIGITALENABLE bit is already set to 1). If the digital output is disabled, the new values will be updated when the DSS.DISPC_CONTROL[1] DIGITALENABLE bit will be set to 1.

12.5.4 DSI Protocol Engine Basic Programming Model

This section describes the programming model of the DSI protocol engine.

12.5.4.1 Software Reset

The DSI protocol engine can be reset by software. This reset can be done for debug purposes or after a protocol error and has the same effect as the hardware reset. The DSI protocol engine can be reset by setting the DSS.DSI_SYSCONFIG[1] SOFT_RESET bit to 1. The software can monitor the DSS.DSI_SYSSTATUS[0] RESET_DONE status bit to wait for the completion of the reset procedure. If after 5 reads, the DSS.DSI_SYSSTATUS[0] RESET_DONE status bit still returns 0, it can be assumed that an error occurred during the reset stage.

NOTE: This software reset is optional as a hardware reset is always performed on the DSI protocol engine at device reset.

12.5.4.2 Power Management

The power management behavior of the DSI protocol engine is controlled by the DSS.DSI_SYSCONFIG register. This register completely controls the way the module interferes with the PRCM module. The DSS.DSI_SYSCONFIG[0] AUTO_IDLE bit should be set to 1 (default value) to enable automatic clock gating in the module.

12.5.4.3 Interrupts

There is a single interrupt request: DSI_IRQ. This interrupt line is merged with another interrupt line from the DISPC_IRQ in a single interrupt request DSS_IRQ. The DSI_IRQ events are generated only for the enabled VC(s). Two registers are used to enable and monitor the DSI interrupt events:

- DSS.DSI_IRQENABLE register: This register indicates the enabled/disabled event for the VCs. Each event for the VC is configured in the DSS.DSI_VCn_IRQENABLE register dedicated to the VC number. In addition, it includes one bit for the enable of error reporting for the complex I/O: Error signaling from the complex I/O: The interrupt is triggered when any error is received from the complex I/O (ErrSyncEsc[4:0], ErrEsc[4:0] (edge trigger interrupt), ErrControl[4:0] and ErrContentionLP0[4:0], ErrContentionLP1[4:0] from the complex I/O).
- DSS.DSI_IRQSTATUS register : The register DSI_IRQSTATUS flags which VC(s) is/have generated an interrupt. Based on the VC number, the register DSI_VCn_IRQSTATUS indicates the event generating the interrupt. In addition, it includes one bit for the status of error reporting for the complex I/O.

12.5.4.4 Global Register Controls

Prior to receive data from the DSI complex I/O, the DSI_PHY_SCP registers in the DSI complex I/O must be configured. Refer to [Section 12.5.6](#) for more details. [Table 12-61](#) details the register access width limitations for all the DSI modules.

Table 12-61. Register Access Width Limitations

| Register Name | Register Access Width |
|---|--------------------------|
| All DSI complex I/O register (DSI_PHY_SCP) | 32-bit only |
| All DSI PLL control module registers | 32-bit only |
| DSI_VCn_LONG_PACKET_HEADER | 32-bit only |
| DSI_VCn_SHORT_PACKET_HEADER | 32-bit only |
| DSI_VCn_LONG_PACKET_PAYLOAD | 16-bit, 32-bit |
| All others DSI protocol engine registers | 8-bit, 16-bit and 32-bit |

CAUTION

In case of different access width detailed in [Table 12-61](#), an OCP error is generated in response to the write using SResp=ERR.

The DSI protocol engine is globally controlled by the DSS.DSI_CTRL register. The interface to the complex I/O is enabled by setting the DSS.DSI_CTRL[0] IF_EN bit. When the interface is disabled, it is possible to provide data to the TX FIFO and read pending data in the RX FIFO. When the DSS.DSI_CTRL[0] IF_EN bit is set to 1, the pending packets should be sent to the DSI complex I/O, the data transfer from the video port should be ignored only when received the next Vertical Sync Event which is received but not send to the DSI complex I/O.

When the DSS.DSI_CTRL[0] IF_EN bit is reset by software, the hardware should finish the transfer of the pending data in the TX FIFO and wait for response if BTA has been sent (Protocol engine is receive mode), then the hardware resets the DSS.DSI_CTRL[0] IF_EN bit. When using the video mode, the VC associated with the video port should be enabled prior to enable the interface according to the following sequence:

- DSS.DSI_CTRL[0] IF_EN bit is equal to 0
- Enable the VC associated with video mode by setting the DSS.DSI_VCn_CTRL[0] VC_EN
- Set the DSS.DSI_CTRL[0] IF_EN bit to 1

12.5.4.5 Virtual Channels

There is one set of registers for each VC. The attributes of the VC define the following characteristics:

- Transfer mode (DSS.DSI_VCn_CTRL[4] MODE bit):
 - Video mode
 - Command mode
- Data type
- Source (DSS.DSI_VCn_CTRL[1] SOURCE bit)
 - Video port
 - L4 interconnect port
- HS or LP forward transmission
- Automatic bus turn-around generation
 - Short packets (DSS.DSI_VCn_CTRL[2] BTA_SHORT_EN bit)
 - Long packets (DSS.DSI_VCn_CTRL[3] BTA_LONG_EN bit)
- DMA request configurations for RX and TX
 - DMA request number (DSS.DSI_VCn_CTRL[29:27] DMA_RX_REQ_NB bit field for RX FIFO and DSS.DSI_VCn_CTRL[23:21] DMA_TX_REQ_NB bit field for TX FIFO)
 - DMA threshold (DSS.DSI_VCn_CTRL[26:24] DMA_RX_THRESHOLD bit field for RX FIFO and DSS.DSI_VCn_CTRL[19:17] DMA_TX_THRESHOLD bit field for TX FIFO)
- Mode speed (DSS.DSI_VCn_CTRL[9] MODE_SPEED bit)
- ECC transmission (DSS.DSI_VCn_CTRL[8] ECC_TX_EN bit)
- CS transmission (DSS.DSI_VCn_CTRL[7] CS_TX_EN bit)

The VC ID not calculated by the DSI module but provided while writing into the registers [DSI_VCn_SHORT_PACKET_HEADER](#) and [DSI_VCn_LONG_PACKET_HEADER](#).

12.5.4.6 Packets

The DSS.DSI_VCn_SHORT_PACKET_HEADER register is used to send only short packets (ECC can be calculated by hardware or by software user for debug purpose). The register is not used for video mode data since the short packets are generated by the hardware using the following information:

- synchronization events received on the video port (assertion/deassertion of the HSYNC and VSYNC input signals)
- DSS.DSI_CTRL[18] VP_HSYNC_END
- DSS.DSI_CTRL[17] VP_HSYNC_START
- DSS.DSI_CTRL[16] VP_VSYNC_END
- DSS.DSI_CTRL[15] VP_VSYNC_START
- DSS.DSI_CTRL[10] VP_HSYNC_POL
- DSS.DSI_CTRL[11] VP_VSYNC_POL
- DSS.DSI_VCn_CTRL[1] SOURCE

The DSS.DSI_VCn_LONG_PACKET_HEADER register is used to provide header for long packets (ECC is always calculated by hardware). The register is used for video mode and command mode. If the video mode is enabled for the VC, it is not possible to transfer concurrently (interleaved in a frame) data using

long packets received on the video port and on the L4 interconnect port since the DSS.DSI_VCn_LONG_PACKET_HEADER register is used by the video mode. The register can be unprogrammed by users to send long packets received on the L4 interconnect port only when software users know that there is no expected data on the video port. The software should correctly program the register to send sequentially long packets in video and command modes.

The DSS.DSI_VCn_LONG_PACKET_PAYLOAD register is used to provide payload data for long packets (Check-sum is calculated by hardware when DSS.DSI_VCn_CTRL[7] CS_TX_EN is set to 1 otherwise the value 0x00 is used). The register is not used in video mode since payload data are provided by the video port. The software should ensure that the following sequence for write accesses to the header and payload registers (DSS.DSI_VCn_LONG_PACKET_HEADER and DSS.DSI_VCn_LONG_PACKET_PAYLOAD, respectively) is followed:

- A long packet header value with WC=0 written in DSS.DSI_VCn_LONG_PACKET_HEADER register can be followed by any access.
- A long packet header value with WC>0 written in DSS.DSI_VCn_LONG_PACKET_HEADER register should be followed by one or more writes to the DSS.DSI_VCn_LONG_PACKET_PAYLOAD register defined by the WC value before writing again to the same DSS.DSI_VCn_LONG_PACKET_HEADER register.

CAUTION

If this sequence is not followed, no error is generated. The access to other DSI registers during this sequence is allowed.

12.5.4.7 DSI Complex I/O

Prior to send/receive any data from the complex I/O, the DSI complex I/O timings should be set according to the display module timings. The DSI complex I/O pads must also be configured first. See [Section 12.5.6, DSI Complex I/O Basic Programming Model](#).

12.5.4.8 Video Mode

The DSS.DSI_VM_TIMING1, DSS.DSI_VM_TIMING2, DSS.DSI_VM_TIMING3, DSS.DSI_VM_TIMING4, DSS.DSI_VM_TIMING5, DSS.DSI_VM_TIMING6, and DSS.DSI_VM_TIMING7 registers define the timings of the video mode.

The DSS.DSI_CTRL[20] BLANKING_MODE bit defines if the long blanking packets or LPS state are used during the blanking periods (except HFP, HBP, HSA defined by other bits) when there is no pending data in TX FIFO ready to be sent. The software should ensure that there is no data in the TX FIFO, no BTA, no RESET trigger sent, and the DSS.DSI_VCn_CTRL[9] MODE_SPEED bit is set to 1 (High-Speed mode) to keep the video mode transfer is HS mode during blanking periods (except for the last blanking period since it is required to go LPS at least once per frame).

The DSS.DSI_CTRL[21] HFP_BLANKING_MODE, DSS.DSI_CTRL[22] HBP_BLANKING_MODE and DSS.DSI_CTRL[23] HSA_BLANKING_MODE define if these blanking can send packets from the TX FIFO or should be kept in HS mode using only long blanking packets.

To ensure that the writes to the register DSS.DSI_VCn_LONG_PACKET_HEADER are correctly handled as header information for video mode long packets, the following registers should be programmed:

- DSS.DSI_VCn_CTRL[0] VC_EN bit set to 1
- DSS.DSI_VCn_CTRL[4] MODE bit set to 1
- DSS.DSI_VCn_LONG_PACKET_HEADER register access
- DSS.DSI_VCn_CTRL[0] VC_EN bit set to 1

NOTE: The DSS.DSI_VCn_CTRL[1] SOURCE and DSS.DSI_VCn_CTRL[9] MODE_SPEED bits are ignored by hardware when the video mode is selected (DSS.DSI_VCn_CTRL[4] MODE bit set to 1)

The interrupt events SYNC_LOST_IRQ and RESYNCHRONIZATION_IRQ indicates if the DSI protocol

engine has not been able to resynchronize the video port timing to its own timing base or if it has been done. The RESYNCHRONIZATION_IRQ indicates software users that the video port works but the configuration of the timings for the display controller (DISPC) and for DSI Protocol engine may need to be modified to avoid the resynchronization to occur. The SYNC_LOST_IRQ and RESYNCHRONIZATION_IRQ events can be respectively monitored in DSS.DSI_IRQSTATUS[18] SYNC_LOST_IRQ and DSS.DSI_IRQSTATUS[5] RESYNCHRONIZATION_IRQ status bits.

The DSS.DSI_VM_TIMING2[27:24] WINDOW_SYNC bit field defines the synchronization period. The recommended value is 0x4 based on the implementation of the resynchronization scheme.

12.5.4.9 Video Port Data Bus

The DSS.DSI_CTRL[7:6] VP_DATA_BUS_WIDTH bit field is used to determine the width of the data bus on the video port. The supported formats are 16-bit, 18-bit and 24-bits.

12.5.4.10 Command Mode

12.5.4.10.1 Command Mode TX FIFO

The single TX FIFO is used on the L4 interconnect port to receive the data to be sent to the peripheral. The configuration of the FIFO for a specific VC should be done only when the VC is disabled.

Users should not enable the VC if there is still some pending data in the TX FIFO for the corresponding space allocated for the VC from previous active period. When the VC space in the TX FIFO is empty, the VC can be enabled.

For each VC, two dedicated DSS.DSI_VCn_LONG_PACKET_HEADER and DSS.DSI_VCn_LONG_PACKET_PAYLOAD registers are used to provide data for long packets. The register DSS.DSI_VCn_SHORT_PACKET_HEADER is used to provide data for short packets (32-bit long).

For each long packet, the DSS.DSI_VCn_LONG_PACKET_HEADER register should be written first and then the DSS.DSI_VCn_LONG_PACKET_PAYLOAD register. The only exception is when the word count defined in the header is equal to 0. In that case, it is not required to write into the payload register. For consecutive long packets, the header should be written into the DSS.DSI_VCn_LONG_PACKET_HEADER register even if the value remains the same.

The TX FIFO stores all the pending bytes to be sent to the peripheral(s). Multiple receivers can be addressed using the VC capability.

The 32-bit write requests only for each VC to the TX FIFO should be kept in order while sending the data to the DSI_PHY inside the VC requests. The only exception is in the case of last 32-bit write for the last bytes of the payload data since it could be 1, 2, 3, or 4 bytes.

Also in case the last transfer is a 32-bit write but the number of valid bytes is 1, 2, or 3 only (calculated using the header word count and the number of bytes are received for the payload), the hardware should store the 32-bit value into the TX FIFO but the invalid bytes are not sent, and are discarded.

When the word count defined in DSS.DSI_VCn_LONG_PACKET_HEADER register is not a multiple of the request threshold value defined in DSS.DSI_VCn_CTRL[19:17] DMA_TX_THRESHOLD bit field, 32-bit requests and/or bytes should be discarded by the hardware to store in FIFO only the exact number of valid bytes.

The DSI protocol module should be able to determine if the bytes in the TX FIFO correspond to a short or long packet without decoder the DT field. When the bytes are written into the DSS.DSI_VCn_SHORT_PACKET_HEADER, DSS.DSI_VCn_LONG_PACKET_HEADER, and DSS.DSI_VCn_LONG_PACKET_PAYLOAD registers, the hardware should store the information concerning long or short packet. A 1-bit flag should be used for each entry of the TX FIFO.

When the VC is disabled, the remaining bytes in the FIFO should be sent to the DSI link. The start event to send data to the DSI link one of the following events:

- All bytes have been received in the FIFO (header + payload).
- The space of the FIFO allocated for the VC is full.
- The space of the FIFO allocated for the VC is not enough to request more data using DMA request

(threshold value bigger than space left in the TX FIFO for the VC).

NOTE: In case the video mode is active, the blanking period should be large enough to allow the transfer of the packet(s).

Sequential arbitration must be set (TX_FIFO_ARBITRATION[3] [DSI_CTRL](#) bit = 0x1) if only one VC is used to send multiple packets during the same blanking period.

When consecutive packets should be sent in HS mode, to ensure that there is no LP transition between them at least one of the following condition should be valid:

- Packets from the same VC
- Short packets or long packets with a payload size multiple of 4 bytes

To flush the FIFO (discard of the data) for some pending bytes, the software should change the allocated size of the chunk FIFO by:

- First disabling the VC resetting [DSS.DSI_VCn_CTRL\[0\]](#) VC_EN bit to 0
- Second change the size of the space of FIFO to 0 by writing the [DSS.DSI_TX_FIFO_VC_SIZE](#) VCn_FIFO_SIZE (n is the VC value between 0 and 3)

If there is an on-going packet transfer from the TX FIFO to DSI_PHY, the flush of the FIFO should stop immediately the transfer. Because the FIFO is accessible to users, it must ensure that there are no bytes left in the FIFO before starting the flush operation. But it can be required in dead-lock situation to flush the FIFO even if there are still bytes in the FIFO, in that case, the software should also take care of having a known state of the whole DSI protocol engine module (software reset may be required) To start of new transfer through the TX FIFO.

Users can check that there is no pending request before changing the size of the allocated FIFO for the VC by reading the relevant [DSS.DSI_VCn_CTRL\[15\]](#) VC_BUSY bit or by using the interrupt [PACKET_SENT_IRQ](#): All the packets have been sent by counting the transferred requests to the L4 interconnect port and the number of requests sent to the DSI complex I/O. This interrupt can be monitoring by reading the [DSS.DSI_VCn_IRQSTATUS\[2\]](#) [PACKET_SENT_IRQ](#) status bit.

The [DSS.DSI_CTRL\[3\]](#) TX_FIFO_ARBITRATION bit defines if the arbitration scheme is:

- Round-robin between enabled VCs with pending ready requests (pending ready request means that all bytes for the packets are in the FIFO or the space of the FIFO for the VC is full) starting from the VC which has the least VC ID number.
- Sequential: All the pending ready requests for one VC are sent before moving to another VC. The condition of "space of the FIFO is full" should be evaluated after the end of each packet.

If users want to use sequential arbitration for all requests for all channels, a single VC should be used. (the VC ID defined in the header provided to the hardware using either the [DSS.DSI_VCn_LONG_PACKET_HEADER](#) or [DSS.DSI_VCn_SHORT_PACKET_HEADER](#) register is not used and not modified by the DSI protocol engine).

The register [DSS.DSI_TX_FIFO_VC_SIZE](#) defines the allocated number of 33-bit values for each VC in the TX FIFO and the start address for each VC. The size of the space allocated in the TX FIFO defined by [DSS.DSI_TX_FIFO_VC_SIZE](#) VCn_FIFO_SIZE (n corresponds to the VC number n) bit fields should be a multiple of the threshold defined in [DSS.DSI_VCn_CTRL\[19:17\]](#) DMA_TX_THRESHOLD bit field. Only the enabled VCs should be taken into account. To change the size of the space of the memory allocated for a specific VC, the VC should be disabled by setting the [DSS.DSI_VCn_CTRL\[0\]](#) VC_EN bit to 0. The whole FIFO may not be used by all the VCs at a given time since a VC can be disabled to change one or multiple parameters. Software users are responsible for correctly configuring the start address and the size for each VC.

[Table 12-62](#) indicates the corresponding values for the size of the space allocated in the FIFO.

Table 12-62. Virtual Channel TX FIFO Size Values

| DSI_TX_FIFO_VC_SIZE.VCn_FIFO_SIZE[n = 0, 3] | Space Size (up to the size of the FIFO) |
|---|---|
| 0 | 0 x 33 bits |
| 1 | 32 x 33 bits |

Table 12-62. Virtual Channel TX FIFO Size Values (continued)

| DSI_TX_FIFO_VC_SIZE.VCn_FIFO_SIZE[n = 0, 3] | Space Size (up to the size of the FIFO) |
|---|---|
| 2 | 64 x 33 bits |
| 3 | 96 x 33 bits |
| 4 | 128 x 33 bits |

The total size of TX FIFO is 128*33 bits. Therefore, the sum of all virtual channel FIFO allocation cannot exceed 128*33 bits.

Table 12-63 indicates the start address of the space in the FIFO.

Table 12-63. Virtual Channel TX FIFO Start Address

| DSI_TX_FIFO_VC_SIZE.VCx_FIFO_ADD[x = 0, 2] | Start Address |
|--|---------------|
| 0 | 0 |
| 1 | 32 |
| 2 | 64 |
| 3 | 96 |
| 4 | 128 |

CAUTION

There must be no overlap of different VCs spaces.

When the TX FIFO is full:

- the overflow interrupt ([FIFO_TX_OVF_IRQ](#)) is generated. To monitor this interrupt request, users can read the [DSS.DSI_VCn_IRQSTATUS\[3\] FIFO_TX_OVF_IRQ](#) status bit.
- there is no L4 interconnect error generated
- the commands are accepted but the data are not written into the FIFO

To ensure that all writes are correctly stored in the TX FIFO, the FIFO should not be full. The software must read the room in the space allocated for the VC in the TX FIFO by reading the [DSS.DSI_TX_FIFO_VC_EMPTYNESS](#) register. In case there is no space allocated in the TX FIFO for the VC, the [DSS.DSI_TX_FIFO_VC_EMPTYNESS](#) register indicates a value of 0 for the VC space emptiness.

When waiting to receive the first VSYNC event on the video port to start the video mode on DSI link no command data from TX FIFO should be sent on the interface. It is required to ensure that when receiving the VSYNC event, there is no on-going command mode transfer that could delay the start of video mode on the DSI link.

12.5.4.10.2 Command Mode RX FIFO

The RX FIFO is used to store the data received from the DSI complex I/O. The data are always packed in the RX FIFO (single or multiple packets receiving during a single or multiple BTA periods).

The read requests access to corresponding VC locations to transfer data for a specific VC. The logic managing the FIFO must be able to extract 32-bit values in-order for a specific VC upon read requests. The byte enable of the read access is ignored. Each read returns one 32-bit value from the RX FIFO. If the application accesses the RX FIFO should extract always 32-bit values. Only in the case of 1, 2, or 3 bytes are remaining in the RX FIFO.

The read requests (single or burst) can be less, equal or greater than the packet size. If the packet size is smaller than the read request, the following packet(s) is also transferred. If the packet size is longer than the read request, only part of the packet is transfer. In that case, the logic should keep the VC information to provide the rest of the data during the next read request(s).

The register `DSS.DSI_RX_FIFO_VC_SIZE` defines the allocated number of 33-bit values for each VC in the RX FIFO and the start address for each VC. Only the enabled VCs should be taken into account. To change the size of the space of the memory allocated for a specific VC, the VC should be disabled by resetting the `DSS.DSI_VCn_CTRL[0]` `VC_EN` bit to 0. The whole FIFO may not be used by the entire VC at a given time since a VC can be disabled to change one or multiple parameters. Software users are responsible for correctly configuring the start address and the size for each VC.

Table 12-64 indicates the corresponding values for the size of the space allocated in the FIFO:

Table 12-64. Virtual Channel RX FIFO Size Values

| <code>DSI_RX_FIFO_VC_SIZE.VCx_FIFO_SIZE[x = 0, 3]</code> | Space Size (up to the size of the FIFO) |
|--|---|
| 0 | 0 x 33 bits |
| 1 | 32 x 33 bits |
| 2 | 64 x 33 bits |
| 3 | 96 x 33 bits |
| 4 | 128 x 33 bits |

The total size of RX FIFO is 128*33 bits. Therefore, the sum of all virtual channel FIFO allocation cannot exceed 128*33 bits.

Table 12-65 indicates the start address of the space in the FIFO.

Table 12-65. Virtual Channel RX FIFO Start Address

| <code>DSI_RX_FIFO_VC_SIZE.VCx_FIFO_ADD[x = 0, 2]</code> | Start Address |
|---|---------------|
| 0 | 0 |
| 1 | 32 |
| 2 | 64 |
| 3 | 96 |
| 4 | 128 |

CAUTION

There must be no overlap of different VCs spaces.

While reading the received bytes in the RX FIFO, only the `DSS.DSI_VCn_SHORT_PACKET_HEADER` register is used since the hardware does not keep track of the header position for long packets and start/end of each packet. The software must extract the information from the bytes read from the RX FIFO. There is no specific hardware to track the received bytes in the RX FIFO. The `DSS.DSI_VCn_LONG_PACKET_HEADER` and `DSS.DSI_VCn_LONG_PACKET_PAYLOAD` registers are not used.

The ECC is only used by the first header when receiving multiple packets during the same LP RX transfer from the peripheral since the DSI Protocol engine does not parse the header to identify the length of the packets. In case of multiple packets, the Check-sum does not be enabled since the hardware checks the check-sum considering a single packet. The ECC in the first header is used to correct and check the header. For the following headers in the same LP RX transfer, the hardware does not detect any header and can not check or/and detect errors in the headers of the packets except for the first packet.

When the RX FIFO is empty:

- there is no OCP error generated
- the commands are accepted and the data for the responses are 0s

12.5.4.10.3 Command Mode DMA Requests

The DMA requests (`DSI_DMA_REQ`) are used to allow automatic transfer by the system DMA or MPU (with less efficiency and through-put capability) from the DSI RX FIFO to the system memory and from the

system memory to the DSI TX FIFO. Two independent DMA requests for RX FIFO and TX FIFO for the same VC are supported. The read and write accesses can use burst structure. The DSI protocol engine should access each write request in a burst without any IDLE between. For read OCP request in a burst to RX FIFO, the acceptance is sent immediately and the response is delayed by at least four L4 interface clock (DSS_L4_ICLK) cycles. In case of register reads, the response is returned in the first clock cycle.

The thresholds used for requests for the TX FIFO and RX FIFO are programmable by software. Users program the DSS.DSI_VCn_CTRL[19:17] DMA_TX_THRESHOLD and DSS.DSI_VCn_CTRL[26:24] DMA_RX_THRESHOLD bit fields for TX FIFO and RX FIFO respectively. The hardware asserts the DMA request based on the threshold value. The size of the space allocated in TX FIFO for each VC should be a multiple of DSS.DSI_VCn_CTRL[19:17] DMA_TX_THRESHOLD bit field value.

The only exception is in the case of the RX FIFO when the LP data transfer finishes and the threshold value is not reached. In that case the DMA request should be asserted. So the drain of the FIFO is supported in that configuration to empty the FIFO even if the number of data received is not a multiple of the threshold value.

In case of TX FIFO, if all the bytes defined by the word count field in the DSS.DSI_VCn_LONG_PACKET_HEADER header register have been received, the DMA request is not asserted anymore even during the last transfer less than DMA_TX_THRESHOLD number of bytes have been received because of the word count being not a multiple of the DMA_TX_THRESHOLD value.

In case of RX FIFO, while the DMA request is used to transfer the data from the RX FIFO to the system memory, the system DMA should be programmed to read the exact number of received bytes in the FIFO. If users do not know the size of the received bytes, the direct access of the RX FIFO through the DSS.DSI_VCn_SHORT_PACKET_HEADER register is performed until the DSS.DSI_VCn_CTRL[20] RX_FIFO_NOT_EMPTY bit goes to 0.

The use of each DMA request is programmable by software. The DSS.DSI_VCn_CTRL[23:21] DMA_TX_REQ_NB is dedicated to DMA request numbering for the TX FIFO. The DSS.DSI_VCn_CTRL[29:27] DMA_RX_REQ_NB is dedicated to DMA request numbering for the RX FIFO.

When the DMA request is used to indicate the number of 32-bit values ready in the RX FIFO or BTA has been received from peripheral indicating end of the transfer from peripheral to host for a transfer to the system memory, the DMA request corresponding to the VC ID is generated.

The system DMA transfers the number of 32-bit values defined in the threshold register or the exact number of bytes received from the peripheral (user should know the number of expected received bytes to program correctly the system DMA). When the system DMA transfers a multiple number of threshold value, the DSI protocol engine should send 0s for the data when there is no more received data in the RX FIFO for the VC. Software users are responsible for parsing the data and determine the valid bytes.

Software users can decide to determine the number of data received in the RX FIFO to read the information in the DSS.DSI_RX_FIFO_VC_FULLNESS register. Then the system DMA can be programmed to read the exact number of bytes from the RX FIFO. The BTA interrupt (BTA_IRQ) should be used to know when to read the number of received bytes. To monitor the BTA interrupt, the user should read the DSS.DSI_VCn_IRQSTATUS[5] BTA_IRQ status bit. The DMA request should not be selected until the system DMA is programmed with the correct number of data to read from RX FIFO.

If the RX FIFO space for the VC is expected to be overflow because the number of data to be received is greater than the space allocated for the VC, the previous programming model should be used. In place, the DMA request should be asserted as soon as the threshold is reached or when BTA is received.

When the DMA request is used to indicate the number of 33-bit entries empty in the TX FIFO for a transfer from the system memory, the DMA request corresponding to the VC ID is generated.

NOTE: To obtain best efficiency of the transfer the size of the request (read or write, single or burst) should be aligned with the threshold value.

Concurrent access using interlaced requests (read/write) to the TX and RX FIFO is supported for the same VC ID or different VC IDs.

12.5.4.11 Ultra-Low Power State

This section describes how to enter/exit to/from ultralow-power state (ULPS).

NOTE: The DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIGy bits (x range is 1 to 3 corresponding to lane #1 to lane #3 and y range is 1 to 2) must be read back after writing to verify that the write operations are effective before proceeding to the next step. This is to take latency at low TxClkEsc frequencies into account.

12.5.4.11.1 Entering ULPS

To enter into ULPS for a clock lane, the following sequence is required:

1. Wait for DSS.DSI_COMPLEXIO_CFG2[16] HS_BUSY and DSS.DSI_COMPLEXIO_CFG2[17] LP_BUSY bits to be reset to 0 and ensure that the DSS.DSI_CLK_CTRL[13] DDR_CLK_ALWAYS_ON bit is 0.
2. TxUlpsClk state should change from inactive to active by setting the DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG2 (x range is 1 to 3 corresponding to lane #1 to lane #3) bit to 1.

To enter into ULPS for a data lane, the following sequence is required:

1. Wait for all TX_FIFOs for all VCs working in HS are empty, for video mode is not active, and for DSS.DSI_COMPLEXIO_CFG2[16] HS_BUSY bit is reset to 0 (in addition, for data lane #1, DSS.DSI_COMPLEXIO_CFG2[17] LP_BUSY bit is reset to 0)
2. TxRequestEsc state should change from inactive to active by setting the DSS.DSI_COMPLEXIO_CFG2.LANEx_ULPS_SIG2 (x range is 1 to 3 corresponding to lane #1 to lane #3) bit to 1.

NOTE: When the DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG2 and DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG1 bits are written to 0, they can be combined into one write. Both bits must be read back to confirm they are effective before proceeding.

12.5.4.11.2 Exiting ULPS

To exit from ULPS for a clock lane, the following sequence is required:

1. Change the state of TxUlpsExit for each lane to ACTIVE by setting the DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG1 (x range is 1 to 3 corresponding to lane #1 to lane #3) bit to 1.
2. Wait for the ULPSACTIVENOT_ALL1_IRQ interrupt indicating that all lanes with TxUlpsExit active have acknowledged by asserting UlpsActiveNot. This is performed by monitoring the DSS.DSI_COMPLEXIO_IRQSTATUS[31] ULPSACTIVENOT_ALL1_IRQ status bit.
3. Start the wake-up timer (GPTimer).
4. Wait for the time-out.
5. Change TxUlpsClk signals to INACTIVE state for the clock lane by resetting the DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG2 (x range is 1 to 3 corresponding to lane #1 to lane #3) bit to 0.
6. Reset the DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG1 (x range is 1 to 3 corresponding to lane #1 to lane #3) bit to 0.

NOTE: When the DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG2 and DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG1 bits are both being written to 0, they can be combined into one write. Both bits must be read back to confirm they are effective before proceeding.

To exit from ULPS for a clock lane, in case ComplexIO is in OFF state (the DSI protocol engine sends ComplexIO to OFF state by setting DSS.DSI_COMPLEXIO_CFG1[28:27] PWROFF = 0x0), the sequence is:

1. Change TxUlpsCik signals to INACTIVE state for the clock lane by resetting the DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG2 (x range is 1 to 3 corresponding to lane #1 to lane #3) bit to 0.
2. Change the state of TxUlpsExit for clock lane to INACTIVE state by resetting the DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG1 (x range is 1 to 3 corresponding to lane #1 to lane #3) bit to 0. This step is necessary only in case a PWROFF command (the command for power control of the complex I/O) is issued while the sequence for exiting is in progress (TxUlpsExit signal is already in ACTIVE state).

NOTE: When the DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG2 and DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG1 bits are both being written to 0, they can be combined into one write. Both bits must be read back to confirm they are effective before proceeding.

To exit from ULPS for a data lane, the following sequence is required:

1. Change the state of TxUlpsExit for each lane to ACTIVE by setting the DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG1 (x range is 1 to 3 corresponding to lane #1 to lane #3) bit to 1.
2. Wait for the ULPSACTIVENOT_ALL1_IRQ interrupt indicating that all lanes with TxUlpsExit active have acknowledged by asserting UlpsActiveNot. This is performed by monitoring the DSS.DSI_COMPLEXIO_IRQSTATUS[31] ULPSACTIVENOT_ALL1_IRQ status bit.
3. Start the application wake-up timer (GPTimer).
4. Wait for the time-out.
5. Change TxRequestEsc signals to INACTIVE state for the data lane by resetting the DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG2 (x range is 1 to 3 corresponding to lane #1 to lane #3) bit to 0.
6. Reset the DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG1 (x range is 1 to 3 corresponding to lane #1 to lane #3) bit to 0.

NOTE: When the DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG2 and DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG1 bits are both being written to 0, they can be combined into one write. Both bits must be read back to confirm they are effective before proceeding.

To exit from ULPS for a data lane, in case ComplexIO is in OFF state (the DSI protocol engine sends ComplexIO into OFF state by setting DSS.DSI_COMPLEXIO_CFG1[28:27] PWROFF = 0x0), the sequence is:

1. Change TxRequestEsc signals to INACTIVE state by resetting the DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG2 (x range is 1 to 3 corresponding to lane #1 to lane #3) bit to 0.
2. Change the state of TxUlpsExit to INACTIVE state by resetting the DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG1 (x range is 1 to 3 corresponding to lane #1 to lane #3) bit to 0. This step is necessary only in case a PWROFF command (the command for power control of the complex I/O) is issued while the sequence for exiting is in progress (TxUlpsExit signal is already in ACTIVE state).

NOTE: When the DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG2 and DSS.DSI_COMPLEXIO_CFG2 LANEx_ULPS_SIG1 bits are both being written to 0, they can be combined into one write. Both bits must be read back to confirm they are effective before proceeding.

When the sequence for entering/exiting into/from ULP state is started for specific lanes, users should wait for the completion of the sequence before changing the state of the same or other lanes.

12.5.4.12 DSI Programming Sequence Example

This section describes distinct configurations of the DSI protocol engine to support different type of traffics.

NOTE: When the VC is used to send video mode data from the video port, the DSS.DSI_VCn_CTRL[9] MODE_SPEED and the DSS.DSI_VCn_CTRL[1] SOURCE bits are ignored.

12.5.4.12.1 Video Mode Transfer

Description: One channel, video mode, no DMA requests, no bus turn-around.

1. Configure the display controller with the timing parameters.
2. Configure the DSS.DSI_VCn_CTRL register as follows:
 - SOURCE bit is ignored by hardware
 - BTA_LONG_EN bit is set to 0: No BTA on long packet
 - BTA_SHORT_EN bit is set to 0: No BTA on short packet
 - MODE bit set to 1: The video mode is selected
 - MODE_SPEED bit is ignored by hardware
3. Configure the DSS.DSI_VM_TIMING1 to DSS.DSI_VM_TIMING7 registers.
4. Set the ForceTxStopMode bit to 1 in the DSS.DSI_TIMING1 register.
5. Enable the channel by setting the DSS.DSI_VCn_CTRL[0] VC_EN bit to 1
6. Enable the module by setting the DSS.DSI_CTRL[0] IF_EN bit to 1.
7. Poll the ForceTxStopMode bit to 0 in the DSS.DSI_TIMING1 register.
8. Enable the LCD video output by setting the DSS.DISPC_CONTROL[0] LCDENABLE bit to 1

CAUTION

The restriction for stopping the video mode is that no frame should be sent by the display controller (DISPC) after disabling video mode in DSI.

12.5.4.12.2 Command Mode Transfer Example 1

CAUTION

In DSI command mode, the display controller must be configured in stall mode by setting the DSS.DISPC_CONTROL[11] STALLMODE bit to 1.

Description: One channel, command mode, no DMA requests, manual bus turn-around

1. Configure the DSS.DSI_VCn_CTRL register as follows:
 - SOURCE bit set to 0: The source is the L4 interconnect port
 - BTA_LONG_EN bit is set to 0: No automatic BTA on long packet
 - BTA_SHORT_EN bit is set to 0: No automatic BTA on short packet
 - MODE bit set to 0: The command mode is selected
2. Enable the packet sent interrupt by setting the DSS.DSI_VCn_IRQENABLE[2] PACKET_SENT_IRQ_EN bit to 1
3. Set the ForceTxStopMode bit to 1 in the DSS.DSI_TIMING1 register.
4. Enable the channel by setting the DSS.DSI_VCn_CTRL[0] VC_EN bit to 1
5. Enable the module by setting the DSS.DSI_CTRL[0] IF_EN bit to 1
6. Poll the ForceTxStopMode bit to 0 in the DSS.DSI_TIMING1 register.
7. For long packet:
 - Write the header value into the DSS.DSI_VCn_LONG_PACKET_HEADER register
 - Write the data into the DSS.DSI_VCn_LONG_PACKET_PAYLOAD register for the full payload. Repeat step until WC is reached (see DSI_VCn_LONG_PACKET_HEADER)

For the short packet:

 - Send short packets through the L4 interconnect: Write the header value into the

- DSS.DSI_VCn_SHORT_PACKET_HEADER register. Repeat step for each short packet.
8. Send one or more packets through L4 interconnect:
 - Write the header value into DSS.DSI_VCn_LONG_PACKET_HEADER register
 - Write the data into DSS.DSI_VCn_LONG_PACKET_PAYLOAD register for the full payload.
 - Repeat step 5 for all the long packets
 9. Send short packets through L4 interconnect:
 - Write the header value into DSS.DSI_VCn_SHORT_PACKET_HEADER register
 - Repeat step 6 for all the short packets
 10. Interrupt routine: Wait for PACKET_SENT_IRQ interrupt generation by polling the DSS.DSI_VCn_IRQSTATUS[2] PACKET_SENT_IRQ status bit and notify the application software when received.
 11. The applicative software forces the bus turn-around:
 - Wait until the PACKET_SENT_IRQ has happened as many times as the number of sent packets
 - Set the DSS.DSI_VCn_CTRL[6] BTA_EN bit to 1 to send manually a BTA
 - Wait until the DSS.DSI_VCn_CTRL[6] BTA_EN bit is reset to 0 by hardware
 12. Receive the packets from the peripheral
 - Start polling the DSS.DSI_VCn_CTRL[20] RX_FIFO_NOT_EMPTY status bit
 - Whenever the RX_FIFO_NOT_EMPTY bit equals to 1, read one word in the RX FIFO

12.5.4.12.3 Command Mode Transfer Example 2

CAUTION

In DSI command mode, the display controller must be configured in stall mode by setting the DSS.DISPC_CONTROL[11] STALLMODE bit to 1.

Description: One channel, command mode, DMA request, automatic bus turn-around

1. Configure the DSS.DSI_VCn_CTRL register as follows:
 - SOURCE bit set to 0: The source is the L4 interconnect port
 - BTA_LONG_EN bit is set to 1: Automatic BTA on long packet
 - BTA_SHORT_EN bit is set to 1: Automatic BTA on short packet
 - MODE bit set to 0: The command mode is selected
2. Enable the packet sent interrupt by setting the DSS.DSI_VCn_IRQENABLE[2] PACKET_SENT_IRQ_EN bit to 1
3. Set the ForceTxStopMode bit to 1 in DSS.DSI_TIMING1 register.
4. Enable the channel by setting the DSS.DSI_VCn_CTRL[0] VC_EN bit to 1
5. Configure the TX FIFO threshold and DMA requests parameters:
 - Program the DSS.DSI_VCn_CTRL[19:17] DMA_TX_THRESHOLD bit field
 - Program the DSS.DSI_VCn_CTRL[23:21] DMA_TX_REQ_NB bit field
6. Program the system DMA to be ready to send data to the L4 interconnect port
7. Enable the module by setting the DSS.DSI_CTRL[0] IF_EN bit to 1
8. Poll the ForceTxStopMode bit to 0 in DSS.DSI_TIMING1 register.
9. Write the header value into DSS.DSI_VCn_LONG_PACKET_HEADER register
10. Interrupt routine: Wait for PACKET_SENT_IRQ interrupt generation by polling the DSS.DSI_VCn_IRQSTATUS[2] PACKET_SENT_IRQ status bit and notify the application software when received.
11. Receive the packets from the peripheral
 - Start polling the DSS.DSI_VCn_CTRL[20] RX_FIFO_NOT_EMPTY status bit
 - Whenever the RX_FIFO_NOT_EMPTY bit equals to 1, read one 32-bit word in the RX FIFO
12. Repeat the steps 7 for all long packets.

12.5.5 DSI PLL Controller Basic Programming Model

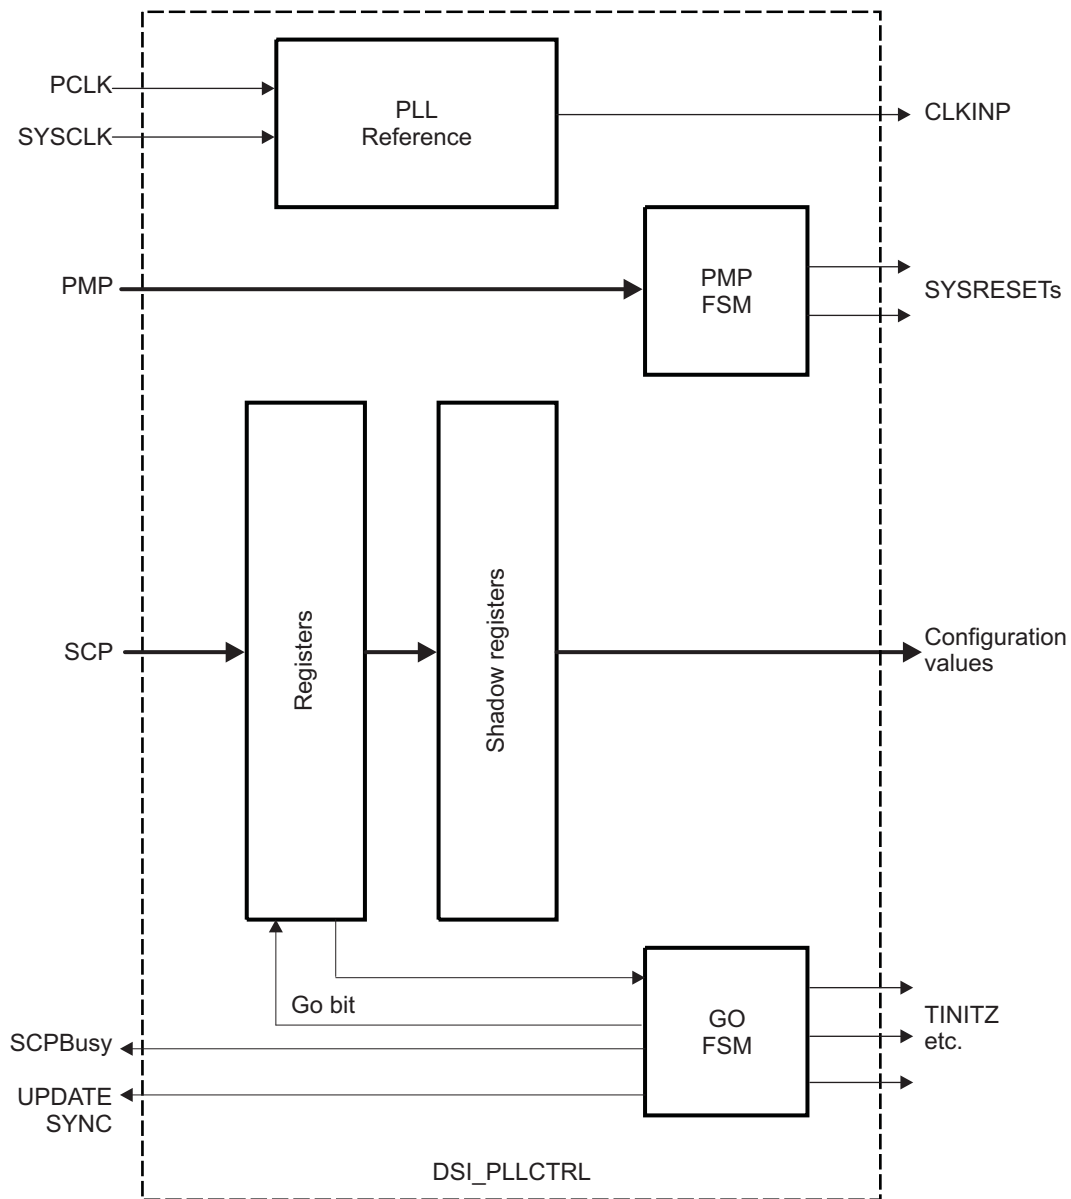

12.5.5.1 Software Reset

The DSI PLL control module does not have its own software reset. It is reset by the DSI protocol engine. Nevertheless, software users can monitor the reset status of the DSI PLL control module by reading the `DSS.DSI_PLL_STATUS[0] DSI_PLLCTRL_RESET_DONE` status bit.

12.5.5.2 DSI PLL Programming Blocks

Figure 12-139 shows the DSI PLL programming blocks.

Figure 12-139. DSI PLL Programming Blocks

dss-181

12.5.5.3 DSI PLL Go Sequence

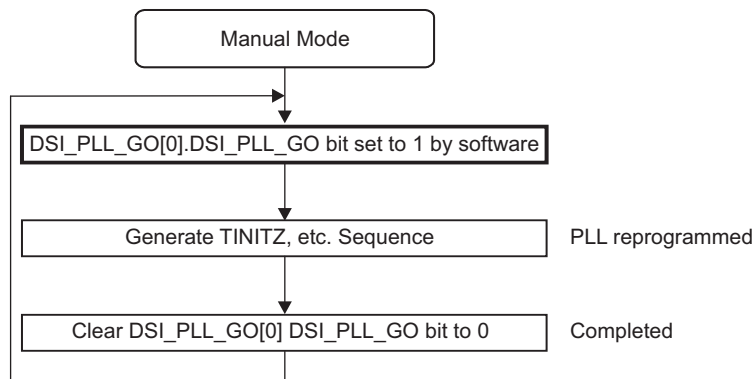

In Manual Mode (DSS.DSI_PLL_CONTROL[0] DSI_PLL_AUTOMODE bit set to 0), the DPLL requires a sequence on TINITZ, TENABLE and TENABLEDIV to update the configuration values and start the locking sequence.

Once all the configuration values have been programmed into the registers, the GO bit should be set. The appropriate sequence should then be sent on the TINITZ, TENABLE & TENABLEDIV pins, respecting the timing requirements of the ADPLLV2. The DSS.DSI_PLL_GO[0] DSI_PLL_GO bit will be cleared to 0 at the end of the sequence.

The TENABLEDIV signal is shared with the HSDIVIDER module, so that will be programmed at the same time. In this mode, the software should deassert CLKINEN by unsetting the DSS.DSI_PLL_CONFIGURATION2[14] DSI_PHY_CLKINEN to 0 and to assert HSDIVBYPASS correctly by setting the DSS.DSI_PLL_CONFIGURATION2[20] DSI_HSDIVBYPASS bit to 1 to prevent uncontrolled frequencies affecting the DSI_PHY and display subsystem during PLL locking. In manual mode the shadow register should be updated anyway so that valid values are present when later selecting automatic mode.

Figure 12-140 shows the DSI PLL Go flowchart in manual mode (DSS.DSI_PLL_CONTROL[0] DSI_PLL_AUTOMODE bit set to 0).

Figure 12-140. DSI PLL Go Sequence (Manual Mode)

dss-182

NOTE: All thick-outlined blocks show operations performed by software. Other blocks show operations performed by hardware.

In automatic Mode (DSS.DSI_PLL_CONTROL[0] DSI_PLL_AUTOMODE bit set to 1), the TINITZ, TENABLE and TENABLEDIV sequence and the update of the PLL configuration from the DSI_PLL_CONFIGURATION2 register will be deferred until the time of the front porch time signal sent by the DISPC module. This is intended to simplify the software to implement a configuration change (such as a frequency change to support a different link bandwidth). In this mode CLKINEN, HSDIVBYPASS and REFEN will be controlled automatically and the register value is overridden.

Figure 12-141 shows the DSI PLL Go flowchart in automatic mode (DSS.DSI_PLL_CONTROL[0] DSI_PLL_AUTOMODE bit set to 1).

Figure 12-141. DSI PLL Go Sequence (Automatic Mode)

dss-183

NOTE: All thick-outlined blocks show operations performed by software. Other blocks show operations performed by hardware.

12.5.5.4 DSI PLL Clock Gating Sequence

Clock gating may be used to reduce system power consumption when the DSI protocol engine indicates that it does not need the clock. If the HSDIVIDER is not used, then the PLL can also be stopped (at the cost of additional unstarting latency).

The DSI protocol engine can verify when the PLL has unstarted by inspecting the LOCK signal (DSS.DSI_PLL_STATUS[1] DSI_PLL_LOCK status bit). Since TxByteClkHS is stopped when CLKIN4DDR is stopped, this should obviate the need for any explicit feedback that the clock has been unstarted in the other case. This flow chart should run even if the DSS.DSI_PLL_GO[0] DSI_PLL_GO bit has not been set.

Figure 12-142 shows the DSI PLL gated mode sequence.

Figure 12-142. Gated Mode Sequence

dss-184

12.5.5.5 DSI PLL Lock Sequence

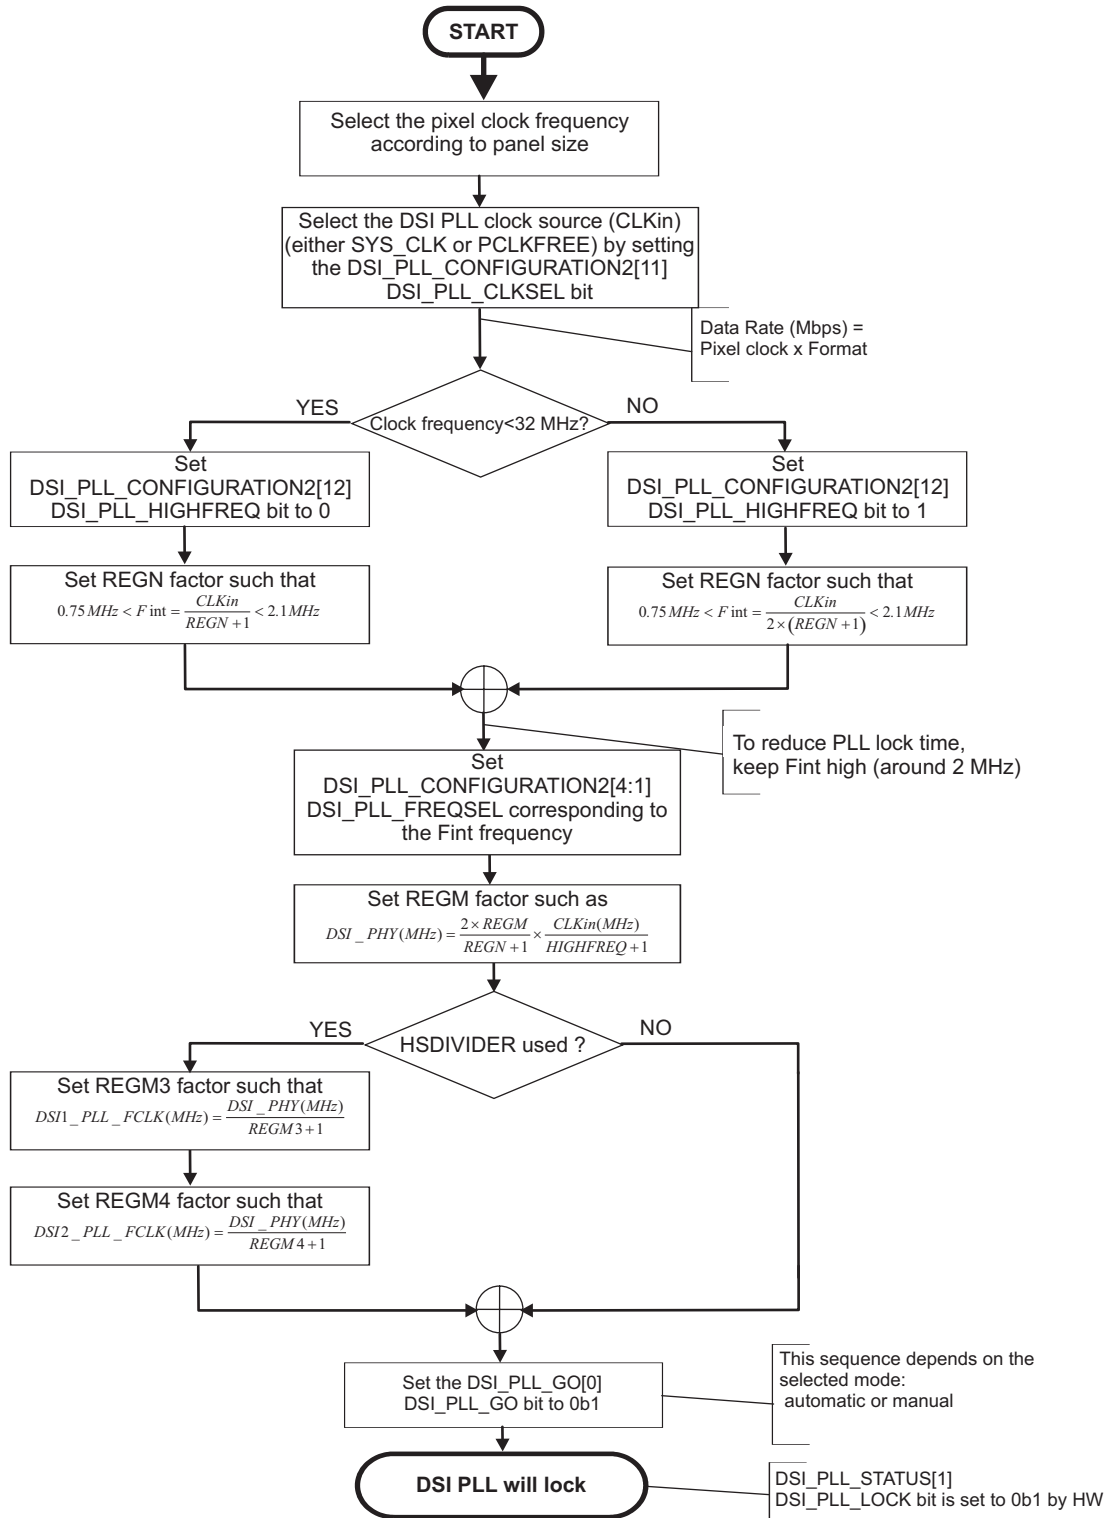

The DSI PLL (ADPLLv2) generates CLKIN4DDR. The HSDIVIDER generates two clocks: DSI1_PLL_FCLK connected to the display controller (DISPC) and the DSI2_PLL_FCLK connected to the DSI protocol engine. If these two clocks are not used, the HSDIVIDER functions are not required.

CLKIN4DDR is twice the data rate and four times the DSI output clock frequency. The DSI PLL factors need to be calculated based on the required input and output frequencies, keeping the PLL internal reference frequency in the appropriate range:

- REGM factor is programmed by DSS.DSI_PLL_CONFIGURATION1[18:8] DSI_PLL_REGM bit field
- REGN factor is programmed by DSS.DSI_PLL_CONFIGURATION1[7:1] DSI_PLL_REGN bit field
- REGM3 factor is programmed by DSS.DSI_PLL_CONFIGURATION1[22:19] DSI_CLOCK_DIV bit field
- REGM4 factor is programmed by DSS.DSI_PLL_CONFIGURATION1[26:23] DSIPROTO_CLOCK_DIV bit field

Figure 12-143 shows the programming sequence.

Figure 12-143. DSI PLL Programming Sequence

dss-190

NOTE:

- The REGM3 and REGM4 factors must according with the following conditions:
 - The DSI1_PLL_FCLK and DSI2_PLL_FCLK frequencies must be a multiple of the PCLK frequency (for proper settings of PCD and LCD factors in the DISPC)
 - The DSI1_PLL_FCLK and DSI2_PLL_FCLK frequencies must be lower than 173 MHz
- Most of the other DSI PLL programming values are available for software flexibility but it is not recommended to update the values in normal use. See [Section 12.5.5.7](#) for details on DSI PLL recommended values.

DSI PLL programming examples:

- WVGA Display on one data pair: Pixel clock (PCLK) = 30 MHz with 18-BPP pixel format

The data rate is $30 \times 18 = 540$ Mbps on one data lane. Therefore, the frequency on the data lane is twice the data rate: 1080 MHz.

The frequency on the clock lane is 270 MHz (1080 divided by 4).

The SYS_CLK at 26 MHz is selected as the clock reference by setting the DSS.DSI_PLL_CONFIGURATION2[11] DSI_PLL_CLKSEL to 0b0.

Set the DSS.DSI_PLL_CONFIGURATION2[12] DSI_PLL_HIGHFREQ to 0b0 as PCLK is lower than 32 MHz.

Set Fint to 2 MHz as PLL internal reference frequency: Set REGN to 12 (divide by 13) by setting the DSS.DSI_PLL_CONFIGURATION1[7:1] DSI_PLL_REGN bit field to 0xC and set DSI_PLL_CONFIGURATION2[4:1] DSI_PLL_FREQSEL bit field to 0x7 (1.75 to 2.1 MHz range)

To get CLKIN4DDR to 1080 MHz, set the REGM factor to 270 by setting the DSS.DSI_PLL_CONFIGURATION1[18:8] DSI_PLL_REGM to 0x10E.

$CLKIN4DDR = 2 \times 270/13 \times 26/1 = 1080$ MHz

Since DSI1_PLL_FCLK and DSI2_PLL_FCLK (REGM3 and REGM4 factors) must be multiple of PCLK and also lower than 173 MHz, program these frequencies to 90 MHz by setting the REGM3 and REGM4 factors to 11 (divide by 12). This is done by setting the DSS.DSI_PLL_CONFIGURATION1[22:19] DSS_CLOCK_DIV bit field and DSS.DSI_PLL_CONFIGURATION1[26:23] DSIPROTO_CLOCK_DIV to 0xB:

$DSI1_PLL_FCLK = DSI2_PLL_FCLK = 1080/12 = 90$ MHz

- XGA Display on two data pairs: Pixel clock (PCLK) = 60 MHz with 16-BPP pixel format
The data rate is $(60 \times 16)/2 = 480$ Mbps on each data lane. Therefore, the frequency on the data lane is twice the data rate: 960 MHz.

The frequency on the clock lane is 240 MHz (960 divided by 4).

The SYS_CLK at 26 MHz is selected as the clock reference by setting the DSS.DSI_PLL_CONFIGURATION2[11] DSI_PLL_CLKSEL bit to 0b0.

Set the DSS.DSI_PLL_CONFIGURATION2[12] DSI_PLL_HIGHFREQ bit to 0b0 as the source clock frequency (SYS_CLK in this example) is lower than 32 MHz.

Set Fint to 2 MHz as PLL internal reference frequency: Set REGN to 12 (divide by 13) by setting the DSS.DSI_PLL_CONFIGURATION1[7:1] DSI_PLL_REGN bit field to 0xC and set DSI_PLL_CONFIGURATION2[4:1] DSI_PLL_FREQSEL bit field to 0x7 (1.75 to 2.1 MHz range)

To get CLKIN4DDR to 960 MHz, set the REGM factor to 240 by setting the DSS.DSI_PLL_CONFIGURATION1[18:8] DSI_PLL_REGM to 0x0F0.

$CLKIN4DDR = 2 \times 240/13 \times 26/1 = 960$ MHz

Since DSI1_PLL_FCLK and DSI2_PLL_FCLK (REGM3 and REGM4 factors) must be multiple of PCLK and also lower than 173 MHz, program these frequencies to 120 MHz by setting the REGM3 and REGM4 factors to 7 (divide by 8). This is done by setting the DSS.DSI_PLL_CONFIGURATION1[22:19] DSS_CLOCK_DIV bit field and DSS.DSI_PLL_CONFIGURATION1[26:23] DSIPROTO_CLOCK_DIV to 0x7:

$$\text{DSI1_PLL_FCLK} = \text{DSI2_PLL_FCLK} = 960/8 = 120 \text{ MHz}$$

12.5.5.6 DSI PLL Error Handling

The PLL lock and recalibration signals may be monitored to detect loss of lock or requirement to recalibrate (due to large temperature change since the last lock request):

- The DSS.DSI_PLL_STATUS[1] DSI_PLL_LOCK status bit gives the DSI PLL lock state.
- The DSS.DSI_PLL_STATUS[2] DSI_PLL_RECAL status bit informs if the PLL must be uncalibrated

These signals can also generate interrupts at DSI protocol engine level:

- - DSS.DSI_IRQSTATUS[9], PLL_RECAL_IRQ bit
 - DSS.DSI_IRQSTATUS[8] PLL_UNLOCK_IRQ
 - DSS.DSI_IRQSTATUS[7] PLL_LOCK_IRQ
- The PLL_LOCK_IRQ interrupt indicates that the DSI PLL is locked. To monitor this event, read the DSS.DSI_IRQSTATUS[7] PLL_LOCK_IRQ bit. Set this bit to 1 to clear the status bit.
- The PLL_UNLOCK_IRQ interrupt indicates that the DSI PLL is unlocked. To monitor this event, read the DSS.DSI_IRQSTATUS[8] PLL_UNLOCK_IRQ bit. Set this bit to 1 to clear the status bit.
- The PLL_RECAL_IRQ interrupt indicates that the DSI PLL must be recalibrated. To monitor this event, read the DSS.DSI_IRQSTATUS[9] PLL_RECAL_IRQ bit. Set this bit to 1 to clear the status bit.

The PLL reference loss and limp status signals can also be monitored :

- The DSS.DSI_PLL_STATUS[3] DSI_PLL_LOSSREF status bit informs if the DSI PLL has lost the reference.
- The DSS.DSI_PLL_STATUS[4] DSI_PLL_LIMP status bit informs about the DSI PLL limp status.

12.5.5.7 DSI PLL Recommended Values

Table 12-66 shows the DSI PLL recommended values.

Table 12-66. Recommended Programming Values

| Field Name | Value | Description |
|----------------------|--------------------|---|
| DSI_HSDIV_SYSRESET | 0 | Allow power FSM to control |
| DSI_PLL_SYSRESET | 0 | Allow power FSM to control |
| DSI_PLL_HALTMODE | - | See Section 12.5.5.4 for details |
| DSI_PLL_GATEMODE | - | See Section 12.5.5.4 for details |
| DSI_PLL_AUTOMODE | - | See Section 12.5.5.4 for details |
| DSI_PLL_GO | 1->0 | Write a 1 when PLL is to be (re-)locked with new parameters. This bit is cleared by hardware when the PLL request has completed |
| DSIPROTO_CLOCK_DIV | See ⁽¹⁾ | DSI protocol engine clock divider |
| DSS_CLOCK_DIV | See ⁽¹⁾ | DSS clock divider |
| DSI_PLL_REGM | See ⁽¹⁾ | Feedback clock divider |
| DSI_PLL_REGN | See ⁽¹⁾ | Reference clock divider |
| DSI_PLL_STOPMODE | 1 | Required to use GATEMODE bit |
| DSI_HSDIVBYPASS | 0 | PLL is controlling HSDIVIDER bypass |
| DSI_PROTO_CLOCK_PWDN | 0 | If PLL/HSDIVIDER is used as the DSI protocol clock source |
| DSI_PROTO_CLOCK_EN | 1 | If PLL/HSDIVIDER is used as the DSI protocol clock source |
| DSS_CLOCK_PWDN | 0 | If PLL/HSDIVIDER is used as the DSS clock source |
| DSS_CLOCK_EN | 1 | If PLL/HSDIVIDER is used as the DSS clock source |

⁽¹⁾ The bit field value should be set according to the desired clock frequency.

Table 12-66. Recommended Programming Values (continued)

| Field Name | Value | Description |
|------------------------|--------------------|--|
| DSI_BYPASSEN | 0 | To use PLL as the clock source. For small displays it may be possible to use the DSS functional clock, in which case this bit should be set to 1 |
| DSI_PHY_CLKINEN | 1 | Enable CLKIN4DDR |
| DSI_PLL_REFEN | 1 | Enable PLL reference |
| DSI_PLL_HIGHFREQ | 0/1 | Set to 1 if the clock reference is higher than 32 MHz (21 MHz if DSS.DSI_PLL_CONFIGURATION1[7:1] DSI_PLL_REGN = 0) |
| DSI_PLL_CLKSEL | 0/1 | Set to 0 to use DSS2_ALWON_FCLK as the PLL reference or set to 1 to use PCLKFREE as the PLL reference, in this case the DISPC must be using DSS1_ALWON_FCLK. |
| DSI_PLL_LOCKSEL | 0x0 | Phase lock criteria to lock the PLL |
| DSI_PLL_DRIFTGUARDEN | 0x0 | The RECAL status/interrupt should be used to decide when to perform a PLL uncalibration No automatic uncalibration will be performed |
| DSI_PLL_TIGHTPHASELOCK | 0 | Normal criteria |
| DSI_LOWCURRSTDBY | 0/1 | Set to 0 for fast PLL unlock, but higher standby current Set to 1 for leakage level standby current, but longer unlock time |
| DSI_PLL_PLLLPMODE | 0 | Normal operation For smaller display sizes may be possible to set to 1 |
| DSI_PLL_FREQSEL | See ⁽²⁾ | Must be set according to the PLL internal reference frequency (after N divider) See register descriptions for values |
| DSI_PLL_IDLE | 0 | PLL active |

⁽²⁾ The bit field value should be set according to the desired clock frequency.

12.5.6 DSI Complex I/O Basic Programming Model

12.5.6.1 Software Reset

The clock domain using the TxByteClkHS from the DSI complex I/O has dedicated reset done information in the [DSS.DSI_COMPLEXIO_CFG1\[29\]](#) RESET_DONE bit. The [DSS.DSI_SYSCONFIG\[1\]](#) SOFT_RESET bit is used to reset the TxByteClkHS power domain. A dummy read using the SCP interface to any DSI_PHY register is required after DSI_PHY reset to complete the reset of the DSI complex I/O.

12.5.6.2 Reset-Done Bits

The DSI complex I/O has several clock domains. The reset status for each clock domain is provided in [DSS.DSI_PHY_CFG5](#) register:

- [DSS.DSI_PHY_CFG5\[31\]](#) RESETDONETXBYTECLK bit : Reset done for the TXBYTECLK domain.
- [DSS.DSI_PHY_CFG5\[28:26\]](#) RESETDONETXCLKESCi bits: Reset done for the TXCLKESC domain for lane i (i between 0 and 2).
- [DSS.DSI_PHY_CFG5\[30\]](#) RESETDONESCPCCLK bit: Reset done for the SCP clock domain. Software users must perform a dummy read on this bit to initiate the reset sequence of the SCP finite state machine. When the reset sequence is complete, the RESETDONESCPCCLK signal goes high and software users can read again the [DSS.DSI_PHY_CFG5\[30\]](#) RESETDONESCPCCLK bit to ensure that the value is now 1.

NOTE: The software should not write in the DSI_PHY_SCP registers before the DSS.DSI_PHY_CFG5[30] RESETDONESCPCCLK bit is set to 1.

- DSS.DSI_PHY_CFG5[29] RESETDONEPWRCLK bit: Reset done for the PWR clock domain. The reset sequence of the PWR finite state machine is complete when the RESETDONEPWRCLK signal goes high.

12.5.6.3 Pad Configuration

The number of lanes is configurable through the DSS.DSI_COMPLEXIO_CFG1 register.

It is not allowed to change on the fly the position (by modifying the DATA_i_POSITION with *i*=1 or 2 and CLOCK_POSITION bit fields), P/N order (Positive/Negative order of the differential pair by modifying the DATA_i_POL with *i*=1 or 2 and CLOCK_POL) or number of active data lanes (by modifying the DSS.DSI_COMPLEXIO_CFG1[10:8] DATA2_POSITION bit). To add or remove the lane #2, it is required to be in OFF mode for the DSI complex I/O.

The minimum requirement for the number of lanes is one clock lane and one data lane. Note that by default, the data lane 2 is not connected (the DSS.DSI_COMPLEXIO_CFG1[10:8] DATA2_POSITION bit reset value is 0).

12.5.6.4 Display Timing Configuration

Depending on the CLKIN4DDR frequency settings programmed with the DSI PLL control module, software users must program accordingly the timing parameters in the DSI complex I/O registers.

12.5.6.4.1 High-Speed Clock Transmission

Figure 12-144 shows an example of high-speed Clock Transmission.

Figure 12-144. High-Speed Clock Transmission

dss-185

TXByteClkHS is an output clock which is derived by dividing the CLKIN4DDR clock by 16.

To begin transmission, the protocol drives TXREQUESTHS high on a rising edge of TXByteClkHS. The PHY detects this signal on the next rising edge, following which it initiates the LP Start of Transmission (SoT) procedure.

During a high-speed Clock Transmission, these parameters are defined in multiples of CLKIN4DDR and programmed by the following register bit fields:

- TLPX timing is programmed by the DSS.DSI_PHY_CFG1[22:16] TLPX_HALF bit field.
 - THS-PREPARE timing is programmed by the DSS.DSI_PHY_CFG0[31:24] THS_PREPARE bit field.
 - TCLK-ZERO timing is programmed by the DSS.DSI_PHY_CFG1[7:0] TCLK_ZERO bit field.
- . TCLK-ZERO is extended, if required, so that the entire LP SoT procedure lasts an integer number of TXByteClkHS cycles.

At the end of the SoT procedure, HS clock transmission begins. At the same time, TXREADYHS is made high.

To stop clock transmission, the protocol drives TXREQUESTHS low on a rising edge of TXByteClkHS. The DSI_PHY detects this change in TXREQUESTHS on the next edge and stops clock transmission. TXREADYHS is made low.

The DSI_PHY then goes through the LP End of Transmission (EoT) procedure. TCLK-TRAIL and THS-EXIT parameters are also multiples of CLKIN4DDR and programmed by the following register fields:

- TCLK-TRAIL timing is programmed by the DSS.DSI_PHY_CFG1[15:8] TCLK_TRAIL bit field.
- THS-EXIT timing is programmed by the DSS.DSI_PHY_CFG0[7:0] THS_EXIT bit field.

The DSI_PHY completes the SoT and EoT procedures, once begun, irrespective of any change in PPI signals. If TXREQUESTHS goes low during the SoT procedure, the PHY start the EoT procedure immediately after finishing the SoT procedure and no clock is transmitted.

STOPSTATE is high whenever the line is in LP-11 state, as determined by the outputs of the Low Power Receivers. This signal is not synchronized with TXByteClkHS.

It is requires that the high speed clock be present for some time before (TCLK-PRE) and some time after (TCLK-POST) high speed data transmission. The protocol must ensure that these timings are met by asserting and deasserting TXREQUESTHS appropriately.

The PHY ensures that the clock signal has a quadrature-phase with respect to a toggling bit sequence on any Data Lane, and a rising edge in the center of the first transmitted bit of every Data byte. These relations are not described in the timing diagram.

CLKIN4DDR can be shut off 300ns after the clock lane goes to STOPSTATE. Alternatively, CLKIN4DDR can be shut down after TCLK-Trail + THS-Exit + 2 Tbyteclk periods after TxRequestHS falling edge is received by DSI_PHY.

The DSI protocol engine should ensure that TXREQUESTESC, TXULPSCLK and TURNREQUEST are low whenever TXREQUESTHS is asserted.

12.5.6.4.2 High-Speed Data Transmission

Figure 12-145 shows an example of high-speed Data Transmission.

Figure 12-145. High-Speed Data Transmission

dss-186

TXByteClkHS is an output clock which is derived by dividing CLKIN4DDR by 16.

To begin transmission, the protocol drives TXDATAHS with the first byte of data on a rising edge of TXByteClkHS. It also makes TXREQUESTHS high the same rising edge. The PHY detects TXREQUESTHS going high on the next rising edge of TXByteClkHS, following which it initiates the LP Start of Transmission (SoT) procedure.

During a high-speed Data Transmission, these timings are multiple of CLKIN4DDR and programmed by the following register bit fields:

- TLPX timing is programmed by the DSS.DSI_PHY_CFG1[22:16] TLPX_HALF bit field.
- THS-PREPARE + THS-ZERO timing is programmed by the DSS.DSI_PHY_CFG0[23:16] THS_PREPARE_THS_ZERO bit field.

. THS-ZERO will be extended, if required, so that the entire LP SoT procedure lasts an integer number of TXByteClkHS cycles. THS-SYNC corresponds to the length of the sync pattern which is eight high-speed bits.

Towards the end of the SoT procedure, the PHY makes TXREADYHS high on a positive edge of TXByteClkHS and then start accepting data from TXDATAHS from the next positive edge onwards. The protocol is expected to provide (new) valid data on TXDATAHS on every positive edge of TXByteClkHS if TXREADYHS is high.

At the end of the SoT procedure, HS data transmission begins. HS Data Transmission happens LSB first.

To stop data transmission, the protocol drives TXREQUESTHS low on a rising edge of TXByteClkHS. The PHY detects this change in TXREQUESTHS on the next edge and stops data transmission. TXREADYHS is made low and data on TXDATAHS, from that point, is ignored.

The PHY then goes through the LP End of Transmission (EoT) procedure. THS-TRAIL and THS-EXIT are also multiples of CLKIN4DDR and programmed by the following register bit fields:

- THS-TRAIL timing is programmed by the DSS.DSI_PHY_CFG0[15:8] THS_TRAIL bit field.
- THS-EXIT timing is programmed by the DSS.DSI_PHY_CFG0[7:0] THS_EXIT bit field.

The PHY completes the SoT and EoT procedures, once begun, irrespective of any change in PPI signals. If TXREQUESTHS goes low during the SoT procedure, the PHY start the EoT procedure immediately after finishing the SoT procedure and no data is transmitted.

STOPSTATE is high whenever the line is in LP-11 state, as determined by the outputs of the Low Power Receivers. This signal is not synchronized with TXByteClkHS.

The Protocol should ensure that TXREQUESTESC, TXULPCLK and TURNREQUEST are low whenever TXREQUESTHS is asserted.

12.5.6.4.3 Other DSI_PHY Transmission and Reception

The timing of the following sequences defined in the DSI_PHY protocol cannot be programmed by users:

- Low-power data transmission
- Escape mode trigger command transmission
- ULP state command transmission on data lanes
- ULP state transmission on clock lane
- Turn-around request in transmit mode
- Turn-around request in receive mode
- Low-power data in receive mode
- Low-power trigger in receive mode
- ULP state command on clock lane in receive mode
- ULP state command on data lane in receive mode

12.5.6.5 Error Handling

A dedicated register for the DSI complex I/O, DSS.DSI_COMPLEXIO_IRQSTATUS, indicates the state of each error provided by the DSI complex I/O error signals. The DSI_PHY reports the following errors:

- DSS.DSI_COMPLEXIO_IRQSTATUS[7:5] ERR_ESCi_IRQ: ERRESC is asserted if an unrecognized Escape entry command is received. This remains high until the next change in the line state.
- DSS.DSI_COMPLEXIO_IRQSTATUS[2:0] ERRSYNCESci_IRQ: If the number of bits received during a low-power data transmission is not a multiple of eight when the transmission ends, ERRSYNCESC is made high and remains high until the next change in line state.
- DSS.DSI_COMPLEXIO_IRQSTATUS[12:10] ERRCONTROLi_IRQ: ERRCONTROL is asserted if an incorrect line state sequence is detected. For example, if a turn-around request or escape mode request is immediately followed by a Stop state instead of the required Bridge state, this signal is asserted and remains asserted until the next change in the line state.
- DSS.DSI_COMPLEXIO_IRQSTATUS ERRCONTENTIONLP0_i_IRQ: ERRCONTENTION0LPDX and ERRCONTENTION0LPDY are asserted when the Lane module detects a contention situation on lines DX and DY respectively while trying to drive the lines low. Contention is detected only if it lasts at least 50ns
- DSS.DSI_COMPLEXIO_IRQSTATUS ERRCONTENTIONLP1_i_IRQ: ERRCONTENTION1LPDX and ERRCONTENTION1LPDY are asserted when the Lane module detects a contention situation on lines DX and DY respectively while trying to drive the lines high. Contention is detected only if it lasts at least 50ns

The ULPSACTIVENOT signal goes low which indicates to the protocol that the PHY has entered ULP state. When all the ULPSActiveNot signals are low, the DSS.DSI_COMPLEXIO_IRQSTATUS[30] ULPSACTIVENOT_ALL0_IRQ event is generated. When all the ULPSActiveNot signals are high, the DSS.DSI_COMPLEXIO_IRQSTATUS[31] ULPSACTIVENOT_ALL1_IRQ event is generated.

When any of the events defined in DSS.DSI_COMPLEXIO_IRQSTATUS register happened, the DSS.DSI_IRQSTATUS[10] COMPLEXIO_ERR_IRQ bit is set to 1 at DSI protocol engine level.

The software must take appropriate action when receiving the interrupt indicating the error from the complex I/O. The action can be:

- Reset of the DSI protocol engine module
- Reset of the peripheral through reset trigger or directly driving the hardware reset pin of the display module
- Ignore the error

12.5.7 RFBI Basic Programming Model

The RFBI programming model must be used for LCD display support only.

12.5.7.1 DISPC Control Registers

The following DISPC registers are used in RFBI mode:

- The STALL mode is selected by setting the DSS.DISPC_CONTROL[11] STALLMODE bit. The DSS.DISPC_CONTROL[5] GOLCD bit should not be set to 1 but the display controller configuration (DMA engine, pipelines associated to the LCD output,..) should be set before enabling the LCD output by setting the DSS.DISPC_CONTROL[0] LCDENABLE bit to 1.
- To enable the hardware handcheck to avoid underflow, the DSS.DISPC_CONTROL[16] FIFOHANDCHECK should be set to 1. The reset value of this bit is 0. The handcheck applies to the pipelines connected to the LCD output. It should be disabled before resetting the DSS.DISPC_CONTROL[11] STALLMODE bit to 0. The new setting for the FIFO handcheck is used for the following frames.

NOTE: The LCD output is disabled at the end of the transfer of the frame. The software must reenables the LCD output to generate a new frame by setting the DSS.DISPC_CONTROL[0] LCDENABLE to 1. See [Figure 12-146](#).

12.5.7.2 RFBI Control Registers

The following registers define the RFBI control registers:

- DSS.RFBI_CONTROL
- DSS.RFBI_PIXEL_CNT
- DSS.RFBI_LINE_NUMBER

12.5.7.2.1 High Threshold

The DSS.RFBI_CONTROL[6:5] HIGHTHRESHOLD bit field is used to define the threshold to be used for the generation of the DMA request to receive data into the interconnect FIFO (24 × 32 FIFO depth) through the address of the register [RFBI_DATA](#). It should be the size of the burst. The supported values are 4x32, 8x32 and 16x32. The system DMA receives the DMA request and is in charge of providing the correct number of bytes. If the DSS.RFBI_CONTROL[7] DISABLE_DMA_REQ bit is reset, the DMA request is generated when there is enough room in the interconnect FIFO to accept the full burst. In case the RFBI receives writes L4 requests to the [RFBI_DATA](#) location when the interconnect FIFO is full, the request is not accepted. The RFBI waits for a free entry in the interconnect FIFO to accept the L4 request.

If the DSS.RFBI_CONTROL[7] DISABLE_DMA_REQ bit is set, the DMA request is not generated. The threshold value is ignored.

NOTE: Software users can access the [RFBI_DATA](#) location without using the DMA request and without programming the high threshold value (backward mode).

12.5.7.2.2 Bypass Mode

Setting the DSS.RFBI_CONTROL[1] BYPASSMODE bit directly outputs the LCD controller output to the LCD panel. Resetting this bit directs the MPU module to send commands/parameters and data from the input video port FIFO.

12.5.7.2.3 Enable

Setting/resetting the DSS.RFBI_CONTROL[0] ENABLE bit enables/disables the RFBI module. The hardware resets the enable bit after all of the pixels are sent to the panel. The DSS.RFBI_PIXEL_CNT[31:0] PIXELCNT bit field value defines the number of pixels to send to the LCD panel. When the transfer is finished, the configuration used can be modified.

Table 12-67. RFBI Behavior

| RFBI_CONTROL[1] BYPASSMODE bit value | RFBI_CONTROL[0] ENABLE bit value | RFBI Behavior |
|--------------------------------------|----------------------------------|--|
| 0 | 0 | L4 interconnect can write command/param/data and read data/status from the Remote Frame Buffer (RFB). L4 interconnect access can only be done to the CSx actually active |
| 0 | 1 | The DISPC sends pixels to the RFB. |

The stall signal is asserted when the module is disabled. Through the L4 port, pixels can be sent to the LCD panel only when the pixel count has reach the value 0x0

NOTE: The LCD output is disabled at the end of the transfer of the frame. The software must reenale the LCD output to generate a new frame by setting the DSS.DISPC_CONTROL[0] LCDENABLE to 1. See [Figure 12-146](#).

12.5.7.2.4 Configuration Selection

Setting the DSS.RFBI_CONTROL[3:2] CONFIGSELECT bit field selects the configuration number (1 or 0 if bits are set or reset). The registers associated with the configuration output the data to the LCD panel.

If both chip-selects are selected, the configuration for the first chip-select is used (except for the polarity of the RFBI_CS1 signal defined by the second configuration) and both devices connected to the CS signals are driven in parallel. In read mode, if both chip-selects are set, only RFBI_CS0 is asserted to read data from the device connected on RFBI_CS0. In write mode with two chip-selects selected, the RFBI can write to the two devices simultaneously.

12.5.7.2.5 ITE Bit

Set the DSS.RFBI_CONTROL[4] ITE bit to start capturing the data from the display controller. This bit has no effect if the trigger mode is set to external. The display controller must be configured in the STALL mode to account for the RFBI_DISPC_STALL signal. Setting the trigger mode to external (DSS.RFBI_CONFIG[3:2] TRIGGERMODE bit field set to 0x1 or 0x2) causes the DSS.RFBI_CONTROL[4] ITE bit to be ignored. The corresponding chip-select must be selected when this bit is set by users.

The RFBI_DISPC_STALL signal is asserted when at least one of the following cases occur:

- Default status when no data to capture from the display controller
- High FIFO threshold reached
- End of the transfer (number of data to output)
- Reset of the RFBI module
- DSS.RFBI_CONTROL[0] ENABLE bit reset to 0x0

The RFBI_DISPC_STALL signal is deasserted when the DSS.RFBI_CONTROL[0] ENABLE bit is set to 0x1 and at least one of the following cases occur:

- Low FIFO threshold reached
- External TE occurs and the DSS.RFBI_CONFIG[3:2] TRIGGERMODE bit field is set to 0x1 or 0x2 for automatic external trigger (start of the transfer, the FIFO pointers are reset, the FIFO is empty).
- DSS.RFBI_CONTROL[4] ITE bit set to 0x1 by users (start of the transfer, the FIFO pointers are reset, the FIFO is empty).

12.5.7.2.6 Number of Pixels to Transfer

Setting the DSS.RFBI_PIXEL_CNT[31:0] PIXELCNT bit field value directs the application to indicate the number of pixels to be transferred to the LCD panel. The value can be changed only when the DSS.RFBI_CONTROL[0] ENABLE is reset.

During the transfer, the hardware decrements the register when a pixel is sent to the remote frame buffer. When the DSS.RFBI_CONTROL[0] ENABLE bit is set and a new value is written in the DSS.RFBI_PIXEL_CNT register when the current value in the register is a non-zero (the remaining number of pixels to transfer), the ongoing transfer is aborted.

From the L4 interconnect side, if DSS.RFBI_CONFIGi[10:9] CYCLEFORMAT bit field is equal to 0x3 and DSS.RFBI_CONFIGi[8:7] L4FORMAT is equal to 0x0, an even number of write accesses to the data register should be performed before accessing any other register (CMD/PARAM/STATUS/READ).

When DSS.RFBI_CONFIGi[10:9] CYCLEFORMAT bit field is 0x3 - meaning that 2 pixels are sent over 3 cycles -, the number of pixels to be programmed in the DSS.RFBI_PIXEL_CNT[31:0] PIXELCNT bit field should be a multiple of 2. If another CYCLEFORMAT is used, the value for PIXELCNT can be odd or even. This constraint is valid for data provided on the L4 interconnect port and from the display controller.

If the DSS.RFBI_CONFIGi[10:9] CYCLEFORMAT bit field is equal to 0x3, DSS.RFBI_CONFIGi[8:7] L4FORMAT is equal to 0, and back to back register write is processed, the following registers should be written after the first data: RFBI_CMD, RFBI_PARAM, RFBI_READ, and RFBI_STATUS. The whole data transfer should first be performed before being able to write to any other registers (RFBI_CMD, RFBI_PARAM, RFBI_READ, and RFBI_STATUS).

12.5.7.2.7 Programmable Line Number

When the trigger mode is set to external trigger mode with HSYNC and VSYNC or the TE, the hardware resets the line counter when the VSYNC occurs and, after a programmable number of lines (the HSYNC pulse occurs for every line), the transfer to the LCD panel begins. When the programmable line number is 0, only the VSYNC pulse indicates the beginning of the transfer in both modes: HSYNC/VSYNC and TE (logical OR operation between HSYNC and VSYNC).

12.5.7.3 RFBI Configuration

The following registers define the RFBI configuration:

- DSS.RFBI_SYSCONFIG
- DSS.RFBI_SYSSTATUS
- DSS.RFBI_CONFIG0 (configuration 0) and DSS.RFBI_CONFIG1 (configuration 1)
- DSS.RFBI_VSYNC_WIDTH
- DSS.RFBI_HSYNC_WIDTH

The configuration register for one configuration can be accessed only when the configuration is not in use (based on the value of the RFBI_CONTROL[3:2] CONFIGSELECT bit field).

12.5.7.3.1 Parallel Mode

The DSS.RFBI_CONFIGi[1:0] PARALLELMODE bit field (with $i = 0, 1$) defines the width of the interface (8-, 9-, 12-, or 16-bit parallel).

12.5.7.3.2 Trigger Mode

Setting the DSS.RFBI_CONFIG[3:2] TRIGGERMODE bit field configures the trigger on the external TE signal (RFBI_TE_VSYNC), or external with VSYNC/HSYNC with the programmable number of HSYNCs to begin the transfer in both cases or the internal programmable DSS.RFBI_CONTROL[4] ITE bit.

12.5.7.3.3 VSYNC Pulse Width (Minimum Value)

The DSS.RFBI_VSYNC_WIDTH[15:0] MINVSYNCPULSEWIDTH bit field defines the minimum number of L4 clock cycles of the VSYNC pulse for detection on VSYNC. It allows differentiation between VSYNC and HSYNC, which are ORed on the same signal and is also used in the VSYNC/HSYNC mode on the two separate input lines.

- The VSYNC pulse width must be at least equal to two L4 cycles when HSYNC is not present.
- The VSYNC pulse width must be at least equal to four L4 cycles when HSYNC is present.

12.5.7.3.4 HSYNC Pulse Width (Minimum Value)

The DSS.RFBI_HSYNC_WIDTH[15:0] MINHSYNCPULSEWIDTH bit field defines the minimum number of L4 clock cycles of the HSYNC pulse for detection on HSYNC. It allows differentiation between VSYNC and HSYNC, which are ORed on the same signal, and is also used in the VSYNC/HSYNC mode on the separate two input lines. The HSYNC pulse width must always be at least equal to two L4 cycles to be detected.

12.5.7.3.5 Cycle Format

Setting the DSS.RFBI_CONFIGi[10:9] CYCLEFORMAT bit field (with $i = 0, 1$) defines which registers are used to format the data in the interconnect FIFO with the appropriate number of bits (starting from the LSB) and with the alignment on the interface as follows:

- DSS.RFBI_DATA_CYCLE_i (if DSS.RFBI_CONFIG[10:9] CYCLEFORMAT bit field = 00) only
or
- DSS.RFBI_DATA_CYCLE1_i and DSS.RFBI_DATA_CYCLE2_i (if DSS.RFBI_CONFIG[10:9] CYCLEFORMAT bit field = 01)
or
- DSS.RFBI_DATA_CYCLE1_i, DSS.RFBI_DATA_CYCLE2_i, and DSS.RFBI_DATA_CYCLE3_i (if DSS.RFBI_CONFIG[10:9] CYCLEFORMAT bit field = 10)

The data from the display controller and from the L4 interconnect are formatted based on the configuration of the DSS.RFBI_DATA_CYCLE_i registers.

12.5.7.3.6 Unused Bits

Based on the configuration, the undefined bits for each cycle are defined with the previous values of the bits at the same position in the previous cycle, 0s, or 1s (the unused bits can be at any position). The DSS.RFBI_CONFIGi[12:11] UNUSEDBITS bit field (with $i = 0, 1$) is used.

12.5.7.3.7 RFBI Timings

The timing registers for one configuration can be accessed only when the configuration is not in use (based on the value of the DSS.RFBI_CONTROL[3:2] CONFIGSELECT bit field). Granularity is defined using the DSS.RFBI_CONFIGi[4] TIMEGRANULARITY bit. This feature allows the extension of programmable ranges of timing parameters for the RFBI interface. Refer to [Table 12-68](#) for the bits configuration values.

- Chip-select assertion/deassertion time
RFBI_A0 setup time to chip-select assertion is assured by the programmable chip-select assertion time from the start access time:
DSS.RFBI_ONOFF_TIMEi[3:0] CSONTIME bit field (with $i = 0, 1$).
The chip-select deassertion time from the start access time is programmable:
DSS.RFBI_ONOFF_TIMEi[9:4] CSOFFTIME bit field (with $i = 0, 1$)

CAUTION

Configuring `DSS.RFBI_ONOFF_TIMEi[3:0]` `CSONTIME` = `DSS.RFBI_ONOFF_TIMEi[9:4]` `CSOFFTIME` = 0 (with $i = 0, 1$) is not supported and must be avoided. This configuration creates contention on the bus and progressively damages the LCD panel.

- Chip-select pulse width

The total chip-select pulse width is the time when write cycle time or read cycle time has completed and is programmable:

`DSS.RFBI_CYCLE_TIMEi[17:12]` `CSPULSEWIDTH` bit field (with $i = 0, 1$)

It applies on the read-to-write, write-to-read, read-to-read, and write-to-write access based on:

- The `DSS.RFBI_CYCLE_TIMEi` [19] `RRENABLE` bit: Read-to-read access
- The `DSS.RFBI_CYCLE_TIMEi` [20] `WWENABLE` bit: Write-to-write access
- The `DSS.RFBI_CYCLE_TIMEi` [18] `RWENABLE` bit: Read-to-write access
- The `DSS.RFBI_CYCLE_TIMEi` [21] `WRENABLE` bit: Write-to-read access

By default, it applies to any access (read-to-read, read-to-write, write-to-read, write-to-write) when the chip-select changes.

- Access time

The total access time is the time from when `A0` becomes valid until data are sampled before deasserting the `RE` signal; access time is programmable:

`DSS.RFBI_CYCLE_TIMEi[27:22]` `ACCESSTIME` bit field (with $i = 0, 1$)

When reading the data on the bus, the data are sampled at the end of the access time, which occurs before the end of the read off time (`DSS.RFBI_ONOFF_TIMEi[29:24]` `REOFFTIME`, with $i = 0, 1$).

- Write enable cycle time

The total write enable cycle time is the time from when `A0` becomes valid until write cycle completion; the write enable cycle time is programmable:

The `DSS.RFBI_CYCLE_TIMEi[5:0]` `WECYCLETIME` bit field (with $i = 0, 1$)

- Write enable assertion/deassertion time

The `WE` assertion delay time from start access time is programmable:

`DSS.RFBI_ONOFF_TIMEi[13:10]` `WEONTIME` bit field (with $i = 0, 1$)

The `WE` deassertion delay time from the start access time is programmable:

`DSS.RFBI_ONOFF_TIMEi[19:14]` `WEOFFTIME` bit field (with $i = 0, 1$)

- Read enable cycle

The total read enable cycle time is the time when `A0` becomes valid until read cycle completion; the read enable cycle time is programmable:

The `DSS.RFBI_CYCLE_TIMEi[11:6]` `RECYCLETIME` bit field (with $i = 0, 1$)

- Read enable assertion/deassertion time

The `RE` assertion delay time from the start access time is programmable:

`DSS.RFBI_ONOFF_TIMEi[23:20]` `REONTIME` bit field (with $i = 0, 1$)

The `RE` deassertion delay time from the start access time is programmable:

`DSS.RFBI_ONOFF_TIMEi[29:24]` `REOFFTIME` bit field (with $i = 0, 1$)

At cycle time completion (read access or write access) all control signals (`RFBI_CSi`, `RFBI_WR`, and `RFBI_RD`, with $i = 0, 1$) are deasserted regardless of their deassertion time parameter values, if they are not deasserted already.

However, an exception to this forced deassertion exists when a pipelined request to the same chip-select or to a different chip-select is pending. Also, a control signal with deassertion time parameters equal to the cycle time parameter is not necessarily deasserted when a pipelined request to the same chip-select or different chip-select is pending. This prevents any unnecessary glitch transitions.

If no inactive cycles are required between successive accesses to the same chip-select (the DSS.RFBI_CYCLE_TIME_i[17:12] CSPULSEWIDTH bit field = 0, with $i = 0, 1$), and if assertion time parameters associated with the following access equal 0, the asserted control signals (RFBI_CS_i, RFBI_WR, and RFBI_RD, with $i = 0, 1$) stay asserted. This is applicable to any read/write-to-read/write access combination.

Table 12-68 summarizes the configurations values for each timing bit.

Table 12-68. RFBI Timings Configuration

| Configuration bits ⁽¹⁾ | Granularity ⁽²⁾ | |
|---|----------------------------|----------|
| | one | two |
| DSS.RFBI_ONOFF_TIME _i [3:0] CSONTIME | 0 to 15 | 0 to 30 |
| DSS.RFBI_ONOFF_TIME _i [9:4] CSOFFTIME | 0 to 63 | 0 to 126 |
| DSS.RFBI_CYCLE_TIME _i [17:12] CSPULSEWIDTH | 0 to 63 | 0 to 126 |
| DSS.RFBI_CYCLE_TIME _i [27:22] ACESSTIME | 0 to 63 | 0 to 126 |
| DSS.RFBI_CYCLE_TIME _i [5:0] WECYCLETIME | 0 to 63 | 0 to 126 |
| DSS.RFBI_ONOFF_TIME _i [13:10] WEONTIME | 0 to 15 | 0 to 30 |
| DSS.RFBI_ONOFF_TIME _i [19:14] WEOFFTIME | 0 to 63 | 0 to 126 |
| DSS.RFBI_CYCLE_TIME _i [11:6] RECYCLETIME | 0 to 63 | 0 to 126 |
| DSS.RFBI_ONOFF_TIME _i [23:20] REONTIME | 0 to 15 | 0 to 30 |
| DSS.RFBI_ONOFF_TIME _i [29:24] REOFFTIME | 0 to 63 | 0 to 126 |

⁽¹⁾ Where $i = 0$ or 1 .

⁽²⁾ Number of L4Clk cycles. The granularity can be configured using the DSS.RFBI_CONFIG_i[4] TIMEGRANULARITY bit.

12.5.7.3.8 RFBI State-Machine

Referring to Table 12-37, the signals RFBI_A0, RFBI_RD, and RFBI_WR are asserted/deasserted based on the register accessed (DSS.RFBI_CMD, DSS.RFBI_PARAM, DSS.RFBI_DATA, DSS.RFBI_READ, and DSS.RFBI_STATUS). When the DSS.RFBI_SYSSTATUS[8] BUSY bit is set by hardware, any access to the registers is stalled, except for the RFBI_DATA register.

The DSS.RFBI_SYSSTATUS[9] BUSYRFBIDATA bit indicates whether there are still pending data in the interconnect FIFO associated with the register RFBI_DATA only.

- **Command register**
Write a command at a time by writing in the DSS.RFBI_CMD register. If the previous command is not processed, the DSS.RFBI_SYSSTATUS[8] BUSY bit is set by hardware and the access to writing a new command is stalled.
- **Parameter register**
Write a parameter at a time by writing in the DSS.RFBI_PARAM register.
If the previous parameter is not processed, the DSS.RFBI_SYSSTATUS[8] BUSY bit is set by hardware and the access to writing a new parameter is stalled.
- **Data register**
Write one or two pixels at a time by writing in the RFBI_DATA register (when DSS.RFBI_CONFIG_i[10:9] CYCLEFORMAT = 0x3 with $i = 0, 1$, two pixels must be written contiguously, no other access to RFBI registers except DSS.RFBI_DATA is allowed).
The pixels are formatted based on the specified cycle format. If two pixels are written into the 32-data register, the DSS.RFBI_CONFIG_i[8:7] L4FORMAT bit field indicates the number of pixels for each L4 access to the register and the order of the pixels
If the previous data are not processed, the DSS.RFBI_SYSSTATUS[8] BUSY bit is set by hardware and any access for writing new data is stalled. When the DSS.RFBI_SYSSTATUS[8] BUSY bit is reset by hardware, the access is not stalled.
- **Read/status register**
Send through the command and parameter registers the correct information to receive data in the data or status register. The read data from the LCD panel is initiated by writing into the DSS.RFBI_READ or DSS.RFBI_STATUS registers. In this case, the DSS.RFBI_SYSSTATUS[8] BUSY bit is set until the data are available in the register.

When the DSS.RFBI_SYSSTATUS[8] BUSY bit is set by hardware, the read or write access is stalled until the register is updated with a new value from the LCD panel. To avoid the stall, the software can poll the DSS.RFBI_SYSSTATUS[8] BUSY bit until it is reset by hardware. To receive the data, send the appropriate command/parameters.

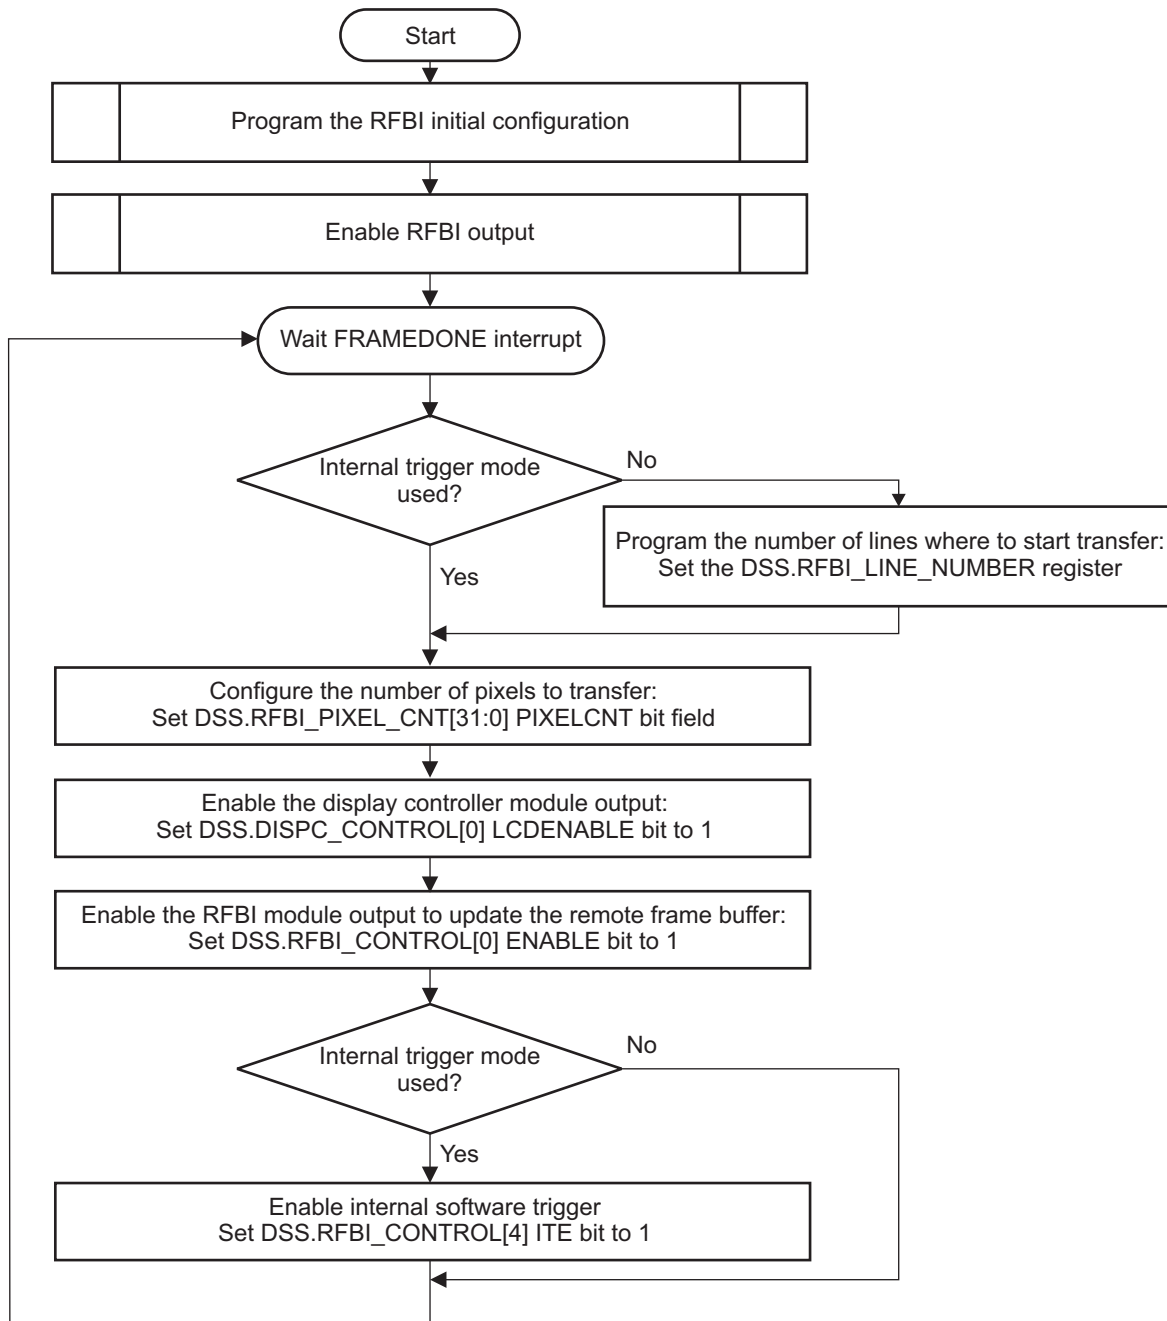

12.5.7.3.9 RFBI Configuration Flow Charts

The RFBI configuration depends on the trigger mode used by the application. The available trigger modes are:

- Internal trigger mode when setting the DSS.RFBI_CONFIGi[3:2] TRIGGERMODE bit field to 0x0
- External trigger mode:
 - TE external trigger mode when setting the DSS.RFBI_CONFIGi[3:2] TRIGGERMODE bit field to 0x1
 - HSYNC/VSYNC external trigger mode when setting the DSS.RFBI_CONFIGi[3:2] TRIGGERMODE bit field to 0x2

Figure 12-146 gives an example of how to program and use the RFBI module:

Figure 12-146. How to Use RFBI

dss-192

Figure 12-147 details how to configure the RFBI registers:

Figure 12-147. RFBI Initial Configuration

dss-193

Figure 12-148 describes how to enable the RFBI module.

Figure 12-148. RFBI Output Enable

dss-324

12.5.8 Video Encoder Basic Programming Model

12.5.8.1 Video Encoder Software Reset

By setting the `DSS.VENC_F_CONTROL[8]` RESET bit to 1, the video encoder is reset. This bit is automatically cleared by hardware when the reset is done.

NOTE: Before changing the standard (NTSC or PAL) and all the related registers, a software reset is required to properly initialize the VENC module.

12.5.8.2 Video DAC Settings

The video output format can be either:

- one composite video (CVBS) output signal with video DAC1 or

- two separated luma/chroma output signals with both video DAC1(luma analog signal) and DAC2 (chroma analog signal)

Selection is performed with DSS.VENC_OUT_SEL[6] VENC_OUT_SEL bit:

- When VENC_OUT_SEL bit is set to 0 (reset value), video DAC1 is selected for composite video (CVBS) signal
- When VENC_OUT_SEL bit is set to 1, video DAC1 is selected for luma signal

One of the first VENC settings is to enable the output of the video DACs. This setting depends on the video output format:

- CVBS video output format: Enable video DAC1 composite output by setting the DSS.VENC_OUTPUT_CONTROL[1] COMPOSITE_ENABLE bit to 1
- Separated luma/chroma output format: Enable video DAC1 luma output by setting the DSS.VENC_OUTPUT_CONTROL[0] LUMA_ENABLE bit to 1 and enable video DAC2 chroma output by setting the DSS.VENC_OUTPUT_CONTROL[2] CHROMA_ENABLE bit to 1

12.5.8.3 Video Encoder Programming Sequence

1. Set the DSS.VENC_F_CONTROL[8] RESET bit to 1 to perform a software reset of the VENC module.
2. Before any configuration change, save the DSS.DISPC_IRQENABLE register value (DSS interrupts context), and then disable the display subsystem interrupts by setting the DSS.DISPC_IRQENABLE register to 0x0000.
3. Configure the video encoder registers as described in [Table 12-69](#), depending on the video standard used (PAL or NTSC). The DSS.VENC_F_CONTROL and DSS.VENC_SYNC_CTRL registers must be the last ones to be changed by software.
4. Set the DSS.DISPC_CONTROL[6] GODIGITAL bit and the DSS.DISPC_CONTROL[1] DIGITALENABLE bit to 1.
5. Wait for the first VSYNC pulse signal.
6. Clear the SYNCLOSTDIGITAL interrupt by setting the DSS.DISPC_IRQSTATUS[15] SYNCLOSTDIGITAL bit to 1.
7. Set the DSS.DISPC_IRQENABLE register to the value saved in step 2 (restore the DSS interrupts context).

12.5.8.4 Video Encoder Register Settings

For video encoder programming, see [Table 12-69](#). This table lists the register values to use in standard applications. These values are validated programming values only for the TV display support (NTSC 601 and PAL 601 standards).

Table 12-69. Video Encoder Register Programming Values

| Register Name | NTSC 601 | PAL 601 |
|-----------------------|------------|------------|
| VENC_F_CONTROL | 0x00000000 | 0x00000000 |
| VENC_VIDOUT_CTRL | 0x00000001 | 0x00000001 |
| VENC_SYNC_CTRL | 0x00008040 | 0x00000040 |
| VENC_LLEN | 0x00000359 | 0x0000035F |
| VENC_FLENS | 0x0000020C | 0x00000270 |
| VENC_HFLTR_CTRL | 0x00000000 | 0x00000000 |
| VENC_CC_CARR_WSS_CARR | 0x043F2631 | 0x2F7225ED |
| VENC_C_PHASE | 0x00000000 | 0x00000000 |
| VENC_GAIN_U | 0x00000102 | 0x00000111 |
| VENC_GAIN_V | 0x0000016C | 0x00000181 |
| VENC_GAIN_Y | 0x0000012F | 0x00000140 |
| VENC_BLACK_LEVEL | 0x00000043 | 0x0000003B |
| VENC_BLANK_LEVEL | 0x00000038 | 0x0000003B |
| VENC_X_COLOR | 0x00000007 | 0x00000007 |
| VENC_M_CONTROL | 0x00000001 | 0x00000002 |

Table 12-69. Video Encoder Register Programming Values (continued)

| Register Name | NTSC 601 | PAL 601 |
|---------------------------------------|---|---|
| VENC_BSTAMP_WSS_DATA | 0x00000038 | 0x0000003F |
| VENC_S_CARR | 0x21F07C1F | 0x2A098ACB |
| VENC_LINE21 | 0x00000000 | 0x00000000 |
| VENC_LN_SEL | 0x01310011 | 0x01290015 |
| VENC_L21_WC_CTL | 0x0000F003 | 0x0000F603 |
| VENC_HTRIGGER_VTRIGGER | 0x00000000 | 0x00000000 |
| VENC_SAVID_EAVID | 0x069300F4 | 0x06A70108 |
| VENC_FLEN_FAL | 0x0016020C | 0x00180270 |
| VENC_LAL_PHASE_RESET | 0x00060107 | 0x00040135 |
| VENC_HS_INT_START_STOP_X | 0x008E0350 | 0x00880358 |
| VENC_HS_EXT_START_STOP_X | 0x000F0359 | 0x000F035F |
| VENC_VS_INT_START_X | 0x01A00000 | 0x01A70000 |

| VENC_VS_INT_STOP_Y_VS_EXT_START_X | 0x01AC0024 | 0x01AF0000 |
| VENC_VS_EXT_STOP_X_VS_EXT_START_Y | 0x020D01AC | 0x000101AF |
| VENC_VS_EXT_STOP_Y | 0x00000006 | 0x00000025 |
| VENC_AVID_START_STOP_X | 0x03480078 | 0x03530083 |
| VENC_AVID_START_STOP_Y | 0x02060024 | 0x026C002E |
| VENC_FID_INT_START_X_FID_INT_START_Y | 0x0001008A | 0x0001008A |
| VENC_FID_INT_OFFSET_Y_FID_EXT_START_X | 0x01AC0106 | 0x002E0138 |
| VENC_FID_EXT_START_Y_FID_EXT_OFFSET_Y | 0x01060006 | 0x01380001 |
| VENC_TVDETPG_INT_START_STOP_X | 0x00140001 | 0x00140001 |
| VENC_TVDETPG_INT_START_STOP_Y | 0x00010001 | 0x00010001 |
| VENC_GEN_CTRL | 0x00F90000 | 0x00FF0000 |
| VENC_OUTPUT_CONTROL | 0x0000000A (composite video CVBS) 0x0000000D (split video S-video) | 0x0000000A (composite video CVBS) 0x0000000D (split video S-video) |
| VENC_OUTPUT_TEST | 0x00000000 | 0x00000000 |

NOTE: The following display controller registers must be programmed to the NTSC 601 video standard:

DSS.DISPC_SIZE_DIG[10:0] PPL = $720 - 1 = 719 = 0x2CF$

DSS.DISPC_SIZE_DIG[26:16] LPP = $(482/2) - 1 = 240 = 0xF0$

DSS.DISPC_GFX_BA0 or DSS.DISPC_VIDn_BA0 = Base address of even bit field data

DSS.DISPC_GFX_BA1 or DSS.DISPC_VIDn_BA1 = Base address of odd bit field data

12.5.9 SDI Basic Programming Model

This section describes how to configure the SDI module for FlatLink3G-compliant LCD panel support.

Configure the SDI, and then configure the display controller.

12.5.9.1 SDI Configuration

NOTE: To use the SDI with the TI FlatLink3G display panel:

- Set the DSS.DISPC_CONTROL[3] STNTFT bit to 1 (active matrix display operation mode)
- Set the DSS.DISPC_CONTROL[9:8] TFTDATALINES bit field to 0x3 (24-bit data output)
- Set the DSS.DSS_SDI_CONTROL[1:0] SDI_BWSEL bit field to 0x2 (color depth is 24 bits)

12.5.9.1.1 SDI PLL Configuration

The programming of the PLL divisor must be consistent with the choice of the number of data pairs. The PLL divisor determines the multiplication factor from the pixel clock frequency to data rate.

Table 12-70 lists some example values of the PLL settings for TI FlatLink3G.

Table 12-70. PLL Divisor Example Values for TI FlatLink3G

| | | 24-BPP data | | |
|-----------------------------------|--|-------------|--------------|--------------|
| | | 1 data pair | 2 data pairs | 3 data pairs |
| Recommended values | Pixel clock frequency (MHz) | 15 | 30 | 65 |
| | DSS.DSS_PLL_CONTROL[16:11] | | | |
| | SDI_PLL_REGN bit field (N factor = SDI_PLL_REGN bit field value + 1) | 0x7 | 0xE | 0xF |
| | DSS.DSS_PLL_CONTROL[10:1] | | | |
| | SDI_PLL_REGM bit field (M factor) | 0xF0 | 0xE1 | 0x140 |
| | DDS.DSS_PLL_CONTROL[19] | | | |
| | SDI_PLL_HIGHFREQ | 0 | 0 | 1 |
| Effective PLL divisor value (M/N) | 30 | 15 | 10 | |

For more details on SDI PLL programming settings, see Section 12.6.3.

12.5.9.1.2 Signal Features Configuration

For proper SDI operation, configure the following features in the display controller:

- Set the DSS.DISPC_POL_FREQ[16] RF bit to drive HSYNC and VSYNC on the rising edge of PCLK.
 - Set the DSS.DISPC_POL_FREQ[17] ONOFF bit.
 - Clear the DSS.DISPC_POL_FREQ[14] IPC bit to drive the pixel data on the rising edge of PCLK.
 - Set the DSS.DISPC_CONTROL[29] LCDENABLEPOL bit to set the LCD-enable signal active high.
- The following settings are not required by the SDI2 interface, but these polarities settings are the common polarities used by FlatLink3G displays:
- Set the DSS.DISPC_POL_FREQ[13] IHS bit to 1 to set HSYNC active low.
 - Set the DSS.DISPC_POL_FREQ[12] IVS bit to 1 to set VSYNC active low.
 - Clear the DSS.DISPC_POL_FREQ[15] IEO bit to set the data enable active high.

12.5.9.1.3 Number of Data Pairs

To select the number of data pairs used to transmit display data between the device and the display panel, set the DSS.DSS_SDI_CONTROL[3:2] SDI_PRSEL field.

Table 12-71 lists the different values for these bits based on the number of data pairs.

Table 12-71. SDI Pixel Data Format

| | DSS.DSS_SDICONTROL[3:2] SDI_PRSEL |
|---|--------------------------------------|
| 1 data pair (DATA1 pair) | 00 |
| 2 data pairs (DATA1 and DATA2 pair) | 01 |
| 3 data pairs (DATA1, DATA2, and DATA3 pair) | 10 |

12.5.9.2 SDI Power-Management Programming Sequence

This section describes the software sequence for powering on and powering down the SDI module.

12.5.9.2.1 SDI Reset State

After DSS power domain reset or power-on reset, the SDI module is in low-power mode by default with the following configuration:

- Display SS pads multiplexing is in parallel mode and not in SDI mode:
 - CONTROL.CONTROL_PADCONF_DSS_DATA10[2:0]MUXMODE0 and CONTROL.CONTROL_PADCONF_DSS_DATA10[18:16]MUXMODE1 field values is 0x0: SDI_DATA1N/SDI_DATA1P signals are not mapped on dss_data10/dss_data11 pins.
 - CONTROL.CONTROL_PADCONF_DSS_DATA12[2:0]MUXMODE0 and CONTROL.CONTROL_PADCONF_DSS_DATA12[18:16]MUXMODE1 bit field values is 0x0: SDI_DATA2N/SDI_DATA2P signals are not mapped on dss_data12/dss_data13 pins.
 - CONTROL.CONTROL_PADCONF_DSS_DATA14[2:0]MUXMODE0 and CONTROL.CONTROL_PADCONF_DSS_DATA14[18:16]MUXMODE1 bit field values is 0x0: SDI_DATA3N/SDI_DATA3P signals are not mapped on dss_data14/dss_data15 pins.
 - CONTROL.CONTROL_PADCONF_DSS_DATA18[2:0]MUXMODE0 and CONTROL.CONTROL_PADCONF_DSS_DATA18[18:16]MUXMODE1 bit field values is 0x0: SDI_VSYNC/SDI_HSYNC signals are not mapped on dss_data18/dss_data19 pins.
 - CONTROL.CONTROL_PADCONF_DSS_DATA20[2:0]MUXMODE0 and CONTROL.CONTROL_PADCONF_DSS_DATA20[18:16]MUXMODE1 bit field values is 0x0: SDI_DEN/SDI_STP signals are not mapped on dss_data20/dss_data21 pins.
 - CONTROL.CONTROL_PADCONF_DSS_DATA22[2:0]MUXMODE0 and CONTROL.CONTROL_PADCONF_DSS_DATA22[18:16]MUXMODE1 bit field values is 0x0: SDI_CLKP/SDI_CLKN signals are not mapped on dss_data22/dss_data23 pins.
- SDI PLL is in reset mode: the DSS.DSS_PLL_CONTROL[18]SDI_PLL_SYSRESET bit value is 0x0.

12.5.9.2.2 SDI Power_On Sequence

When exiting OFF mode, to power-on the SDI module, software users must program the following sequence:

1. Program the SDI pads multiplexing configuration:
 - (a) Set the CONTROL.CONTROL_PADCONF_DSS_DATA10[2:0]MUXMODE0 bit field to 0x1 to select SDI_DATA1N signal on dss_data10 pin and CONTROL.CONTROL_PADCONF_DSS_DATA10[18:16]MUXMODE1 bit field to 0x1 to select SDI_DATA1P signal on dss_data11 pin.
 - (b) For 2-data and 3-data pair mode: set the CONTROL.CONTROL_PADCONF_DSS_DATA12[2:0]MUXMODE0 bit field to 0x1 to select SDI_DATA2N on dss_data12 pin and CONTROL.CONTROL_PADCONF_DSS_DATA12[18:16]MUXMODE1 bit field to 0x1 to select SDI_DATA2P signal on dss_data13 pin.
 - (c) For 3-data pair mode: set the CONTROL.CONTROL_PADCONF_DSS_DATA14[2:0]MUXMODE0 bit field to 0x1 to select SDI_DATA3N on dss_data14 pin and CONTROL.CONTROL_PADCONF_DSS_DATA14[18:16]MUXMODE1 bit field to 0x1 to select SDI_DATA3P signal on dss_data15 pin.
 - (d) Set the CONTROL.CONTROL_PADCONF_DSS_DATA18[2:0]MUXMODE0 bit field to 0x1 to select SDI_VSYNC signal on dss_data18 pin and CONTROL.CONTROL_PADCONF_DSS_DATA18[18:16]MUXMODE1 bit field to 0x1 to select

- SDI_HSYNC signal on dss_data19 pin.
- (e) Set the CONTROL.CONTROL_PADCONF_DSS_DATA20[2:0]MUXMODE0 bit field to 0x1 to select SDI_DEN signal on dss_data20 pin and CONTROL.CONTROL_PADCONF_DSS_DATA20[18:16]MUXMODE1 bit field to 0x1 to select SDI_STP signal on dss_data21 pin.
 - (f) Set the CONTROL.CONTROL_PADCONF_DSS_DATA22[2:0]MUXMODE0 bit field to 0x1 to select SDI_CLKP signal on dss_data22 pin and CONTROL.CONTROL_PADCONF_DSS_DATA22[18:16]MUXMODE1 bit field to 0x1 to select SDI_CLKN signal on dss_data23 pin.
2. Wait 1 ms.
 3. Release the SDI PLL reset signal by setting the DSS.DSS_PLL_CONTROL[18]SDI_PLL_SYSRESET bit to 0x1.

NOTE: The same software sequence is needed when the DSS power domain is set to ON.

12.5.9.2.3 SDI Power-Down Sequence

To power down the SDI module, software users must program the following sequence:

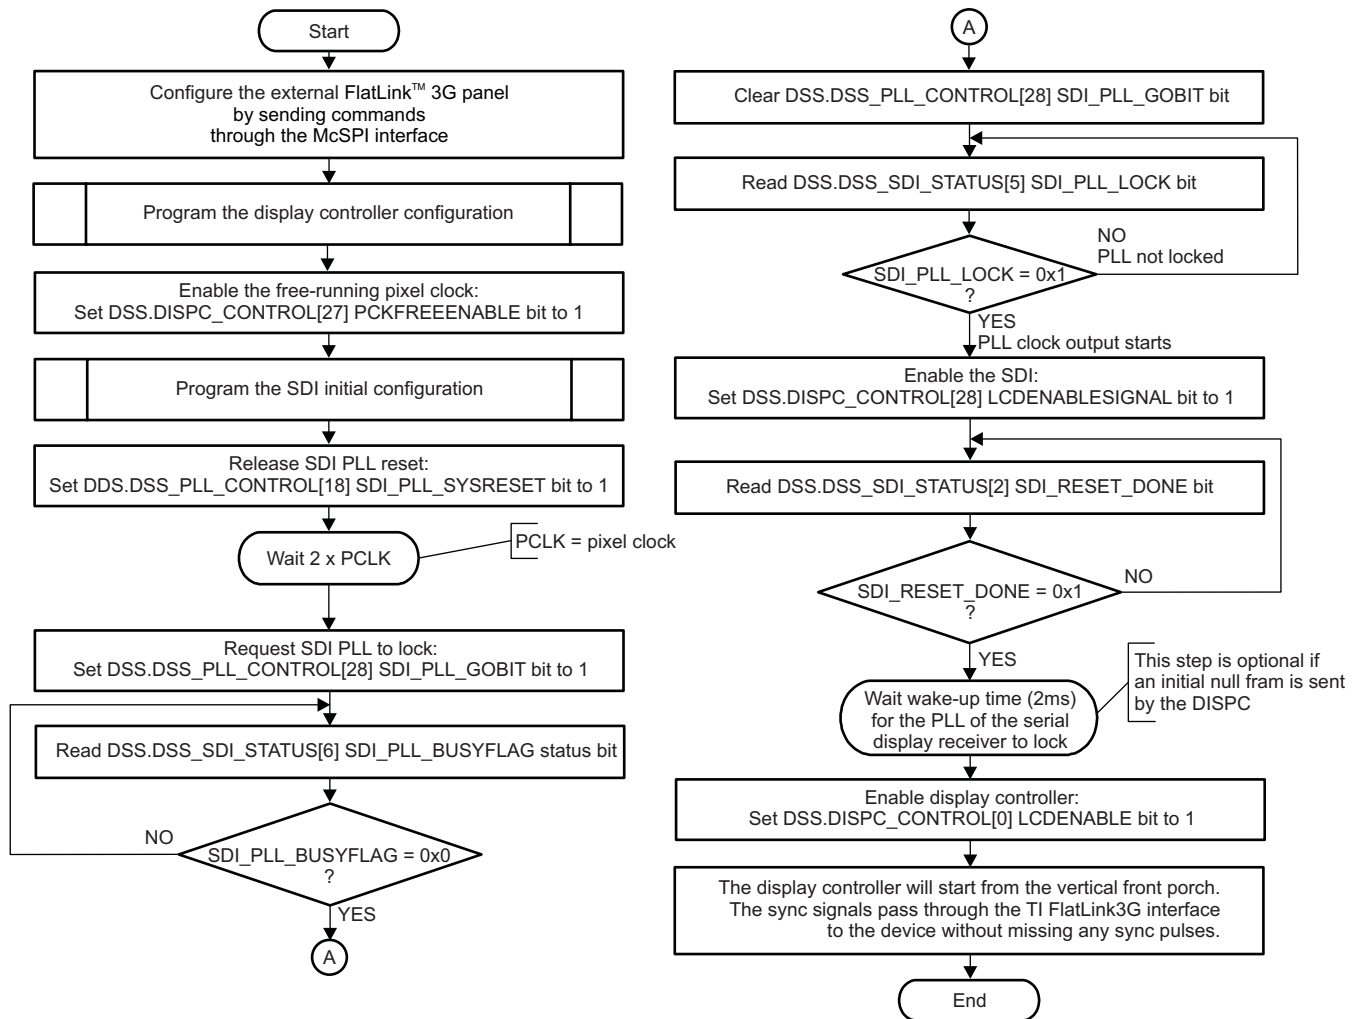

1. Power down the SDI PLL by setting the DSS.DSS_PLL_CONTROL[18]SDI_PLL_SYSRESET bit to 0x0.
2. Power-down the SDI pads:
 - (a) Set the CONTROL.CONTROL_PADCONF_DSS_DATA10[2:0]MUXMODE0 bit field to 0x0 to un-select SDI_DATA1N signal on dss_data10 pin and CONTROL.CONTROL_PADCONF_DSS_DATA10[18:16]MUXMODE1 bit field to 0x0 to un-select SDI_DATA1P signal on dss_data11 pin.
 - (b) For 2-data and 3-data pair mode: set the CONTROL.CONTROL_PADCONF_DSS_DATA12[2:0]MUXMODE0 bit field to 0x0 to un-select SDI_DATA2N on dss_data12 pin and CONTROL.CONTROL_PADCONF_DSS_DATA12[18:16]MUXMODE1 bit field to 0x0 to un-select SDI_DATA2P signal on dss_data13 pin.
 - (c) For 3-data pair mode: set the CONTROL.CONTROL_PADCONF_DSS_DATA14[2:0]MUXMODE0 bit field to 0x0 to un-select SDI_DATA3N on dss_data14 pin and CONTROL.CONTROL_PADCONF_DSS_DATA14[18:16]MUXMODE1 bit field to 0x0 to un-select SDI_DATA3P signal on dss_data15 pin.
 - (d) Set the CONTROL.CONTROL_PADCONF_DSS_DATA18[2:0]MUXMODE0 bit field to 0x0 to un-select SDI_VSYNC signal on dss_data18 pin and CONTROL.CONTROL_PADCONF_DSS_DATA18[18:16]MUXMODE1 bit field to 0x0 to un-select SDI_HSYNC signal on dss_data19 pin.
 - (e) Set the CONTROL.CONTROL_PADCONF_DSS_DATA20[2:0]MUXMODE0 field to 0x0 to un-select SDI_DEN signal on dss_data20 pin and CONTROL.CONTROL_PADCONF_DSS_DATA20[18:16]MUXMODE1 bit field to 0x0 to un-select SDI_STP signal on dss_data21 pin.
 - (f) Set the CONTROL.CONTROL_PADCONF_DSS_DATA22[2:0]MUXMODE0 bit field to 0x0 to un-select SDI_CLKP signal on dss_data22 pin and CONTROL.CONTROL_PADCONF_DSS_DATA22[18:16]MUXMODE1 bit field to 0x0 to un-select SDI_CLKN signal on dss_data23 pin.

NOTE: The same software sequence is needed to shut-down the DSS power domain.

12.5.9.3 SDI Start Sequence

Figure 12-149 describes the SDI start sequence.

Figure 12-149. SDI Start Sequence

dss-108

NOTE: The lock status of the SDI PLL is connected to the GPIO_81 signal of the GPIO3 module. To avoid polling, configure the GPIO3 module to generate an interrupt when the SDI PLL is locked (lock status is 1). For more information, see [Chapter 21, General-Purpose Interface](#).

NOTE: TI provides a global solution with OMAP device associated to a programmable 27-bit serial display interface receiver, the SN65LVDS302 receiver. For more details on SN65LVDS302 device, see the TI public web at www.ti.com.

12.5.9.4 SDI Stop Sequence

Figure 12-150 describes the SDI stop sequence.

Figure 12-150. SDI Stop Sequence

dss-110

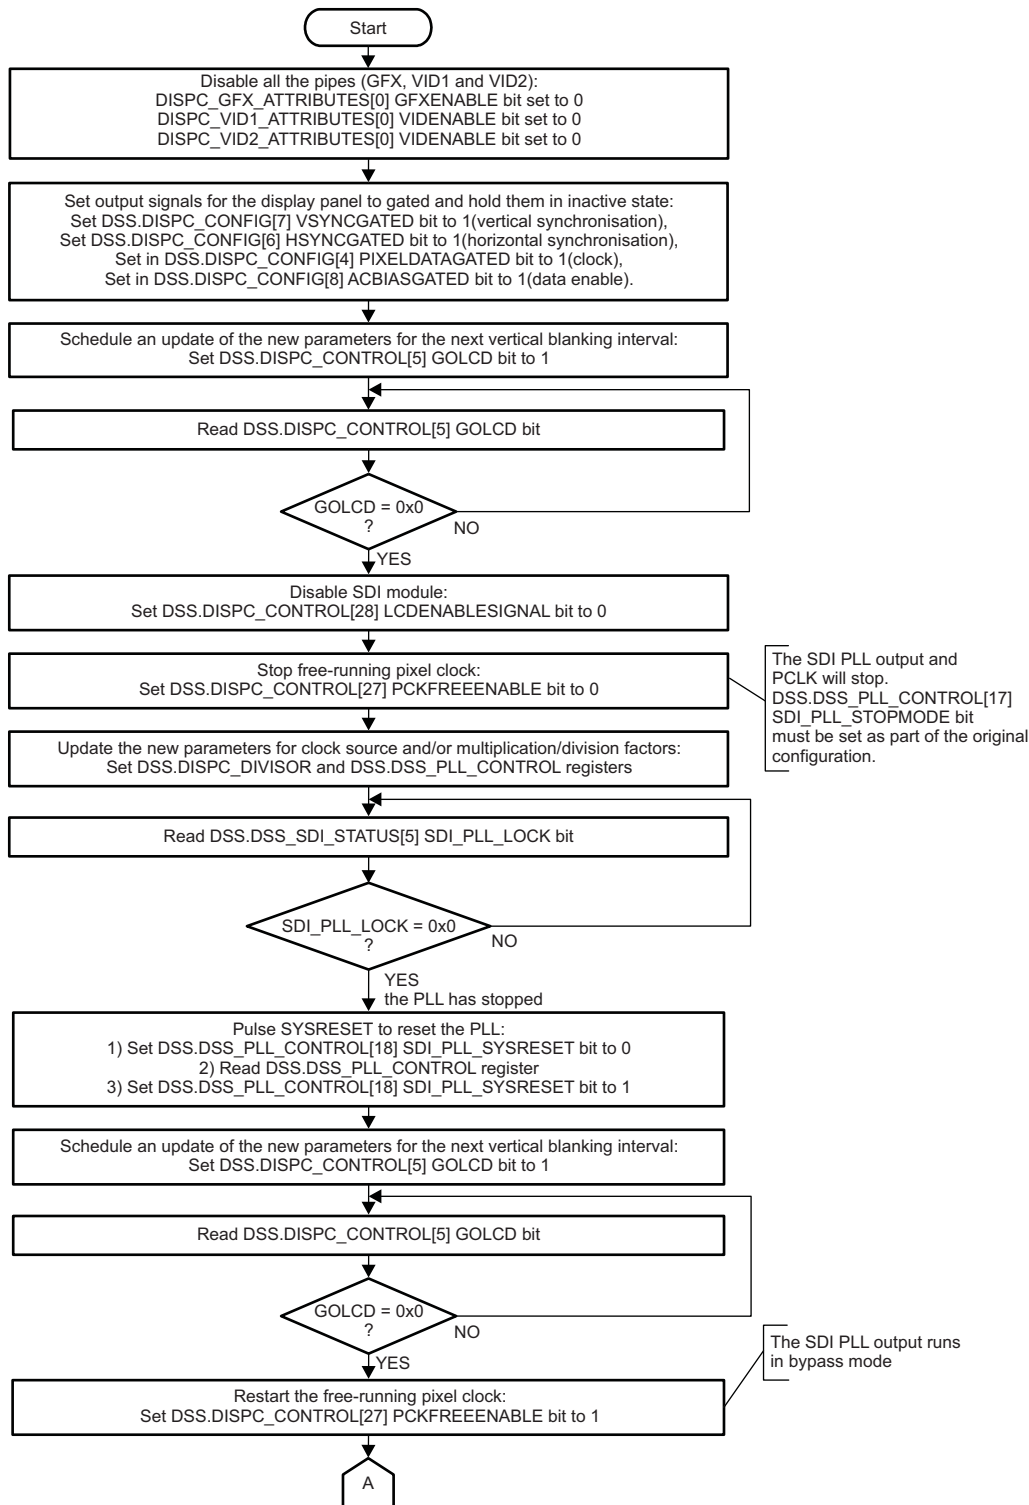

12.5.9.5 Clock Source/Frequency Change Sequence

To change clock source or frequency, the simplest procedure is to follow the stop and start sequences documented above. If it is desired to change these without stopping the display a more rigorous procedure must be used as follows. The intent of this procedure is to perform the changes as quickly as possible during the vertical blanking interval and hence to minimize any visible display effect due to the increased blanking time.

12.5.9.5.1 Complete Sequence

Figure 12-151 and Figure 12-152 describe the clock source and frequency change sequence of the SDI.

Figure 12-151. SDI Clock Source/Frequency Change Sequence Part A

dss-111

Figure 12-152. SDI Clock Source/Frequency Change Sequence Part B

dss-109

NOTE: One interface reference cycle is defined as follows:

Pixel Clock Frequency (PCLK)/SDI_PLL_REGN[5:0]/SDI_PLL_HIGHFREQ

Assuming the DSS.DSS_PLL_CONTROL[25:22] SDI_PLL_FREQSEL bit field value is between 0xB and 0xF and the DSS.DSS_PLL_CONTROL[27:26] SDI_PLL_LOCKSEL bit field is set to 0x0.

NOTE: The lock status of the SDI PLL is connected to the GPIO_81 signal of the GPIO3 module. To avoid polling, configure the GPIO3 module to generate an interrupt when the SDI PLL is locked (lock status is 1). For more information, see [Chapter 21, General-Purpose Interface](#).

NOTE: TI provides a global solution with OMAP device associated to a programmable 27-bit serial display interface receiver, the SN65LVDS302 receiver. For more details on SN65LVDS302 device, see the TI public web at www.ti.com.

12.5.9.5.2 Simplified Sequence When LCD and PCD Are Swapped

If the values in the DSS.DISPC_DIVISOR[23:16] LCD and DSS.DISPC_DIVISOR[7:0] PCD are exchanged (for example to reduce the internal display controller functional clock frequency while keeping the pixel clock frequency unchanged) with no other changes in the clock path, then there will be no discontinuity in the pixel clock. As a consequence the change will be transparent to the SDI module.

12.5.9.6 SDI Error Management

The DSS.DSS_SDI_STATUS[3] SDI_ERROR status bit indicates an internal buffer underflow/overflow. If such an error occurs, the SDI module must be disabled and enabled again to realign the buffer. This is done by setting the DSS.DISPC_CONTROL[28] LCDENABLESIGNAL bit to 0 (disabling) and to 1 (enabling). Ensure that the DSS.DSS_SDI_STATUS[2] SDI_RESET_DONE bit is set to 1. If this SDI error occurs during the debug phase, it is often due to programming incompatible values for MDIV, NDIV, and PDIV parameters for SDI PLL settings.

The SDI_ERROR internal signal is connected to the GPIO_82 internal signal of the GPIO3 module. Using the GPIO_82 signal, the GPIO3 bank generates two interrupts (GPIO3_MPU_IRQ and GPIO3_IVA2_IRQ) to alert the MPU or IVA2.2 subsystems, respectively, about any SDI error. For additional information, see [Chapter 21, General-Purpose Interface](#).

12.6 Display Subsystem Use Cases and Tips

This section gives some generic use cases and tips for setting the modules of the display subsystem.

12.6.1 How to Configure the Scaling Unit in the DISPC Module

This section describes the scaling capability of the display controller (DISPC). The scaling unit is a part of the video pipeline is used when transferring pixels from the system memory (SDRAM or on-chip SRAM) to the LCD panel or the TV set. The scaling unit consists of two scaling blocks: The vertical scaling block followed by the horizontal scaling block. The input pixel format is RGB24. In case the pixel format in system memory is not RGB, the color space conversion unit in front of the scaling unit converts the YUV pixels into RGB pixels. The two scaling units are independent: Neither of them, only one, or both can be used simultaneously

12.6.1.1 Filtering

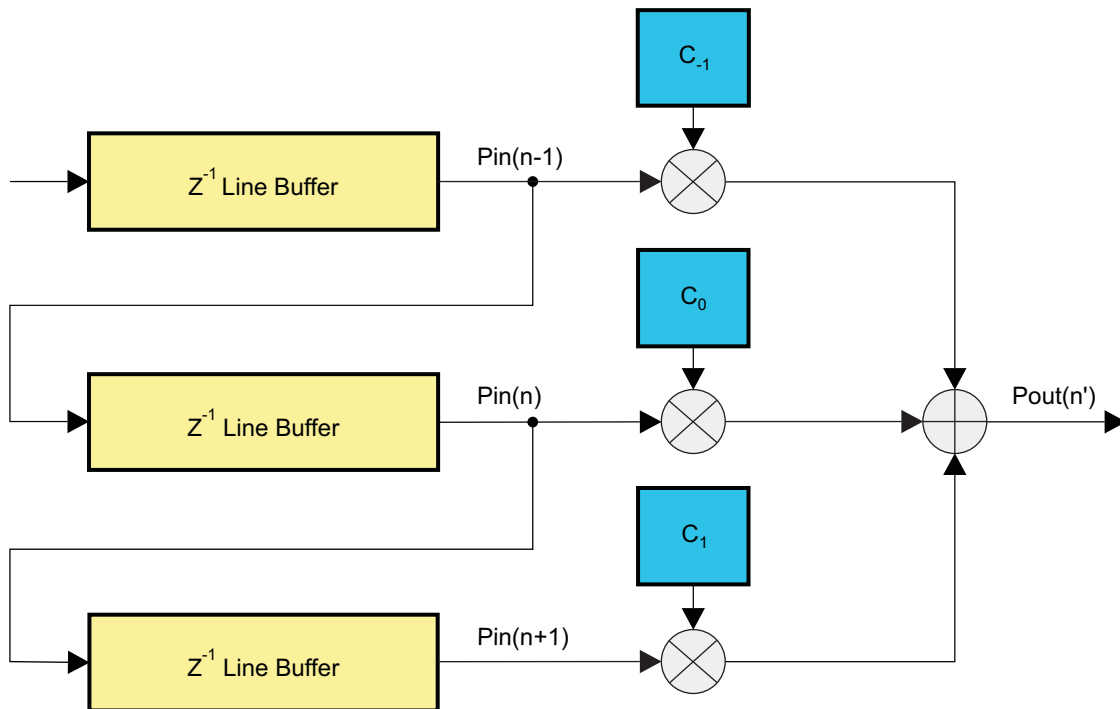

The scaling is used to down-scale, up-scale, or process the image while keeping the same size. It is applied independently horizontally and vertically. The same filtering applies for each color component (R, G, or B).

12.6.1.1.1 Vertical Filtering

The vertical filtering unit is based on a poly-phase rotation architecture with eight phases and three taps. That means that 24 coefficients are programmable

The vertical 3-tap filtering macro architecture is shown in [Figure 12-153](#).

Figure 12-153. Vertical Filtering Macro Architecture (Three Taps)

dss-112

For the 3-tap vertical up-/downsampling the equation is (with the example of R component):

$$R_{out}(n) = \left(\sum_{i=-1}^{i=1} C_i(\Phi) \times R_{in}(n+i) \right) \gg 7$$

dss-E067

(9)

Legend:

- Rout: R component output
- C_i(): Vertical FIR coefficients
- Rin: R component input
- The line (n+1) is older than line (n).

The programmable three coefficients of the poly-phase filters are signed 8-bit values (except for the central coefficient C₀(), which is unsigned).

The vertical filtering unit can be configured to support five taps.

The vertical 5-tap filtering macro architecture is shown in Figure 12-154.

Figure 12-154. Vertical Filtering Macro Architecture (Five Taps)

dss-113

For the 5-tap vertical up/downsampling the equation is (with the example of R component):

$$Rout(n) = \left(\sum_{i=-2}^{i=2} C_i(\Phi) \times Rin(n+i) \right) \gg 7$$

dss-E066

(10)

Legend:

- Rout: R component output
- C_i(): Vertical FIR coefficients with C₊₂()=C₀₀() and C₋₂()=C₂₂()
- Rin: R component input
- The line (n+1) is older than line (n).

NOTE: If the 5-tap resizer is used for RGB16 and YUV422 picture formats, the width of the input picture must be a multiple of 2 pixels and more than 5 pixels. This leads to the following register configuration:

```
DISPC_VIDn_ATTRIBUTES[21] VIDVERTICALTAPS == 1
DISPC_VIDn_PICTURE_SIZE[10:0] VIDORGSIZEX > 4 and even
```

The programmable five coefficients of the poly-phase filters are signed 8-bit values (except for the central coefficient C₀(), which is unsigned).

In case of three taps, the memory lines are merged into three lines instead of six lines (one line is used as a cache line).

The first line is duplicated to fill up the two first lines (3-tap configuration) and the three first lines (5-tap configuration).

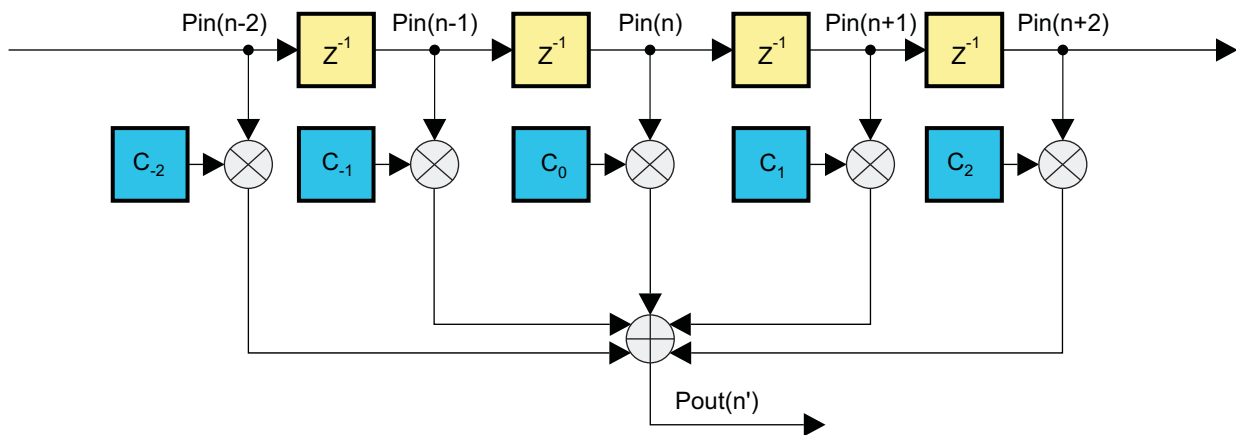

The last line is duplicated if the scaling logic requires loading of more lines and the last line has been reached

12.6.1.1.2 Horizontal Filtering

The horizontal filtering unit is based on a poly-phase rotation architecture with eight phases and five taps. That means that 40 coefficients are programmable.

The horizontal filtering macro architecture is shown in [Figure 12-155](#).

Figure 12-155. Horizontal Filtering Macro Architecture (Five Taps)

dss-114

For the 5-tap horizontal up-/downsampling, the equation is (with the example of R component):

$$R_{out}(n) = \left(\sum_{i=-3}^{i=3} C_i(\Phi) \times R_{in}(n+i) \right) \gg 7$$

dss-E115

(11)

Legend:

- Rout: R component output
- C(i): Vertical FIR coefficients
- Rin: R component input
- The line (n+1) is older than line (n).

To horizontally and vertically filter the video layer, the phase is calculated separately. The programmable coefficients of the poly-phase filters are signed 8-bit values (except for the central coefficient C₀(i), which is unsigned).

The first pixel is duplicated to fill up the three first pixel-buffers (5-tap configuration). The last pixel is duplicated if the scaling logic requires loading of more pixels and the last pixel has been reached

12.6.1.2 Scaling Algorithms

The up-/downsampling finite state machines (FSM) below are detailed in this section.

[Figure 12-156](#) presents the vertical up-/downsampling FSM.

Figure 12-156. Vertical Up-/Down-Sampling Algorithm

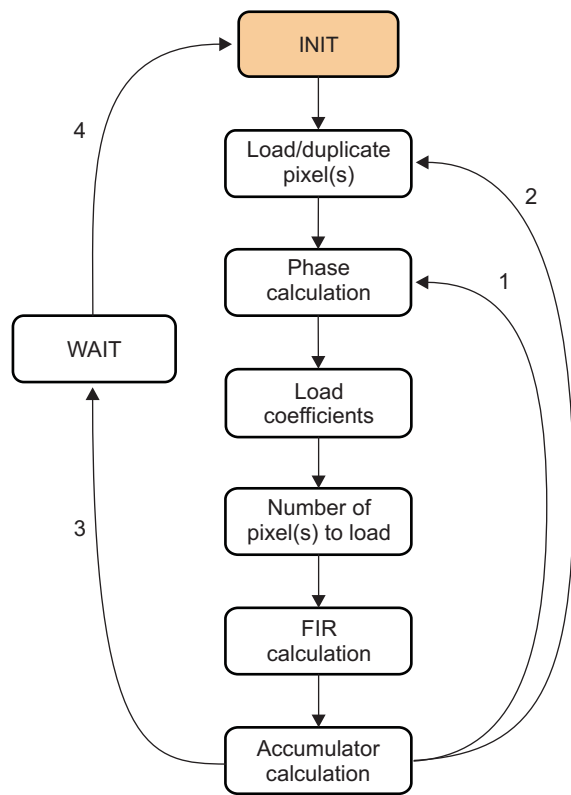

- 1: New pixel on the same line
- 2: New pixel on following line (no line to load)
- 3: New pixel on following line (line[s] to load)
- 4: End of frame
- 5: Restart of a new frame

| | |
|---------------------------|--|
| INIT | Initialisation of buffer with duplication, accu value reset with register value based on the field polarity if present |
| Phase calculation | Phase = accu[9:7] |
| Number of line(s) to load | Number of element(s) = ((accu + 512 + inc) >> 10) - ((accu + 512) >> 10) |
| FIR calculation | $Rout(n) = \left(\sum_{i=-p}^{i=p} Ci(\phi) * Rin(n+i) \right) >> 7$ |
| Accumulator calculation | Accu = accu + inc |

dss-116

Figure 12-157 presents the horizontal up-/downsampling FSM.

Figure 12-157. Horizontal Up-/Down-Sampling Algorithm

- 1: New pixel (no pixel to load)
- 2: New pixel (pixel(s) to load)
- 3: End of line
- 4: Restart of a line

- INIT** Initialization of buffer with duplication, accu value reset with register value based on the field polarity if present
- Phase calculation** Phase = accu[9:7]
- Number of line(s) to load** Number of element(s) = ((accu + 512 + inc) >> 10) - ((accu + 512) >> 10)
- FIR calculation** $R_{out}(n) = \left(\sum_{i=-p}^{i=p} C_i(\phi) * R_{in}(n + i) \right) >> 7$
- Accumulator calculation** Accu = accu + inc

dss-117

12.6.1.3 Scaling Settings

NOTE:

- In this section, the screen word refers to LCD panel or TV set.
- n indicates pipeline 0 or 1 because there are two video pipelines in the DISPC.

12.6.1.3.1 Register List

The following registers define the scaling registers for the video layer n configuration:

- DSS.DISPC_VIDn_BAj
- DSS.DISPC_VIDn_ATTRIBUTES
- DSS.DISPC_VIDn_FIR

| $C_1()$ | VidFIRVC $_0()$ |
| $C_{00}()$ | VidFIRVC $_{00}()$ |

The corresponding registers for programming the vertical FIR coefficients (5-tap configuration) are:

- VidFIRVC $_{22}()$ = DSS.DISPC_VIDn_FIR_COEF_Vi[15:8] VIDFIRVC22
- VidFIRVC $_2()$ = DSS.DISPC_VIDn_FIR_COEF_HVi[31:24] VIDFIRVC2
- VidFIRVC $_1()$ = DSS.DISPC_VIDn_FIR_COEF_HVi[23:16] VIDFIRVC1
- VidFIRVC $_0()$ = DSS.DISPC_VIDn_FIR_COEF_HVi[15:8] VIDFIRVC0
- VidFIRVC $_{00}()$ = DSS.DISPC_VIDn_FIR_COEF_Vi[7:0] VIDFIRVC00

Table 12-74 lists the registers for programming the horizontal FIR coefficients (5-tap configuration).

Table 12-74. Horizontal FIR Coefficients Corresponding Table (5-Tap Configuration)

| $C_x()$ | VidFIRHC $_x()$ |
|------------|-----------------|
| $C_{-2}()$ | VidFIRHC $_4()$ |
| $C_{-1}()$ | VidFIRHC $_3()$ |
| $C_0()$ | VidFIRHC $_2()$ |
| $C_1()$ | VidFIRHC $_1()$ |
| $C_2()$ | VidFIRHC $_0()$ |

The corresponding registers for programming the vertical FIR coefficients (3-tap configuration) are:

- VidFIRHC $_4()$ = DSS.DISPC_VIDn_FIR_COEF_HVi[7:0] VIDFIRHC4
- VidFIRHC $_3()$ = DSS.DISPC_VIDn_FIR_COEF_Hi[31:24] VIDFIRHC3
- VidFIRHC $_2()$ = DSS.DISPC_VIDn_FIR_COEF_Hi[23:16] VIDFIRHC2
- VidFIRHC $_1()$ = DSS.DISPC_VIDn_FIR_COEF_Hi[15:8] VIDFIRHC1
- VidFIRHC $_0()$ = DSS.DISPC_VIDn_FIR_COEF_Hi[7:0] VIDFIRHC0

12.6.1.3.2 Enabling

The video pipeline #n is enabled/disabled by setting/resetting the DSS.DISPC_VIDn_ATTRIBUTES[0].VIDENABLE bit. While the video pipeline is enabled/disabled, the video layer is visible/not visible on the screen (LCD panel or TV set).

The video up-/downsampling block for the video pipeline #n is programmed by setting the DSS.DISPC_VIDn_ATTRIBUTES[6:5] VIDRESIZEENABLE bit field:

- When the VIDRESIZEENABLE[1] bit is set to 1, the video vertical up-/downsampling block is enabled. When set to 0, the vertical resize processing is disabled.
- When the VIDRESIZEENABLE[0] bit is set to 1, the video horizontal up-/downsampling block is enabled. When set to 0, the horizontal resize processing is disabled.
- When the VIDRESIZEENABLE[1:0] is set to 0x3, both horizontal and vertical resize processing are enabled.

NOTE:

- Set a valid configuration before enabling the video up-/downsampling block.
 - Vertical and horizontal downsampling are limited to a 0.25 resize factor. When processing a down-scaling with a vertical factor between 0.5 and 0.25, a 5-tap filter configuration must be used. See [Section 12.6.1.3.5](#) for more information concerning the filter coefficients.
-

12.6.1.3.3 Factor

The following register bit fields define the increment value of the video up-/downsampling block for video pipeline n:

- Vertical up-/downsampling increment value (DSS.DISPC_VIDn_FIR[27:16] VIDFIRVINC bit field, with n = 1 or 2): The unsigned integer value range is [1:4096]. The software calculates the value using the following equation:

$$\text{VIDFIRVINC}[11:0] = 1024 \times \frac{\text{VIDORGSIZEY}[10:0]}{\text{VIDSIZEY}[10:0]}$$

dss-E118

(12)

NOTE:

- If the VIDFIRVINC[11:0] bit field value is greater than 4096, it is clipped to 4096. If VIDSIZEY[10:0] equals 0x1, VIDSIZEY[10:0] is replaced by 0x2 in the previous equation.
 - The VIDORGSIZEY[10:0] and VIDSIZEY[10:0] bit field values must be programmed with the value desired minus 1.
-
- Horizontal up-/downsampling increment value (the DSS.DISPC_VIDn_FIR[11:0] VIDFIRHINC bit field, with n = 1 or 2): The unsigned integer value range is [1:4096]. The software calculates the value using the following equation:

$$\text{VIDFIRHINC}[11:0] = 1024 \times \frac{\text{VIDORGSIZEX}[10:0]}{\text{VIDSIZEX}[10:0]}$$

dss-E119

(13)

NOTE:

- If the VIDFIRHINC[11:0] bit field value is greater than 4096, it is clipped to 4096. If VIDSIZEX[10:0] equals 1, VIDSIZEX[10:0] is replaced by 2 in the previous equation.
 - The VIDORGSIZEX[10:0] and VIDSIZEX[10:0] bit field values must be programmed with the value desired minus 1.
-

12.6.1.3.4 Initial Phase

- Vertical up-/downsampling accumulator value DSS.DISPC_VIDn_ACCUI[25:16] VIDVERTICALACCU bit fields

The unsigned integer value range is [0:1023]. The accumulator value indicates on which phase the vertical filtering starts. The value 0 indicates that the phase 0 is the first phase used by the hardware to generate the first data.

- Vertical up-/downsampling accumulator value DSS.DISPC_VIDn_ACCUI[9:0] VIDHORIZONTALACCU bit fields

The unsigned integer value range is [0:1023]. The accumulator value indicates on which phase the horizontal filtering starts. The value 0 indicates that the phase 0 is the first phase used by the hardware to generate the first data

Table 12-75 lists the vertical/horizontal accumulator values and phases

Table 12-75. Vertical/Horizontal Accumulator Phase

| Accumulator Value | Phases |
|-------------------|--------|
| 0 | 0 |
| 128 | 1 |
| 256 | 2 |
| 384 | 3 |
| 512 | 4 |
| 640 | 5 |
| 768 | 6 |
| 896 | 7 |

NOTE: For LCD output, the initial phase is always 0 (horizontal and vertical.) For TV output, the vertical phases (odd and even) can be nonzero values.

12.6.1.3.5 Coefficients

- **Vertical up-/downsampling coefficients (DSS.DISPC_VIDn_FIR_COEF_HVi and DSS.DISPC_VIDn_FIR_COEF_V)**

The 3-tap vertical up-/downsampling coefficients are defined in DSS.DISPC_VIDn_FIR_COEF_HVi registers. There are eight registers for the eight phases with three coefficients for each of them so a total of 24 programmable coefficients for the vertical up-/downsampling block. Each register contains two 8-bit signed coefficients and one 8-bit unsigned coefficient (central one).

In addition, there are 2-tap vertical up-/downsampling coefficients defined in DSS.DISPC_VIDn_FIR_COEF_Vi registers. There are eight registers for the eight phases with two coefficients for each of them so a total of 16 programmable coefficients for the vertical up-/downsampling block used in addition of the 3-tap registers defined above. Each register contains two 8-bit signed coefficients ($C_{22}()$ and $C_{00}()$).

In case of 5-tap configuration, both sets of registers, DSS.DISPC_VIDn_FIR_COEF_HVi and DSS.DISPC_VIDn_FIR_COEF_V, are used. In case of 3-tap configuration, only one set of registers, DSS.DISPC_VIDn_FIR_COEF_HV, is used.

- **Horizontal up-/downsampling coefficients (DSS.DISPC_VIDn_FIR_COEF_Hi and DSS.DISPC_VIDn_FIR_COEF_HV)**

The 5-tap horizontal up-/downsampling coefficients are defined in DSS.DISPC_VIDn_FIR_COEF_Hi and DSS.DISPC_VIDn_FIR_COEF_HVi registers. There are eight registers for the eight phases with five coefficients for each register, for a total of 40 programmable coefficients for the horizontal up-/downsampling block.

Each DSS.DISPC_VIDn_FIR_COEF_Hi register contains three 8-bit signed coefficients and one 8-bit unsigned coefficient (central one), and each DSS.DISPC_VIDn_FIR_COEF_HVi contains one 8-bit signed coefficient.

Table 12-76 through Table 12-81 give the programmable coefficients for the FIR up/downsampling filters (Max-Fauque-Berthier method).

12.6.1.3.5.1 Up-Sampling

Table 12-76 gives the 24 coefficients to program the vertical upsampling (3-tap configuration).

Table 12-76. Up-Sampling Vertical Filter Coefficients (Three Taps)

| Phases | VidFIRVC ₂ () | VidFIRVC ₁ () | VidFIRVC ₀ () |
|--------|--------------------------|--------------------------|--------------------------|
| 0 | 0 | 128 | 0 |
| 1 | 3 | 123 | 2 |
| 2 | 12 | 111 | 5 |
| 3 | 32 | 89 | 7 |
| 4 | 0 | 64 | 64 |
| 5 | 7 | 89 | 32 |
| 6 | 5 | 111 | 12 |
| 7 | 2 | 123 | 3 |

Table 12-77 gives the 40 coefficients to program the vertical upsampling (5-tap configuration).

Table 12-77. Up-Sampling Vertical Filter Coefficients (Five Taps)

| Phases | VidFIRVC ₂₂ () | VidFIRVC ₂ () | VidFIRVC ₁ () | VidFIRVC ₀ () | VidFIRVC ₀₀ () |
|--------|---------------------------|--------------------------|--------------------------|--------------------------|---------------------------|
| 0 | 0 | 0 | 128 | 0 | 0 |
| 1 | -1 | 13 | 124 | -8 | 0 |
| 2 | -2 | 30 | 112 | -11 | -1 |
| 3 | -5 | 51 | 95 | -11 | -2 |
| 4 | 0 | -9 | 73 | 73 | -9 |
| 5 | -2 | -11 | 95 | 51 | -5 |
| 6 | -1 | -11 | 112 | 30 | -2 |
| 7 | 0 | -8 | 124 | 13 | -1 |

Table 12-78 gives the 40 coefficients to program the horizontal upsampling (5-tap configuration).

Table 12-78. Up-Sampling Horizontal Filter Coefficients (Five Taps)

| Phases | VidFIRHC ₄ () | VidFIRHC ₃ () | VidFIRHC ₂ () | VidFIRHC ₁ () | VidFIRHC ₀ () |
|--------|--------------------------|------------------------------|--------------------------|--------------------------|--------------------------|
| 0 | 0 | 0 | 128 | 0 | 0 |
| 1 | -1 | 13 | 124 | -8 | 0 |
| 2 | -2 | 30 | 112 | -11 | -1 |
| 3 | -5 | 51 | 95 | -11 | -2 |
| 4 | 0 | -9 | 73 | 73 | -9 |
| 5 | -2 | -11 | 95 | 51 | -5 |
| 6 | -1 | -11 | 112 | 30 | -2 |
| 7 | 0 | -8 | 124 | 13 | -1 |

The upsampling coefficients register configuration (vertical three taps and horizontal five taps) is the following:

- DSS.DISPC_VIDn_FIR_COEF_H0 = 0x00800000
- DSS.DISPC_VIDn_FIR_COEF_HV0 = 0x00800000
- DSS.DISPC_VIDn_FIR_COEF_H1 = 0x0D7CF800
- DSS.DISPC_VIDn_FIR_COEF_HV1 = 0x037B02FF
- DSS.DISPC_VIDn_FIR_COEF_H2 = 0x1E70F5FF
- DSS.DISPC_VIDn_FIR_COEF_HV2 = 0x0C6F05FE
- DSS.DISPC_VIDn_FIR_COEF_H3 = 0x335FF5FE
- DSS.DISPC_VIDn_FIR_COEF_HV3 = 0x205907FB
- DSS.DISPC_VIDn_FIR_COEF_H4 = 0xF74949F7
- DSS.DISPC_VIDn_FIR_COEF_HV4 = 0x00404000
- DSS.DISPC_VIDn_FIR_COEF_H5 = 0xF55F33FB
- DSS.DISPC_VIDn_FIR_COEF_HV5 = 0x075920FE

- DSS.DISPC_VIDn_FIR_COEF_H6 = 0xF5701EFE
- DSS.DISPC_VIDn_FIR_COEF_HV6 = 0x056F0CFF
- DSS.DISPC_VIDn_FIR_COEF_H7 = 0xF87C0DFF
- DSS.DISPC_VIDn_FIR_COEF_HV7 = 0x027B0300

NOTE: In this case, the DSS.DISPC_VIDn_FIR_COEF_Vi registers are not used.

The upsampling coefficients register configuration (both vertical and horizontal five taps) is the following:

- DSS.DISPC_VIDn_FIR_COEF_H0 = 0x00800000
- DSS.DISPC_VIDn_FIR_COEF_HV0 = 0x00800000
- DSS.DISPC_VIDn_FIR_COEF_V0 = 0x00000000
- DSS.DISPC_VIDn_FIR_COEF_H1 = 0x0D7CF800
- DSS.DISPC_VIDn_FIR_COEF_HV1 = 0x0D7CF8FF
- DSS.DISPC_VIDn_FIR_COEF_V1 = 0x0000FF00
- DSS.DISPC_VIDn_FIR_COEF_H2 = 0x1E70F5FF
- DSS.DISPC_VIDn_FIR_COEF_HV2 = 0x1E70F5FE
- DSS.DISPC_VIDn_FIR_COEF_V2 = 0x0000FEFF
- DSS.DISPC_VIDn_FIR_COEF_H3 = 0x335FF5FE
- DSS.DISPC_VIDn_FIR_COEF_HV3 = 0x335FF5FB
- DSS.DISPC_VIDn_FIR_COEF_V3 = 0x0000FBFE
- DSS.DISPC_VIDn_FIR_COEF_H4 = 0xF74949F7
- DSS.DISPC_VIDn_FIR_COEF_HV4 = 0xF7404000
- DSS.DISPC_VIDn_FIR_COEF_V04 = 0x000000F7
- DSS.DISPC_VIDn_FIR_COEF_H5 = 0xF55F33FB
- DSS.DISPC_VIDn_FIR_COEF_HV5 = 0xF55F33FE
- DSS.DISPC_VIDn_FIR_COEF_V5 = 0x0000FEFB
- DSS.DISPC_VIDn_FIR_COEF_H6 = 0xF5701EFE
- DSS.DISPC_VIDn_FIR_COEF_HV6 = 0xF5701EFF
- DSS.DISPC_VIDn_FIR_COEF_V6 = 0x0000FFFE
- DSS.DISPC_VIDn_FIR_COEF_H7 = 0xF87C0DFF
- DSS.DISPC_VIDn_FIR_COEF_HV7 = 0xF87C0D00
- DSS.DISPC_VIDn_FIR_COEF_V7 = 0x000000FF

12.6.1.3.5.2 Down-Sampling

Table 12-79 gives the 24 coefficients to program the vertical downsampling (3-tap configuration).

Table 12-79. Down-Sampling Vertical Filter Coefficients (Three Taps)

| Phases | VidFIRVC ₂ () | VidFIRVC ₁ () | VidFIRVC ₀ () |
|--------|--------------------------|--------------------------|--------------------------|
| 0 | 36 | 56 | 36 |
| 1 | 40 | 57 | 31 |
| 2 | 45 | 56 | 27 |
| 3 | 50 | 55 | 23 |
| 4 | 18 | 55 | 55 |
| 5 | 23 | 55 | 50 |
| 6 | 27 | 56 | 45 |
| 7 | 31 | 57 | 40 |

Table 12-80 gives the 40 coefficients to program the vertical downsampling (5-tap configuration).

Table 12-80. Down-Sampling Vertical Filter Coefficients (Five Taps)

| Phases | VidFIRVC ₂₂ () | VidFIRVC ₂ () | VidFIRVC ₁ () | VidFIRVC ₀ () | VidFIRVC ₀₀ () |
|--------|---------------------------|--------------------------|--------------------------|--------------------------|---------------------------|
| 0 | 0 | 36 | 56 | 36 | 0 |
| 1 | 4 | 40 | 55 | 31 | -2 |
| 2 | 8 | 44 | 54 | 27 | -5 |
| 3 | -12 | 48 | 53 | 22 | -7 |
| 4 | -9 | 17 | 52 | 51 | 17 |
| 5 | -7 | 22 | 53 | 48 | 12 |
| 6 | -5 | 27 | 54 | 44 | 8 |
| 7 | -2 | 31 | 55 | 40 | 4 |

Table 12-81 gives the 40 coefficients to program the horizontal downsampling (5-tap configuration).

Table 12-81. Down-Sampling Horizontal Filter Coefficients (Five Taps)

| Phases | VidFIRHC ₄ () | VidFIRHC ₃ () | VidFIRHC ₂ () | VidFIRHC ₁ () | VidFIRHC ₀ () |
|--------|--------------------------|------------------------------|--------------------------|--------------------------|--------------------------|
| 0 | 0 | 36 | 56 | 36 | 0 |
| 1 | 4 | 40 | 55 | 31 | -2 |
| 2 | 8 | 44 | 54 | 27 | -5 |
| 3 | -12 | 48 | 53 | 22 | -7 |
| 4 | -9 | 17 | 52 | 51 | 17 |
| 5 | -7 | 22 | 53 | 48 | 12 |
| 6 | -5 | 27 | 54 | 44 | 8 |
| 7 | -2 | 31 | 55 | 40 | 4 |

The downsampling coefficients register configuration (vertical three taps and horizontal five taps) is the following:

- DSS.DISPC_VIDn_FIR_COEF_H0 = 0x24382400
- DSS.DISPC_VIDn_FIR_COEF_HV0 = 0x24382400
- DSS.DISPC_VIDn_FIR_COEF_H1 = 0x28371FFE
- DSS.DISPC_VIDn_FIR_COEF_HV1 = 0x28391F04
- DSS.DISPC_VIDn_FIR_COEF_H2 = 0x2C361BFB
- DSS.DISPC_VIDn_FIR_COEF_HV2 = 0x2D381B08
- DSS.DISPC_VIDn_FIR_COEF_H3 = 0x303516F9
- DSS.DISPC_VIDn_FIR_COEF_HV3 = 0x3237170C
- DSS.DISPC_VIDn_FIR_COEF_H4 = 0x11343311
- DSS.DISPC_VIDn_FIR_COEF_HV4 = 0x123737F7
- DSS.DISPC_VIDn_FIR_COEF_H5 = 0x1635300C
- DSS.DISPC_VIDn_FIR_COEF_HV5 = 0x173732F9
- DSS.DISPC_VIDn_FIR_COEF_H6 = 0x1B362C08
- DSS.DISPC_VIDn_FIR_COEF_HV6 = 0x1B382DFB
- DSS.DISPC_VIDn_FIR_COEF_H7 = 0x1F372804
- DSS.DISPC_VIDn_FIR_COEF_HV7 = 0x1F3928FE

NOTE:

- In this case, the DSS.DISPC_VIDn_FIR_COEF_Vi registers are not used.
- In this case, the downsampling factor must be higher than 1/2.

The downsampling coefficients register configuration (both the vertical and the horizontal five taps) is the following:

- DSS.DISPC_VIDn_FIR_COEF_H0 = 0x24382400
- DSS.DISPC_VIDn_FIR_COEF_HV0 = 0x24382400
- DSS.DISPC_VIDn_FIR_COEF_V0 = 0x00000000
- DSS.DISPC_VIDn_FIR_COEF_H1 = 0x28371FFE
- DSS.DISPC_VIDn_FIR_COEF_HV1 = 0x28371F04
- DSS.DISPC_VIDn_FIR_COEF_V1 = 0x000004FE
- DSS.DISPC_VIDn_FIR_COEF_H2 = 0x2C361BFB
- DSS.DISPC_VIDn_FIR_COEF_HV2 = 0x2C361B08
- DSS.DISPC_VIDn_FIR_COEF_V2 = 0x000008FB
- DSS.DISPC_VIDn_FIR_COEF_H3 = 0x303516F9
- DSS.DISPC_VIDn_FIR_COEF_HV3 = 0x3035160C
- DSS.DISPC_VIDn_FIR_COEF_V3 = 0x00000CF9
- DSS.DISPC_VIDn_FIR_COEF_H4 = 0x11343311
- DSS.DISPC_VIDn_FIR_COEF_HV4 = 0x113433F7
- DSS.DISPC_VIDn_FIR_COEF_V4 = 0x0000F711
- DSS.DISPC_VIDn_FIR_COEF_H5 = 0x1635300C
- DSS.DISPC_VIDn_FIR_COEF_HV5 = 0x163530F9
- DSS.DISPC_VIDn_FIR_COEF_V5 = 0x0000F90C
- DSS.DISPC_VIDn_FIR_COEF_H6 = 0x1B362C08
- DSS.DISPC_VIDn_FIR_COEF_HV6 = 0x1B362CFB
- DSS.DISPC_VIDn_FIR_COEF_V6 = 0x0000FB08
- DSS.DISPC_VIDn_FIR_COEF_H7 = 0x1F372804
- DSS.DISPC_VIDn_FIR_COEF_HV7 = 0x1F3728FE
- DSS.DISPC_VIDn_FIR_COEF_V7 = 0x0000FE04

NOTE: This configuration must be used for vertical downsampling factors between 1/2 and 1/4

12.6.2 Display Low-Power Refresh Settings

This section describes the display low-power refresh application on the device. The display subsystem remains active while saving power by putting unused power domains and unused modules into idle mode. This process can be expanded to include the screen saver mode in which the MPU subsystem wakes up to update the frame buffer and then returns to idle mode. On an OMAP platform, where power consumption is of high importance, the display modes must be configured properly to achieve optimal power savings.

The display low-power refresh mode can be used in the following scenarios:

- During the period of time when there is no application running and the backlight turns off.
- Once the backlight turns off, the LCD display can be shut off or can be refreshed showing the time and date. The screen saver mode can be used to update the time every minute.

This section discusses the methodology for finding optimal power savings. These settings are detailed for a 16-bit, 240 x 320 pixel QVGA LCD.

12.6.2.1 Display Low-Power Refresh Overview

When the device is not in idle mode, meaning all clocks are on and the power is applied to all power domains, the following activity typically occurs with respect to the display subsystem:

- The MPU subsystem is processing
- The display subsystem DMA controller is moving data from the SDRAM frame buffer location to the display subsystem internal FIFO.
- The LCD data is being sent from the internal FIFO to the display panel.

When the MPU goes into idle mode, the following activity occurs:

- The display subsystem DMA controller remains active, moving data from the SDRAM frame buffer to the internal FIFO.
- The SDRAM will go in and out of self-refresh between transfers.
- The display subsystem internal FIFO will continue to send LCD data to the display panel.

This procedure is named as the display low-power refresh scenario.

NOTE: In the device, the display subsystem has its own power domain (the DSS power domain).

12.6.2.2 Display Subsystem Clock

12.6.2.2.1 Display Subsystem Clock Configuration

The display subsystem contains two possible functional clock sources, DSS functional clock 1 (DSS1_ALWON_FCLK) and DSI PLL functional clock 1 (DSI1_PLL_FCLK):

- DSS1_ALWON_FCLK is sourced from DPLL4 (DPLL4_ALWON_FCLK), with several multipliers available and is configured in the PRCM.CM_CLKSEL_DSS[4:0] CLKSEL_DSS1 bit field.
- DSI1_PLL_FCLK is one of the two output clocks from the DSI PLL.

The pixel clock is set as either DSS1_ALWON_FCLK or DSI1_PLL_FCLK by configuring the DSS.DSS_CONTROL[0] DISPC_CLK_SWITCH bit

NOTE: When the DSI PLL is in bypass mode, the DSI1_PLL_FCLK clock is the DSS2_ALWON_FCLK clock. This ensures the backward compatibility with OMAP2 devices.

The LCD logic clock is determined by the DSS.DISPC_DIVISOR[23:16] LCD bit field. This divisor is used on the DSS functional clock that is selected in the DSS_CONTROL register (either DSS1_ALWON_FCLK or DSS2_ALWON_FCLK). This LCD divisor selects the logical clock frequency which is used to clock the logic in the display subsystem. For some applications there is a required minimum logical clock frequency. The lower the logical clock frequency then the lower the power consumption.

The pixel clock is determined by setting the DSS.DISPC_DIVISOR[7:0] PCD bit field. This divisor is used on the LCD logic clock.

In the following example, the DPLL4 clock (DPLL4_ALWON_FCLK) is enabled and running at 266 MHz:

The PRCM.CM_CLKSEL2_PLL[18:8] PERIPH_DPLL_MULT bit field is set to 0x4 and the PRCM.CM_CLKSEL2_PLL[6:0] PERIPH_DPLL_DIV bit field is set to 0x1 (DPLL4 x 4/(1+1)):

$$DPLL4_ALWON_FCLKOUTX2 = DPLL4_ALWON_FCLK(266MHz) \times 4/2 = 532 \text{ MHz}$$

NOTE: The DPLL4_ALWON_FCLKOUTX2 clock is an internal clock in DPLL4 module after the DPLL_MULT and DPLL_DIV stages. The DPLL4_M4X2_CLK clock is one of the DPLL4 output clocks and is the clock source for DSS1_ALWON_FCLK.

The DSS.DSS_CONTROL[0] DSS_CLK_SWITCH bit is set to 0x0 to select DSS1_ALWON_FCLK as the display subsystem functional clock:

$$DSS1_ALWON_FCLK = DPLL4_M4X2_CLK$$

The PRCM.CM_CLKSEL_DSS[4:0] CLKSEL_DSS1 bit field is set to 0x08:

$$DSS1_ALWON_FCLK = \frac{DPLL4_ALWON_FCLKOUTX2(532MHz)}{8} = 66.5 \text{ MHz}$$

dss-E120

(14)

The DSS.DISPC_DIVISOR[23:16] LCD bit field is set to 0x01:

$$\text{LogicClock} = \frac{DSS1_ALWON_FCLK(66.5MHz)}{1} = 66.5 \text{ Mhz}$$

dss-E121

(15)

The DSS.DISPC_DIVISOR[6:0] PCD bit field is set to 0x0C:

$$\text{PixelClock} = \frac{\text{LogicClock}(66.5\text{MHz})}{12} = 5.54 \text{ Mhz}$$

dss-E122

(16)

12.6.2.2.1.1 Pixel Clock Frequency Settings to Reduce Power Consumption

Power consumption is reduced when a low pixel clock frequency is used. If the clock frequency is set too low, however, the frames-per-second (FPS) are reduced. This can result in visible flickering on the screen each time the screen is refreshed. To avoid electrical polarization problems, refer to the appropriate LCD panel datasheet to determine the maximum range of pixel clock frequency variation. To save power, therefore, the pixel clock frequency during low-power mode must be set as low as possible, but high enough to eliminate visible flickering

12.6.2.2.1.2 Display Subsystem Divider Settings to Reduce Power Consumption

The pixel clock is determined by the DSS.DISPC_DIVISOR[7:0] PCD and DSS.DISPC_DIVISOR[23:16] LCD settings. In most cases, the LCD[7:0] bit field is set to 0x1 and the PCD[7:0] bit field is used as the main divider. To reduce power consumption, software users should investigate if the DSS.DISPC_DIVISOR[23:16] LCD bit field can be set to a value other than 0x1 and then decrease DSS.DISPC_DIVISOR[7:0] PCD bit field value. For example, if the desired pixel clock is 1.625 MHz with a 13-MHz functional clock, then this pixel clock can be achieved by setting DSS.DISPC_DIVISOR[23:16] LCD to 0x1 and DSS.DISPC_DIVISOR[7:0] PCD to 0x8. The same pixel clock can be achieved by setting DSS.DISPC_DIVISOR[23:16] LCD to 0x2 and DSS.DISPC_DIVISOR[7:0] PCD to 0x4.

12.6.2.2.2 Display Subsystem Clock Enable

To take the DSS out of reset, all DSS-related clocks must be enabled, and the DPLL4 clock must be enabled. After taking the DSS out of reset, these clocks can be disabled if they are not used. The following clocks must be enabled before the DSS can come out of reset:

- PRCM.CM_FCLKEN_DSS[0] EN_DSS1 = 0x1
- PRCM.CM_FCLKEN_DSS[1] EN_DSS2 = 0x1
- PRCM.CM_FCLKEN_DSS[2] EN_TV = 0x1
- PRCM.CM_ICLKEN_DSS[0] EN_DSS = 0x1
- PRCM.CM_CLKEN_PLL[18:16] EN_PERIPH_DPLL = 0x7

Once these clocks are enabled, the display subsystem can be taken out of reset.

The following sections explain the display low-power mode configuration options, which are determined by product requirements (LCD panel type).

12.6.2.3 DPLL4 in Low-Power Mode

For optimal power savings in low-power mode, DPLL4 can be put into low-power stop mode. Thus the DSS1_ALWON_FCLK clock cut when DPLL4 is in low-power stop mode. Software users must switch from DSS1_ALWON_FCLK to DSI1_PLL_FCLK by setting the DSS.DSS_CONTROL[0] DISPC_CLK_SWITCH bit to 0x1.

NOTE: Before switching to DSI1_PLL_FCLK, the DSI PLL and the HS divider must be programmed and the DSI PLL must be locked.

DPLL4 can be put in low-power stop mode in either of the following methods:

- Manually: When setting the PRCM.CM_CLKEN_PLL[18:16] EN_PERIPH_DPLL bit to 0x1.
- Automatically: When setting the PRCM.CM_AUTOIDLE_PLL[5:3] AUTO_PERIPH_DPLL bit field to 0x1. DPLL4 is automatically put in low-power stop mode when none of the 96-MHz and 54-MHz clocks are required anymore. DPLL4 is also restarted automatically.

Software users must remember to change the clock configuration after enabling DPLL4 when leaving low-power mode by setting the DSS.DSS_CONTROL[0] DISPC_CLK_SWITCH bit to 0x0. The DSS1_ALWON_FCLK clock will be selected.

Lock time must be considered before disabling the DSS1_ALWON_FCLK clock.

12.6.2.4 Autoidle and Smart Idle

12.6.2.4.1 Autoidle

To further save power consumption, the autoidle feature at the module can be enabled for the active modules. For example, the PRCM and the system control modules are active during this mode. By enabling the autoidle feature, the clocks at the module level are gated when they are not needed.

The RFBI, display controller, and L4 interfaces can internally gate their clocks to decrease power consumption if no transaction is present on the related bus. The following bits must be set to enable this functionality:

- DSS.DSS_SYSCONFIG[0] AUTOIDLE bit (1: Autoidle; 0: Clock free-running) for the display subsystem
- DSS.RFBI_SYSCONFIG[0] AUTOIDLE bit (1: Autoidle; 0: Clock free-running) for the RFBI
- DSS.DISPC_SYSCONFIG[0] AUTOIDLE bit (1: Autoidle; 0: Clock free-running) for the display controller
- DSS.DISPC_CONFIG[9] FUNCGATED bit (1: Functional clocks gated enabled, 0: Functional clocks gated disabled) for the display controller

12.6.2.4.2 Smart-Idle

The smart-idle feature can be enabled to allow the module to enter idle when the clocks are not needed. The smart-idle feature can be enabled for the display subsystem submodules to further save power consumption:

- Display subsystem: DSS.DSS_SYSCONFIG[4:3] SIDLEMODE
- Display controller: DSS.DISPC_SYSCONFIG[4:3] SIDLEMODE
- RFBI: DSS.RFBI_SYSCONFIG[4:3] SIDLEMODE

12.6.2.5 FIFO Thresholds

The display subsystem internal FIFO is used to move data to the LCD panel. This FIFO is filled by the display subsystem DMA controller. The DMA controller is triggered to start and stop based on two thresholds:

- DSS.DISPC_GFX_FIFO_THRESHOLD[11:0] GFXFIFOWHRESHOLD
- DSS.DISPC_GFX_FIFO_THRESHOLD[27:16] GFXFIFOHIGHTHRESHOLD

When the level of the FIFO reaches the low threshold, the internal DMA controller begins to fill the FIFO with the data in the frame buffer. Once the amount of pixel data reaches the high threshold, the internal DMA controller stops.

12.6.2.5.1 FIFO Threshold Settings to Reduce Power Consumption

Power consumption is reduced by increasing the difference between the high and low FIFO threshold levels, thereby leaving the SDRAM in self-refresh for a longer period of time. To perform this reduction, consider the following:

- The low FIFO threshold level must be as low as possible, but not low enough to cause any underflow.
- The high FIFO threshold level must not exceed the FIFO size minus one burst. A value above this limit results in the DMA controller trying to fill the FIFO to a level that cannot be reached, which will increase power consumption.
- The difference between high and low FIFO threshold levels must not be less than one burst size. These settings do not reduce power consumption because the SDRAM never goes into self-refresh, but they will avoid underflow.

12.6.2.6 Vertical and Horizontal Timings

The vertical and horizontal timings and the pixel clock speed determine the number of frames updated per second. Figure 12-158 shows the timings for a 240 x 320 pixel QVGA LCD panel. If the pulse width (also called blanking) and the front porch parameters are increased, more setup time is added before the data is transferred. This additional time is beneficial for delaying the data transfer if the data is not ready because of bandwidth limitations. Care must be taken to determine the fps when modifying these parameters.

Use the following formula to determine the fps for a 240 x 320 QVGA LCD:

$$f_{ps} = \frac{1}{[(Hsw + 1) + (Hrp + 1) + 240 + (Hbp + 1)] \times [(Vsw + 1) + Vrp + 320 + Vbp]} \times (PCLK)$$

dss-E123

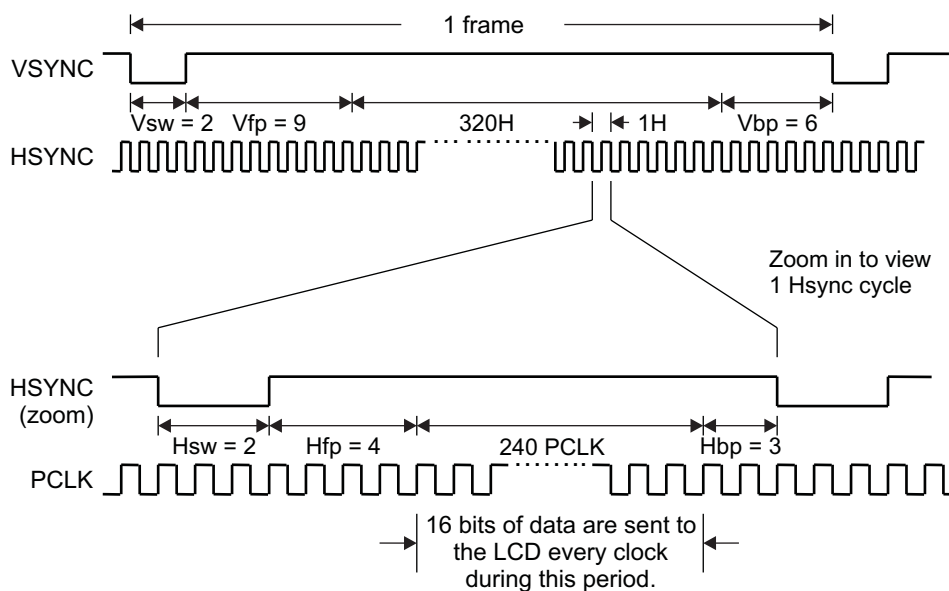

(17)

With:

- Hsw: DSS.DISPC_TIMING_H[7:0] HSW bit field value
- Hp: DSS.DISPC_TIMING_H[19:8] HFP bit field value
- Hbp: DSS.DISPC_TIMING_H[31:20] HBP bit field value
- Vsw: DSS.DISPC_TIMING_V[7:0] VSW bit field value
- Vp: DSS.DISPC_TIMING_V[19:8] VFP bit field value
- Vpb: DSS.DISPC_TIMING_V[31:20] VBP bit field value
- PCLK: Pixel clock period

The horizontal (Hsw) and vertical (Vsw) pulse widths and the horizontal front (Hp) and back (Hbp) porches are increased by 1 because the value is programmed as the desired value minus 1.

Figure 12-158. QVGA LCD Timings

The fps for the example of 6-MHz pixel clock with the setting shown in Figure 12-158 is as follows:

$$f_{ps} = \frac{1}{[(2 + 1) + 4 + 240 + 3] \times [(2 + 1) + 9 + 320 + 6]} \times 166.67 \times 10^{-9}$$

dss-E125

(18)

$$fps = 71Hz$$

12.6.2.6.1 Horizontal and Vertical Timing Settings to Reduce Power Consumption

The number of fps that the screen is refreshed is also determined by the vertical and horizontal timings. Consequently, longer timings between frames (blanking periods) reduce the fps and reduce average power consumption. Shorter blanking periods increase fps and increases power consumption. If the blanking between frames is too small, a FIFO underflow may occur.

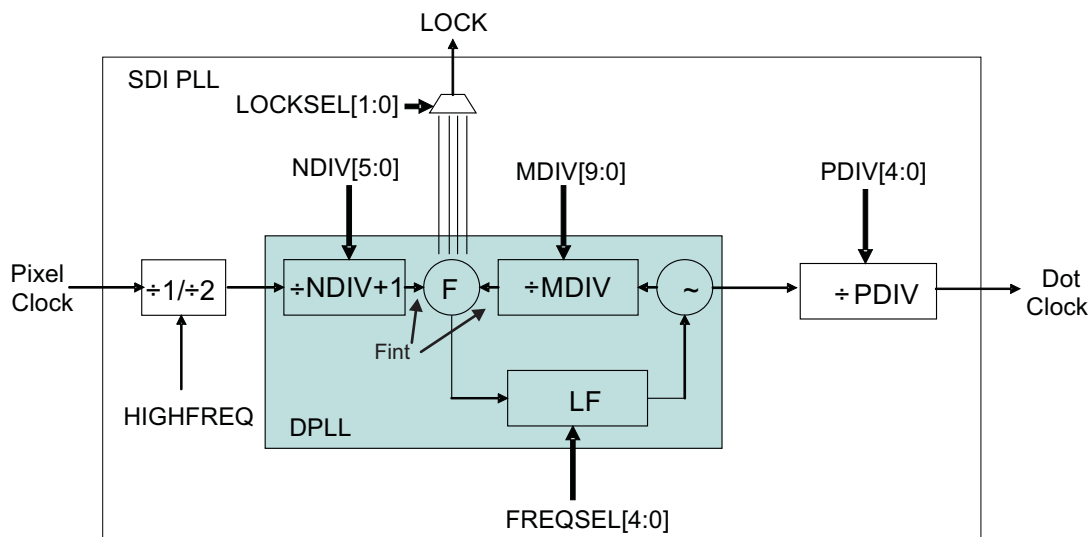

12.6.3 How to Configure the Serial Display Interface Module With FlatLink3G Protocol

This section describes the basic settings of Serial Display Interface (SDI) module and related Phase-Locked Loop (PLL).

12.6.3.1 SDI PLL Architecture

The SDI PLL architecture is based on the Digital Phase-Locked Loop (DPLL) that is described in , *Power, Reset, and Clock Management*. [Figure 12-159](#) gives a functional description of the SDI PLL.

Figure 12-159. SDI PLL Architecture

dss-126

NOTE:

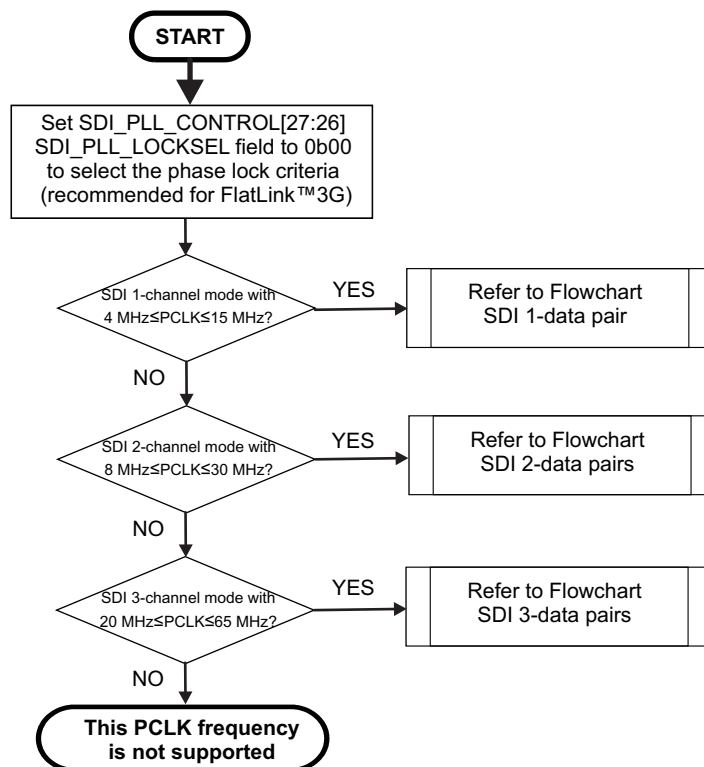

- FlatLink3G data rate is always at SCLK frequency.
- Software programmers must ensure that Pixel Clock = Dot Clock. If it is not the case the DSS.DSS_SDI_STATUS[3] SDI_ERROR status bit will be set indicating the pixel buffer overflow/underflow.

12.6.3.2 SDI PLL Configuration

The SDI PLL configuration depends on the pixel clock (PCLK), and on the number of data pairs in the FlatLink 3G protocol.

The following flowcharts detail the SDI PLL configuration from the PCLK frequency point of view. [Figure 12-160](#) is the main flowchart. See [Figure 12-161](#), [Figure 12-162](#), and [Figure 12-163](#) for details in PLL setting depending the PCLK input frequency.

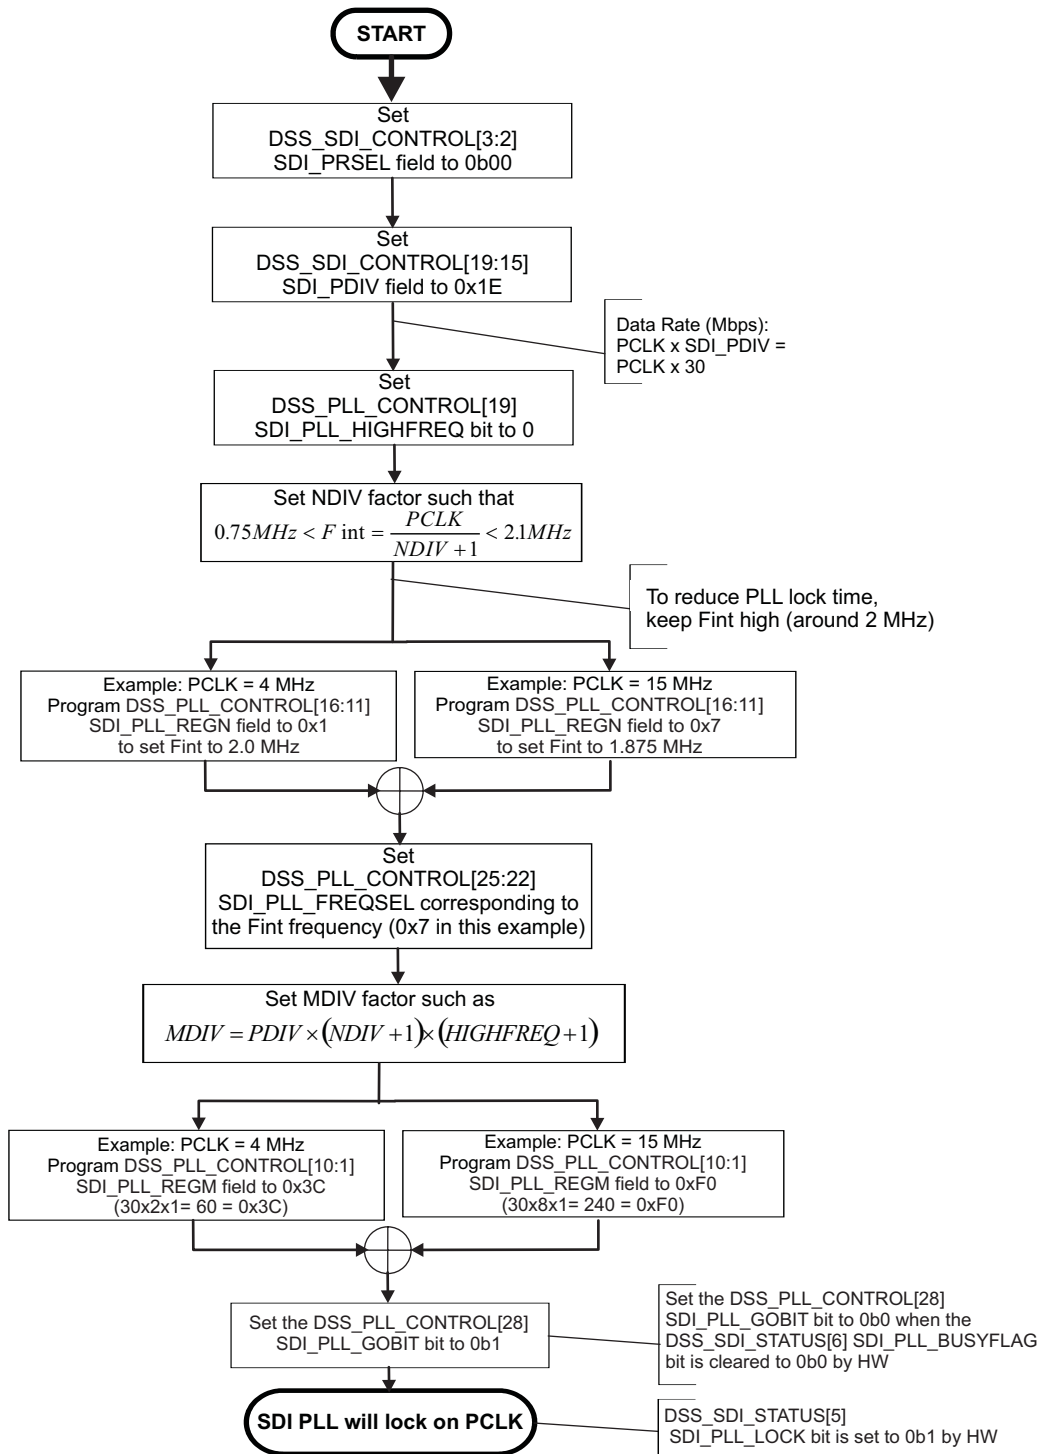

Figure 12-160. Main Flowchart

dss-127

NOTE: Compliance with the above ranges is required to meet the SN65LVDS302 receiver specifications.

Figure 12-161. Flowchart SDI 1-Data Pair

dss-128

Figure 12-162. Flowchart SDI 2-Data Pairs

dss-129

Figure 12-163. Flowchart SDI 3-Data Pairs

dss-130

CAUTION

The PLL low-power mode (LP mode) can be activated with DSS.DSS_PLL_CONTROL[21] SDI_PLL_PLLLPMode bit. By setting this bit to 1, software users reduce the power and increases the jitter. In LP mode, there is no effect on lock time; but in this mode, the SDI PLL allows only 0.75-2.1MHz range (DSS.DSS_PLL_CONTROL[25:22] SDI_PLL_FREQSEL bit field value between 0x3 and 0x7). If software users are using the range 7.5 MHz to 21 MHz (DSS.DSS_PLL_CONTROL[25:22] SDI_PLL_FREQSEL bit field value between 0xB and 0xF) in non-LP mode, and then switching to LP mode and setting the PLL in the range of 0.75 MHz to 2.1 MHz, there will be an effect on the lock time.

12.6.3.3 Application Example: HVGA Display

The following example details the SDI PLL settings for a half-VGA display with the following parameters shown in Figure 12-164.

Figure 12-164. HVGA Display

dss-131

12.6.3.3.1 HVGA Display

- Display resolution: 320 x 480
- Frame refresh rate: 58.4 Hz
- Vertical visible pixel: 480 lines
- Vertical front porch: 20 lines
- Vertical sync: 5 lines
- Vertical back porch: 3 lines
- Horizontal visible pixel: 320 columns
- Horizontal front porch: 10 columns
- Horizontal sync: 5 columns
- Horizontal back porch: 3 columns

The calculation of the total number of pixel and Blanking overhead is as follows:

- Visible area pixel count: $480 \times 320 = 153600$ pixel
- Total frame pixel count: $(480 + 20 + 5 + 3) \times (320 + 10 + 5 + 3) = 171704$ pixel
- Blanking overhead: $(171704 - 153600) / 153600 = 11.8\%$

This application requires the following SDI parameters:

- Pixel clock frequency: $171704 \times 58.4 \text{ Hz} = 10.03 \text{ MHz}$
- Serial data rate:
 - 1-channel mode: $10.03 \text{ MHz} \times 30 \text{ bit/channel} = 300.9 \text{ Mbps}$
 - 2-channel mode: $10.03 \text{ MHz} \times 15 \text{ bit/channel} = 150.45 \text{ Mbps}$

12.6.3.3.2 SDI PLL Settings for 1-Channel Mode:

- 1-data pair: Set [DSS_SDI_CONTROL\[3:2\]](#) SDI_PRSEL bit field to 0b00.
- Set the [DSS_SDI_CONTROL\[19:15\]](#) SDI_PDIV bit field to 0x1E.
- Set the [DSS_PLL_CONTROL\[19\]](#) SDI_PLL_HIGHFREQ bit to 0.
- Set the [DSS_PLL_CONTROL\[16:11\]](#) SDI_PLL_REGN bit field to 0x4. Thus Fint will be set to 2 MHz.
- Set the [DSS_PLL_CONTROL\[25:22\]](#) SDI-PLL_FREQSEL bit field to 0x7.
- Set [DSS_PLL_CONTROL\[10:1\]](#) SDI_PLL_REGM bit field to 0x96 ($30 \times 5 \times 1 = 150 = 0x96$).

12.6.3.3.3 SDI PLL Settings for 2-Channel Mode:

- 2-data pair: Set [DSS_SDI_CONTROL\[3:2\]](#) SDI_PRSEL bit field to 0b01.
- Set the [DSS_SDI_CONTROL\[19:15\]](#) SDI_PDIV bit field to 0x0F.
- Set the [DSS_PLL_CONTROL\[19\]](#) SDI_PLL_HIGHFREQ bit to 0.
- Set the [DSS_PLL_CONTROL\[16:11\]](#) SDI_PLL_REGN bit field to 0x4. Thus Fint will be set to 2 MHz.
- Set the [DSS_PLL_CONTROL\[25:22\]](#) SDI-PLL_FREQSEL bit field to 0x7.
- Set [DSS_PLL_CONTROL\[10:1\]](#) SDI_PLL_REGM bit field to 0x4B ($15 \times 5 \times 1 = 75 = 0x4B$).

12.6.4 How to Interface OMAP Device With SN65LVDS302 Receiver for an XGA Display Application

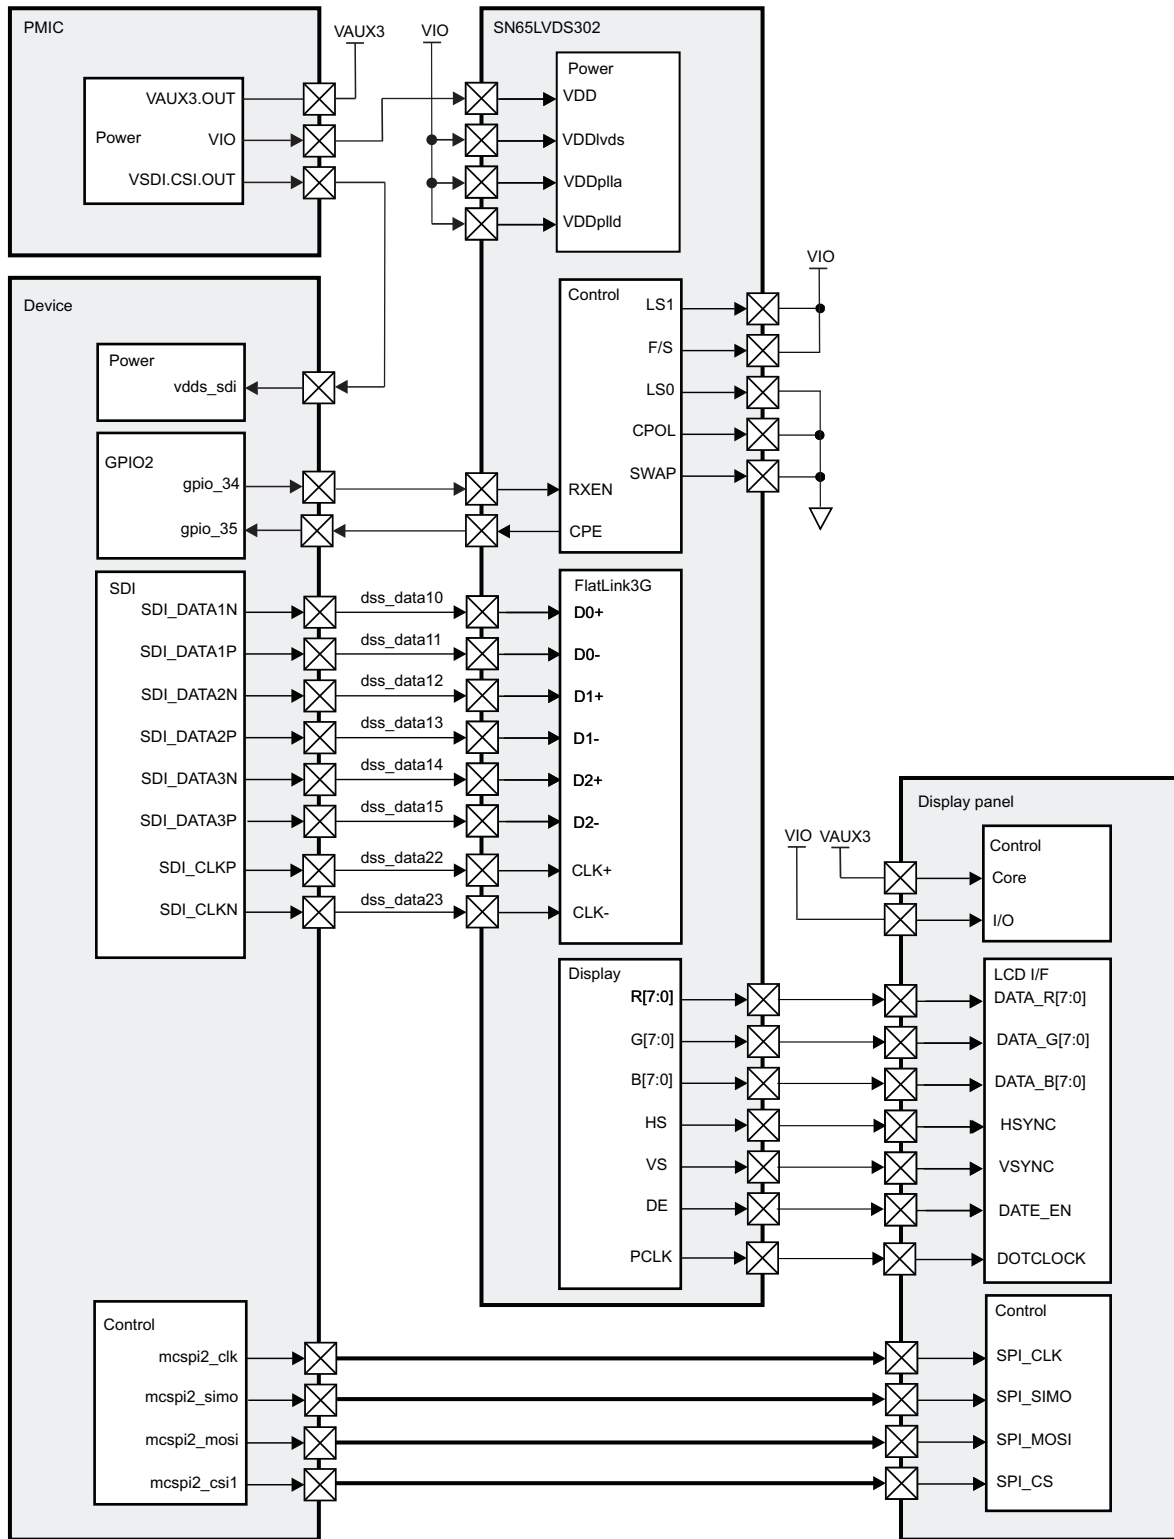

Texas Instruments Inc. provides a full FlatLink3G solution with the device associated to a SN65LVDS302 receiver. This section will also detail the hardware connections between these two devices and the basic software settings

This use case is based on the usage of a large (XGA) 16 Mega colors display requiring the three data channels and the complete output data bus to be used. Some adaptations may be adopted if the device is used in a less demanding use case

12.6.4.1 Hardware Connections

[Figure 12-165](#) details the hardware connections with the device, the SN65LVDS302 receiver, the display panel and the power IC. The power IC can be the companion chip

Figure 12-165. Hardware Connections for FlatLink3G Application

F98-001

NOTE: The SN65LVDS302 device was design-optimized for robustness to operate reliably in a dense environment with other digital switching ICs. In cell phone designs, the SN65LVDS302 often shares a power supply with the LCD display driver provided through the FPC interconnect. To minimize the power supply noise floor it is suggested to provide good decoupling near the SN65LVDS302 power pins. Using four capacitors (2x0.01F and 2x0.1F) was found to provide good performance. At the very least, it is recommended to install one 0.1F and one 0.01F capacitor near the SN65LVDS302. To avoid large current loops and trace inductance, the trace length between decoupling cap and IC power inputs pins must be minimized. Placing the capacitor underneath the SN65LVDS302 device on the bottom of the PCB is often a good choice

12.6.4.2 SN65LVDS302 Receiver Description

SN65LVDS302 is a serial interface receiver which converts the Flatlink™3G signals (3 sub-LVDS data pairs) into 27 signals (24 RGB bits, HS, VS and DE signals). It also provides a pixel clock (4 MHz to 65 MHz) which is formed from the sub-LVDS input clock pair, internally multiplied for data deserialization and then divided by same factor.

The device may operate in different modes, depending on the input data format. One, two or all of the three data pairs will be used, following the LS0 and LS1 configuration. The clock division rate will automatically be selected from 30 to 10. Pixel clock polarity can be chosen using the CPOL signal

The output bus order is configurable by SWAP pin configuration (R[7:0], G[7:0], B[7:0] or B[0:7], G[0:7], R[0:7]). Furthermore, the CMOS outputs rising/falling edges will be selected between slow or fast depending on F/S input to fit display timing constraints with regards to EMI and consumption consequences.

In the XGA display application detailed in Figure 7, the configuration is the following:

- LS1 = 1 and LS0 = 0: 3-data pairs mode is selected
- SWAP = 0: The data output format is R[7:0], G[7:0], B[7:0]
- F/S = 1: The CMOS bus time rise is selected in fast output
- CPOL = 0: The output clock polarity is rising edge

For more details on SN65LVDS302 receiver, please see the SN65LVDS302 data sheet (SLLS733)

The RXEN signal will enable the OMAP device to control SN65LVDS302 activity which will signal channel parity error through CPE signal. These two previous signals are connected to OMAP GPIO2 module

12.6.4.3 SDI Software Settings

12.6.4.3.1 SDI Configuration

To use the SDI with the TI FlatLink3G display panel:

- Set the DSS.DISPC_CONTROL[3] STNTFT bit to 0b1 (active matrix display operation mode)
- Set the DSS.DISPC_CONTROL[9:8] TFTDATALINES bit field to 0x3 (24-bit data output)
- Set the DSS.DSS_SDI_CONTROL[1:0] SDI_BWSEL bit field to 0x2 (color depth is 24 bits)

12.6.4.3.2 Signal Features Configuration

For proper SDI operation, configure the following features in the display controller:

- Set the DSS.DISPC_POL_FREQ[16] RF bit to 0b1 for driving HSYNC and VSYNC on the rising edge of PCLK.
- Set the DSS.DISPC_POL_FREQ[17] ONOFF bit to 0b1.
- Clear the DSS.DISPC_POL_FREQ[14] IPC bit to 0b0 for driving the pixel data on the rising edge of PCLK
- Set the DSS.DISPC_CONTROL[29] LCDENABLEPOL bit to 0b1 for setting the LCD-enable signal active high.

The following settings are not required by the SDI2 interface, but these polarities settings are the common polarities used by FlatLink3G displays:

- Clear the DSS.DISPC_POL_FREQ[13] IHS bit to 0b0 for setting HSYNC active high.
- Clear the DSS.DISPC_POL_FREQ[12] IVS bit to 0b0 for setting VSYNC active high.
- Clear the DSS.DISPC_POL_FREQ[15] IEO bit to 0b0 for setting the data enable active high.

12.6.4.3.3 SDI PLL Configuration

The SDI module settings for an XGA display application with 20% blanking overhead are detailed in this section.

- XGA display: 1024 x 768 = 786432 pixels
- 20% blanking overhead: 157286 pixels
- Visible are pixel count: 786432 + 157286 = 943718
- Frame Refresh Rate: 60 Hz
- Pixel Clock Frequency: 943718 x 60 = 56.6 MHz (in 20-65 MHz range for 3-data pairs).
- Serial Data rate: 3-channel mode : 56.6 MHz x 10 bit/channel = 566 Mbps

12.6.4.3.3.1 SDI PLL settings for 3-Channel Mode:

- 3-data pair: Set DSS_SDI_CONTROL[3:2] SDI_PRSEL bit field to 0b10
- Set the DSS_SDI_CONTROL[19:15] SDI_PDIV bit field to 0x0A
- Set the DSS_PLL_CONTROL[19] SDI_PLL_HIGHFREQ bit to 1 as PCLK>32 MHz
- Set the DSS_PLL_CONTROL[16:11] SDI_PLL_REGN bit field to 0xE. Thus Fint will be set to 2.02 MHz
- Set the DSS_PLL_CONTROL[25:22] SDI_PLL_FREQSEL bit field to 0x7
- Set DSS_PLL_CONTROL[10:1] SDI_PLL_REGM bit field to 0x12C ($10 \times (14+1) \times 2 = 300 = 0x12C$)

Set the SDI_PLL_CONTROL[27:26] SDI_PLL_LOCKSEL bit field to 0b00 to select the phase lock criteria to 0b00 (recommended for FlatLink3G mode)

12.6.4.4 SN65LVDS302 Receiver Settings

12.6.4.4.1 Receiver Power-Up

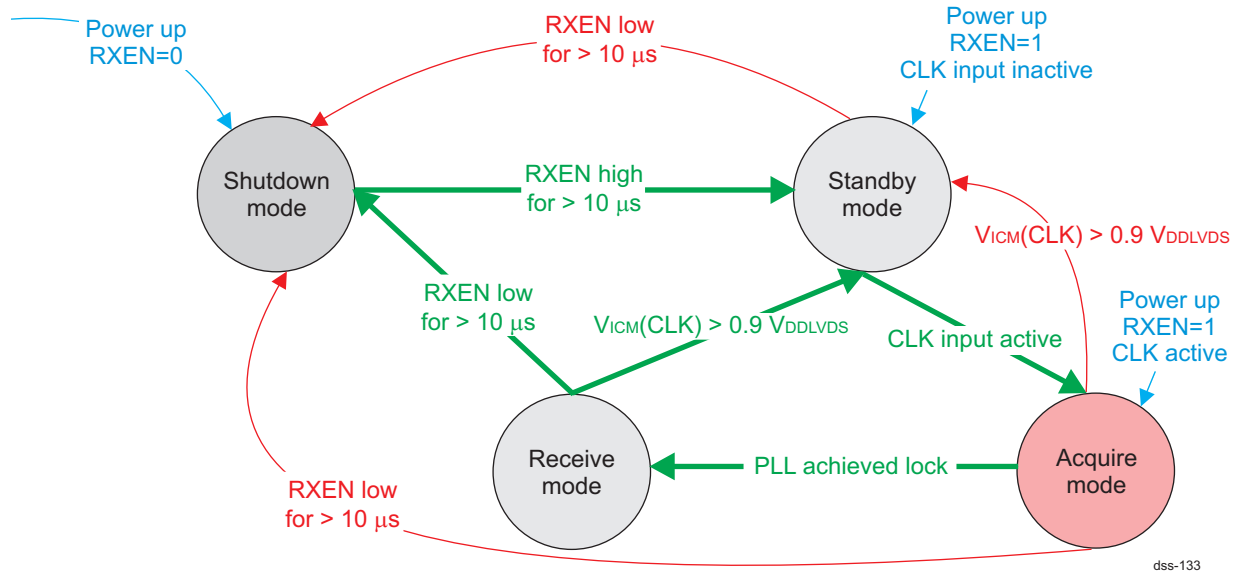

At power up, the receiver is enabled immediately if RXEN=1 (enters Acquire mode) and disabled if RXEN=0 (enters shutdown mode). The receiver may be turned off at any time by pulling RXEN low for at least 10 μ s. This disables the CMOS drivers and turns off the receiver PLL, putting the device in shutdown mode. The RXEN signal is connected to the gpio_34 pin of the device. Thus the GPIO2 module can control the receiver power-up.

NOTE: The RXEN input incorporates glitch suppression logic to avoid unwanted switching. The input must be pulled continuously low for at least 10 μ s to force the receiver to enter shutdown. The gpio_34 signal must be set continuously high by the OMAP device for at least 10 μ s to activate the receiver. An input pulse shorter than 5 μ s is interpreted as a glitch and is ignored.

12.6.4.4.2 Receiver Modes and Transitions

Figure 12-166 details the SN65LVDS302 receiver modes and transitions.

Figure 12-166. SN65LVDS302 Receiver Modes and Transitions

12.6.4.4.2.1 Modes Description

- Shutdown mode**
 The SN65LVDS302 receiver may be put in Shutdown mode by holding the RXEN pin low. This turns off most of the receiver circuitry including the Sub-LVDS receivers, PLL, and deserializers. The Sub-LVDS input impedance remains 100- while any input signal becomes ignored. All outputs will hold a static output pattern: R[0:7]=G[0:7]=B[0:7]=VS=HS=high; DE=PCLK=low. The current draw in Shutdown mode will be nearly zero
- Standby mode**
 The SN65LVDS302 receiver will enter the Standby mode when the SN65LVDS302 receiver is not in Shutdown mode but the clock input common mode range on the Sub-LVDS clock input shifts to VDDLVDs. The CLK input incorporates a pull-up circuitry. This circuit will shift the Sub-LVDS clock input common mode voltage to VDDLVDs in the absence of any input signal. All circuitry, except for the Sub-LVDS clock input Standby monitor will be shutdown. The Sub-LVDS input impedance remains 100- while any input signal on the data inputs D0, D1, and D2 becomes ignored. All outputs will hold a static output pattern: R[0:7]=G[0:7]=B[0:7]=VS=HS=high; DE=PCLK=low. The current draw in Standby mode will be very low.
- Active Modes**
 The SN65LVDS302 receiver will be in active mode when the device is enabled by pulling RXEN high and VICM on the CLK input is driven below 0.9xVDD by an external input signal. Current draw in active mode will be dependent on operating frequency and the number of data transitions in the data payload
- Acquire Mode (PLL approaches lock)**
 While the SN65LVDS302 receiver is enabled and a Sub-LVDS clock input present, the receiver PLL will pursue lock to the input clock. As long as the PLL is not locked the output data bus will hold a static output pattern: R[0:7]=G[0:7]=B[0:7]=VS=HS=high; DE=PCLK=low.
- Receive Mode**
 When the receiver PLL achieves lock, the receiver enters the normal receive mode with the output bus presenting the deserialized data.

12.6.4.4.2.2 Mode Transitions

Table 12-82. SN65LVDS302 Receiver Mode Transitions

| Mode Transition | Use Case | Transition Specifics |
|-----------------------------|---|--|
| Shutdown to Standby | Drive RXEN high to enable receiver | <ul style="list-style-type: none"> • 1. RXEN high for longer than 10 μs • 2. Receiver enters Standby mode <ul style="list-style-type: none"> – a. R[0:7]=G[0:7]=B[0:7]=VS=HS remain high and DE=PCLK low – b. receiver turns on clock input monitor |
| Standby to acquire | Transmitter activity detected | <ul style="list-style-type: none"> • 1. CLK input monitor detects clock input activity • 2. Outputs remain static • 3. the receiver PLL becomes enabled |
| Acquire to Receive | Link is ready to receive data from OMAP SDI module. | <ul style="list-style-type: none"> • 1. PLL is active and achieves lock within 2 μs • 2. D1, D2, and D3 become active • 3. first Data word was recovered • 4. parallel output bus switches from static output pattern to output first valid data word |
| Receive to Standby | Receiver requested to enter Standby mode by input common mode voltage $V_{ICM} > 0.9 V_{DDLVDs}$ (that is, transmitter output clock turns high-impedance) | <ul style="list-style-type: none"> • 1. Transmitter disables outputs • 2. RX Input monitor detects $V_{ICM} > 0.9 V_{DDLVDs}$ • 3. R[0:7]=G[0:7]=B[0:7]=VS=HS transition to high and DE=PCLK to low on next falling PLL clock edge • 4. PLL shuts down • 5. Clock activity input monitor remains active |
| Receive/Standby to Shutdown | Turn off receiver | <ul style="list-style-type: none"> • 1. RXEN pulled low for longer than 10 μs • 2. Receiver immediately puts all outputs into high impedance • 3. Most receiver blocks are shut down for least power consumption |

12.6.4.4.3 Parity Error Detection and Handling

The SN65LVDS302 receiver performs an error checking on the basis of a parity bit that is transmitted across the LVDS interface from the transmitting device. Once the SN65LVDS302 detects the presence of the clock and the receiver PLL has locked onto PCLK, then the parity is checked. The parity bit covers the 27-bit data payload (reserved bits are not covered in the parity calculations). Odd Parity bit signaling is used. The parity error is output on the output CPE pin:

- If the sum of the 27 data bits and the parity bit result in an odd number, the receive data are assumed to be valid and CPE output will be held low.
- If the sum equals an even number, parity error is declared and CPE output will indicate high for half a PCLK period.

The CPE output will be set with the data bit transition and cleared after 1/2 the data bit time. The receiver CPE output pin is connected to gpio_35 pin. The OMAP device can use the gpio_35 input pin to generate an IRQ, respectively GPIO2_MPU_IRQ for MPU subsystem and GPIO2_IVA2_IRQ for IVA2.2 subsystem. This will allow the OMAP device to count every detected parity error with a simple counter triggered by GPIO2 module interrupt request.

When a parity error is detected, the data on that PCLK cycle is not output. Instead, the last valid data from a previous PCLK cycle is repeated on the output bus. This is to prevent any bit error that may occur on the LVDS link from causing perturbations in VS, HS or DE that may be visually disruptive to the display panel.

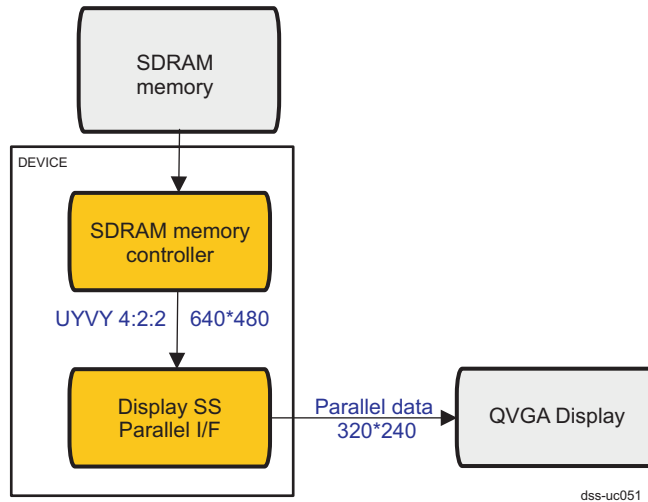

12.6.5 Camcorder Use Case: How to Configure the Display Subsystem When Connected With a QVGA LCD Panel

12.6.5.1 Overview

This section describes the configuration and used of a QVGA LCD panel through the parallel data interface (in RFBI by-pass mode).

The display subsystem reads each image from the SDRAM memory in the UYVY 4:2:2 format and converts it to a RGB18-666 pixel format to send to the QVGA LCD panel (see [Figure 12-167](#)).

Figure 12-167. Overview

The camcorder use case is configured as follows:

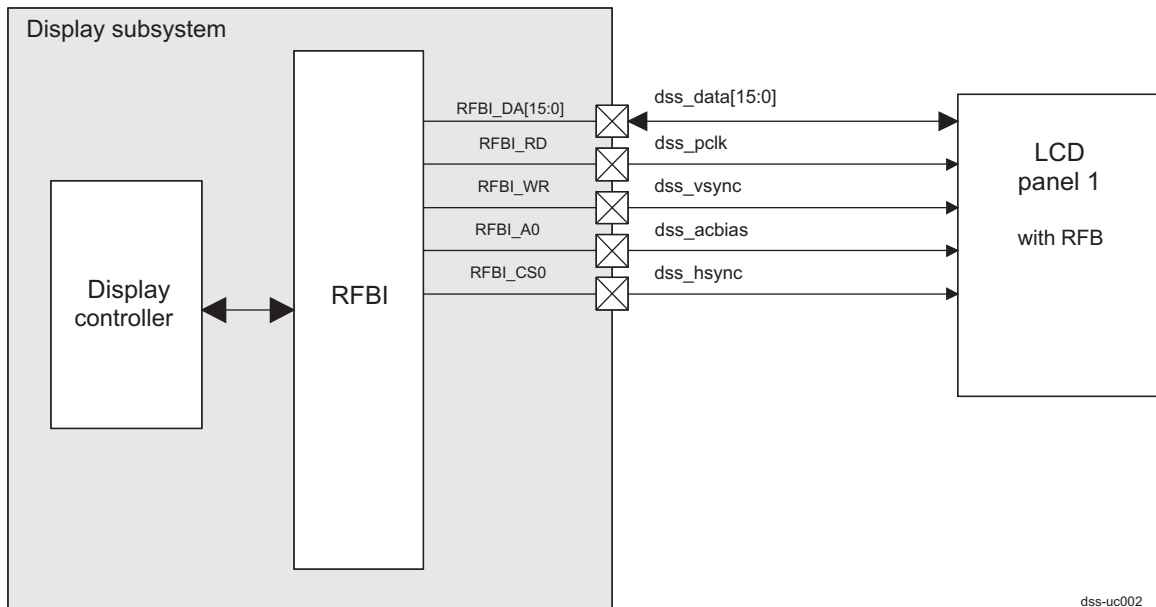

- Input Image: VGA 640*480 pixels , UYVY 4:2:2 format
- Output Image Pixel: QVGA 320*240 pixels , RGB18-666
- Pixel Clock (PCLK): 6 MHz to allow a video display of 60 frames per second
- No DMA requests to the system DMA, but the display subsystem uses its DMA controller to access the data into SDRAM
- VSYNC, SYNCLOST, VID1FIFOUNDERFLOW, and VID1ENDWINDOW interrupts used to monitor the video1 channel

12.6.5.2 Environment

In this use case, the display subsystem is connected to a QVGA LCD panel by the parallel interface.

[Figure 12-168](#) details the OMAP device connections with the LCD panel.

Figure 12-168. Environment

12.6.5.2.1 LCD panel Features

The LCD panel includes the following features:

- Display format 320(H) x 240(V)
- Color mode: 18 bit/pixel R:5 G:6 B:5 (65 536 colors)

12.6.5.3 Data Path

In this use case, the display subsystem manages the following:

- Video stream (UYVY 4:2:2) between the SDRAM controller (SDRC) and the display controller through the internal DMA controller (L3 interconnect)
- Video stream (RGB16) between the display controller and the parallel module
- Video stream (parallel data) between the parallel module and the QVGA LCD panel

Figure 12-169 shows the data flow inside the display subsystem highlighted in red.

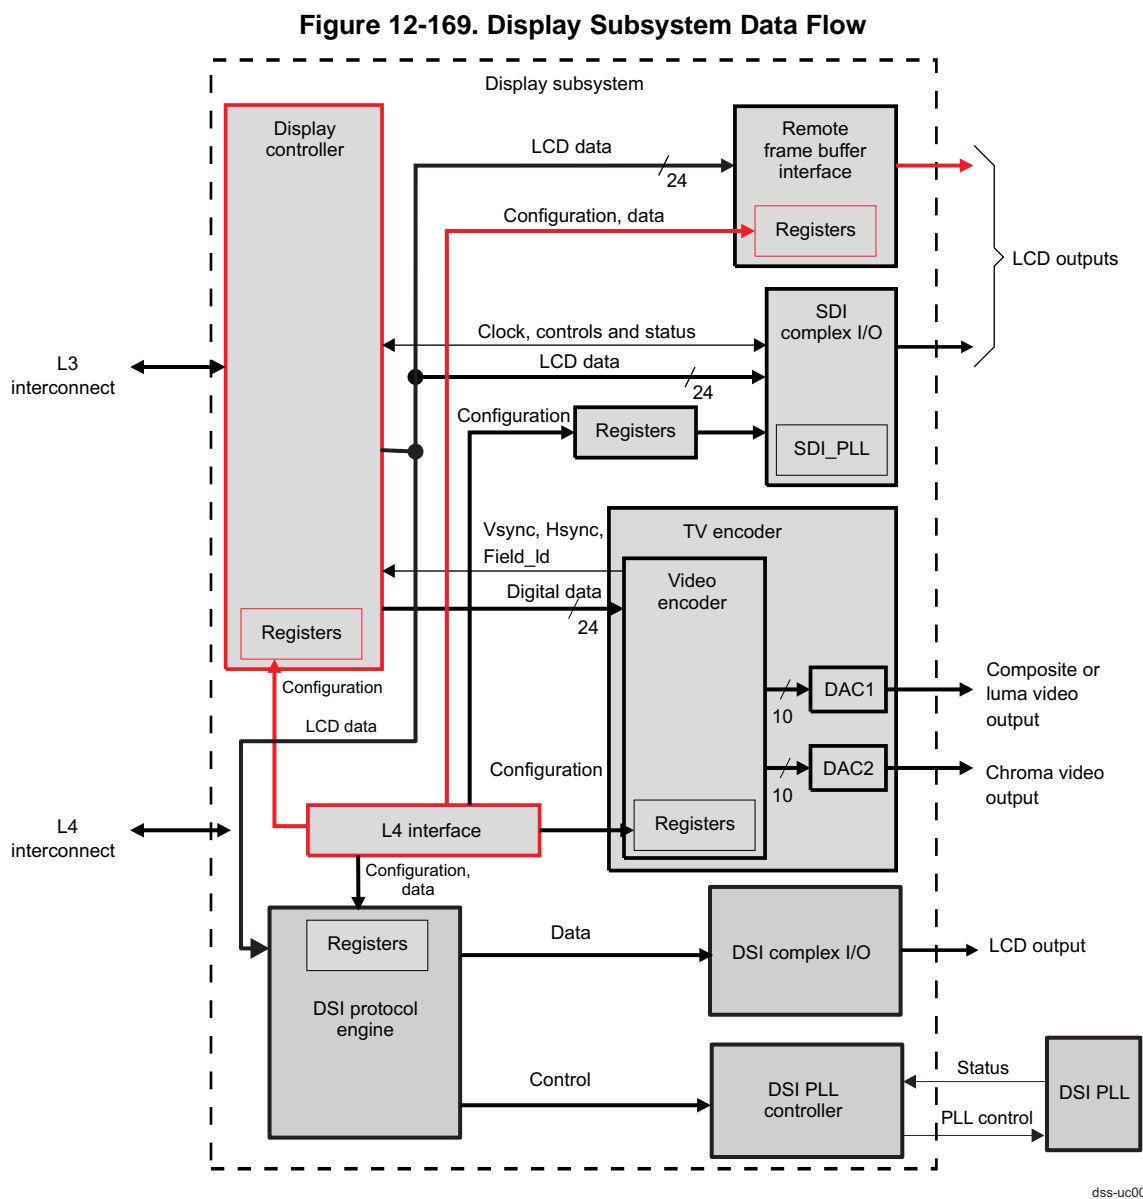

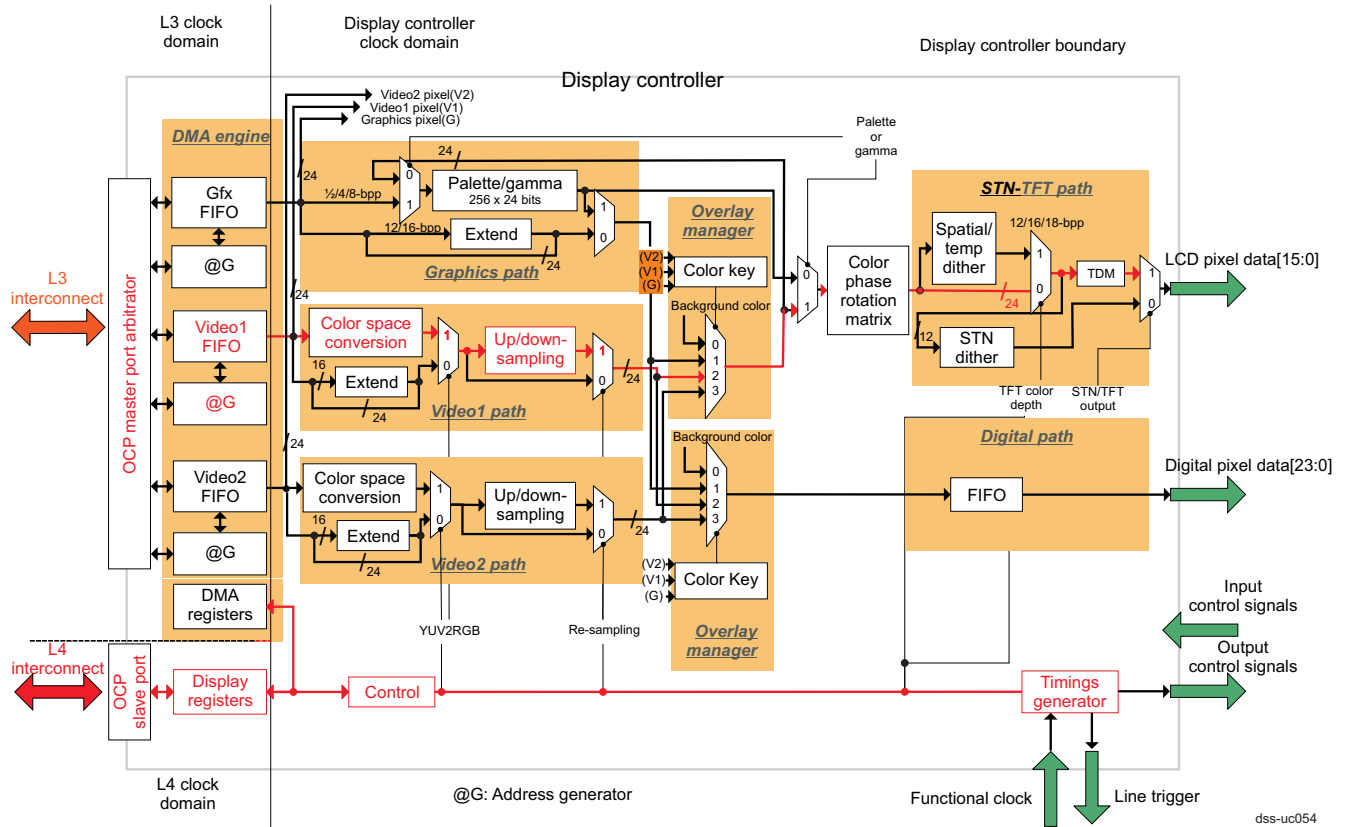

Figure 12-170 shows the data flow inside the display controller submodule highlighted in red.

Figure 12-170. Display Controller Data Flow

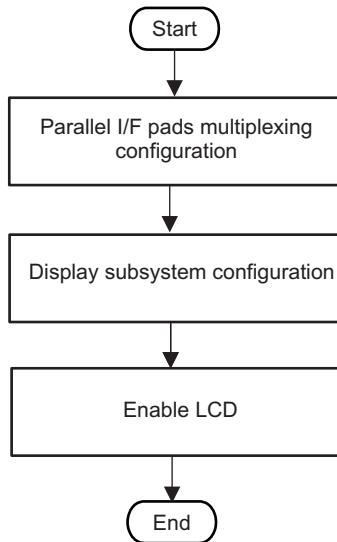

dss-uc054

12.6.5.4 Programming Flow

This section details the programming flow of the display panel configuration for the camcorder use case. The display panel is configured in 3 steps (see Figure 12-171).

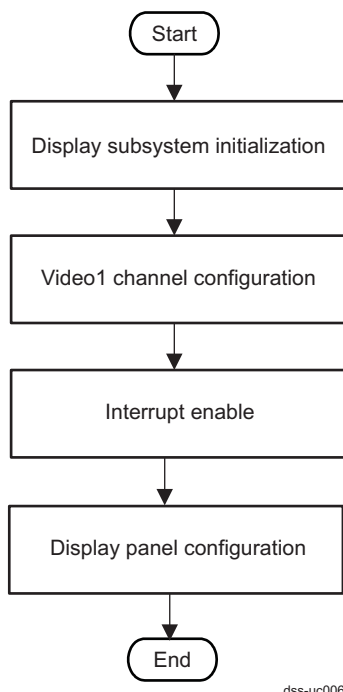

Figure 12-171. Display Panel Configuration for the Camcorder Use Case

dss-uc055

Figure 12-172 shows the programming flow of the display subsystem initial configuration, which consists of four steps:

Figure 12-172. Display Subsystem Configuration for Camcorder Use Case

12.6.5.4.1 Pads Multiplexing Configuration

All parallel pads are multiplexed in mode 1 on the dss_data pins:

Table 12-83 shows all the System Control Module registers.

Table 12-83. Registers Print for QVGA LCD panel Pads Multiplexing Configuration

| Register Name | Address | Value | Value Description |
|--------------------------------|-------------|-------------|--|
| SCM.CONTROL_PADCONF_DSS_PCLK | 0x4800 20D4 | 0x0110 0110 | Configure dss_pclk and dss_hsync pads in mode 0 |
| SCM.CONTROL_PADCONF_DSS_VSYNC | 0x4800 20D8 | 0x0100 0110 | Configure dss_vsync and dss_acbias pads in mode 0 |
| SCM.CONTROL_PADCONF_DSS_DATA0 | 0x4800 20DC | 0x0100 0100 | Configure dss_data0 and dss_data1 pads in mode 0 |
| SCM.CONTROL_PADCONF_DSS_DATA2 | 0x4800 20E0 | 0x0100 0100 | Configure dss_data2 and dss_data3 pads in mode 0 |
| SCM.CONTROL_PADCONF_DSS_DATA4 | 0x4800 20E4 | 0x0100 0100 | Configure dss_data4 and dss_data5 pads in mode 0 |
| SCM.CONTROL_PADCONF_DSS_DATA6 | 0x4800 20E8 | 0x0100 0100 | Configure dss_data6 and dss_data7 pads in mode 0 |
| SCM.CONTROL_PADCONF_DSS_DATA8 | 0x4800 20EC | 0x0100 0100 | Configure dss_data8 and dss_data9 pads in mode 0 |
| SCM.CONTROL_PADCONF_DSS_DATA10 | 0x4800 20F0 | 0x0100 0100 | Configure dss_data10 and dss_data11 pads in mode 0 |
| SCM.CONTROL_PADCONF_DSS_DATA12 | 0x4800 20F4 | 0x0100 0100 | Configure dss_data12 and dss_data13 pads in mode 0 |
| SCM.CONTROL_PADCONF_DSS_DATA14 | 0x4800 20F8 | 0x0100 0100 | Configure dss_data14 and dss_data15 pads in mode 0 |

12.6.5.4.2 Display Subsystem Initialization

Figure 12-173 details the display subsystem initialization.

Figure 12-173. Display Subsystem Initialization

dss-uc006

12.6.5.4.2.1 Display Subsystem Clock and Power Management

The display subsystem clock (DSS1_ALWON_FCLK) is provided by the DPLL4 module in the PRCM (DPLL4_M4_X2). The software should set the following PRCM registers:

1. The DPLL4_ALWON_FCLKOUT clock is sourced by the system clock (SYS_CLK) at 26 MHz and calculated as follows:

$$DPLL4_ALWON_FCLKOUT = \frac{SYS_CLK(19.2\text{ MHz}) \times 2 \times M(0xE1)}{N(0x9) + 1} = 864\text{ MHz}$$

dss-uc020

Set the M multiplier to 225 by setting the PRCM.CM_CLKSEL2_PLL[18:8] PERIPH_DPLL_MULT bit field to 0xE1.

Set the N divider to 9 by setting the PRCM.CM_CLKSEL2_PLL[6:0] PERIPH_DPLL_DIV bit field to 0x09.

2. To follow the timing requirements for the use case, the DPLL4_M4_X2 clock frequency is calculated as follows:

$$DPLL4_M4X2_CLK = \frac{DPLL4_ALWON_FCLKOUT(864\text{ MHz})}{9} = 96\text{ MHz}$$

dss-ucE007

Set the DPLL4 ratio by programming to 0x9 the PRCM.CM_CLKSEL_DSS[4:0] CLKSEL_DSS1 bit field.

3. Enable the display subsystem functional clock (DSS1_ALWON_FCLK): Set the PRCM.CM_FCLKEN_DSS[0] EN_DSS1 to 0x1.
4. Enable the display subsystem TV functional clock (DSS_TV_FCLK): Set the PRCM.CM_FCLKEN_DSS[2] EN_TV to 0x1.
5. Enable the display subsystem interface clock (DSS_L4_ICLK): Set the PRCM.CM_ICLKEN_DSS[0] EN_DSS to 0x1.

Table 12-84 describes the registers from the PRCM to be configured for the display subsystem clock configuration step and the use case values.

Table 12-84. Registers Print for Display Subsystem Clock Management

| Register Name | Address | Value | Value Description |
|---------------------|-------------|-------------|---|
| PRCM.CM_FCLKEN_DSS | 0x4800 4E00 | 0x0000 0005 | Enable DSS1_LWON_FCLK and DSS_TV_FCLK |
| PRCM.CM_ICLKEN_DSS | 0x4800 4E10 | 0x0000 0001 | Enable DSS_L4_ICLK |
| PRCM.CM_CLKSEL2_PLL | 0x4800 4D44 | 0x0000 E109 | DPLL4 multiplier set to 0xE1 and divider set to 0x9 |
| PRCM.CM_CLKSEL_DSS | 0x4800 4E40 | 0x0001 0009 | DPLL4 M4X2 divider set to 0x9 |

The display subsystem power management is programmed by the following PRCM registers:

1. Disable the autoidle mode: Set the PRCM.CM_AUTOIDLE_DSS register to 0x0.
2. Disable the DSS domain sleep dependency: Set the PRCM.CM_SLEEPDEP_DSS register to 0x0.
3. Disable the automatic transition between active and inactive: Set the PRCM.CM_CLKSTCTRL_DSS register to 0x0.

Table 12-85 describes the registers from the PRCM to be configured for the display subsystem power management step and the use case values.

Table 12-85. Registers Print for Display Subsystem Power Management

| Register Name | Address | Value | Value Description |
|-----------------------|------------|-------------|--|
| PRCM.CM_AUTOIDLE_DSS | 0x48004E30 | 0x0000 0000 | Disable autoidle mode |
| PRCM.CM_SLEEPDEP_DSS | 0x48004E44 | 0x0000 0000 | Disable the DSS domain sleep dependency |
| PRCM.CM_CLKSTCTRL_DSS | 0x48004E48 | 0x0000 0000 | Disable the automatic clock state transition |

12.6.5.4.2.2 Display Subsystem Software Reset

Perform a software reset as described in the following flowchart (see Figure 12-174).

Figure 12-174. Software Reset Flowchart

dss-uc008

CAUTION

To update the RESETDONE status bit correctly, all interface and functional clocks, even for the TV output, must be provided to the display subsystem.

Table 12-86 describes the registers to be configured for the display subsystem software reset step and the use case values.

Table 12-86. Registers Print for Display Subsystem Software Reset

| Register Name | Address | Value | Value Description |
|---------------|-------------|-------------|--|
| DSS_SYSCONFIG | 0x4805 0010 | 0x0000 0002 | Initiate a software reset. The DSS_SYSCONFIG[1] SOFTRESET is automatically reset by hardware |
| DSS_SYSSTATUS | 0x4805 0014 | 0x0000 0001 | The DSS_SYSSTATUS[0] RESETDONE is set to 1 when the reset sequence is done |

12.6.5.4.3 Video1 Channel Configuration

The video1 channel is configured by programming the following steps:

1. Select the UYVY 4:2:2 format by programming the DSS.DISPC_VID1_ATTRIBUTES[4:1] VIDFORMAT bit field to 0xB.
2. Select the LCD data flow by programming the DSS.DISPC_VID1_ATTRIBUTES[16] VIDCHANNELOUT bit to 0x0.
3. Select the video DMA burst size to 16x32 by setting the DSS.DISPC_VID1_ATTRIBUTES[15:14] VIDBURSTSIZE to 0x2.
4. Program the image base address by setting the DSS.DISPC_VID1_BA0 register.
5. Program the FIFO thresholds as follows:

To set the FIFO high threshold to 1023 bytes (maximum value allowed), set the DSS.DISPC_VID1_FIFO_THRESHOLD[27:16] VIDFIFOHIGHTHRESHOLD bit field to 0x3FF.

Set the FIFO low threshold as described in the following equation:

$$\text{VIDFIFOWHRESHOLD} = \text{VIDFIFOHIGHTHRESHOLD} (0x3FF) - \frac{\text{VIDBURSTSIZE}(16x32)}{8} = 959 (0x3BF)$$

dss-ucE009

Program the DSS.DISPC_VID1_FIFO_THRESHOLD[11:0] VIDFIFOWHRESHOLD to 0x3BF.

6. Program the windows X-position to 0 (first column starting on the left edge of the screen) and the window Y-position to 0 (first row starting at the top of the screen): Set the DSS.DISPC_VID1_POSITION[10:0] VIDPOSX and the DSS.DISPC_VID1_POSITION[26:16] VIDPOSY registers to 0x0.
7. Program the window width to 320 by setting the DSS.DISPC_VID1_SIZE[10:0] VIDSIZEX to 0x13F.
8. Program the window height to 240 by setting the DSS.DISPC_VID1_SIZE[26:16] VIDSIZEY to 0xEF.
9. Program the picture width to 640 by setting the DSS.DISPC_VID1_PICTURE_SIZE[10:0] VIDORGSIZEX to 0x27F.
10. Program the picture height to 480 by setting the DSS.DISPC_VID1_PICTURE_SIZE[26:16] VIDORGSIZEY to 0x1DF.
11. Because the video format is in UYVY, software users must program the color conversion module as follows:
 - To enable the color conversion module, set the DSS.DISPC_VID1_ATTRIBUTES[9] VIDCOLORCONVENABLE bit to 1.
 - To select a limited range for color space conversion, set the DSS.DISPC_VID1_ATTRIBUTES[11] VIDFULLRANGE bit to 0.

The DSS.DISPC_VID1_COEFi registers (with i = 0 to 4) have nine 11-bit coefficients defined for the programmable color space conversion block for video pipeline 1:

$$\begin{bmatrix} R \\ G \\ B \end{bmatrix} = \frac{1}{256} * \begin{bmatrix} RY & RCr & RCb \\ GY & GCr & GCb \\ BY & BCr & BCb \end{bmatrix} * \begin{bmatrix} Y - 16 \\ Cr - 128 \\ Cb - 128 \end{bmatrix}$$

dss-ucE010

The nine coefficient values for color space conversion from UYVY 4:2:2 to RGB are as follows:

RY = 298, RCb = 0, RCr = 409

GY = 298, GCb = (unsigned) (-11), GCr = (unsigned) (-208)

BY = 298, BCb = 517, BCr = 0

12. Configure the video1 channel for VRFB rotation settings as shown in [Table 12-87](#):

Table 12-87. VRFB Rotation Configuration

| Rotation | Registers | Value |
|-------------|--|-------------------------------------|
| 0 degree | DSS.DISPC_VID1_BA0 DSS.DISPC_VID1_PIXEL_INC DSS.DISPC_VID1_ROW_INC | VBA0 1 (2048 - iw) x ps + 1 |
| 90 degrees | DSS.DISPC_VID1_BA0 DSS.DISPC_VID1_PIXEL_INC DSS.DISPC_VID1_ROW_INC | VBA90 1 (2048 - ih) x ps + 1 |
| 180 degrees | DSS.DISPC_VID1_BA0 DSS.DISPC_VID1_PIXEL_INC DSS.DISPC_VID1_ROW_INC | VBA180 1 (2048 - iw) x ps + 1 |
| 270 degrees | DSS.DISPC_VID1_BA0 DSS.DISPC_VID1_PIXEL_INC DSS.DISPC_VID1_ROW_INC | VBA270 1 (2048 - ih) x ps + 1 |

In the use case context, the input video format is UYVY for a VGA display (640 * 480). As a consequence, the VRFB configuration is as described in [Table 12-88](#).

Table 12-88. VRFB Rotation Configuration for a VGA Display (UYVY format)

| Rotation | Registers | Value |
|-------------|--|---------------------|
| 0 degree | DSS.DISPC_VID1_BA0 DSS.DISPC_VID1_PIXEL_INC DSS.DISPC_VID1_ROW_INC | VBA0 1 6273 |
| 90 degrees | DSS.DISPC_VID1_BA0 DSS.DISPC_VID1_PIXEL_INC DSS.DISPC_VID1_ROW_INC | VBA90 1 7233 |
| 180 degrees | DSS.DISPC_VID1_BA0 DSS.DISPC_VID1_PIXEL_INC DSS.DISPC_VID1_ROW_INC | VBA180 1 6273 |
| 270 degrees | DSS.DISPC_VID1_BA0 DSS.DISPC_VID1_PIXEL_INC DSS.DISPC_VID1_ROW_INC | VBA270 1 7233 |

For more information on VRFB module and settings, see the VRFB use case and tips section in , *Memory Subsystem*.

According to the rotation angle, program the DSS.DISPC_VID1_ATTRIBUTES[13] VIDROTATION and the DSS.DISPC_VID1_ATTRIBUTES[18] VIDROWREPEATENABLE bits as described in [Table 12-89](#).

Table 12-89. Video Rotation Register Settings (UYVY Only)

| Rotation | Registers Field Name | Registers Field Value |
|-------------|--|-----------------------|
| 0 degree | DSS.DISPC_VID1_ATTRIBUTES[13] VIDROTATION | 0x0 |
| | DSS.DISPC_VID1_ATTRIBUTES[18] VIDROWREPEATENABLE | 0x0 |
| 90 degrees | DSS.DISPC_VID1_ATTRIBUTES[13] VIDROTATION | 0x1 |
| | DSS.DISPC_VID1_ATTRIBUTES[18] VIDROWREPEATENABLE | 0x1 |
| 180 degrees | DSS.DISPC_VID1_ATTRIBUTES[13] VIDROTATION | 0x2 |
| | DSS.DISPC_VID1_ATTRIBUTES[18] VIDROWREPEATENABLE | 0x0 |
| 270 degrees | DSS.DISPC_VID1_ATTRIBUTES[13] VIDROTATION | 0x3 |
| | DSS.DISPC_VID1_ATTRIBUTES[18] VIDROWREPEATENABLE | 0x1 |

13. Because the video size is in 640 * 480, the scaling unit must be used to downsample to a size of 320 * 240 using a 3 taps configuration.

The video scaling block for the video pipeline 1 is set in downscaling for horizontal and vertical by setting the following bit field in DSS.DISPC_VIDn_ATTRIBUTES[6:5] :

- VIDRESIZEENABLE bit field to 0x03
- VIDHRESIZECONF bit field to 0x1
- VIDVRESIZECONF bit field to 0x1

14. Program the downscaling of 2 by setting DSS.DISPC_VIDn_FIR to 0x0800 0800.

All taps coefficients are programmed as in [Table 12-90](#).

[Table 12-90](#) describes the registers to be configured for the video1 channel configuration step and the use case values.

Table 12-90. Registers Print for Video1 Channel Configuration

| Register Name | Address | Value | Value Description |
|----------------------------|-------------|-------------------------------------|---|
| DISPC_VID1_ATTRIBUTES | 0x4805 04CC | 0x0000 8216 (for 0-degree rotation) | See the programming steps described above for details. |
| DISPC_VID1_BA0 | 0x4805 04BC | Base address value | Base address for an image in SDRAM. Depends on the rotation angle (see Table 12-88). |
| DISPC_VID1_FIFO_THRESH_OLD | 0x4805 04D0 | 0x03FF 03BF | FIFO high and low thresholds for DMA request generation |
| DISPC_VID1_POSITION | 0x4805 04C4 | 0x0000 0000 | No X-position and Y-position offsets |
| DISPC_VID1_SIZE | 0x4805 04C8 | 0x00EF 013F | QVGA display:320*240 |
| DISPC_VID1_PICTURE_SIZE | 0x4805 04E4 | 0x01DF 027F | VGA display: 640*480 |
| DISPC_VID1_CONV_COEF0 | 0x4805 0530 | 0x0199 012A | Color space conversion: RCR and RY coefficients |
| DISPC_VID1_CONV_COEF1 | 0x4805 0534 | 0x012A 0000 | Color Space Conversion: GY and RCB coefficients |
| DISPC_VID1_CONV_COEF2 | 0x4805 0538 | 0x07F5 0730 | Color Space Conversion: GCB and GCR coefficients |
| DISPC_VID1_CONV_COEF3 | 0x4805 053C | 0x0000 012A | Color Space Conversion: BCR and BY coefficients |
| DISPC_VID1_CONV_COEF4 | 0x4805 0540 | 0x0000 0205 | Color Space Conversion: BCB coefficient |
| DISPC_ROW_INC | 0x4805 04D8 | Image row increment | Image stride. Depends on the rotation angle (see Table 12-88). |
| DISPC_PIXEL_INC | 0x4805 04DC | 0x0000 0001 | Pixel increment set to 1 because VRFB module is in charge of rotating the image |
| DISPC_VID1_FIR | 0x4805 04E0 | 0x0800 0800 | Vertical and horizontal ratio for downscaling |

12.6.5.4.4 Interrupts Enable

The interrupts enable stage is as follows:

1. To clear all display controller IRQs, set the DSS.DISPC_IRQSTATUS register to 0xFFFF.
2. To enable the VSYNC interrupt, set the DSS.DISPC_IRQENABLE[1] VSYNC bit to 1.
3. To enable the VID1FIFOUNDERFLOW interrupt, set the DSS.DISPC_IRQENABLE[10] VID1FIFOUNDERFLOW bit to 1.
4. To enable the ENDVID1WINDOW interrupt, set the DSS.DISPC_IRQENABLE[11] ENDVID1WINDOW bit to 1.
5. To enable the SYNCLOST interrupt, set the DSS.DISPC_IRQENABLE[14] SYNCLOST bit to 1.

Table 12-91 describes the registers to be configured for the interrupts enable step and the use case values.

Table 12-91. Registers Print for Interrupts Enable

| Register Name | Address | Value | Value Description |
|-----------------|-------------|-------------|---|
| DISPC_IRQSTATUS | 0x4805 0418 | 0xFFFF FFFF | Clear all DISPC interrupt requests. This register is automatically reset by hardware. |

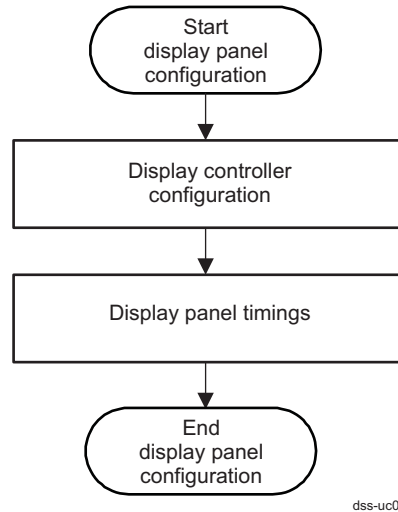

Table 12-91. Registers Print for Interrupts Enable (continued)

| | | | |
|---------------------------------|-------------|-------------|--|
| DISPC_IRQENABLE | 0x4805 041C | 0x0000 4C02 | Enable the VSYNC, VID1FIFOUNDERFLOW, ENDVID1WINDOW, and SYNCLOST IRQs. |
|---------------------------------|-------------|-------------|--|

12.6.5.4.5 Display Panel Configuration

Figure 12-175 shows the structure of the display panel configuration stage:

Figure 12-175. Display Panel Configuration Flowchart

dss-uc011

12.6.5.4.5.1 Display Controller Configuration

To interface the DISPC with the QVGA LCD panel (320*240), the following settings are required:

1. The QVGA LCD panel is an active matrix: set the DSS.[DISPC_CONTROL](#)[3] STNTFT bit to 1 (active matrix display operation mode).
2. Select 16-bit data output by setting the DSS.[DISPC_CONTROL](#)[9:8] TFTDATALINES bit field to 0x1.
3. Bypass the RFBI module by setting the DSS.[DISPC_CONTROL](#)[16:15] GPOUT[1:0] bit field to 0x3.
4. Select the color panel option by setting the DSS.[DISPC_CONTROL](#)[2]MONOCOLOR bit to 0x0.
5. Program the LCD enable signal active high by setting the DSS.[DISPC_CONTROL](#)[29] LCDENABLEPOL bit to 1.
6. Disable the free-running pixel clock by setting the DSS.[DISPC_CONTROL](#)[27] PCKFREEENABLE bit to 0.
7. Program the number of lines per panel to 240 by setting the DSS.[DISPC_SIZE_LCD](#)[26:16] LPP bit field to 0xEF (239 = 240 -1).
8. Program the number of pixels per line to 320 by setting the DSS.[DISPC_SIZE_LCD](#)[10:0] PPL bit field to 0x13F (319 = 320 -1).
9. The palette module is bypassed: set the DSS.[DISPC_CONFIG](#)[2:1] LOADMODE bit field to 0x2 (frame data only).

12.6.5.4.5.2 Display Panel Timings

Figure 12-176 details the timing values description for the QVGA LCD panel.

Figure 12-176. QVGA LCD Panel Timings

The following steps define the timing generation of HSYNC/VSYNC signals based on the QVGA LCD panel specification:

1. Program the horizontal front porch to 9 by setting the DSS.DISPC_TIMING_H[19:8] HFP bit field to 0x8 (9-1).
2. Program the horizontal back porch to 60 by setting the DSS.DISPC_TIMING_H[31:20] HBP bit field to 0x3B (60-1).
3. Program the horizontal synchronization pulse width to 2 by setting the DSS.DISPC_TIMING_H[7:0] HSW bit field to 0x1 (2-1).
4. Program the vertical front porch to 1 by setting the DSS.DISPC_TIMING_V[19:8] VFP bit field to 1.
5. Program the vertical back porch to 5 by setting the DSS.DISPC_TIMING_V[31:20] VBP bit field to 5.
6. Program the vertical synchronization pulse width to 0 by setting the DSS.DISPC_TIMING_V[7:0] VSW bit field to 0.
7. For QVGA LCD panel, the line clock signal is active high and inactive low. As a consequence, invert HSYNC by setting the DSS.DISPC_POL_FREQ[13] IHS bit to 0.
8. For QVGA LCD panel, the frame clock signal is active high and inactive low. As a consequence, invert VSYNC by setting the DSS.DISPC_POL_FREQ[12] IVS bit to 0.
9. Drive HSYNC and VSYNC on the falling edge of PCLK by setting the DSS.DISPC_POL_FREQ[16] RF bit to 0 and the the DSS.DISPC_POL_FREQ[17] ONOFF bit to 0.
10. Drive the pixel data on the rising edge of PCLK by clearing the DSS.DISPC_POL_FREQ[14] IPC bit to 0.
11. Set the data enable active high by clearing the DSS.DISPC_POL_FREQ[15] IEO bit to 0.

The visible pixel count is $320 * 240 = 76\ 800$ pixels.

The Total Frame Pixel Count (with the values given above) is $(320+8+59+1) * (240+5+1+0) = 95\ 448$ pixels.

The camcorder application displays 60 frame per second.

The pixel clock required for 60 fps is: $95\ 448 * 60\ \text{Hz} = 5,72688\ \text{MHz}$.

On the other hand, the pixel clock is defined by the following equation:

$$\text{PixelClock} = \frac{\text{Functional Clock}}{\text{LCD factor} * \text{PCD factor}}$$

dss-ucE013

To program the pixel clock to 5.72688 MHz, software users must set:

1. Set the DSS.DISPC_DIVISOR[23:16] LCD bit field to 0x2.

$$\text{LogicClock} = \frac{\text{DSS1_ALWON_FCLK}}{2} = 48 \text{ Mhz}$$

dss-ucE014

2. Set the DSS.DISPC_DIVISOR[7:0] PCD bit field to 0x8.

$$\text{PixelClock} = \frac{\text{LogicClock}}{8} = 6 \text{ Mhz}$$

dss-ucE015

Table 12-92 describes the registers to be configured for the display panel configuration step and the use case values.

Table 12-92. Registers Print for Display Panel Configuration

| Register Name | Address | Value | Value Description |
|----------------|-------------|-------------|---|
| DISPC_CONTROL | 0x4805 0440 | 0x0001 8108 | See Section 12.6.5.4.5.1, <i>Display Controller Configuration</i> , for more details. |
| DISPC_SIZE_LCD | 0x4805 047C | 0x00EF 013F | QVGA display: 320 * 240 |
| DISPC_CONFIG | 0x4805 0444 | 0x0000 0004 | Disable the palette |
| DISPC_TIMING_H | 0x4805 0464 | 0x03B0 0801 | Program horizontal timings |
| DISPC_TIMING_V | 0x4805 0468 | 0x0050 0100 | Program vertical timings |
| DISPC_POL_FREQ | 0x4805 046C | 0x0000 0000 | Program the HSYNC and VSYNC signals for QVGA LCD panel |
| DISPC_DIVISOR | 0x4805 0470 | 0x0002 0008 | Set the divisors to program the PCLK frequency at 6 MHz. |

12.6.5.4.6 LCD Enable

The LCD enable step is composed of the following stages:

1. To enable the video1 layer, set the DSS.DISPC_VID1_ATTRIBUTES[0] VIDENABLE bit to 1. The video DMA engine fetches encoded pixels from the system memory only when the video layer is enabled.
2. To enable the display controller output, set the DSS.DISPC_CONTROL[0] LCDENABLE bit to 1.
3. To account for all DISPC configuration done, set the DSS.DISPC_CONTROL[5] GOLCD bit to 1 to indicate that all shadow registers of the video1 pipeline connected to the LCD output are latched by the hardware. The hardware can now update the internal registers at the VFP start period and the image displayed on the panel.

Table 12-93 describes the registers to be configured for the LCD enable step and the use case values.

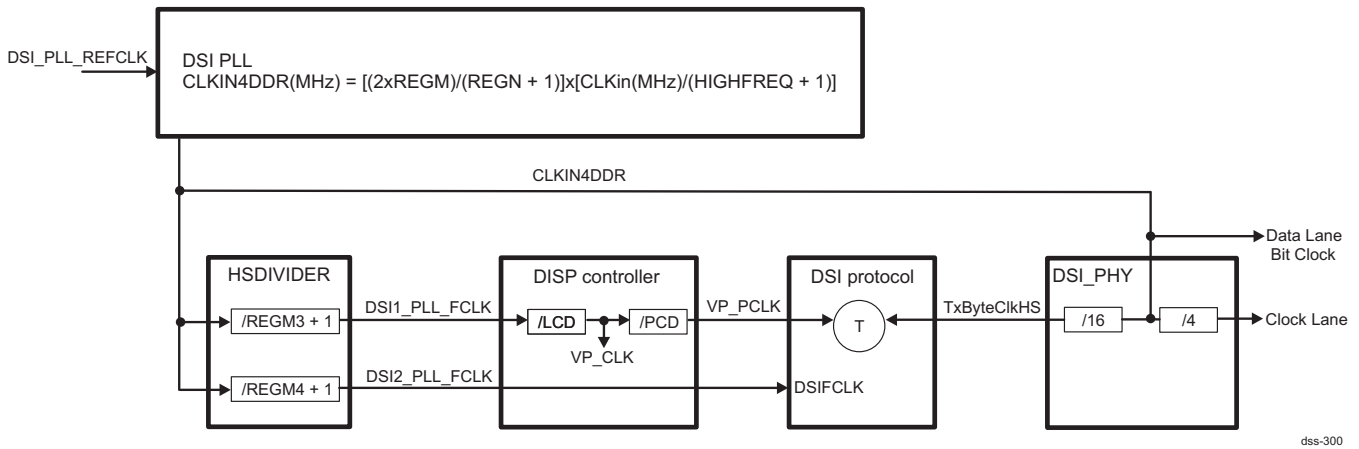

Table 12-93. Registers Print for LCD Enable

| Register Name | Address | Value | Value Description |
|-----------------------|-------------|-------------|--|
| DISPC_CONTROL | 0x4805 0440 | 0x0001 8129 | Set DISPC_CONTROL[0] LCDENABLE and DISPC_CONTROL[5] GOLCD bits to 1. |
| DISPC_VID1_ATTRIBUTES | 0x4805 04CC | 0x0000 83F7 | Enable the DISPC_VID1_ATTRIBUTES[0] VIDENABLE. |

12.6.6 How to Configure the DSI PLL in Video Mode

Figure 12-177 shows a global overview of the DSI clock tree when used in video mode.

Figure 12-177. DSI Clock Tree in Video Mode

The settings of the DSI PLL registers can be summarized by four equations.

Equation 1

$$N * T_{VP_CLK} = T_L * T_{TxByteClkHS}$$

dss-301

(19)

where

$$T_L = T_{HS} + HSA_{DSI} + T_{HE} + HFP_{DSI} + (WC + 6) / ND_L + HBP_{DSI}$$

N is an integer

NDL: Number of data lane

WC: Word count or payload in bytes

T_{HS} and T_{HE} are equal to 4/NDL and 0 if they are disabled.

HSA_{DSI} is HSA period in video mode.

T_{HS} is the length of HSYNC start short packet in number of byte clock cycles (TxByteClkHS).

T_{HE} is the length of HSYNC end short packet in number of byte clock cycles (TxByteClkHS).

HBP_{DSI} is HBP period in video mode.

HFP_{DSI} is HFP period in video mode.

NOTE: HSA_{DSI} timing is not used and does not have to be programmed when HE short packet is not generated.

Equation 2

$$R = T_{TxByteClkHS} / T_{VP_PCLK}$$

dss-302

(20)

To synchronize DISPC and DSI protocol engine, users should follow the ratio T between TxByteClkHS and VP_PCLK as listed in Table 12-94.

Table 12-94. Ratio R

| Number of Data Lanes | Pixel Format | Ratio R |
|----------------------|---------------|---------|
| 1 | 16-bits pixel | 1/2 |
| 1 | 18-bits pixel | 4/9 |
| 1 | 24-bits pixel | 1/3 |
| 2 | 16-bits pixel | 1 |
| 2 | 18-bits pixel | 8/9 |
| 2 | 24-bits pixel | 2/3 |

All cases are covered by:

$$F_{VP_PCLK} * \text{bits_per_pixel} = F_{TxByteClkHS} * \text{NDL} * 8$$

dss-310

Equation 3

$$(HSA_{DISPC} + HFP_{DISPC} + PPL + HBP_{DISPC}) * T_{VP_PCLK} = (4/NDL + HFP_{DSI} + (WC + 6)/NDL + HBP_{DSI}) * T_{TxByteClkHS}$$

dss-303
(21)

Equation 4

$$HFP_{DSI} = ((HFP_{DISPC} * bits_per_pixel) / (NDL * 8)) - (2 / NDL)$$

dss-309
(22)

Example

The desired performances are:

- Clock lane at 150 MHz
- RGB24-888
- 1-data lane
- LCD size 480*640 with $HSA_{DISP} = HFP_{DISP} = HBP_{DISP} = 20$, $VSA_{DISP} = VFP_{DISP} = VBP_{DISP} = 2$

Step 1. Determine REGM and REGN

To obtain correct stability, Fint should be kept between 0.75 MHz and 2.1 MHz. In this case, Fint is maintained at 2 MHz. For more information, refer to the DSI PLL programming model.

$$REGN = (F_{DSI_PLL_REFCLK} / F_{int}) - 1$$

$$REGN = 12$$

$$REGM = (REGN+1)*F_{CLKIN4DDR} / (2 * F_{DSI_PLL_REFCLK})$$

$$REGM = 150$$

dss-318

Where DSS2_ALWON_FCLK= 26 MHz is used as a reference clock for $F_{DSI_PLL_REFCLK}$

Step 2. Determine VP_PCLK and TxByteClkHS clocks.

TxByteClkHS frequency is equal to 37.5 MHz. With ratio R equal to 1/3, VP_PCLK frequency is equal to 12,5 MHz. The frame rate can be estimated by:

$$\text{Frame rate} = F_{VP_PCLK} / (HSA_{DISPC} + HFP_{DISPC} + PPL + HBP_{DISPC}) * (VSA_{DISPC} + VFP_{DISPC} + LPP + VBP_{DISPC})$$

$$\text{Frame rate} = 12,5 \text{ MHz} / (540) * (646)$$

$$\text{Frame rate} = 35,83 \text{ frame/sec}$$

dss-323

Step 3. Determine LCD, PCD and REGM3

$$T_{CLKIN4DDR} = T_{TxByteClkHS} / 16 = T_{VP_PCLK} / ((REGM3 + 1) * LCD * PCD)$$

$$((REGM3 + 1) * LCD * PCD) = 16 * 3$$

dss-315

If LCD and PCD are set to 1 and 3 respectively, REGM3 is equal to 15.

Step 4. Verify N as integer

Firstly, TL must be determined

$$(HSA_{DISPC} + HFP_{DISPC} + PPL + HBP_{DISPC}) * T_{VP_PCLK} / T_{TxByteClkHS} = T_L = 1620$$

dss-316

From **Equation 1**,

$$N * T_{VP_CLK} = T_L * T_{TxByteClkHS}$$

$$N = T_{TxByteClkHS} * T_L / T_{VP_CLK} = T_L / (R * PCD)$$

$$N = 14580$$

N is an integer.

Step 5. Determine HFP and HBP of the DSI protocol engine

From **Equation 3**,

$$(HSA_{DISPC} + HFP_{DISPC} + PPL + HBP_{DISPC}) * T_{VP_PCLK} / T_{TxByteClkHS} - (4/NDL + (WC + 6)/NDL) = HFP_{DSI} + HBP_{DSI}$$

$$HFP_{DSI} + HBP_{DSI} = 170$$

dss-317

From **Equation 4**,

$$HFP_{DSI} = ((HFP_{DISPC} * \text{bits_per_pixel}) / (NDL * 8)) - (2 / NDL)$$

$$HFP_{DSI} = 58$$

$$HBP_{DSI} = 170 - 58 = 112$$

dss-321

12.6.7 DSI Video Mode Using the DISPC Video Port

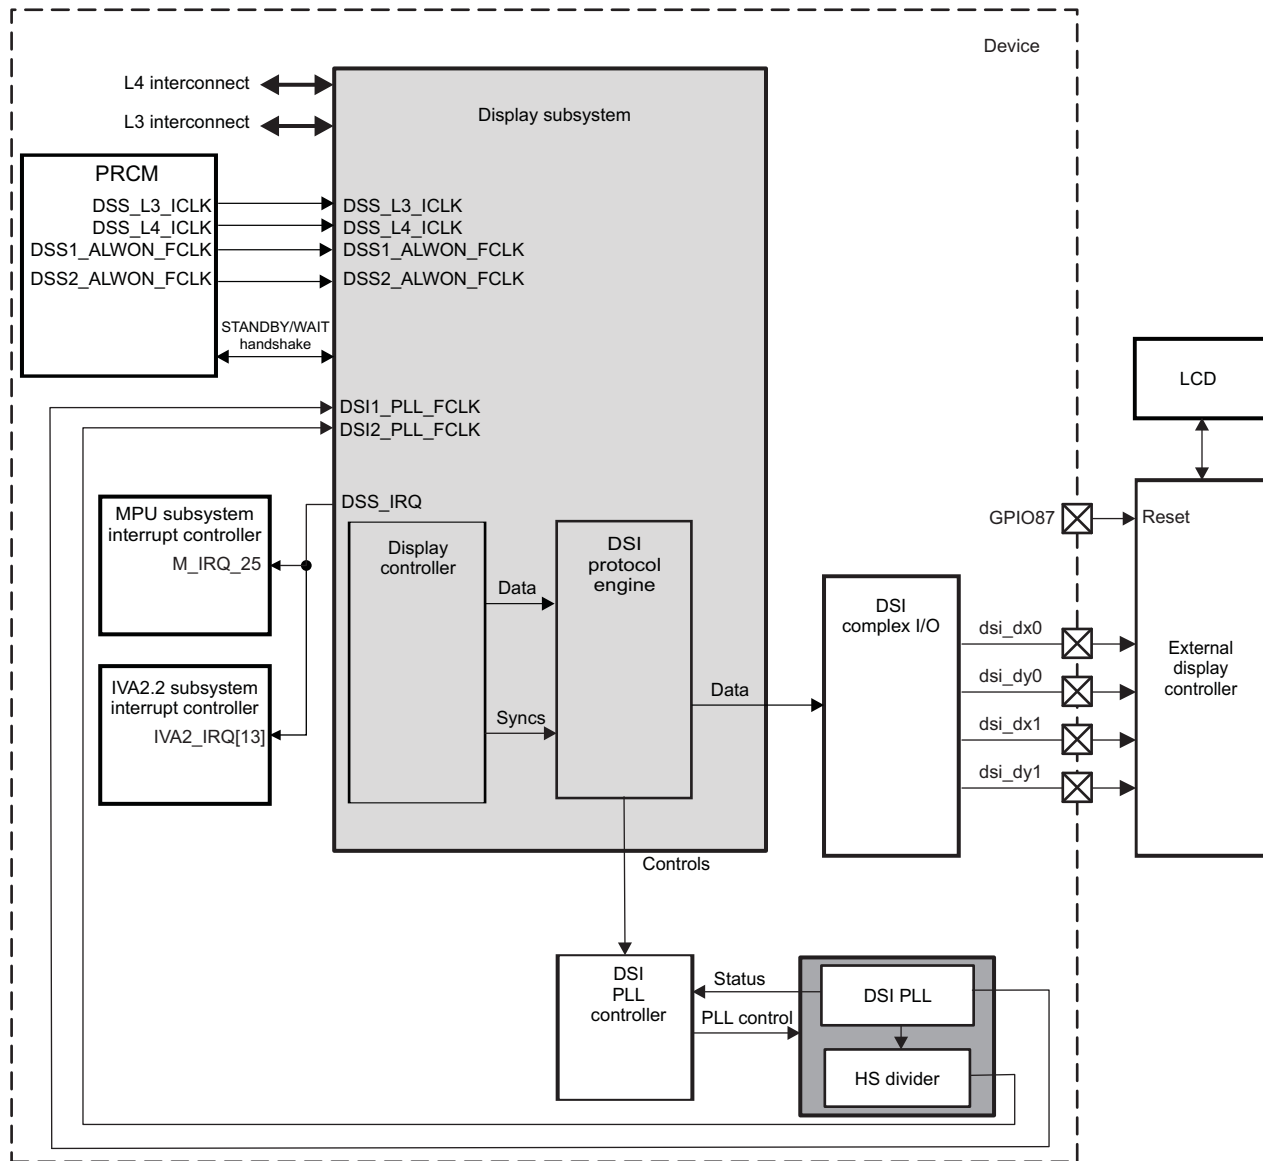

This section details the basic programming model of video mode using the DISPC video port.

The DSI interface is connected to an external MIPI display controller and the following parameters are used:

- 1 data lane: $NDL = 1$
- Clock lane at 150 MHz (DSI_DDR_CLK)
- LCD size is 640 × 480:
 - 480 pixels per line (PPL)
 - 680 lines per panel (LPP)
- Display controller input format: YUV
- Display controller output format: RGB888, that is 24 bits per pixel (BPP)
- Word Count: $WC = 3 \times PPL$
- DSS2_ALWON_FLCK=26 MHz is used as a reference clock for DSI PLL
- Virtual channel 0 (VC0) is used for video mode.
- Interleaving is not used.
- It is assumed that all modules used in these programming models are in after-POR state.

Figure 12-178 is an overview of the connections in the display subsystem.

Figure 12-178. Overview

dss-330

The steps listed in [Table 12-95](#) are described in the following sections.

Table 12-95. Main Steps

| Steps | Section |
|--|--|
| Configure DSS clocks | Section 12.6.7.1, Display Subsystem Clock Configuration |
| Configure the DSI and DSI PLL | Section 12.6.7.2, Configure DSI, DSI PLL and Complex I/O |
| Configure the external MIPI display controller | Section 12.6.7.3, Initialization of the External MIPI Display Controller |
| Configure the DISPC | Section 12.6.7.4, Configure the DISPC |
| Enable video mode using the DISPC video port | Section 12.6.7.5, Enable Video Mode Using the DISPC Video Port |

The programming model must be followed in the order of the following sections.

12.6.7.1 Display Subsystem Clock Configuration

[Table 12-96](#) lists the steps required to enable the clocks.

Table 12-96. PRCM Registers

| Steps | Registers | Value |
|--|--------------------------------|-------|
| Set the divided DPLL value for DSS1. | CM_CLKSEL_DSS[4:0] CLKSEL_DSS1 | 0x9 |
| Disable autoidle mode. | CM_AUTOIDLE_DSS[31:0] | 0x0 |
| Domain sleep is disabled. | CM_SLEEPDEP_DSS[31:0] | 0x0 |
| Automatic transition between active and inactive are disabled. | CM_CLKSTCTRL_DSS[31:0] | 0x0 |
| Enable DSS1, DSS2 and TV clock (DSS1_ALWON_FCLK, DSS2_ALWON_FCLK and TV_CLK). TV_CLK is only need for correct Reset. | CM_FCLKEN_DSS[31:0] | 0x7 |
| Enable the subsystem interface clock (DSS_L3_ICLK and DSS_L4_ICLK). | CM_ICLKEN_DSS[31:0] | 0x1 |

12.6.7.2 Configure DSI, DSI PLL and Complex I/O

12.6.7.2.1 Reset DSI Modules

Table 12-97 lists the steps required to reset the DSI modules.

Table 12-97. Resets

| Steps | Registers | Value |
|---|-----------------------------|----------|
| Reset IRQ status. | DSI_IRQSTATUS[31:0] | 0x0 |
| OCP and functional clock are maintained during wakeup, smart idle, and reset DSI. | DSI_SYSCONFIG[31:0] | 0x312 |
| Wait until RESET_DONE ≠ 0. | DSI_SYSSTATUS[0] RESET_DONE | Read 0x1 |

12.6.7.2.2 Set Up DSI DPLL

Table 12-98 lists the steps required to configure DSI PLL.

Table 12-98. DSI PLL Configuration Registers

| Steps | Registers | Value |
|--|---|----------|
| Turn on PLL and HSDIVIDER. | DSI_CLK_CTRL[31:30] PLL_PWR_CTRL | 0x2 |
| Wait until PLL_PWR_STATUS = 0x2. | DSI_CLK_CTRL[29:28] PLL_PWR_STATUS | Read 0x2 |
| See the calculation following this table. | DSI_PLL_CONFIGURATION1[26:23] DSIPROTO_CLK_DIV | 5 |
| See the calculation following this table. | DSI_PLL_CONFIGURATION1[22:19] DSS_CLOCK_DIV | 15 |
| See the calculation following this table. | DSI_PLL_CONFIGURATION1[18:8] DSI_PLL_REGM | 150 |
| See calculation following this table. | DSI_PLL_CONFIGURATION1[7:1] DSI_PLL_REGN | 12 |
| Enable PLLStopMode. | DSI_PLL_CONFIGURATION1[0] | 0x1 |
| The DSI protocol engine clock divider, DSS clock divider, CLKIN4DDR, and PLL reference clock are enabled. PLL internal reference frequency is between 1.75 and 2.1MHz. | DSI_PLL_CONFIGURATION2[31:0] | 0x5600E |
| Manual mode | DSI_PLL_CONTROL[31:0] | 0x0 |
| Request PLL locking sequence. | DSI_PLL_GO[0] DSI_PLL_GO | 0x1 |
| Read until DSI_PLL_GO = 0 | DSI_PLL_GO[0] DSI_PLL_GO | Read 0x0 |
| PLL is locked. | DSI_PLL_STATUS[1] DSI_PLL_LOCK | Read 0x1 |

Table 12-98. DSI PLL Configuration Registers (continued)

| Steps | Registers | Value |
|---|-------------------------------------|-------------|
| Turn on PLL and HSDIVIDER; the DSI functional clock > 30-MHz sync is rising/rising; the DSISyncClk signal is automatically asserted/deasserted; the L3_ICLK clock to the DSI complex I/O is not gated; and LPCLKDIVISOR = 8 | DSI_CLK_CTRL [31:0] | 0x8024 4008 |

1. Calculate the divider value for the DSI protocol engine clock source:

$$\text{RegM4} = \text{FCLKIN4DDR} / \text{DSI2_PLL_FCLK} - 1$$

$$\text{FCLKIN4DDR} = 4 \times \text{FCLKIN}$$

$$\text{RegM4} = 5$$

2. Determine LCD, PCD, and REGM3:

Calculate the divider value for DSS clock source: Same as Step 3.

$$\text{RegM3} = ((\text{BPP} \times 2) / (\text{DISPC_LCD} \times \text{DISPC_PCD} \times \text{NDL})) - 1$$

$$\text{RegM3} = 15$$

dss-E127

3. Calculate N Divider for PLL:

$$\text{FCLKIN4DDR} = \text{FCLKIN} \times 4$$

$$\text{RegN} = (\text{FDSI_PLL_REFCLK} / \text{Fint}) - 1$$

$$\text{FDSI_PLL_REFCLK} = 26 \text{ MHz (system clock)}$$

$$\text{Fint} = 2 \text{ MHz (reduce PLL lock time)}$$

$$\text{RegN} = 12$$

dss-E128

4. Calculate M divider for PLL:

$$\text{RegM} = ((\text{RegN} + 1) \times (\text{FCLKIN4DDR} / (2 \times \text{FDSI_PLL_REFCLK})))$$

$$\text{FCLKIN4DDR} = 4 \times 150 \text{ MHz}$$

$$\text{RegM} = 150$$

dss-E129

12.6.7.2.3 Switch to DSI PLL Clock Source

Select the DSI_PLL1 clock as the DISPC functional clock, and select the DSI_PLL2 clock as the DSI functional clock: Set [DSS_CONTROL](#) to 0x3.

12.6.7.2.4 Set Up DSI Protocol Engine

12.6.7.2.4.1 Set Up DSI Control Registers

[Table 12-99](#) lists the steps to set up the DSI control registers. [Table 12-100](#) lists the steps to set up the DSI complex I/O registers.

Table 12-99. DSI Control Registers

| Steps | Registers | Value |
|--|--|----------|
| Enable SYNCLOST event. | DSI_IRQENABLE [31:0] | 0x4 0000 |
| Set PACKET_SENT_IRQ_EN. | DSI_VC0_IRQENABLE [31:0] | 0x4 |
| While the HSYNC START pulse is detected, the associated short packet HSYNC START is generated. | DSI_CTRL [17] VP_HSYNC_START | 0x1 |
| While the VSYNC START pulse is detected, the associated short packet VSYNC START is generated. | DSI_CTRL [15] VP_VSYNC_START | 0x1 |

Table 12-99. DSI Control Registers (continued)

| Steps | Registers | Value |
|--|---------------------------------|-------|
| Set the trigger reset mode to <i>immediate</i> . | DSI_CTRL[14] TRIGGER_RESET_MODE | 0x1 |
| Activate two line buffers. | DSI_CTRL[13:12] LINE_BUFFER | 0x2 |
| HSYNC signal on the video port is active high. | DSI_CTRL[10] VP_HSYNC_POL | 0x1 |
| VSYNC on the video port is active high. | DSI_CTRL[11] VP_VSYNC_POL | 0x1 |
| Set the Data Enable signal on the video port as active high. | DSI_CTRL[9] VP_DE_POL | 0x1 |
| Set the size of the video port data bus for the RGB format: 0x2 for RGB 888. | DSI_CTRL[7:6] VP_DATA_BUS_WIDTH | 0x2 |
| VP_CLK_RATIO is not used if video port is used to provide data in video mode | DSI_CTRL[4] VP_CLK_RATIO | 0x0 |
| Set the arbitration scheme for granting the VC pending ready requests in the TX FIFO as Sequential Scheme. | DSI_CTRL[3] TX_FIFO_ARBITRATION | 0x1 |
| Enable the ECC check for the received header. | DSI_CTRL[2] ECC_RX_EN | 0x1 |

Table 12-100. DSI Complex I/O Registers

| Steps | Registers | Value |
|--|---|-------------|
| GOBIT, complex I/O power ON, select data, and clock position | DSI_COMPLEXIO_CFG1 | 0x4800 0032 |
| Clear Reg | DSI_COMPLEXIO_IRQSTATUS | 0xC3F39CE7 |
| Disable IRQ | DSI_COMPLEXIO_IRQENABLE | 0x0 |
| Enable I/F | DSI_CTRL[0] IF_EN | 0x1 |
| Disable I/F | DSI_CTRL[0] IF_EN | 0x0 |
| Wait until IF_EN = 0 | DSI_CTRL[0] IF_EN | Read 0x0 |
| Enable Low Power clock | DSI_CLK_CTRL[20] LP_CLK_ENABLE | 0x1 |
| Reset is done. | DSI_COMPLEXIO_CFG1[29] RESET_DONE | Read 0x1 |
| Power control is on. | DSI_COMPLEXIO_CFG1[26:25] PWR_STATUS | Read 0x1 |
| Reset is complete. | DSI_SYSSTATUS[0] RESETDONE | Read 0x1 |

12.6.7.2.4.2 Configure DSI Timing and Virtual Channels

Table 12-101 lists the steps to configure DSI timing and the virtual channels.

Table 12-101. DSI Timing Registers

| Steps | Registers | Value |
|--|----------------------|--------------|
| STOP_STATE_COUNTER_IO = 0x999 | DSI_TIMING1[31:0] | 0x0000 0999 |
| HS_TX_TO_X8, HS_TX_TO_COUNTER = 0x0FD2, LP_RX_TO_X16, LP_RX_TO_COUNTER = 0x00CD | DSI_TIMING2[31:0] | 0x2FD2 40CD |
| (HSA<<24) (HFP<<12) HBP | DSI_VM_TIMING1[31:0] | 0x0000 700A |
| (WINDOW_SYNC<<24) (VSA<<16) (DSI_VFP<<8) VBP | DSI_VM_TIMING2[31:0] | 0x0401 0101 |
| (TL<<16) DSI_VACT | DSI_VM_TIMING3[31:0] | 0x05BB 0280 |
| (ENTER_HS_MODE_LATENCY<<16) EXIT_HS_MODE_LATENCY | DSI_VM_TIMING7[31:0] | 0x0000 C000A |
| DDR_CLK_PRE<<8 DDR_CLK_POST | DSI_CLK_TIMING[31:0] | 0x0000 0F0B |
| HS speed, ECC generation for the Transmit, Enable CheckSum generation for the Payload. | DSI_VC0_CTRL[31:0] | 0x2080 0390 |

- Freq TxByteClkHS :

$$FHSB = FCLKIN4DDR / 16$$

$$FVPP = FCLKIN4DDR / ((RegM3 + 1) \times DISPC_LCD * DISPC_PCD)$$

$$FVP = FCLKIN4DDR / (RegM3 + 1)$$
- Length of the line in video mode in Nb of byte clock cycles (TxByteClkHS):

$$TL = FHSB / FVPP \times (DISPC_HSA + DISPC_HFP + PPL + DISPC_HBP)$$

$$TL1f = (BPP / (8 \times NDL)) \times (DISPC_HSA + DISPC_HFP + PPL + DISPC_HBP)$$
- Blanking periods (HBP + HFP) in DSI are calculated based on the following formula:

$$(DISPC_HSA + DISPC_HBP + PPL + DISPC_HFP) \times Fppi = (HS + HBP + ((WC + 6) / NDL) + HFP) \times Fvp$$

$$HBP + HFP = (TVPP / THSB) \times (DISPC_HSA + DISPC_HFP + PPL + DISPC_HBP) - (HS + (WC + 6) / NDL)$$

$$HBPplusHFP = (FHSB / FVPP) \times (DISPC_HSA + DISPC_HFP + PPL + DISPC_HBP) - (HS + WC + 6) / NDL$$

$$HBPplusHFPf = ((FHSB / FVPP) \times (DISPC_HSA + DISPC_HFP + PPL + DISPC_HBP)) - ((HS + WC + 6) / NDL)$$

$$HFP = (DISPC_HFP \times BPP) / (NDL \times 8) - (2 / NDL)$$

$$HBP = HBPplusHFP - HFP$$

dss-E132

12.6.7.2.5 Configure DSI_PHY

For the calculation of DSI_PHY timing, see [Table 12-102](#). See [Section 12.4.3.2, Clock Requirements](#), for details on timing calculation.

Table 12-102. Calculate DSI_PHY Timing

| Steps | Registers | Value |
|--------------------------------------|---|-----------------------------------|
| See Section 12.4.3.2 | DSI_PHY_CFG0 [31:24] THS_PREPARE | ceil(70 ns/DDR clock period) + 2 |
| | DSI_PHY_CFG0 [23:16] THS_PREPARE_THS_ZERO | ceil(175 ns/DDR clock period) + 2 |
| | DSI_PHY_CFG0 [7:0] THS_EXIT | ceil(145 ns/DDR clock period) |
| | DSI_PHY_CFG0 [15:8] THS_TRAIL | ceil(60 ns/DDR clock period) + 5 |
| | DSI_PHY_CFG2 [7:0] TCLK_PREPARE | ceil(65 ns/DDR clock period) |
| | DSI_PHY_CFG1 [7:0] TCLK_ZERO | ceil(260 ns/DDR clock period) |
| | DSI_PHY_CFG1 [15:0] TCLK_TRAIL | ceil(60 ns/DDR clock period) + 2 |
| | DSI_PHY_CFG1 [22:16] TLPX_HALF | ceil(26.5 ns/DDR clock period) |

NOTE: Keep Reserved bits at reset value in the [DSI_PHY_CFG1](#) and [DSI_PHY_CFG2](#) registers.

12.6.7.2.6 Drive Stop State

[Table 12-103](#) lists the steps to Drive Stop State.

Table 12-103. Drive Stop State

| Steps | Registers | Value |
|--------------------------------------|---|----------|
| Force TX stop mode | DSI_TIMING [15] FORCE_TX_STOP_MODE_IO | 0x1 |
| Wait until FORCE_TX_STOP_MODE_IO = 0 | DSI_TIMING [15] FORCE_TX_STOP_MODE_IO | Read 0x0 |

12.6.7.3 Initialization of the External MIPI Display Controller

1. Wait for the external MIPI display controller initialization after power up.
In this example, the external MIPI display controller is reset using GPIO 87.
2. Configure the external MIPI display controller.

12.6.7.4 Configure the DISPC

12.6.7.4.1 Reset DISPC

Table 12-104 lists the step sequence to reset the DISPC.

Table 12-104. Reset DISPC

| Steps | Registers | Value |
|---|-----------------------------------|----------|
| Reset the DISPC. | DISPC_SYSCONFIG[1] SOFTRESET | 0x1 |
| DISPC is reset. | DISPC_SYSCONFIG[0] RESETDONE | Read 0x1 |
| No standby: MStandby is never asserted. | DISPC_SYSCONFIG [13:12] MIDLEMODE | 0x1 |
| Disable idle mode. | DISPC_SYSCONFIG [4:3] SIDLEMODE | 0x1 |
| Disable all interrupts. | DISPC_IRQENABLE[31:0] | 0x0 |

12.6.7.4.2 Configure DISPC Timing, Window, and Color

Table 12-105 lists the steps to configure the DISPC registers. Table 12-106 lists the steps to configure the color space coefficient registers.

Table 12-107 lists the steps to configure DISPC_CONTROL.

Table 12-105. Configure DISPC Registers

| Steps | Registers | Value |
|--|---------------------------|--|
| Set horizontal timings. | DISPC_TIMING_H | $(HBP - 1 \ll 20) (HFP - 1 \ll 8) HSA - 1$ |
| Set vertical timing. | DISPC_TIMING_V | $(HBP - 1 \ll 20) (HFP - 1 \ll 8) HSA - 1$ |
| Set LCD – PCD display controller and pixel clock divisor. | DISPC_DIVISOR | $LDC = \%1 \text{ PXLCLK} = \%4$ |
| Set the size of the LCD – 1. | DISPC_SIZE_LCD | $(LPP - 1 + DSI_VFP) \ll 16 (PPL - 1)$ |
| Set default RGB value when there is no data. | DISPC_DEFAULT_COLOR0 | 0xFF |
| Set video FIFO height and low threshold. | DISPC_VID1_FIFO_THRESHOLD | 0xfc00c0 |
| Set the X Y location of the upper left pixel (0 = 0) to the upper left corner. | DISPC_VID1_POSITION | 0x0 |
| Set size of the window. | DISPC_VID1_SIZE | $(LPP - 1) \ll 16 (PPL - 1)$ |
| Set the size of the picture. | DISPC_VID1_PICTURE_SIZE | $(LPP - 1) \ll 16 (PPL - 1)$ |
| Set the input address picture. | DISPC_VID1_BA0 | 0x– |

Table 12-106. Configure Color Space Coefficient Registers

| Comments | Registers | Value |
|--------------------------|-----------------------|------------|
| RCR and RY coefficients | DISPC_VID1_CONV_COEF0 | 0X0199012A |
| GY and RCB coefficients | DISPC_VID1_CONV_COEF1 | 0X012A0000 |
| GCB and GCR coefficients | DISPC_VID1_CONV_COEF2 | 0X079C0730 |
| BCR and BY coefficients | DISPC_VID1_CONV_COEF3 | 0X0000012A |
| BCB coefficient | DISPC_VID1_CONV_COEF4 | 0X00000205 |

Table 12-107. Configure DISPC_CONTROL

| Comments | Registers | Value |
|---|----------------------------------|-------|
| Enable pixel clock free-running. | DISPC_CONTROL[27] PCLKFREEENABLE | 0x1 |
| I/O pad mode selection: Bypass | DISPC_CONTROL[16] GPOUT1 | 0x1 |
| I/O pad mode selection: Bypass | DISPC_CONTROL[15] GPOUT0 | 0x1 |
| Normal mode selected | DISPC_CONTROL[11] STALLMODE | 0x0 |
| 3 for RGB888 | DISPC_CONTROL[9:8] TFTDATALINES | 0x3 |
| The hardware has finished updating the internal shadow registers of the pipeline(s) connected to the LCD output using the user values. The hardware resets the bit when the update completes. | DISPC_CONTROL[5] GOLCD | 0x0 |
| Active matrix display operation mode | DISPC_CONTROL[3] STNTFT | 0x1 |
| LCD interface is disabled. | DISPC_CONTROL[0] LCDENABLE | 0x0 |

The input image is converted from UYVY into RGB (see [Table 12-108](#)) :

Table 12-108. Configure DISPC_VID1_ATTRIBUTES

| Comments | Registers | Value |
|---|--|-------|
| Row of VIDn will not be read twice. | DISPC_VID1_ATTRIBUTES[18] VIDROWREPEATENABLE | 0x0 |
| 8 x 32-bit bursts | DISPC_VID1_ATTRIBUTES[15:14] VIDBURSTSIZE | 0x1 |
| Full range selected: Y is not modified before the color space conversion. | DISPC_VID1_ATTRIBUTES[11] VIDFULLRANGE | 0x1 |
| Enable color space conversion CbYCr to RGB. | DISPC_VID1_ATTRIBUTES[9] VIDCOLORCONVENABLE | 0x1 |
| UYVY | DISPC_VID1_ATTRIBUTES[4:1] VIDFORMAT | 0xB |
| Video disabled | DISPC_VID1_ATTRIBUTES[0] VIDENABLE | 0x0 |

12.6.7.5 Enable Video Mode Using the DISPC Video Port

[Table 12-109](#) lists the steps to enable DISPC to send frames continuously.

Table 12-109. Enable DISPC

| Steps | Registers | Value |
|---------------------------|------------------------------------|-------------|
| Set up long packet header | DSI_VC0_LONG_PACKET_HEADER[31:0] | 0x0005 A03E |
| Enable VC0. | DSI_VC0_CTRL[1] VC_EN | 0x1 |
| Enable IF. | DSI_CTRL[0] IF_EN | 0x1 |
| Wait until IF_EN ≠ 0. | DSI_CTRL[0] IF_EN | Read 0x0 |
| Enable VID1. | DISPC_VID1_ATTRIBUTES[0] VIDENABLE | 0x1 |
| Enable LCD interface. | DISPC_CONTROL[0] LCDENABLE | 0x1 |
| Enable GOLCD. | DISPC_CONTROL[5] GOLCD | 0x1 |
| Wait until GOLCD = 0. | DISPC_CONTROL[5] GOLCD | Read 0x0 |

12.6.8 DSI Command Mode Using the DISPC Video Port

This section presents some generic use cases and tips for setting the modules of the display subsystem.

12.6.8.1 Display Subsystem Use Cases and Tips

This section explains the basic programming model of command mode using the DISPC video port.

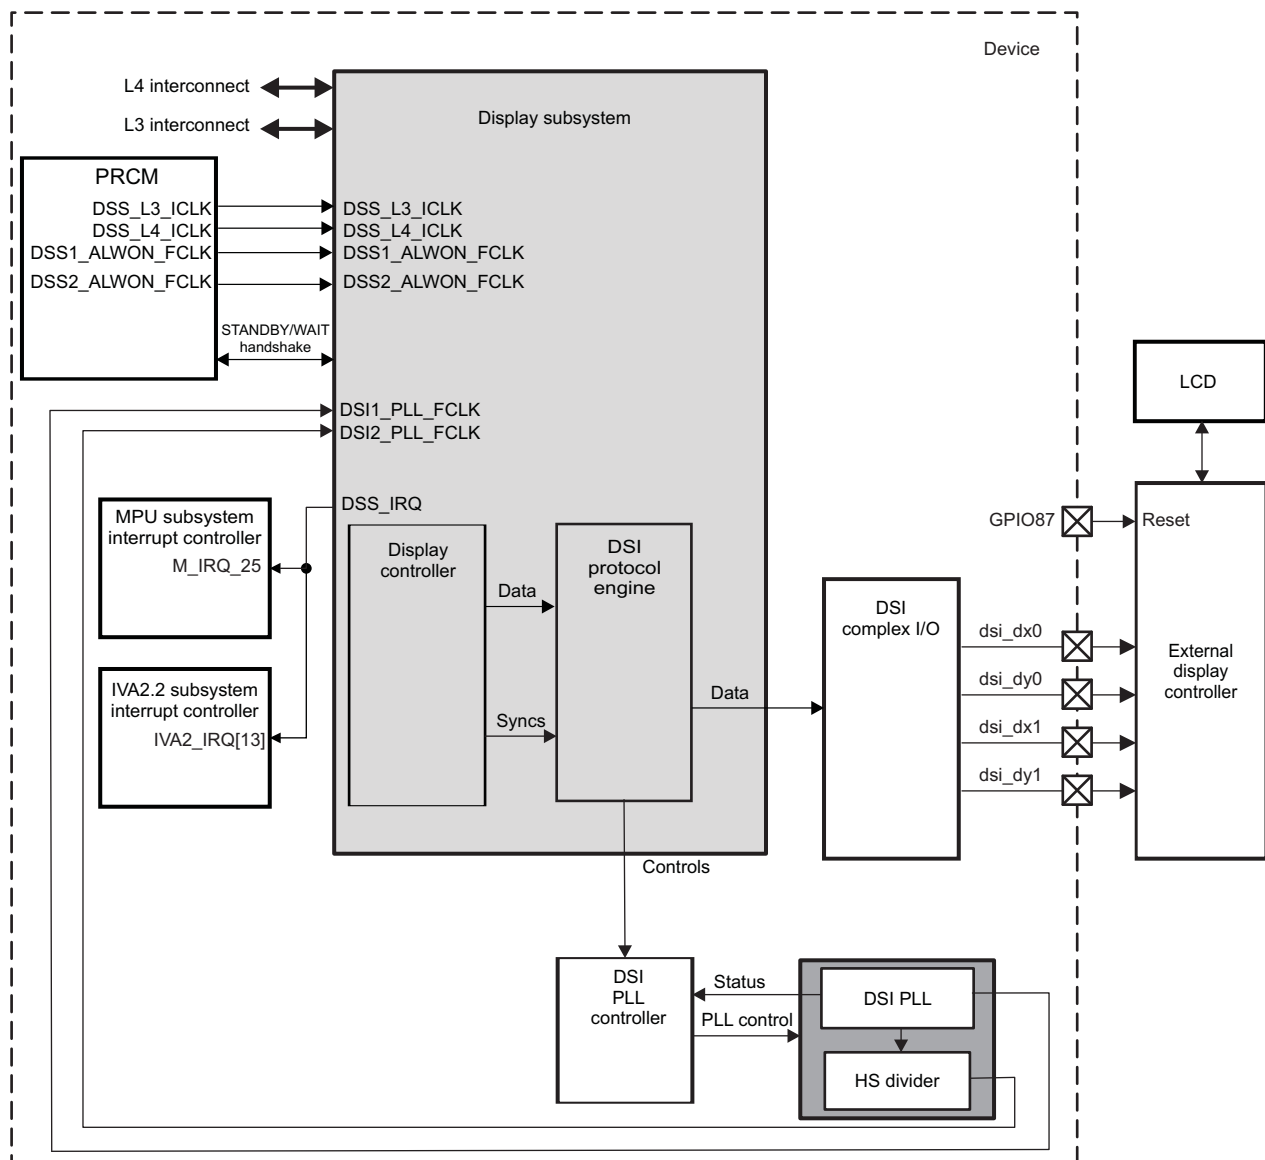

The DSI interface is connected to an external MIPI DISPC using the following parameters:

- One data lane: NDL = 1

- Clock lane at 150 MHz (DSI_DDR_CLK)
- LCD size is 640 x 480:
 - 480 PPL
 - 680 LPP
- DISPC input format: YUV
- DISPC output format: RGB888 (24 BPP)
- Word Count: WC = 3 x PPL
- DSS2_ALWON_FLCK = 26 MHz used as a reference clock for DSI PLL
- Virtual channel 1 (VC1) used for command mode to configure the external DISPC, and virtual channel 0 (VC0) used to send data
- Automatic TE used for synchronization
- Interleaving not used
- It is assumed that all modules used in these programming models are in after-POR state.

Figure 12-179 is an overview of the connections in the display subsystem.

Figure 12-179. Overview

dss-330

Table 12-110 lists the steps of the main sequence and the sections that describe them.

Table 12-110. Main Sequence

| Steps | Register/Bit Field/Programming Model |
|--|---|
| Configure DSS clocks. | Section 12.6.8.1.1 , <i>Configure DSS Clocks at the PRCM Module</i> |
| Configure the DSI protocol engine and DSI PLL. | Section 12.6.8.1.2 , <i>Configure DSI Protocol Engine, DSI PLL, and Complex I/O</i> |
| Configure the external MIPI display controller. | Section 12.6.8.1.3 , <i>Initialization of the External MIPI Display Controller</i> |
| Configure the DISPC. | Section 12.6.8.1.4 , <i>Configure the DISPC</i> |
| Enable command mode using the DISPC video port. | Section 12.6.8.1.5 , <i>Enable Command Mode Using the DISPC Video Port</i> |
| Send a frame data to LCD panel using automatic TE. | Section 12.6.8.1.6 , <i>Send Frame Data to LCD Panel Using Automatic TE</i> |

The programming model must follow the step sequence.

12.6.8.1.1 Configure DSS Clocks at the PRCM Module

Table 12-111 lists the steps required to enable the clocks.

Table 12-111. Configure DSS Clocks at the PRCM Module

| Steps | Register/Bit Field/Programming Model | Value |
|---|---|-------|
| Set the divided DPLL value for DSS1. | CM_CLKSEL_DSS[4:0] CLKSEL_DSS1 | 0x9 |
| Disable autoidle mode. | CM_AUTOIDLE_DSS[0] AUTO_DSS | 0x0 |
| Domain sleep is disabled. | CM_SLEEPDEP_DSS[2:0] EN_IVA2, EN_MPU, EN_CORE | 0x0 |
| Disable automatic transition. | CM_CLKSTCTRL_DSS[1:0] CLKTRCTRL_DSS | 0x0 |
| Enable the DSS1_ALWON_FCLK, DSS2_ALWON_FCLK, and TV_CLK functional clocks. ⁽¹⁾ | CM_FCLKEN_DSS[2:0] EN_TV, EN_DSS2, EN_DSS1 | 0x7 |
| Enable the DSS_L3_ICLK and DSS_L4_ICLK interface clocks. | CM_ICLKEN_DSS[0] EN_DSS | 0x1 |

⁽¹⁾ TV_CLK is required only for a correct reset.

12.6.8.1.2 Configure DSI Protocol Engine, DSI PLL, and Complex I/O

Table 12-112 lists the steps to configure the DSI protocol engine, DSI PLL, and complex I/O and the sections that describe the sequence.

Table 12-112. Configure DSI Protocol Engine, DSI PLL, and Complex I/O

| Steps | Register/Bit Field/Programming Model |
|---------------------------------|--|
| Reset DSI modules. | Section 12.6.8.1.2.1 , <i>Reset DSI Modules</i> |
| Configure DSI DPLL. | Section 12.6.8.1.2.2 , <i>Configure DSI PLL</i> |
| Switch to DSI PLL clock source. | Section 12.6.8.1.2.3 , <i>Switch to DSI PLL Clock Source</i> |
| Configure DSI protocol engine. | Section 12.6.8.1.2.4 , <i>Configure DSI Protocol Engine</i> |
| Configure DSI_PHY. | Section 12.6.8.1.2.5 , <i>Configure DSI_PHY</i> |
| Drive stop state. | Section 12.6.8.1.2.6 , <i>Drive Stop State</i> |

12.6.8.1.2.1 Reset DSI Modules

Table 12-113 lists the steps required to reset the DSI modules.

Table 12-113. Reset DSI Modules

| Steps | Register/Bit Field/Programming | Value |
|--|----------------------------------|-------|
| Clear DSI IRQ status. | DSI_IRQSTATUS[31:0] | 0x0 |
| Maintain interface and functional clock during wakeup. | DSI_SYSCONFIG[9:8] CLOCKACTIVITY | 0x3 |

Table 12-113. Reset DSI Modules (continued)

| Steps | Register/Bit Field/Programming | Value |
|---|--------------------------------|-------|
| Enable smart-idle for power management. | DSI_SYSCONFIG[4:3] SIDLEMODE | 0x2 |
| Set DSI reset. | DSI_SYSCONFIG[1] SOFT_RESET | 0x1 |
| Wait until RESET_DONE = 1. | DSI_SYSSTATUS[0] RESET_DONE | |

12.6.8.1.2.2 Configure DSI PLL

Table 12-114 lists the steps required to configure the DSI PLL.

Table 12-114. Configure DSI PLL

| Steps | Register/Bit Field/Programming | Value |
|---|--|-------|
| Enable PLL and HSDIVIDER. | DSI_CLK_CTRL[31:30] PLL_PWR_CMD | 0x2 |
| Wait until PLL_PWR_STATUS = 0x2. | DSI_CLK_CTRL[29:28] PLL_PWR_STATUS | |
| Set the REGM4 value (see). | DSI_PLL_CONFIGURATION1[26:23] DSIPROTO_CLK_DIV | 5 |
| Set the REGM3 value (see). | DSI_PLL_CONFIGURATION1[22:19] DSS_CLOCK_DIV | 15 |
| Set the REGN value (see). | DSI_PLL_CONFIGURATION1[7:1] DSI_PLL_REGN | 12 |
| Set the REGM value (see). | DSI_PLL_CONFIGURATION1[18:8] DSI_PLL_REGM | 150 |
| Enable PLL STOPMODE. | DSI_PLL_CONFIGURATION1[0] DSI_PLL_STOPMODE | 0x1 |
| Set the PLL internal reference frequency range between 1.75 and 2.1 MHz. | DSI_PLL_CONFIGURATION2[4:1] DSI_PLL_FREQSEL | 0x7 |
| Enable PLL reference clock control. | DSI_PLL_CONFIGURATION2[13] DSI_PLL_REFEN | 0x1 |
| Enable CLKIN4DDR control. | DSI_PLL_CONFIGURATION2[14] DSI_PHY_CLKINEN | 0x1 |
| Enable DSS clock divider. | DSI_PLL_CONFIGURATION2[16] DSS_CLOCK_EN | 0x1 |
| Enable DSI protocol engine clock divider. | DSI_PLL_CONFIGURATION2[18] DSI_PROTO_CLOCK_EN | 0x1 |
| Enable DSI configuration update with DISPC_UPDATE_SYNC. | DSI_PLL_CONTROL[0] DSI_PLL_AUTOMODE | 0x0 |
| Start PLL locking sequence. | DSI_PLL_GO[0] DSI_PLL_GO | 0x1 |
| Wait until DSI_PLL_GO = 0. | DSI_PLL_GO[0] DSI_PLL_GO | |
| Check whether PLL is locked. | DSI_PLL_STATUS[1] DSI_PLL_LOCK | 0x1 |
| Set the LP mode clock ratio. | DSI_CLK_CTRL[12:0] LP_CLK_DIVISOR | 0x8 |
| Set L3_ICLK clock to the DSI complex I/O to not gated. | DSI_CLK_CTRL[14] CIO_CLK_ICG | 0x1 |
| Enable the automatic assertion/deassertion of the DSIStopClk signal. | DSI_CLK_CTRL[18] HS_AUTO_STOP_ENABLE | 0x1 |
| Specify that the DSI functional clock is higher than 30 MHz with a synchronization rising/rising. | DSI_CLK_CTRL[21] LP_RX_SYNCHRO_ENABLE | 0x1 |
| Turn on PLL and HSDIVIDER. | DSI_CLK_CTRL[31:30] PLL_PWR_CMD | 0x2 |

1. Calculate the divider value for the DSI protocol engine clock source:

$$\text{RegM4} = \text{FCLKIN4DDR} / \text{FDSI_PLL_REFCLK} - 1$$

$$\text{FCLKIN4DDR} = 4 \times \text{FCLKIN}$$

$$\text{RegM4} = 5$$

dss-E126

2. Determine LCD, PCD, and REGM3:

Calculate the divider value for the DSS clock source: Same as Step 3.

$$\text{RegM3} = ((\text{BPP} \times 2) / (\text{DISPC_LCD} \times \text{DISPC_PCD} \times \text{NDL})) - 1$$

$$\text{RegM3} = 15$$

dss-E127

3. Calculate N divider for PLL:

$$\text{FCLKIN4DDR} = \text{FCLKIN} \times 4$$

$$\text{RegN} = (\text{FDSI_PLL_REFCLK} / \text{FINT}) - 1$$

$$\text{FDSI_PLL_REFCLK} = 26 \text{ MHz (system clock)}$$

$$\text{Fint} = 2 \text{ MHz (reduce PLL lock time)}$$

$$\text{RegN} = 12$$

dss-E128

4. Calculate M divider for PLL:

$$\text{RegM} = ((\text{RegN} + 1) \times (\text{FCLKIN4DDR} / (2 \times \text{FDSI_PLL_REFCLK})))$$

$$\text{FCLKIN4DDR} = 4 \times 150 \text{ MHz}$$

$$\text{RegM} = 150$$

dss-E129

12.6.8.1.2.3 Switch to DSI PLL Clock Source

Table 12-115 lists the sequence to switch the DSI and DISPC module clocks to DSI PLL clock source.

Table 12-115. Switch to DSI PLL Clock Source

| Steps | Register/Bit Field/Programming | Value |
|--------------------------------------|---------------------------------|-------|
| Switch DISPC clock to DSI1_PLL_FCLK. | DSS_CONTROL[0] DISPC_CLK_SWITCH | 0x1 |
| Switch DSI clock to DSI2_PLL_FCLK. | DSS_CONTROL[1] DSI_CLK_SWITCH | 0x1 |

12.6.8.1.2.4 Configure DSI Protocol Engine

12.6.8.1.2.4.1 Set Up DSI Control Registers

Table 12-116 lists the steps required to set up the DSI control registers. Table 12-117 lists the steps to set up the DSI complex I/O registers.

Table 12-116. DSI Control Registers

| Steps | Register/Bit Field/Programming | Value |
|--|--------------------------------------|-------|
| Enable SYNCLOST event. | DSI_IRQENABLE[18] SYNC_LOST_IRQ_EN | 0x1 |
| Enable IRQ to indicate that packet has been sent on VC1. | DSI_VC1_IRQENABLE[2] PACKET_SENT_IRQ | 0x1 |
| Enable IRQ to indicate that packet has been sent on VC0. | DSI_VC0_IRQENABLE[2] PACKET_SENT_IRQ | 0x1 |
| Set the trigger reset mode to <i>immediate</i> . | DSI_CTRL[14] TRIGGER_RESET_MODE | 0x1 |
| Activate the two line buffers. | DSI_CTRL[13:12] LINE_BUFFER | 0x2 |
| Set the size of the video port data bus to 24 bits (RGB 888). | DSI_CTRL[7:6] VP_DATA_BUS_WIDTH | 0x2 |
| Define the ratio between VP_CLK and VP_PCLK. | DSI_CTRL[4] VP_CLK_RATIO | 0x1 |
| Set the arbitration scheme for granting the VC pending ready requests in the TX FIFO as sequential scheme. | DSI_CTRL[3] TX_FIFO_ARBITRATION | 0x1 |
| Enable the ECC check for the received header. | DSI_CTRL[2] ECC_RX_EN | 0x1 |

Table 12-117. DSI Complex I/O Registers

| Steps | Register/Bit Field/Programming | Value |
|--|--|-------|
| Determine the position of the clock lane. | DSI_COMPLEXIO_CFG1[2:0] CLOCK_POSITION | 0x2 |
| Determine the position of data 1 lane. | DSI_COMPLEXIO_CFG1[6:4] DATA1_POSITION | 0x3 |
| Turn on COMPLEXIO. | DSI_COMPLEXIO_CFG[28:27] PWR_CMD | 0x1 |
| Enable the synchronization of the shadow registers with DISPC_UPDATE_SYNC. | DSI_COMPLEXIO_CFG1[30] GOBIT | 0x1 |

Table 12-117. DSI Complex I/O Registers (continued)

| Steps | Register/Bit Field/Programming | Value |
|------------------------------------|--------------------------------------|------------|
| Clear all COMPLEXIO IRQ status. | DSI_COMPLEXIO_IRQSTATUS | 0xC3F39CE7 |
| Disable all COMPLEXIO IRQs. | DSI_COMPLEXIO_IRQENABLE | 0x0 |
| Enable interface. | DSI_CTRL[0] IF_EN | 0x1 |
| Disable interface. | DSI_CTRL[0] IF_EN | 0x0 |
| Wait until IF_EN = 0. | DSI_CTRL[0] IF_EN | |
| Enable the LP clock. | DSI_CLK_CTRL[20] LP_CLK_ENABLE | 0x1 |
| Check whether reset is complete. | DSI_COMPLEXIO_CFG1[29] RESET_DONE | 0x1 |
| Check whether power control is on. | DSI_COMPLEXIO_CFG1[26:25] PWR_STATUS | 0x1 |
| Check whether reset is complete. | DSI_SYSSTATUS[0] RESETDONE | 0x1 |

12.6.8.1.2.4.2 Configure DSI Timing and Virtual Channels

Table 12-118 lists the steps to configure DSI timing and the virtual channels.

Table 12-118. DSI Timing Registers

| Steps | Register/Bit Field/Programming | Value |
|---|--|-------------|
| Determine the number of DSI_FCLK clock cycles for the STOP-STATE counter. | DSI_TIMING1[12:0] STOP_STATE_COUNTER_IO | 0x999 |
| Disable the multiplication factor of 4 for the number of DSI_FCLK clock cycles for the STOP-STATE counter. | DSI_TIMING1[13] STOP_STATE_X4_IO | 0x0 |
| Disable the multiplication factor of 16 for the number of DSI_FCLK clock cycles for the STOP-STATE counter. | DSI_TIMING1[14] STOP_STATE_X16_IO | 0x0 |
| Clear turn-around timer settings. | DSI_TIMING1[30:16] | 0x0000 |
| Determine the number of DSI_FCLK clock cycles for the LP RX timer. | DSI_TIMING2[12:0] LP_RX_TO_COUNTER | 0x0CD |
| Disable the multiplication factor of 4 for the number of DSI_FCLK clock cycles for the LP RX timer. | DSI_TIMING2[13] LP_RX_TO_X4 | 0x0 |
| Enable the multiplication factor of 16 for the number of DSI_FCLK clock cycles for the LP RX timer. | DSI_TIMING2[14] LP_RX_TO_X16 | 0x1 |
| Determine the number of TxByteClkHS clock cycles for the HS RX timer. | DSI_TIMING2[12:0] HS_TX_TO_COUNTER | 0xFD2 |
| Disable the multiplication factor of 8 for the number of TxByteClkHS clock cycles for the HS TX timer. | DSI_TIMING2[13] HS_TX_TO_X8 | 0x0 |
| Enable the multiplication factor of 16 for the number of TxByteClkHS clock cycles for the HS TX timer. | DSI_TIMING2[14] HS_TX_TO_X16 | 0x1 |
| DDR_CLK_PRE<<8 DDR_CLK_POST | DSI_CLK_TIMING[31:0] | 0x0000 0F0B |
| Configuration of VC1 | | |
| Enable the checksum generation for the transmit payload. | DSI_VC1_CTRL[7] CS_TX_EN | 0x1 |
| Enable the ECC generation for the transmit header. | DSI_VC1_CTRL[8] ECC_TX_EN | 0x1 |
| Disable DMA request for TX FIFO. | DSI_VC1_CTRL[23:21] DMA_TX_REQ_NB | 0x4 |
| Disable DMA request for RX FIFO. | DSI_VC1_CTRL[29:27] DMA_RX_REQ_NB | 0x4 |
| Configuration of VC0 | | |
| Selects source of data and enable VP_STALL. | DSI_VC0_CTRL[1] SOURCE | 0x1 |
| Enable the checksum generation for the transmit payload. | DSI_VC0_CTRL[7] CS_TX_EN | 0x1 |

Table 12-118. DSI Timing Registers (continued)

| Steps | Register/Bit Field/Programming | Value |
|--|---|-------|
| Enable the ECC generation for the transmit header. | DSI_VC0_CTRL[8] ECC_TX_EN | 0x1 |
| Enable high-speed mode to send short and long packets to the peripheral. | DSI_VC0_CTRL[9] MODE_SPEED | 0x1 |
| Disable DMA request for TX FIFO. | DSI_VC0_CTRL[23:21] DMA_TX_REQ_NB | 0x4 |
| Disable DMA request for RX FIFO. | DSI_VC0_CTRL[29:27] DMA_RX_REQ_NB | 0x4 |
| Configuration TX and RX FIFO | | |
| Set size of the RX FIFO allocated for VC1 to 32 x 33 bits. | DSI_RX_FIFO_VC_SIZE[15:12] VC1_FIFO_SIZE | 0x1 |
| Set size of the TX and TX FIFO allocated for VC1 to 96 x 33 bits. | DSI_TX_FIFO_VC_SIZE[15:12] VC1_FIFO_SIZE | 0x3 |

- Freq HSBYTE_CLK:
 - FHSB = FCLKIN4DDR / 16
 - FVPP = FCLKIN4DDR / ((RegM3 + 1) × DISPC_LCD * DISPC_PCD)
 - FVP = FCLKIN4DDR / (RegM3 + 1)
- Length of the line in video mode in number of byte clock cycles (PPI clk):
 - TL = FHSB / FVPP × (DISPC_HSA + DISPC_HFP + PPL + DISPC_HBP)
 - TL1f = (BPP / (8 × NDL)) × (DISPC_HSA + DISPC_HFP + PPL + DISPC_HBP)
- Blanking periods (HBP + HFP) in DSI are calculated based on the following formula:
 - $(DISPC_HSA + DISPC_HBP + PPL + DISPC_HFP) \times Fppi = (HS + HBP + ((WC + 6) / NDL) + HFP) \times Fvp$
 - $HBP + HFP = (TVPP / THSB) \times (DISPC_HSA + DISPC_HFP + PPL + DISPC_HBP) - (HS + (WC + 6) / NDL)$
 - $HBPplusHFP = (FHSB / FVPP) \times (DISPC_HSA + DISPC_HFP + PPL + DISPC_HBP) - (HS + WC + 6) / NDL$
 - $HBPplusHFPf = ((FHSB / FVPP) \times (DISPC_HSA + DISPC_HFP + PPL + DISPC_HBP)) - ((HS + WC + 6) / NDL)$
 - $HFP = (DISPC_HFP \times BPP) / (NDL \times 8) - (2 / NDL)$
 - $HBP = HBPplusHFP - HFP$

dss-E131

dss-E132

12.6.8.1.2.5 Configure DSI_PHY Timing

Table 12-119 summarizes DSI_PHY timing. For more details on timing calculation, see Section 12.4.3.2, Clock Requirements.

Table 12-119. Configure DSI_PHY Timing

| Steps | Register/Bit Field/Programming | Value |
|---|--|-----------------------------------|
| Settings of the DSI protocol timing. For a complete description of timing specifications, see Section 12.4.3.2, Clock Requirements. | DSI_PHY_CFG0[31:24] THS_PREPARE | ceil(70 ns/DDR clock period) + 2 |
| | DSI_PHY_CFG0[23:16] THS_PREPARE_THS_ZERO | ceil(175 ns/DDR clock period) + 2 |
| | DSI_PHY_CFG0[7:0] THS_EXIT | ceil(145 ns/DDR clock period) |
| | DSI_PHY_CFG0[15:8] THS_TRAIL | ceil(60 ns/DDR clock period) + 5 |
| | DSI_PHY_CFG2[7:0] TCLK_PREPARE | ceil(65 ns/DDR clock period) |
| | DSI_PHY_CFG1[7:0] TCLK_ZERO | ceil(260 ns/DDR clock period) |
| | DSI_PHY_CFG1[15:0] TCLK_TRAIL | ceil(60 ns/DDR clock period) + 2 |
| | DSI_PHY_CFG1[22:16] TLPX_HALF | ceil(26.5 ns/DDR clock period) |

NOTE: Keep Reserved bits at reset value in the [DSI_PHY_CFG1](#) and [DSI_PHY_CFG2](#) registers.

12.6.8.1.2.6 Drive Stop State

[Table 12-120](#) lists the steps to drive the stop state.

Table 12-120. Drive Stop State

| Steps | Register/Bit Field/Programming | Value |
|---------------------------------------|--------------------------------------|-------|
| Force TX stop mode. | DSI_TIMING[15] FORCE_TX_STOP_MODE_IO | 0x1 |
| Wait until FORCE_TX_STOP_MODE_IO = 0. | DSI_TIMING[15] FORCE_TX_STOP_MODE_IO | |

12.6.8.1.3 Initialization of the External MIPI LCD Controller

[Table 12-121](#) lists the steps to initialize the external MIPI LCD controller.

Table 12-121. Initialization of the External MIPI LCD Controller

| Steps | Register/Bit Field/Programming | Value |
|---|--------------------------------|-------|
| Reset the MIPI LCD controller using GPIO87. | – | 0x1 |
| Wait until initialization of the external MIPI LCD controller is finished after power up. | – | – |
| Configure the external MIPI LCD controller. | – | – |

12.6.8.1.4 Configure the DISPC

12.6.8.1.4.1 Reset DISPC

[Table 12-122](#) lists the steps to reset the DISPC.

Table 12-122. Reset DISPC

| Steps | Register/Bit Field/Programming | Value |
|--|---|-------|
| Reset the DISPC. | DISPC_SYSCONFIG [1] SOFTRESET | 0x1 |
| Wait until RESETDONE = 1. | DISPC_SYSCONFIG [0] RESETDONE | |
| Disable master interface power management. | DISPC_SYSCONFIG [13:12] MIDLEMODE | 0x1 |
| Disable slave interface power management. | DISPC_SYSCONFIG [4:3] SIDLEMODE | 0x1 |
| Disable all DISPC interrupts. | DISPC_IRQENABLE [31:0] | 0x0 |

12.6.8.1.4.2 Configure DISPC Timing, Window, and Color

[Table 12-123](#) lists the steps to configure the DISPC registers. [Table 12-106](#) lists the steps to configure the color space coefficient registers.

[Table 12-124](#) lists the steps to configure [DISPC_CONTROL](#).

Table 12-123. Configure DISPC Registers

| Steps | Register/Bit Field/Programming | Value |
|---|--|-------|
| Configure LCD output | | |
| Set the logic clock divisor (LCD). | DISPC_DIVISOR [23:16] LCD | 0x1 |
| Set the pixel clock divisor (PCD). | DISPC_DIVISOR [7:0] PCD | 0x4 |
| Set the number of lines on the LCD panel. | DISPC_SIZE_LCD [26:16] LPP | 0x2A7 |
| Set the number of PPL on the LCD panel. | DISPC_SIZE_LCD [10:0] PPL | 0x1DF |

Table 12-123. Configure DISPC Registers (continued)

| Steps | Register/Bit Field/Programming | Value |
|---|--|-------|
| Set solid background color. | DISPC_DEFAULT_COLOR0 | 0xFF |
| Configure VIDEO pipeline VID1. | | |
| Set VID1 FIFO low threshold. | DISPC_VID1_FIFO_THRESHOLD[11:0] VIDFIFOLOWTHRESHOLD | 0x0C0 |
| Set VID1 FIFO high threshold. | DISPC_VID1_FIFO_THRESHOLD[27:16] VIDFIFOHIGHTHRESHOLD | 0xFC0 |
| Set the X position of the VID1 window. | DISPC_VID1_POSITION[10:0] VIDPOSX | 0x0 |
| Set the Y position of the VID1 window. | DISPC_VID1_POSITION[26:16] VIDPOSY | 0x0 |
| Set the number of lines of the VID1 window. | DISPC_VID1_SIZE[26:16] VIDSIZEY | 0x2A7 |
| Set the number of pixels of the VID1 window. | DISPC_VID1_SIZE[10:0] VIDSIZEX | 0x1DF |
| Define the base address of the VID1 frame buffer. | DISPC_VID1_BA0 | 0x– |

Table 12-124. Configure DISPC_CONTROL

| Comments | Register/Bit Field/Programming | Value |
|--|----------------------------------|-------|
| Enable pixel clock free-running. | DISPC_CONTROL[27] PCLKFREEENABLE | 0x1 |
| Disable RFBI. | DISPC_CONTROL[16] GPOUT1 | 0x1 |
| | DISPC_CONTROL[15] GPOUT0 | 0x1 |
| Enable the stall mode. | DISPC_CONTROL[11] STALLMODE | 0x1 |
| Select size of DATALINES. | DISPC_CONTROL[9:8] TFTDATALINES | 0x3 |
| Select active matrix display operation mode. | DISPC_CONTROL[3] STNTFT | 0x1 |
| Disable LCD output interface. | DISPC_CONTROL[0] LCDENABLE | 0x0 |
| Update the internal DISPC registers. | DISPC_CONTROL[5] GOLCD | 0x1 |

12.6.8.1.5 Enable Command Mode Using DISPC Video Port

Table 12-125 lists the steps to enable DISPC to send frames continuously. Two bus turn-arounds (BTA) must be generated (see the MIPI DSI specification for details):

- The first BTA gives bus possession to the display module.
- The second BTA obtains the TE trigger.

Table 12-125. Enable Command Mode and Automatic TE

| Steps | Register/Bit Field/Programming | Value |
|---|--|-------------|
| Insert DCS write memory continue code. | DSI_CTRL[25] DCS_CMD_CODE | 0x0 |
| Enable automatic insertion of DCS command codes when data is sourced by the video port. | DSI_CTRL[24] DCS_CMD_ENABLE | 0x1 |
| Enable VC1. | DSI_VC1_CTRL[0] VC_EN | 0x1 |
| Enable VC0. | DSI_VC0_CTRL[0] VC_EN | 0x1 |
| Enable the interface. | DSI_CTRL[0] IF_EN | 0x1 |
| Wait until IF_EN = 1. | DSI_CTRL[0] IF_EN | |
| Send the sequence to receive the TE trigger from the peripheral. In this use case, code 0x35 + 1 parameter VC = 0, data type = 0x15, DCS write + 1 parameter. | DSI_VC1_SHORT_PACKET_HEADER[31:0] HEADER | 0x0000 3515 |
| Wait until PACKET_SENT_IRQ = 1. | DSI_VC1_IRQSTATUS[2] PACKET_SENT_IRQ | |
| Write 1 to clear PACKET_SENT_IRQ. | DSI_VC1_IRQSTATUS[2] PACKET_SENT_IRQ | 0x1 |

12.6.8.1.6 Send Frame Data to LCD Panel Using Automatic TE

Table 12-126 summarizes the steps to send a frame data to the LCD panel using automatic TE.

Table 12-126. Send Frame Data to LCD Panel Using Automatic TE

| Steps | Register/Bit Field/Programming | Value |
|--|---|--------------------|
| Enable the transfer between DISPC and DSI. Reset after the transfer is done. | DISPC_CONTROL[0] LCDENABLE | 0x1 |
| Specify the number of bytes to send. When DCS insertions is used, word count (WC) must include this one DCS byte. | DSI_VC0_TE[23:0] TE_SIZE | (WC+1)*LPP |
| Set up long packet header. Send 0x39 DCS long write/write_LUT command packet used to send larger blocks of data to a display module that implements a DCS. | DSI_VC0_LONG_PACKET_HEADER[31:0] HEADER | (WC+1) << 8 + 0x39 |
| Enable TE control. | DSI_VC0_TE[30] TE_EN | 0x1 |
| Wait until RX FIFO is empty, RX_FIFO_NOT_EMPTY = 0. | DSI_VC1_CTRL[20] RX_FIFO_NOT_EMPTY | 0x0 |
| Wait until TX FIFO is not full. TX_FIFO_FULL = 0. | DSI_VC1_CTRL[16] TX_FIFO_FULL | 0x0 |
| Enable first BTA to give bus possession to the display module. | DSI_VC1_CTRL[6] BTA_EN | 0x1 |
| Wait until BTA IRQ. | DSI_VC1_IRQSTATUS[5] BTA_IRQ | 0x1 |
| Write 1 to clear BTA IRQ. | DSI_VC1_IRQSTATUS[5] BTA_IRQ | 0x1 |
| Enable second BTA to get the TE trigger. | DSI_VC1_CTRL[6] BTA_EN | 0x1 |
| Wait until BTA IRQ. | DSI_VC1_IRQSTATUS[5] BTA_IRQ | 0x1 |
| Write 1 to clear BTA IRQ. | DSI_VC1_IRQSTATUS[5] BTA_IRQ | 0x1 |
| Wait until transfer is complete. | DSI_VC0_TE[30] TE_EN | Read 0x0 |

12.7 Display Subsystem Register Manual

CAUTION

- The DISS, DISPC, RFBI, and VENC registers have no register data width access restriction and can be accessed in 8-bit, 16-bit and 32-bit access..
- The DSI complex I/O and DSI PLL control module registers are limited to 32-bit data access; 16-bit and 8-bit data accesses are not allowed and can corrupt register content.
- The DSI protocol engine DSS.DSI_VCn_LONG_PACKET_HEADER and DSS.DSI_VCn_SHORT_PACKET_HEADER registers are limited to 32-bit data access; 16-bit and 8-bit data accesses are not allowed and can corrupt register content.
- The DSI protocol engine DSS.DSI_VCn_LONG_PACKET_PAYLOAD register is limited to 32-bit and 16-bit data access; 8-bit data accesses are not allowed and can corrupt register content.
- All other DSI protocol engine registers have no register data width access restriction and can be accessed in 8-bit, 16-bit and 32-bit access.

Table 12-127 summarizes the display subsystem instance.

Table 12-127. Instance Summary

| Module Name | Base Address | Size |
|-------------------------|--------------|-----------|
| DSI Protocol Engine | 0x4804 FC00 | 512 bytes |
| DSI_PHY | 0x4804 FE00 | 64 bytes |
| DSI PLL Controller | 0x4804 FF00 | 32 bytes |
| Display Subsystem | 0x4805 0000 | 512 bytes |
| Display Controller | 0x4805 0400 | 1K byte |
| Display Controller VID1 | 0x4805 0400 | 1K byte |
| Display Controller VID2 | 0x4805 0400 | 1K byte |
| RFBI | 0x4805 0800 | 256 bytes |
| Video Encoder | 0x4805 0C00 | 256 bytes |

12.7.1 Display Subsystem Register Mapping Summary

Table 12-128 through Table 12-133 summarize the display subsystem register mapping.

Table 12-128. Display Subsystem Register Mapping Summary

| Register Name | Type | Register Width (Bits) | Address Offset | Physical Address |

Table 12-139. DSS_SYSCONFIG

| | | | |
|-------------------------|--|-----------------|------|
| Address Offset | 0x010 | Instance | DISS |
| Physical address | 0x4805 0010 | | |
| Description | This register controls the various parameters of the interconnect interface. | | |
| Type | RW | | |

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|----------|----------|-----------|----------|---|---|---|---|
| Reserved | | | | | | | | | | | | | | | | | | | | | | | | Reserved | Reserved | SOFTRESET | AUTOIDLE | | | | |

| Bits | Field Name | Description | Type | Reset |
|------|------------|---|------|------------|
| 31:5 | Reserved | Write 0s for future compatibility. Reads return zero. | RW | 0x00000000 |
| 4:3 | Reserved | Reserved. Keep at reset value. | RW | 0x0 |
| 2 | Reserved | Write 0s for future compatibility . Reads return zero. | RW | 0 |
| 1 | SOFTRESET | Software reset. Set this bit to 1 to trigger a module reset. The bit is automatically reset by the hardware. During reads, it always returns 0. 0x0: Normal mode 0x1: The module is reset | RW | 0 |
| 0 | AUTOIDLE | Enable power management capability | RW | 1 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|---|------|-------|
| | | 0x0: OCP clock is free-running | | |
| | | 0x1: Automatic OCP clock gating strategy is applied based on the OCP interface activity | | |

| Reserved | | | | | | | | SDI_PLL_GOBIT | | | | | | | | SDI_PLL_LOCKSEL | | | | | | | | SDI_PLL_FREQSEL | | | | | | | | SDI_PLL_PLLLPMODE | | | | | | | | SDI_PLL_LOWCURRSTBY | | | | | | | | SDI_PLL_HIGHFREQ | | | | | | | | SDI_PLL_SYSRESET | | | | | | | | SDI_PLL_STOPMODE | | | | | | | | SDI_PLL_REGN | | | | | | | | | | | | | | | | SDI_PLL_REGM | | | | | | | | | | | | | | | | SDI_PLL_IDLE |

| Bits | Field Name | Description | Type | Reset |
|-------|---------------------|--|------|-------|
| 31:29 | Reserved | Reserved | RW | 0x0 |
| 28 | SDI_PLL_GOBIT | Requests PLL locking sequence. See the programming guide section for the use of this bit in conjunction with DSS_STATUS[6] SDI_PLL_BUSYFLAG 0: Inactive 1: Request PLL locking sequence | RW | 0 |
| 27:26 | SDI_PLL_LOCKSEL | Selects the lock criteria for PLL 0x0: Phase Lock (recommended setting for FlatLink3G) 0x1: Fine Phase Lock 0x2: Frequency Lock | RW | 0x0 |
| 25:22 | SDI_PLL_FREQSEL | PLL internal reference frequency (Fint) range selection 0x3: 0.75MHz to 1.0MHz 0x4: 1.0MHz to 1.25MHz 0x5: 1.25MHz to 1.5MHz 0x6: 1.5MHz to 1.75MHz 0x7: 1.75MHz to 2.1MHz 0xB: 7.5MHz to 10MHz 0xC: 10MHz to 12.5MHz 0xD: 12.5MHz to 15MHz 0xE: 15MHz to 17.5MHz 0xF: 17.5MHz to 21MHz Other: Reserved | RW | 0x0 |
| 21 | SDI_PLL_PLLLPMODE | Select the power/performance of the PLL 0x0: Full performance, minimized jitter 0x1: Reduced power, increased jitter | RW | 0 |
| 20 | SDI_PLL_LOWCURRSTBY | PLL Low Current Standby 0x0: Low Current Standby is not selected. 0x1: Low Current Standby is selected. | RW | 0 |
| 19 | SDI_PLL_HIGHFREQ | Enables a division of pixel clock by 2 before input of PLL. Required for pixel clock frequency above 32 MHz 0x0: Pixel clock is not divided. 0x1: Pixel clock is divided by 2. | RW | 0 |
| 18 | SDI_PLL_SYSRESET | SDI PLL reset bit. Active low default 0x0 : PLL under reset 0x1 : PLL operational | RW | 0 |
| 17 | SDI_PLL_STOPMODE | 0xSDI PLL STOPMODE 0x0 : STOPMODE is not selected 0x1 : STOPMODE is selected | RW | 0 |
| 16:11 | SDI_PLL_REGN | SDI PLL REGN register | RW | 0x00 |
| 10:1 | SDI_PLL_REGM | SDI PLL REGM register | RW | 0x000 |
| 0 | SDI_PLL_IDLE | SDI PLL IDLE 0x0: IDLE is not selected 0x1: IDLE is selected | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|------|---------------------|--|------|------------|
| 31:9 | Reserved | Reserved | R | 0x00000000 |
| 8 | DSI_PLL_CLK2_STATUS | DSI2_PLL_FCLK clock selection status (DSI mux) Indicates if the DSI protocol engine is running from the DSI2_PLL_FCLK clock Read 0: DSI2_PLL_FCLK is not selected (unused by DSI). Read 1: DSI2_PLL_FCLK is selected (used by DSI). | R | 0 |
| 7 | DSS_DSI_CLK1_STATUS | DSS1_ALWON_FCLK clock selection status (DSI mux) Indicates if the DSI protocol engine is running from the DSS1_ALWON_FCLK clock Read 0: DSS1_ALWON_FCLK is not selected (unused by DSI). Read 1: DSS1_ALWON_FCLK is selected (used by DSI). | R | 1 |
| 6 | SDI_PLL_BUSYFLAG | PLL locking sequence status. See the programming guide section for the use of this bit in conjunction with DSS_PLL_CONTROL[28] SDI_PLL_GOBIT Read 0: PLL lock request has completed. Read 1: PLL lock request is in progress. | R | 0 |
| 5 | SDI_PLL_LOCK | SDI PLL lock status See the programming guide section for the use of this bit Read 0: PLL is not locked Read 1: PLL is locked | R | 0 |
| 4 | SDI_PLL_RECAL | SDI DPLL re-calibration status If this bit is active, the PLL must be recalibrated Read 0x0: Recalibration is not required. Read 0x1: Recalibration is required. | R | 0 |
| 3 | SDI_ERROR | SDI error status bit See programming guide section for error recovery procedure Read 0x0: No error Read 0x1: Error condition required | R | 0 |

| Bits | Field Name | Description | Type | Reset |
|------|-----------------------|--|------|-------|
| 2 | SDI_RESET_DONE | SDI reset done status This status is delayed until the PLL output has started running Read 0x0: SDI reset is in progress Read 0x1: SDI reset has completed | R | 0 |
| 1 | DSI_PLL_CLK1_STATUS | DSI1_PLL_FCLK clock selection status (DISPC mux) Indicates if the display controller is running from the DSI1_PLL_FCLK clock Read 0: DSI1_PLL_FCLK is not selected (unused by DISPC). Read 1: DSI1_PLL_FCLK is selected (used by DISPC). | R | 0 |
| 0 | DSS_DISPC_CLK1_STATUS | DSS1_ALWON_FCLK clock selection status (DISPC mux) Indicates if the display controller is running from the DSS1_ALWON_FCLK clock Read 0: DSS1_ALWON_FCLK is not selected (unused by DISPC). Read 1: DSS1_ALWON_FCLK is selected (used by DISPC). | R | 1 |

| Bits | Field Name | Description | Type | Reset |
|-------|---------------|--|------|---------|
| 31:14 | Reserved | Write 0s for future compatibility. Read returns 0. | RW | 0x00000 |
| 13:12 | MIDLEMODE | Master interface power management, standby/waitcontrol 0x0: Force standby. MStandby is asserted only when the module is disabled. 0x1: No standby: MStandby is never asserted. 0x2: Smart Standby. MStandby is asserted based on the internal activity of the module. 0x3: Reserved | RW | 0x0 |
| 11:10 | Reserved | Write 0s for future compatibility. Read returns 0. | RW | 0x00 |
| 9:8 | CLOCKACTIVITY | Clock activity during wakeup mode period 0x0: interface and functional clocks can be switched off. 0x1: Functional clocks can be switched off and interface clocks are maintained during wakeup period. 0x2: Interface clocks can be switched off and functional clocks are maintained during wakeup period. 0x3: Interface and functional clocks are maintained during wakeup period. | RW | 0x0 |
| 7:5 | Reserved | Write 0s for future compatibility. Read returns 0. | RW | 0x0 |
| 4:3 | SIDLEMODE | Slave interface power management, idle req/ack control 0x0: Force idle. An idle request is acknowledged unconditionally. 0x1: No idle. An idle request is never acknowledged. 0x2: Smart idle. Idle request is acknowledged based on the internal activity of the module. 0x3: Reserved | RW | 0x0 |
| 2 | ENWAKEUP | Wakeup feature control 0x0: Wakeup is disabled. 0x1: Wakeup is enabled. | RW | 0 |
| 1 | SOFTRESET | Software reset. Set this bit to 1 to trigger a module reset. The bit is automatically reset by the hardware. During reads, it always returns 0. 0x0: Normal mode 0x1: The module is reset. | RW | 0 |
| 0 | AUTOIDLE | Internal interface clock gating strategy 0x0: Interface clock is free-running. 0x1: Automatic L3 and L4 interface clock gating strategy is applied based on interface activity. | RW | 1 |

| Bits | Field Name | Description | Type | Reset |
|-------|------------------------------------|---|------|-------|
| 31:30 | SPATIALTEMPORAL DITHERINGFRAMES | Spatial/Temporal dithering number of frames wr: VFP 0x0: Spatial only 0x1: Spatial and temporal over two frames 0x2: Spatial and temporal over four frames 0x3: Reserved | RW | 0x0 |
| 29 | LCDENABLEPOL | LCD Enable Signal Polarity 0x0: Active low 0x1: Active high | RW | 0 |
| 28 | LCDENABLESIGNAL | LCD Enable Signal: LCD interface active/inactive 0x0: Signal disabled 0x1: Signal enabled | RW | 0 |
| 27 | PCKFREEENABLE | Pixel clock free-running enabled/disabled 0x0: Clock disabled 0x1: Clock enabled | RW | 0 |
| 26:25 | TDMUNUSEDBITS | State of unused bits (TDM mode only) WR: VFP 0x0: Low level (0) 0x1: High level (1) 0x2: Unchanged from previous state 0x3: Reserved | RW | 0x0 |

| Bits | Field Name | Description | Type | Reset |
|-------|---------------------|--|------|-------|
| 24:23 | TDMCYCLEFORMAT | Cycle format (TDM mode only) WR: VFP 0x0: 1 cycle for 1 pixel 0x1: 2 cycles for 1 pixel 0x2: 3 cycles for 1 pixel 0x3: 3 cycles for 2 pixels | RW | 0x0 |
| 22:21 | TDMPARALLELMODE | Output Interface width (TDM mode only) WR: VFP 0x0: 8-bit parallel output interface selected 0x1: 9-bit parallel output interface selected 0x2: 12-bit parallel output interface selected 0x3: 16-bit parallel output interface selected | RW | 0x0 |
| 20 | TDMENABLE | Enable the multiple cycle format (TDM mode used only for Active Matrix mode with the RFBI enable bit off). WR: VFP 0x0: TDM disabled 0x1: TDM enabled | RW | 0 |
| 19:17 | HT | Hold Time for digital output WR: EVSYNC Encoded value (from 0 to 7) holds time for digital output. The data will be held for (HT + 1) external digital clock periods. | RW | 0x0 |
| 16 | GPOUT1 | General Purpose Output Signal 0x0: The GPout1 is reset. 0x1: The GPout1 is set. | RW | 0 |
| 15 | GPOUT0 | General Purpose Output Signal 0x0: The GPout0 is reset. 0x1: The GPout0 is set. | RW | 0 |
| 14 | GPIN1 | General Purpose Input Signal WR: VFP Read 0x0: The GPin1 has been reset. Read 0x1: The GPin1 has been set. | R | 0 |
| 13 | GPIN0 | General Purpose Input Signal WR: VFP Read 0x0: The GPin0 has been reset. Read 0x1: The GPin0 has been set. | R | 0 |
| 12 | OVERLAYOPTIMIZATION | Overlay Optimization (available when graphics format is NOT is 1-, 2-, and 4-BPP) WR: VFP or EVSYNC 0x0: Graphics data below video1 window fetched from memory or no overlap between graphics and video1 windows. 0x1: Graphics data below video1 window not fetched from memory. | RW | 0 |
| 11 | STALLMODE | Stall mode for the LCD output wr: VFP 0x0: Normal mode selected 0x1: Stall mode selected. The Display Controller sends the data without considering the VSYNC/HSYNC. The LCD output is disabled at the end of the transfer of the frame. The S/W has to re-enable the LCD output to generate a new frame. The stall mode is used in RFBI and DSI command modes. | RW | 0 |
| 10 | Reserved | Reserved for non-GP devices | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|------|----------------|---|------|-------|
| 9:8 | TFTDATALINES | Number of lines of the LCD interface WR: VFP 0x0: 12-bit output aligned on the LSB of the pixel data interface 0x1: 16-bit output aligned on the LSB of the pixel data interface 0x2: 18-bit output aligned on the LSB of the pixel data interface 0x3: 24-bit output aligned on the LSB of the pixel data interface | RW | 0x0 |
| 7 | STDITHERENABLE | Spatial temporal dithering enable WR: VFP 0x0: Spatial/temporal dithering logic disabled 0x1: Spatial/temporal dithering logic enabled | RW | 0 |
| 6 | GODIGITAL | Digital GO Command 0x0: The hardware has finished updating the internal shadow registers of the pipeline(s) associated with the digital output using the user values. The hardware resets the bit when the update is completed. 0x1: Users have finished programming the shadow registers of the pipeline(s) associated with the digital output and the hardware can update the internal registers at the external VSYNC. | RW | 0 |
| 5 | GOLCD | LCD GO Command 0x0: The hardware has finished updating the internal shadow registers of the pipeline(s) connected to the LCD output using the user values. The hardware resets the bit when the update is completed. 0x1: Users have finished programming the shadow registers of the pipeline(s) associated with the LCD output and the hardware can update the internal registers at the VFP start period. | RW | 0 |
| 4 | M8B | Mono 8-bit mode WR: VFP 0x0: Pixel data [3:0] is used to output four pixel values to the panel at each pixel clock transition (only in Passive Mono 8-bit mode). 0x1: Pixel data [7:0] is used to output eight pixel values to the panel each pixel clock transition (only in Passive Mono 8-bit mode). | RW | 0 |
| 3 | STNTFT | LCD display type WR: VFP 0x0: Passive or Passive Matrix display operation enabled. Passive Matrix dither logic enabled. 0x1: Active Matrix display operation enabled. Passive Matrix Dither logic and output FIFO bypassed. | RW | 0 |
| 2 | MONOCOLOR | Monochrome/Color WR: VFP 0x0: Color operation enabled (Passive Matrix mode only) 0x1: Monochrome operation enabled (Passive Matrix mode only) | RW | 0 |
| 1 | DIGITALENABLE | Digital enable 0x0: Digital output disabled (at the end of the current field if interlace output when the bit is reset) 0x1: Digital output enabled | RW | 0 |
| 0 | LCDENABLE | LCD enable 0x0: LCD output disabled (at the end of the frame when the bit is reset) 0x1: LCD output enabled | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|--------|---------------------------|---|------|---------|
| 31: 20 | Reserved | Write 0s for future compatibility. Read returns 0 | RW | 0x00000 |
| 19 | TVALPHABLENDER ENABLE | Selects the alpha blender (TV output) 0x0: Alpha blender is disabled. 0x1: The alpha blender is enabled. | RW | 0 |
| 18 | LCDALPHABLENDER ENABLE | Selects the alpha blender (LCD output) 0x0: Alpha blender is disabled. 0x1: The alpha blender is enabled. | RW | 0 |
| 17 | FIFOFILLING | Controls if the FIFO are refilled only when the LOW threshold is reached or if all FIFO are refilled when at least one of them reaches the LOW threshold. 0x0: Each FIFO is refilled when it reaches LOW threshold. 0x1: All FIFOs are refilled up to high threshold when at least one of them reaches the LOW threshold. (only active FIFOs should be considered and when reaching the end of the frame the FIFO goes to empty condition so no need to fill it again). | RW | 0 |
| 16 | FIFOHANDCHECK | Controls the handshake between FIFO and RFBI STALL to prevent from underflow. The bit should be set to 0 when the module is not in STALL mode. 0x0: Only the STALL signal from RFBI is used regardless of the FIFO fullness information to provide data to the RFBI module. 0x1: The STALL signal from RFBI is used in combination with the FIFO fullness information to provide data to the RFBI module only when it does not generated FIFO underflow. | RW | 0 |
| 15 | CPR | Color phase rotation control wr: VFP 0x0: Color phase rotation disabled 0x1: Color phase rotation enabled | RW | 0 |
| 14 | FIFOMERGE | FIFO merge control wr: EVSYNC or VFP 0x0: FIFO merge disabled Each FIFO is dedicated to one pipeline. 0x1: FIFO merge enabled All the FIFOS are merged into a single one to be used by the single active pipeline. | RW | 0 |
| 13 | TCKDIGSELECTION | Transparency color key selection (digital output) wr: EVSYNC 0x0: Graphics destination transparency color key selected in normal mode or graphics source transparency color key selected in alpha mode 0x1: Video source transparency color key selected in normal mode | RW | 0 |
| 12 | TCKDIGENABLE | Transparency color key enabled (digital output) wr: EVSYNC 0x0: Disable the transparency color key for digital output 0x1: Enable the transparency color key for digital output | RW | 0 |
| 11 | TCKLCDSELECTION | Transparency color key selection (LCD output) WR: VFP 0x0: Graphics destination transparency color key selected in normal mode or graphics source transparency color key selected in alpha mode 0x1: Video source transparency color key selected in normal mode | RW | 0 |
| 10 | TCKLCDENABLE | Transparency color key enabled (LCD output) WR: VFP * | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|------|-------------------|---|------|-------|
| | | 0x0: Disable the transparency color key for the LCD 0x1: Enable the transparency color key for the LCD | | |
| 9 | FUNCGATED | Functional clocks gated enabled WR: immediate 0x0: Functional clocks gated disabled 0x1: Functional clocks gated enabled | RW | 0 |
| 8 | ACBIASGATED | ACBias Gated Enabled WR: VFP 0x0: ACBias Gated Disabled 0x1: ACBias Gated Enabled | RW | 0 |
| 7 | VSYNCGATED | VSYNC Gated Enabled WR: VFP 0x0: VSYNC Gated Disabled 0x1: VSYNC Gated Enabled | RW | 0 |
| 6 | HSYNCGATED | HSYNC Gated Enabled WR: VFP 0x0: HSYNC Gated Disabled 0x1: HSYNC Gated Enabled | RW | 0 |
| 5 | PIXELCLOCKGATED | Pixel Clock Gated Enabled WR: VFP 0x0: Pixel Clock Gated Disabled 0x1: Pixel Clock Gated Enabled | RW | 0 |
| 4 | PIXELDATAGATED | Pixel Data Gated Enabled WR: VFP 0x0: Pixel Data Gated Disabled 0x1: Pixel Data Gated Enabled | RW | 0 |
| 3 | PALETTEGAMMatable | Palette/Gamma Table selection WR: EVSYNC or VFP 0x0: LUT used as palette (only if graphics format is BITMAP1, 2, 4, and 8) 0x1: LUT used as gamma table (only if graphics format is NOT BITMAP1, 2, 4, and 8 or no graphics window present) | RW | 0 |
| 2:1 | LOADMODE | Loading Mode for the Palette/Gamma Table WR: EVSYNC or VFP 0x0: Palette/Gamma Table and data are loaded every frame. 0x1: Palette/Gamma Table to be loaded. Users set the bit when the palette/gamma table has to be loaded. H/W resets the bit when table has been loaded. (DISPC_GFX_ATTRIBUTES . GfxEnable has to be set to 1). 0x2: Frame data only loaded every frame 0x3: Palette/Gamma Table and frame data loaded on first frame then switch to 10 (H/W). | RW | 0x0 |
| 0 | PIXELGATED | Pixel Gated Enable (only for Active Matrix Display) WR: VFP 0x0: Pixel clock always toggles (only in Active Matrix mode) 0x1: Pixel clock only toggles when there is valid data to display. (only in Active Matrix mode) | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|-------|--------------------------|---|------|----------|
| 31:16 | Reserved | Write 0s for future compatibility. Read returns 0. | RW | 0x000000 |
| 15 | GFXSELFREFRESH | Enables the self refresh of the graphics window from its own FIFO only. 0x0: The graphics pipeline accesses the interconnect to fetch data from the system memory 0x1: The graphics pipeline does not need anymore to fetch data from memory. Only the graphics FIFO is used. It takes effect after the frame has been loaded in the FIFO | RW | 0 |
| 14 | GFXARBITRATION | Determines the priority of the graphics pipeline. The graphics pipeline is one of the high priority pipeline. The arbitration wheel gives always the priority first to the high priority pipelines using round-robin between them. When there is only normal priority pipelines sending requests, the round-robin applies between them. 0x0: The graphics pipeline is one of the normal priority pipeline. 0x1: The graphics pipeline is one of the high priority pipeline. | RW | 0 |
| 13:12 | GFXROTATION | Graphics rotation flag (used only in case of RGB24 packed format) 0x0: No rotation 0x1: Rotation by 90 degrees 0x2: Rotation by 180 degrees 0x3: Rotation by 270 degrees | RW | 0x0 |
| 11 | GFXFIFOPRELOAD | Graphics preload value 0x0: H/W prefetches pixels up to the preload value defined in the preload register. 0x1: H/W prefetches pixels up to high threshold value. | RW | 0 |
| 10 | GFXENDIANNESS | Graphics endianness 0x0: Little endian operation is selected. 0x1: Big endian operation is selected. | RW | 0 |
| 9 | GFXNIBBLEMODE | Graphics Nibble Mode (only for 1-, 2- and 4-BPP) 0x0: Nibble mode is disabled 0x1: Nibble mode is enabled | RW | 0 |
| 8 | GFXCHANNELOUT | Graphics Channel Out configuration wr: immediate 0x0: LCD output selected 0x1: 24-bit output selected | RW | 0 |
| 7:6 | GFXBURSTSIZE | Graphics DMA Burst Size 0x0: 4x32bit bursts 0x1: 8x32bit bursts 0x2: 16x32bit bursts 0x3: Reserved | RW | 0x0 |
| 5 | GFXREPLICATION ENABLE | GfxReplicationEnable 0x0: Disable Graphics replication logic 0x1: Enable Graphics replication logic | RW | 0 |
| 4:1 | GFXFORMAT | Graphics format; Other enums: Reserved (0x7, 0xA, 0xB and 0xF) 0x0: BITMAP 1 (CLUT) 0x1: BITMAP 2 (CLUT) 0x2: BITMAP 4 (CLUT) 0x3: BITMAP 8 (CLUT) 0x4: RGB 12 (un-packed in 16-bit container) 0x5: ARGB16 0x6: RGB 16 | RW | 0x0 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|--|------|-------|
| | | 0x8: RGB 24 (un-packed in 32-bit container) | | |
| | | 0x9: RGB 24 (packed in 24-bit container) | | |
| | | 0xC: ARGB32 | | |
| | | 0xD: RGBA32 | | |
| | | 0xE: RGBx 32 (24-bit RGB aligned on MSB of the 32-bit container) | | |
| 0 | GFXENABLE | GfxEnable | RW | 0 |
| | | 0x0: Graphics disabled (graphics pipeline inactive and graphics window not present) | | |
| | | 0x1: Graphics enabled (graphics pipeline active and graphics window present on the screen) | | |

| Bits | Field Name | Description | Type | Reset |
|--------|---------------------|---|------|--------|
| 31: 25 | RESERVED | Write 0s for future compatibility. Read returns 0. | RW | 0x0000 |
| 24 | VIDSELFREFRESH | Enables the self refresh of the video window from its own FIFO only. 0x0: The video pipeline accesses the interconnect to fetch data from the system memory 0x1: The video pipeline does not need anymore to fetch data from memory. Only the video FIFO is used. It takes effect after the frame has been loaded in the FIFO | RW | 0 |
| 23 | VIDARBITRATION | Determines the priority of the video pipeline. The video pipeline is one of the high priority pipeline. The arbitration wheel gives always the priority first to the high priority pipelines using round-robin between them. When there is only normal priority pipelines sending requests, the round-robin applies between them. 0x0: The video pipeline is one of the normal priority pipeline. 0x1: The video pipeline is one of the high priority pipeline. | RW | 0 |
| 22 | VIDLINEBUFFER SPLIT | Video vertical line buffer split 0x0: Vertical line buffers are not split. 0x1: Vertical line buffers are split into two. | RW | 0 |
| 21 | VIDVERTICALTAPS | Video vertical resize tap number 0x0: Three taps are used for the vertical filtering logic. The other two taps are not used. 0x1: Five taps are used for the vertical filtering logic. | RW | 0 |
| 20 | VIDDMAOPTI MIZATION | Video optimization in case of 0x0: The DMA engine fetches one pixel for each 32-bit OCP request (RGB16 and YUV422) while doing 90- and 270-degree rotation (accessing on-chip memory and off-chip memory). | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|-------|--------------------------|--|------|-------|
| | | 0x1: The DMA engine fetches two pixels for each 32-bit OCP request (RGB16 and YUV422) while doing 90- and 270-degree rotation (accessing on-chip memory and off-chip memory). | | |
| 19 | VIDFIFOPRELOAD | Video preload value 0x0: H/W prefetches pixels up to the preload value defined in the preload register. 0x1: H/W prefetches pixels up to the high threshold value. | RW | 0 |
| 18 | VIDROWREPEAT ENABLE | Video Row Repeat (YUV case only when rotating 90 or 270-degree) 0x0: Row of VIDn won't be read twice. 0x1: The Row data are fetched twice to extract both the Y components | RW | 0 |
| 17 | VIDENDIANNESS | Video Endianness 0x0: Little endian operation is selected. 0x1: Big endian operation is selected. | RW | 0 |
| 16 | VIDCHANNELOUT | Video Channel Out configuration wr: Immediate 0x0: LCD output selected 0x1: 24 bit output selected | RW | 0 |
| 15:14 | VIDBURSTSIZE | Video DMA Burst Size 0x0: 4x32bit bursts 0x1: 8x32bit bursts 0x2: 16x32bit bursts 0x3: Reserved | RW | 0x0 |
| 13:12 | VIDROTATION | Video Rotation Flag 0x0: No rotation or VidFormat is RGB 0x1: Rotation by 90 degrees 0x2: Rotation by 180 degrees 0x3: Rotation by 270 degrees | RW | 0x0 |
| 11 | VIDFULLRANGE | VidFullRange 0x0: Limited range selected: 16 subtracted from Y before color space conversion 0x1: Full range selected: Y is not modified before the color space conversion | RW | 0 |
| 10 | VIDREPLICATION ENABLE | VidReplicationEnable 0x0: Disable Video replication logic 0x1: Enable Video replication logic | RW | 0 |
| 9 | VIDCOLORCONV ENABLE | VidColorConvEnable 0x0: Disable Color Space Conversion CbYCr to RGB 0x1: Enable Color Space Conversion CbYCr to RGB | RW | 0 |
| 8 | VIDVRESIZECONF | Video Vertical Resize Configuration 0x0: Up-sampling selected 0x1: Down-sampling selected | RW | 0 |
| 7 | VIDHRESIZECONF | Video Horizontal Resize Configuration 0x0: Up-sampling selected 0x1: Down-sampling selected | RW | 0 |
| 6:5 | VIDRESIZEENABLE | Video Resize Enable 0x0: Disable the resize processing 0x1: Enable the horizontal resize processing | RW | 0x0 |

| Bits | Field Name | Description | Type | Reset |
|------|--------------------------------|--|------|-------|
| | | 0x2: Enable the vertical resize processing | | |
| | | 0x3: Enable both horizontal and vertical resize processing | | |
| 4:1 | VIDFORMAT (Video 1 channel) | Video1 channel Format; Other enums: Reserved (all other values between 0x0 and 0x3, 0x5, 0x7, and between 0xC and 0xF) | RW | 0x0 |
| | | 0x4: RGB12 (16-bit container) | | |
| | | 0x6: RGB 16 | | |
| | | 0x8: RGB 24 (unpacked in 32-bit container) | | |

| Reserved | | | | | | | | VIDORGSIZEY | | | | | | | | Reserved | | | | | | | | VIDORGSIZEX | | | | | | | |

| Bits | Field Name | Description | Type | Reset |
|-------|-------------|---|------|-------|
| 31:27 | Reserved | Write 0s for future compatibility. Read returns 0 | RW | 0x00 |
| 26:16 | VIDORGSIZEY | Number of lines of the video picture Encoded value (from 1 to 2048) to specify the number of lines of the video picture in memory (program to value minus one). | RW | 0x000 |
| 15:11 | Reserved | Write 0s for future compatibility. Read returns 0 | RW | 0x00 |

| Bits | Field Name | Description | Type | Reset |
|------|-------------|--|------|-------|
| 10:0 | VIDORGSIZEX | Number of pixels of the video picture Encoded value (from 1 to 2048) to specify the number of pixels of the video picture in memory (program to value minus one). The size is limited to the size of the line buffer of the vertical sampling block in case the video picture is processed by the vertical filtering unit. ⁽¹⁾ | RW | 0x000 |

⁽¹⁾ For 5-tap RGB16 and YUV422 picture formats, the width of the input picture must be a multiple of 2 pixels and more than 5 pixels. This leads to the following register configuration:

- [DISPC_VIDn_ATTRIBUTES\[21\]](#) VIDVERTICALTAPS is set to 1.
- [DISPC_VIDn_PICTURE_SIZE\[10:0\]](#) VIDORGSIZEX must be even and more than 4.

Table 12-265. RFBI_CONTROL

| | | | |
|-------------------------|---|-----------------|------|
| Address Offset | 0x40 | Instance | RFBI |
| Physical address | 0x4805 0840 | | |
| Description | The control register allows configuration of the RFBI module. | | |
| Type | RW | | |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---------------|-----------------|---------------|-----|--------------|------------|--------|---|---|---|---|---|---|---|---|---|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| RESERVED | | | | | | | | | | | | | | | | SMART_DMA_REQ | DISABLE_DMA_REQ | HIGHTHRESHOLD | ITE | CONFIGSELECT | BYPASSMODE | ENABLE | | | | | | | | | |

| Bits | Field Name | Description | Type | Reset |
|-------|-----------------|--|------|-----------|
| 31: 9 | Reserved | Write 0s for future compatibility Read returns 0 | RW | 0x0000000 |
| 8 | SMART_DMA_REQ | Smart DMA request 0x0: The dmareq is asserted and de-asserted depending on the interconnect FIFO space even if Mldlreq is high in smart idle/no-idle mode and the entire burst gets error responses from the module. 0x1: The dmareq is de-asserted after 2 clk cycles if it has been asserted for more than or equal to 2 clk cycles and Mldlreq is high in smart idle or no idle mode. No more burst requests will be given even if the space is available in the interconnect FIFO. | RW | 0x0 |
| 7 | DISABLE_DMA_REQ | Disable DMA request 0x0: The dmareq is enabled and the signal is generated based on the space available and the request coming into the data register. 0x1: The dmareq is disabled and the signal is not generated at all based on space in the interconnect FIFO. It stays high until the DISABLE DMAREQ is high even if there is space in the interconnect FIFO to take requests. | RW | 0x0 |
| 6:5 | HIGHTHRESHOLD | Defines the interconnect FIFO high threshold used by HW to assert DMA request. Used only if data written to RFBI_DATA are sent using system DMA. 0x0: Size of the transfer of 4 words of 32-bit wide 0x1: Size of the transfer of 8 words of 32-bit wide 0x2: Size of the transfer of 16 words of 32-bit wide | RW | 0x0 |
| 4 | ITE | Internal Trigger 0: H/W waits for ITE bit to be set if in internal trigger mode for the configuration in use. 1: User sets the ITE bit to start the transfer, when H/W takes into account the bit, the H/W resets it. | RW | 0 |
| 3:2 | CONFIGSELECT | Select the CS and configuration 00: No CS selected 01: CS0 selected and configuration #0 10: CS1 selected and configuration #1 11: CS0 and CS1 both selected (only the configuration for CS0 is used) | RW | 0x0 |
| 1 | BYPASSMODE | Bypass Mode 0: The bypass mode not selected 1: The bypass mode is selected | RW | 1 |
| 0 | ENABLE | Enable/Disable flag 0: Disable the RFBI module 1: Enable the RFBI module | RW | 0 |

| | | | |
|-------------------------|--|-----------------|------|
| Address Offset | 0x0000 00C4 | Instance | VENC |
| Physical Address | 0x4805 0CC4 | | |
| Description | Output channel control register Also contains some test control features | | |
| Type | RW | | |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|----|----|-----------|----|----|----|----|----|----|----|----------|----|----|----|----|----|---|---|---------------|------------------|-------------|-----------|--------------|---------------|------------------|-------------|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| RESERVED | | | | | | | | LUMA_TEST | | | | | | | | RESERVED | | | | | | | | CHROMA_SOURCE | COMPOSITE_SOURCE | LUMA_SOURCE | TEST_MODE | VIDEO_INVERT | CHROMA_ENABLE | COMPOSITE_ENABLE | LUMA_ENABLE |

| Bits | Field Name | Description | Type | Reset |
|-------|------------------|---|------|-------|
| 31:26 | RESERVED | Reserved. Read returns 0s. | RW | 0x00 |
| 25:16 | LUMA_TEST | In test mode, DAC 1 input value (if s-video video mode is selected) | RW | 0x000 |
| 15:8 | RESERVED | Reserved. Read returns 0s. | RW | 0x00 |
| 7 | CHROMA_SOURCE | Source of chroma video data in test mode 0x0: Chroma test data comes from internal register OUTPUT_TEST[25:16] 0x1: Chroma test data comes from display controller video port G[1:0], B[7:0] | RW | 0x0 |
| 6 | COMPOSITE_SOURCE | Source of composite video data in test mode 0x0: Composite test data comes from internal register OUTPUT_TEST[9:0] 0x1: Composite test data comes from display controller video port G[1:0], B[7:0] | RW | 0x0 |
| 5 | LUMA_SOURCE | Source of luminance video data in test mode 0x0: Luma test data comes from internal register OUTPUT_CONTROL[25:16] 0x1: Luma test data comes from display controller video port G[1:0], B[7:0] | RW | 0x0 |
| 4 | TEST_MODE | This enables the video DACs to be tested. The values sent to the DACs comes from a register for each output channel (Luma, Composite or Chroma) or from the display controller video port bits G[1:0], B[7:0], depending on the setting of the Source bits 0x0: Video outputs are in normal operation 0x1: Test mode. Video outputs are directly connected to either internal registers or the display controller video port. | RW | 0x0 |

| Bits | Field Name | Description | Type | Reset |
|------|------------------|--|------|-------|
| 3 | VIDEO_INVERT | Controls the video output polarity. This may be used to correct for inversion in an external video amplifier. 0x0: Video outputs are inverted 0x1: Video outputs are normal polarity | RW | 0x1 |
| 2 | CHROMA_ENABLE | Enable the Chrominance output channel 0x0: Chroma output is disabled 0x1: Chroma output is enabled | RW | 0x0 |
| 1 | COMPOSITE_ENABLE | Enable the Composite output channel 0x0: Composite output is disabled 0x1: Composite output is enabled | RW | 0x0 |
| 0 | LUMA_ENABLE | Enable the Luminance output channel 0x0: Luma output is disabled 0x1: Luma output is enabled | RW | 0x0 |

| | | | |
|-------------------------|---|-----------------|---------------------|
| Address Offset | 0x0000 0010 | Instance | DSI_PROTOCOL_ENGINE |
| Physical Address | 0x4804 FC10 | | |
| Description | SYSTEM CONFIGURATION REGISTER This register is the system configuration register. | | |
| Type | RW | | |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----------|----|---------------|----------|-----------|----------|------------|-----------|---|---|---|---|---|---|---|---|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| RESERVED | | | | | | | | | | | | | | | | RESERVED | | CLOCKACTIVITY | RESERVED | SIDLEMODE | ENWAKEUP | SOFT_RESET | AUTO_IDLE | | | | | | | | |

| Bits | Field Name | Description | Type | Reset |
|-------|---------------|---|------|---------|
| 31:14 | RESERVED | Write 0s for future compatibility. Reads returns 0. | RW | 0x00000 |
| 13:10 | RESERVED | Write 0s for future compatibility. | RW | 0x0 |
| 9:8 | CLOCKACTIVITY | Clocks activity during wake up mode period 0x0: Interface and Functional clocks can be switched off 0x1: Functional clocks can be switched off and Interface clocks are maintained during wake up period 0x2: Interface clocks can be switched off and Functional clocks are maintained during wake up period 0x3: Interface and Functional clocks are maintained during wake up period | RW | 0x0 |
| 7:5 | RESERVED | Write 0s for future compatibility. Reads returns 0. | RW | 0x0 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|--|------|-------|
| 4:3 | SIDLEMODE | Slave interface power management, Idle req/ack control 0x0: Force-idle. An idle request is acknowledged unconditionally 0x1: No-idle. An idle request is never acknowledged 0x2: Smart-idle. Acknowledgement to an idle request is given based on the internal activity of the module. 0x3: Reserved | RW | 0x2 |
| 2 | ENWAKEUP | Wake-up mode enable bit 0x0: Wakeup is disabled. 0x1: Wakeup is enabled, | RW | 0x0 |
| 1 | SOFT_RESET | Software reset. Set the bit to 1 to trigger a module reset. The bit is automatically reset by the hw. During reads return 0. 0x0: Normal mode. 0x1: The module is reset | RW | 0x0 |
| 0 | AUTO_IDLE | Internal interface clock gating strategy 0x0: Interface clock is free-running. 0x1: Automatic Interface clock gating strategy is applied based on the module interface activity. | RW | 0x1 |

| Bits | Field Name | Description | Type | Reset |
|-------|--------------------|---|------|-------|
| 31:21 | RESERVED | Write 0s for future compatibility. Reads returns 0. | RW | 0x000 |
| 20 | TA_TO_IRQ | Turn-around Time out. 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset. | RW | 0x0 |
| 19 | LDO_POWER_GOOD_IRQ | Transition of the status signal LDOPWRGOOD from the DSI_PHY indicating a state change for the supply VDDALDODSIPLL from up to down or down to up. 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset. | RW | 0x0 |
| 18 | SYNC_LOST_IRQ | Synchronization with Video port is lost (Video mode only) 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset. | RW | 0x0 |
| 17 | ACK_TRIGGER_IRQ | Acknowledge Trigger 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset. | RW | 0x0 |

| Bits | Field Name | Description | Type | Reset |
|-------|-----------------------|--|------|-------|
| 16 | TE_TRIGGER_IRQ | Tearing Effect Trigger 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset. | RW | 0x0 |
| 15 | LP_RX_TO_IRQ | Interrupt for Low Power Rx Time out 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset. | RW | 0x0 |
| 14 | HS_TX_TO_IRQ | Interrupt for high-speed Tx Time out. 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset. | RW | 0x0 |
| 13 | RESERVED | Write 0s for future compatibility. Reads returns 0. | RW | 0x0 |
| 12:11 | RESERVED | Write 0s for future compatibility. Reads returns 0. | RW | 0x0 |
| 10 | COMPLEXIO_ERR_IRQ | Error signaling from complex I/O: status of the complex I/O errors received from the complex I/O(events are defined in DSI_COMPLEXIO_IRQSTATUS). 0x0: READS: Event is false. 0x1: READS: Event is true (pending). | R | 0x0 |
| 9 | PLL_RECAL_IRQ | PLL recalibration event (assertion of recalibration signal from the DSI PLL Control module) 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset. | RW | 0x0 |
| 8 | PLL_UNLOCK_IRQ | PLL un-lock event (deassertion of lock signal from the DSI PLL Control module) 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset. | RW | 0x0 |
| 7 | PLL_LOCK_IRQ | PLL lock event (assertion of lock signal from the DSI PLL Control module) 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset. | RW | 0x0 |
| 6 | RESERVED | Write 0s for future compatibility. Reads returns 0. | RW | 0x0 |
| 5 | RESYNCHRONIZATION_IRQ | Video mode resynchronization Indicates that the video port works but the configuration of the timings for the display controller (DISPC) and for DSI protocol engine may have to be modified to avoid the resynchronization to occur. 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset. | RW | 0x0 |
| 4 | WAKEUP_IRQ | Wakeup 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset. | RW | 0x0 |

| Bits | Field Name | Description | Type | Reset |
|------|----------------------|---|------|-------|
| 3 | VIRTUAL_CHANNEL3_IRQ | Virtual channel #3 Error signaling from DSI Virtual Channel3: Status of DSI Virtual Channel3 errors received from DSI Virtual Channel3 (events are defined in DSI_VC3_IRQSTATUS). 0x0: READS: Event is false. 0x1: READS: Event is true (pending). | R | 0x0 |
| 2 | VIRTUAL_CHANNEL2_IRQ | Virtual channel #2 Error signaling from DSI Virtual Channel2: Status of DSI Virtual Channel2 errors received from DSI Virtual Channel2 (events are defined in DSI_VC2_IRQSTATUS). 0x0: READS: Event is false. 0x1: READS: Event is true (pending). | R | 0x0 |
| 1 | VIRTUAL_CHANNEL1_IRQ | Virtual channel #1 Error signaling from DSI Virtual Channel1: Status of DSI Virtual Channel1 errors received from DSI Virtual Channel1 (events are defined in DSI_VC1_IRQSTATUS). 0x0: READS: Event is false. 0x1: READS: Event is true (pending). | R | 0x0 |
| 0 | VIRTUAL_CHANNEL0_IRQ | Virtual channel #0 Error signaling from DSI Virtual Channel0: Status of the DSI Virtual Channel0 errors received from DSI Virtual Channel0 (events are defined in DSI_VCO_IRQSTATUS). 0x0: READS: Event is false. 0x1: READS: Event is true (pending). | R | 0x0 |

| Bits | Field Name | Description | Type | Reset |
|-------|-----------------------|---|------|-------|
| 31:21 | RESERVED | Write 0s for future compatibility. Reads returns 0. | RW | 0x000 |
| 20 | TA_TO_IRQ_EN | Turn-around Time out. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs | RW | 0x0 |
| 19 | LDO_POWER_GOOD_IRQ_EN | Transition of the status signal LDOPWRGOOD from the DSI_PHY indicating a state change for the supply VDDALDODSIPLL from up to down or down to up. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs | RW | 0x0 |
| 18 | SYNC_LOST_IRQ_EN | Synchronization with Video port is lost (Video mode only) 0x0: Event is masked 0x1: Event generates an interrupt when it occurs | RW | 0x0 |
| 17 | ACK_TRIGGER_IRQ_EN | Acknowledge trigger 0x0: Event is masked 0x1: Event generates an interrupt when it occurs | RW | 0x0 |
| 16 | TE_TRIGGER_IRQ_EN | Tearing Effect trigger 0x0: Event is masked 0x1: Event generates an interrupt when it occurs | RW | 0x0 |
| 15 | LP_RX_TO_IRQ_EN | Interrupt for Low Power Rx Time out. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs | RW | 0x0 |
| 14 | HS_TX_TO_IRQ_EN | Interrupt for high-speed Tx Time out. 0x0: Event is masked 0x1: Event generates an interrupt when it occurs | RW | 0x0 |
| 13 | RESERVED | Write 0s for future compatibility. Reads returns 0. | RW | 0x0 |
| 12:11 | RESERVED | Write 0s for future compatibility. Reads returns 0. | RW | 0x0 |
| 10 | RESERVED | Write 0s for future compatibility. Reads returns 0. | RW | 0x0 |

| Bits | Field Name | Description | Type | Reset |
|------|--------------------------|---|------|-------|
| 9 | PLL_RECAL_IRQ_EN | PLL recalibration event (assertion of recalibration signal from the DSI PLL Control module) 0x0: Event is masked 0x1: Event generates an interrupt when it occurs | RW | 0x0 |
| 8 | PLL_UNLOCK_IRQ_EN | PLL un-lock event (deassertion of lock signal from the DSI PLL Control module) 0x0: Event is masked 0x1: Event generates an interrupt when it occurs | RW | 0x0 |
| 7 | PLL_LOCK_IRQ_EN | PLL lock event (assertion of lock signal from the DSI PLL Control module) 0x0: Event is masked 0x1: Event generates an interrupt when it occurs | RW | 0x0 |
| 6 | RESERVED | Write 0s for future compatibility. Reads returns 0. | RW | 0x0 |
| 5 | RESYNCHRONIZATION_IRQ_EN | Resynchronization 0x0: Event is masked 0x1: Event generates an interrupt when it occurs | RW | 0x0 |
| 4 | WAKEUP_IRQ_EN | Wakeup 0x0: Event is masked 0x1: Event generates an interrupt when it occurs | RW | 0x0 |
| 3:0 | RESERVED | Write 0s for future compatibility. Reads returns 0. | RW | 0x0 |

Table 12-393. DSI_CTRL

| | | | |
|-------------------------|---|-----------------|---------------------|
| Address Offset | 0x0000 0040 | Instance | DSI_PROTOCOL_ENGINE |
| Physical Address | 0x4804 FC40 | | |
| Description | GLOBAL CONTROL REGISTER This register controls the DSI Protocol Engine module. This register should not be modified dynamically (except IF_EN bit field). | | |
| Type | RW | | |

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 | |
|----------|----|----|----|----|----|----|----|--------------|--------------|----------------|-------------------|-------------------|-------------------|---------------|------------|--------------|----------------|--------------|----------------|--------------------|-------------|--------------|--------------|-----------|------------|-------------------|---------------|--------------|---------------------|-----------|----------|-------|
| RESERVED | | | | | | | | RGB565_ORDER | DCS_CMD_CODE | DCS_CMD_ENABLE | HSA_BLANKING_MODE | HBP_BLANKING_MODE | HFP_BLANKING_MODE | BLANKING_MODE | EOT_ENABLE | VP_HSYNC_END | VP_HSYNC_START | VP_VSYNC_END | VP_VSYNC_START | TRIGGER_RESET_MODE | LINE_BUFFER | VP_VSYNC_POL | VP_HSYNC_POL | VP_DE_POL | VP_CLK_POL | VP_DATA_BUS_WIDTH | TRIGGER_RESET | VP_CLK_RATIO | TX_FIFO_ARBITRATION | ECC_RX_EN | CS_RX_EN | IF_EN |

| Bits | Field Name | Description | Type | Reset |
|-------|-------------------|--|------|-------|
| 31:27 | RESERVED | Write 0s for future compatibility. Reads returns 0. | RW | 0x00 |
| 26 | RGB565_ORDER | Byte order for RBG565 command mode from video port 0x0: Unused 0x1: Byte order as for video mode | RW | 0 |
| 25 | DCS_CMD_CODE | DCS command code value to insert between header and video port data when enabled by DCS_CMD_ENABLE 0x0: DCS write memory continue code is inserted. 0x1: DCS write memory start code is inserted. | RW | 0 |
| 24 | DCS_CMD_ENABLE | Enables automatic insertion of DCS command codes when data is sourced by the video port. 0x0: DCS command code is not inserted when command mode traffic is coming from the Video Port. 0x1: DCS command code is inserted automatically when command mode traffic is coming from the Video Port. | RW | 0 |
| 23 | HSA_BLANKING_MODE | Blanking mode 0x0: Packets in TX FIFO are sent during HSA blanking period of video mode or LPS is used. 0x1: LONG BLANKING PACKETS only are used during HSA blanking period of video mode. | RW | 0x0 |
| 22 | HBP_BLANKING_MODE | Blanking mode 0x0: Packets in TX FIFO are sent during HBP blanking period of video mode or LPS is used. 0x1: LONG BLANKING PACKETS only are used during HBP blanking period of video mode. | RW | 0x0 |
| 21 | HFP_BLANKING_MODE | Blanking mode 0x0: Packets in TX FIFO are sent during HFP blanking period of video mode or LPS is used. 0x1: LONG BLANKING PACKETS only are used during HFP blanking period of video mode. | RW | 0x0 |
| 20 | BLANKING_MODE | Blanking mode 0x0: LPS is used during blanking periods of video mode (except HSA, HBP, HFP defined in HSA_BLANKING_MODE, HBP_BLANKING_MODE and HFP_BLANKING_MODE bit fields respectively) when there is no command mode data in TX FIFO ready to be sent. So blanking periods can be different during the frame depending on the TX FIFO. 0x1: LONG BLANKING PACKETS are used during blanking periods of video mode (except HSA, HBP, HFP defined in HSA_BLANKING_MODE, HBP_BLANKING_MODE and HFP_BLANKING_MODE bit fields respectively) regardless of the packets present in the TX FIFO ready to be sent | RW | 0x0 |
| 19 | EOT_ENABLE | Enable EOT packets at the end of HS transmission. 0x0: No EOT packets 0x1: EOT packet is sent at all HS to LP transitions | RW | 0 |
| 18 | VP_HSYNC_END | HSYNC end pulse. 0x0: Disabled. No HSYNC END short packet is generated. 0x1: Enabled. While the HSYNC END pulse is detected, the associated short packet HSYNC END is generated. | RW | 0x0 |
| 17 | VP_HSYNC_START | HSYNC start pulse. 0x0: Disabled. No HSYNC START short packet is generated. 0x1: Enabled. While the HSYNC start pulse is detected, the associated short packet HSYNC START is generated. | RW | 0x0 |

| Bits | Field Name | Description | Type | Reset |
|-------|--------------------|---|------|-------|
| 16 | VP_VSYNC_END | VSYNC end pulse. 0x0: Disabled. No VSYNC END short packet is generated. 0x1: Enabled. While the VSYNC END pulse is detected, the associated short packet VSYNC END is generated. | RW | 0x0 |
| 15 | VP_VSYNC_START | VSYNC start pulse. 0x0: Disabled. No VSYNC START short packet is generated. 0x1: Enabled. While the VSYNC START pulse is detected, the associated short packet VSYNC START is generated. | RW | 0x0 |
| 14 | TRIGGER_RESET_MODE | Selection of the trigger reset mode 0x0: Synchronized: the mode is only valid if there is VC using the video mode and it is active. The principle is to wait for the current video frame to be transferred on the link. Any data received after the VSYNC are ignored. 0x1: Immediate: all pending requests in TX FIFO are taken into account for transfer scheduling, the RX FIFO is ignored, and the data from video port are ignored as soon as possible. Only the current transfer on DSI link and already scheduled ones are transmitted. All the other transfers are discarded. | RW | 0x0 |
| 13:12 | LINE_BUFFER | Number of line buffers to be used while receiving data on the video port. 0x0: No line buffer 0x1: 1 line buffer 0x2: 2 line buffers | RW | 0x0 |
| 11 | VP_VSYNC_POL | VP vertical synchronization signal polarity 0x0: VSYNC signal on the video port is active low. 0x1: VSYNC signal on the video port is active high. | RW | 0x0 |
| 10 | VP_HSYNC_POL | VP horizontal synchronization signal polarity 0x0: HSYNC signal on the video port is active low. 0x1: HSYNC signal on the video port is active high. | RW | 0x0 |
| 9 | VP_DE_POL | VP data enable signal polarity 0x0: DE signal on the video port is active low. 0x1: DE signal on the video port is active high. | RW | 0x0 |
| 8 | VP_CLK_POL | VP pixel clock polarity 0x0: The DSI Protocol Engine module captures the data on the VP on the pixel clock falling edge. The module connected to the VP must drive the data on the pixel clock rising edge. 0x1: The DSI Protocol Engine module captures the data on the VP on the pixel clock raising edge. The module connected to the VP must drive the data on the pixel clock falling edge. | RW | 0x1 |
| 7:6 | VP_DATA_BUS_WIDTH | Defines the size of the video port data bus 0x0: 16-bits data width (LSB of the 24-bit video port data bus) 0x1: 18-bits data width (LSB of the 24-bit video port data bus) 0x2: 24-bits data width (LSB of the 24-bit video port data bus) | RW | 0x0 |
| 5 | TRIGGER_RESET | Send the reset trigger to the peripheral. 0x0: READS: Reset trigger generation is completed. It is reset by HW when it is completed. WRITES: Cancellation of the request for Reset trigger generation (maybe too late since it is already on going) 0x1: READS: Generation of the reset trigger has been requested by user (could be on going but not completed yet). WRITES: Request for Reset trigger to be sent to the peripheral. | RW | 0x0 |

| Bits | Field Name | Description | Type | Reset |
|------|---------------------|---|------|-------|
| 4 | VP_CLK_RATIO | <p>This bit indicates the clock ratio between VP_CLK and VP_PCLK. The clock VP_PCLK is generated from VP_CLK. It is divided down. The information is only used when the video port is used to provide data in command mode. In the case of video mode, it is not used.</p> <p>0x0: The clock VP_PCLK is the clock VP_CLK divided by 2. The duty cycle of VP_PCLK is 50/50.</p> <p>0x1: The clock VP_PCLK is the clock VP_CLK divided by 3 or more. The duty cycle of VP_PCLK is not 50/50 for odd ratio numbers (3,5,7,...).</p> | RW | 0x0 |
| 3 | TX_FIFO_ARBITRATION | <p>Defines the arbitration scheme for granting the VC pending ready requests in the TX FIFO</p> <p>0x0: Round-Robin Scheme is used</p> <p>0x1: Sequential Scheme is used</p> | RW | 0x0 |
| 2 | ECC_RX_EN | <p>Enables the ECC check for the received header (short and long packets for all VC IDs).</p> <p>0x0: Disabled</p> <p>0x1: Enabled</p> | RW | 0x0 |
| 1 | CS_RX_EN | <p>Enables the checksum check for the received payload (long packet only for all VC IDs).</p> <p>0x0: Disabled</p> <p>0x1: Enabled</p> | RW | 0x0 |
| 0 | IF_EN | <p>Enables the module. When the module is disabled the signals from the complex I/O are gated (no updates of the interrupt status register).</p> <p>It is not possible to change the bit fields in the DSI_CTRL register, except IF_EN when it is enabled. All the other registers can be changed except the ones that require DSI_VCn_CTRL[0] VC_EN to be equal to 0 to be modified.</p> <p>0x0: The interface is disabled. If one of the VC uses the video mode with the video port to receive the data, the DSI protocol engines is disabled when the next VSYNC is received and all the data in the FIFO for the other VCs in command mode are sent to the peripherals (if BTA_EN bit is enabled, the DSI protocol engine needs to wait for the response and BTA from the peripheral before disabling all the internal logic since an acknowledge is requested).</p> <p>0x1: The interface is enabled immediately, the data acquisition on the video port starts on the next VSYNC (video mode) or first data received in the Slave port FIFO (command mode).</p> | RW | 0x0 |

Table 12-395. DSI_COMPLEXIO_CFG1

| | | | |
|-------------------------|--|-----------------|---------------------|
| Address Offset | 0x0000 0048 | Instance | DSI_PROTOCOL_ENGINE |
| Physical Address | 0x4804 FC48 | | |
| Description | COMPLEXIO CONFIGURATION REGISTER for the complex I/O This register contains the lane configuration for the order and position of the lanes (clock and data) and the polarity order for the control of the PHY differential signals in addition to the control bit for the power FSM. | | |
| Type | RW | | |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|-----------|-------|------------|---------|------------|----------|----------------------|------------------|----------|----------|----------|----------|----------|----------|-----------|----------------|-----------|----------------|-----------|----------------|----|----|---|---|---|---|---|---|---|---|---|---|--|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 | |
| SHADOWING | GOBIT | RESET_DONE | PWR_CMD | PWR_STATUS | RESERVED | LDO_POWER_GOOD_STATE | USE_LDO_EXTERNAL | RESERVED | RESERVED | RESERVED | RESERVED | RESERVED | RESERVED | DATA2_POL | DATA2_POSITION | DATA1_POL | DATA1_POSITION | CLOCK_POL | CLOCK_POSITION | | | | | | | | | | | | | |

| Bits | Field Name | Description | Type | Reset |
|------|------------|--|------|-------|
| 31 | SHADOWING | Shadowing configuration. 0x0: Disabled. The writes to the DSIPHY_CFG0 and DSIPHY_CFG1 registers are done like the other SCP registers. 0x1: Enabled. The writes to the DSIPHY_CFG0 and DSIPHY_CFG1 registers are done only when the GO bit is set and when the signal DISPC_UPDATE_SYNC from the display controller module is active. | RW | 0x0 |
| 30 | GOBIT | Allows the synchronized update of the shadow registers when the signal DISPC_UPDATE_SYNC is active. 0x0: Resets the Gobit. The hardware has finished the update of the shadow SCP registers. The bit is reset by Hardware. The software can reset the bit in case users decide to abort it. There is no guarantee that the software reset is done before the transfer of the values to the complex I/O. 0x1: Set the Gobit. Only when the transfer of the new values for the two first registers is completed (2, 1, or 0 transfers are performed based on the number of registers to update), the Gobit is reset. The DISPC_UPDATE_SYNC signal is used to synchronize the update. The bit must be set only when it is in reset state. | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|-------|----------------------|--|------|-------|
| 29 | RESET_DONE | Internal reset monitoring of the power domain using TxByteClkHS from the complex I/O 0x0: Internal module reset is on going. 0x1: Reset completed. | R | 1 |
| 28:27 | PWR_CMD | Command for power control of the complex I/O 0x0: Command to change to OFF state 0x1: Command to change to ON state 0x2: Command to change to ultralow-power state | RW | 0x0 |
| 26:25 | PWR_STATUS | Status of the power control of the complex I/O 0x0: complex I/O in OFF state 0x1: complex I/O in ON state 0x2: complex I/O in ultralow-power state | R | 0x0 |
| 24:22 | RESERVED | Write 0s for future compatibility. Reads returns 0. | RW | 0x0 |
| 21 | LDO_POWER_GOOD_STATE | Indicates the state of the signal LDOPWRGOOD. VDDALDODSIPLL: 1.2-V power supply for the PLL. The voltage is supplied by the internal or external LDO. The interrupt LDO_POWER_GOOD_IRQ is generated when a transition is detected on the signal LDOPWRGOOD from the DSI_PHY. 0x0: VDDALDODSIPLL power supply is down 0x1: VDDALDODSIPLL power supply is up | R | 0x0 |
| 20 | USE_LDO_EXTERNAL | Select the external LDO for the DSI_PHY. 0x0: DSI_PHY internal LDO is used. 0x1: External LDO is used. DSI_PHY LDO is tri-stated. | RW | 0x0 |
| 19 | RESERVED | Write 0s for future compatibility. Reads returns 0. | RW | 0x0 |
| 18:16 | RESERVED | Write 0s for future compatibility. Reads returns 0. | RW | 0x0 |
| 15 | RESERVED | Write 0s for future compatibility. Reads returns 0. | RW | 0x0 |
| 14:12 | RESERVED | Write 0s for future compatibility. Reads returns 0. | RW | 0x0 |
| 11 | DATA2_POL | +/- differential pin order of DATA lane 2. 0x0: +/- pin order (dsi_dx=+ and dsi_dy=-) 0x1: -/+ pin order (dsi_dx=- and dsi_dy=+) | RW | 0x0 |
| 10:8 | DATA2_POSITION | Position and order of the DATA lane 2. 0x0: Not used/connected 0x1: Data lane 2 is at the position 1 (line 1). 0x2: Data lane 2 is at the position 2 (line 2). 0x3: Data lane 2 is at the position 3 (line 3). Other values: reserved | RW | 0x0 |
| 7 | DATA1_POL | +/- differential pin order of DATA lane 1 0x0: +/- pin order (dsi_dx=+ and dsi_dy=-) 0x1: -/+ pin order (dsi_dx=- and dsi_dy=+) | RW | 0x0 |
| 6:4 | DATA1_POSITION | Position and order of the DATA lane 1. 0x1: Data lane 1 is at the position 1 (line 1). 0x2: Data lane 1 is at the position 2 (line 2). 0x3: Data lane 1 is at the position 3 (line 3). Other values: reserved | RW | 0x0 |
| 3 | CLOCK_POL | +/- differential pin order of CLOCK lane. 0x0: +/- pin order (dsi_dx=+ and dsi_dy=-) 0x1: -/+ pin order (dsi_dx=- and dsi_dy=+) | RW | 0x0 |

| Bits | Field Name | Description | Type | Reset |
|------|----------------|--|------|-------|
| 2:0 | CLOCK_POSITION | Position and order of the CLOCK lane. The clock lane is always present. 0x1: Clock lane is at the position 1 (line 1). 0x2: Clock lane is at the position 2 (line 2). 0x3: Clock lane is at the position 3 (line 3). Other values: reserved | RW | 0x0 |

| PLL_PWR_CMD | | PLL_PWR_STATUS | | RESERVED | | | | LP_RX_SYNCHRO_ENABLE | LP_CLK_ENABLE | HS_MANUAL_STOP_CTRL | HS_AUTO_STOP_ENABLE | LP_CLK_NULL_PACKET_SIZE | LP_CLK_NULL_PACKET_ENABLE | CIO_CLK_ICG | DDR_CLK_ALWAYS_ON | LP_CLK_DIVISOR | | | | | | | | | | | | | | | |

| Bits | Field Name | Description | Type | Reset |
|-------|---------------------------|---|------|-------|
| 31:30 | PLL_PWR_CMD | Command for power control of the DSI PLL Control module 0x0: Command to change to OFF state 0x1: Command to change to ON state for PLL only (HSDIVISER is OFF) 0x2: Command to change to ON state for both PLL and HSDIVISER 0x3: Command to change to ON state for both PLL and HSDIVISER (no clock output to the DSI complex I/O) | RW | 0x0 |
| 29:28 | PLL_PWR_STATUS | Status of the power control of the DSI PLL Control module 0x0: DSI PLL Control module in OFF state 0x1: DSI PLL Control module in ON state for PLL only (HSDIVISER is OFF) 0x2: DSI PLL Control module in ON state for both PLL and HSDIVISER 0x3: DSI PLL Control module in ON state for both PLL and HSDIVISER (no clock output to the DSI complex I/O) | R | 0x0 |
| 27:22 | RESERVED | Write 0s for future compatibility. Reads returns 0. | RW | 0x00 |
| 21 | LP_RX_SYNCHRO_ENABLE | Defines if the DSI functional clock is higher or lower than 30 MHz. The information is used to define synchronization to be used for RxValidEsc. 0x0: The DSI functional clock is equal or slower than 30 MHz. The synchronization is falling/rising. 0x1: The DSI functional clock is higher than 30 MHz. The synchronization is rising/rising. | RW | 0x0 |
| 20 | LP_CLK_ENABLE | Controls the gating of the TXCLKESC clock. 0x0: Disabled. The clock is not generated. The value of LP_CLK_DIVISOR[12:0] bit field is not used and does not have to be programmed. 0x1: Enabled. The clock is generated. The value of LP_CLK_DIVISOR[12:0] bit field is used and must be programmed. | RW | 0x0 |
| 19 | HS_MANUAL_STOP_CTRL | In case HS_AUTO_STOP_ENABLE bit is set to 0 (reset value), the bit field allows manual control of the assertion/deassertion of the signal DSISStopClk by users. 0x0: DSISStopClk deassertion unconditionally. 0x1: DSISStopClk assertion unconditionally. | RW | 0x0 |
| 18 | HS_AUTO_STOP_ENABLE | Enables the automatic assertion/deassertion of DSISStopClk signal. 0x0: Auto mode disabled. 0x1: Auto mode enabled. | RW | 0x0 |
| 17:16 | LP_CLK_NULL_PACKET_SIZE | Indicates the size of LP NULL Packets to be sent automatically when after the last LP packet transfer. It is used by the receiver to drain its internal pipeline. The valid values are from 0 to 3 bytes for the payload size. | RW | 0x0 |
| 15 | LP_CLK_NULL_PACKET_ENABLE | Enables the generation of NULL packet in low speed. 0x0: Disabled. The NULL packet is not sent in LP mode after the last LP packet. 0x1: Enabled. The NULL packet is sent in LP mode after the last LP packet. | RW | 0x0 |
| 14 | CIO_CLK_ICG | Controls the signal for gating the L3_ICLK clock provided to the complex I/O 0x0: Disabled. The L3_ICLK clock to the DSI complex I/O is gated. 0x1: Enabled. The L3_ICLK clock to the DSI complex I/O is not gated. | RW | 0x0 |

| Bits | Field Name | Description | Type | Reset |
|------|-------------------|--|------|--------|
| 13 | DDR_CLK_ALWAYS_ON | Defines if the DDR clock is also sent when there is no HS packets sent to the peripheral (low power mode). So TXRequest for the clock lane is not de-asserted. 0x0: Disabled. The DDR clock is only provided when HS packets are sent. 0x1: Enabled. The DDR clock is always sent to the peripheral regardless of the state of the data lanes (HS or LP mode). | RW | 0x0 |
| 12:0 | LP_CLK_DIVISOR | Defines the ratio to be used for the generation of the low-power mode clock from DSI functional clock. The supported values are from 1 to 8191(the value 0 is invalid). The output frequency must be in the range between 20 MHz and 32 kHz. | RW | 0x0001 |

| TA_TO | TA_TO_X16 | TA_TO_X8 | TA_TO_COUNTER | | | | | | | | | | | | | FORCE_TX_STOP_MODE_IO | STOP_STATE_X16_IO | STOP_STATE_X4_IO | STOP_STATE_COUNTER_IO | | | | | | | | | | | | |

| Bits | Field Name | Description | Type | Reset |
|------|------------|---|------|-------|
| 31 | TA_TO | Enables the turn-around timer 0x0: Turn-around counter is disabled. 0x1: Turn-around counter is enabled (required to receive TA interrupt in case the turn-around procedure is not successful). | RW | 0x0 |

| Bits | Field Name | Description | Type | Reset |
|-------|-----------------------|---|------|--------|
| 30 | TA_TO_X16 | Multiplication factor for the number of DSI_FCLK clock cycles defined in TA_TO_COUNTER bit field 0x0: The number of DSI_FCLK clock cycles defined in TA_TO_COUNTER is multiplied by 1x 0x1: The number of DSI_FCLK clock cycles defined in TA_TO_COUNTER is multiplied by 16x | RW | 0x1 |
| 29 | TA_TO_X8 | Multiplication factor for the number of DSI_FCLK clock cycles defined in TA_TO_COUNTER bit field 0x0: The number of DSI_FCLK clock cycles defined in TA_TO_COUNTER is multiplied by 1x 0x1: The number of DSI_FCLK clock cycles defined in TA_TO_COUNTER is multiplied by 8x | RW | 0x1 |
| 28:16 | TA_TO_COUNTER | Turn around counter. It indicates the number of DSI_FCLK clock cycles to wait for the change of the Direction PPI signal according to the TurnRequest signal The value is from 0 to 8191. | RW | 0x1FFF |
| 15 | FORCE_TX_STOP_MODE_IO | Control of ForceTxStopMode signal 0x0: Deassertion of ForceTxStopMode. The hardware reset the bit at the end of the ForceTxStopMode assertion. The SW can reset the bit to stop the assertion of the ForceTxStopMode signal prior to the completion of the period. 0x1: Assertion of ForceTxStopMode | RW | 0x0 |
| 14 | STOP_STATE_X16_IO | Multiplication factor for the number of DSI_FCLK clock cycles defined in STOP_STATE_COUNTER_IO bit field 0x0: The number of DSI_FCLK clock cycles defined in STOP_STATE_COUNTER_IO is multiplied by 1x 0x1: The number of DSI_FCLK clock cycles defined in STOP_STATE_COUNTER_IO is multiplied by 16x | RW | 0x1 |
| 13 | STOP_STATE_X4_IO | Multiplication factor for the number of DSI_FCLK clock cycles defined in STOP_STATE_COUNTER_IO bit field 0x0: The number of DSI_FCLK clock cycles defined in STOP_STATE_COUNTER_IO is multiplied by 1x 0x1: The number of DSI_FCLK clock cycles defined in STOP_STATE_COUNTER_IO is multiplied by 4x | RW | 0x1 |
| 12:0 | STOP_STATE_COUNTER_IO | Stop state counter. It indicates the number of DSI_FCLK clock cycles to assert ForceTxStopMode signal. The value is from 0 to 8191. | RW | 0x1FFF |

| Bits | Field Name | Description | Type | Reset |
|-------|------------------|---|------|--------|
| 31 | HS_TX_TO | Enables the HS TX timer. 0x0: Turn-around counter is disabled. 0x1: Turn-around counter is enabled (required to receive TA interrupt in case the turn-around procedure is not successful). | RW | 0x0 |
| 30 | HS_TX_TO_X16 | Multiplication factor for the number of TxByteClkHS functional clock cycles defined in HS_TX_COUNTER bit field 0x0: The number of TxByteClkHS functional clock cycles defined in HS_TX_TO_COUNTER is multiplied by 1x 0x1: The number of TxByteClkHS functional clock cycles defined in HS_TX_TO_COUNTER is multiplied by 16x | RW | 0x1 |
| 29 | HS_TX_TO_X8 | Multiplication factor for the number of TxByteClkHS functional clock cycles defined in HS_TX_COUNTER bit 0x0: The number of TxByteClkHS functional clock cycles defined in HS_TX_TO_COUNTER is multiplied by 1x 0x1: The number of TxByteClkHS functional clock cycles defined in HS_TX_TO_COUNTER is multiplied by 8x | RW | 0x1 |
| 28:16 | HS_TX_TO_COUNTER | HS_TX_TIMER counter. It indicates the number of TxByteClkHS function clock cycles for the HS TX timer. The value is from 0 to 8191. | RW | 0x1FFF |
| 15 | LP_RX_TO | Enables the LP RX timer. 0x0: Turn-around counter is disabled. 0x1: Turn-around counter is enabled (required to receive TA interrupt in case the turn-around procedure is not successful). | RW | 0x0 |
| 14 | LP_RX_TO_X16 | Multiplication factor for the number of DSI_FCLK clock cycles defined in LP_RX_COUNTER bit field 0x0: The number of DSI_FCLK clock cycles defined in LP_RX_TO_COUNTER is multiplied by 1x 0x1: The number of DSI_FCLK clock cycles defined in LP_RX_TO_COUNTER is multiplied by 16x | RW | 0x1 |
| 13 | LP_RX_TO_X4 | Multiplication factor for the number of DSI_FCLK clock cycles defined in LP_RX_COUNTER bit 0x0: The number of DSI_FCLK clock cycles defined in LP_RX_TO_COUNTER is multiplied by 1x 0x1: The number of DSI_FCLK clock cycles defined in LP_RX_TO_COUNTER is multiplied by 4x | RW | 0x1 |
| 12:0 | LP_RX_TO_COUNTER | LP_RX_TIMER counter. It indicates the number of DSI_FCLK clock cycles for the LP RX timer. The value is from 0 to 8191. | RW | 0x1FFF |

| Bits | Field Name | Description | Type | Reset |
|-------|-------------|---|------|-------|
| 31:28 | RESERVED | Write 0s for future compatibility. Reads returns 0. | RW | 0x0 |
| 27:24 | WINDOW_SYNC | Number of TxByteClkHS clock cycles for the synchronization window. An interrupt for synchronization lost is generated when the received synchronization on video port is not inside the window. The DSI protocol engine does not change its own timings if the synch is inside the window. The valid values are from 0 to 15. | RW | 0x0 |
| 23:16 | VSA | Defines the vertical Sync active period used in video mode in number of lines. The supported values are from 0 to 255 It is used to generate the short packet for End of Vertical synchronization. | RW | 0x00 |
| 15:8 | VFP | Defines the vertical front porch used in video mode in number of lines. The supported values are from 0 to 255 | RW | 0x00 |
| 7:0 | VBP | Defines the vertical back porch used in video mode in number of lines. The supported values are from 0 to 255 | RW | 0x00 |

| Bits | Field Name | Description | Type | Reset |
|-------|-----------------------|--|------|--------|
| 31:16 | ENTER_HS_MODE_LATENCY | Defines the number of TxByteClkHS clock cycles necessary for entering to HS mode. It corresponds to the delay in number of HS clock cycles from assertion of TxRequestHS signal to 1 until assertion of TxReadyHS signal to 1. The supported values are from 0 to 65535 . | RW | 0x0000 |

| Bits | Field Name | Description | Type | Reset |
|------|----------------------|--|------|--------|
| 15:0 | EXIT_HS_MODE_LATENCY | Defines the number of TxByteClkHS clock cycles necessary for exiting from HS mode. It corresponds to the maximum delay in number of TxByteClkHS clock cycles from deassertion of TxRequestHS signal until PPI link is in LP-11 state from which a new entrance to HS mode can be initiated which does not take more than ENTER_HS_MODE_LATENCY clock cycles. The supported values are from 0 to 65535 | RW | 0x0000 |

| Bits | Field Name | Description | Type | Reset |
|-------|-------------------|---|------|-------|
| 31:30 | RESERVED | Write 0s for future compatibility. Reads returns 0. | RW | 0x0 |
| 29:27 | DMA_RX_REQ_NB | Selection of the use of the DMA request (associated to the RX FIFO) 0x0: DSI_DMA_REQ0 is selected 0x1: DSI_DMA_REQ1 is selected 0x2: DSI_DMA_REQ2 is selected 0x3: DSI_DMA_REQ3 is selected 0x4: No DMA req selected | RW | 0x0 |
| 26:24 | DMA_RX_THRESHOLD | Defines the threshold value for the DMA request (associated to the RX FIFO) 0x0: 1 x 32 bits 0x1: 2 x 32 bits 0x2: 4 x 32 bits 0x3: 8 x 32 bits 0x4: 16 x 32 bits 0x5: 32 x 32 bits | RW | 0x0 |
| 23:21 | DMA_TX_REQ_NB | Selection of the use of the DMA request (associated to the TX FIFO) 0x0: DSI_DMA_REQ0 is selected 0x1: DSI_DMA_REQ1 is selected 0x2: DSI_DMA_REQ2 is selected 0x3: DSI_DMA_REQ3 is selected 0x4: No DMA req selected | RW | 0x0 |
| 20 | RX_FIFO_NOT_EMPTY | FIFO status in command mode. Otherwise, this bit can be ignored. 0x0: The RX FIFO is empty (the FIFO does not contain any data for the VC) 0x1: The RX FIFO is not empty (the FIFO contains at least one byte for the VC) | R | 0x0 |
| 19:17 | DMA_TX_THRESHOLD | Defines the threshold value for the DMA request (associated to the TX FIFO) 0x0: 1 x 32 bits 0x1: 2 x 32 bits 0x2: 4 x 32 bits 0x3: 8 x 32 bits 0x4: 16 x 32 bits 0x5: 32 x 32 bits | RW | 0x0 |
| 16 | TX_FIFO_FULL | FIFO status in command mode. Otherwise, this bit can be ignored. 0x0: The TX FIFO is not full (the FIFO can accept at least one more 32-bit value) 0x1: The TX FIFO is full | R | 0x0 |

| Bits | Field Name | Description | Type | Reset |
|-------|-------------------|---|------|-------|
| 15 | VC_BUSY | Indicates if previously scheduled activities (packets, BTA) are still being processed. Forced to 1 by hardware if VC is enabled. Software should check this bit is 0 before changing channel configuration. 0x0: No pending operations for this VC 0x1: Pending operations for this VC | R | 0x0 |
| 14 | PP_BUSY | Line buffer busy status. 0x0: Software is permitted to write a new header for VP command mode traffic. 0x1: Software is NOT permitted to write a new header for VP command mode traffic. | R | 0 |
| 13:10 | RESERVED | Write 0s for future compatibility. Reads returns 0. | RW | 0x00 |
| 9 | MODE_SPEED | Selection of the mode. This bit is ignored by hardware when video mode is selected. 0x0: Low-power mode (CMOS) is used to send short and long packets to the peripheral. 0x1: High speed mode (SLVS) is used to send short and long packets to the peripheral. | RW | 0x0 |
| 8 | ECC_TX_EN | Enables the ECC generation for the transmit header (short and long packets). 0x0: Disabled 0x1: Enabled | RW | 0x0 |
| 7 | CS_TX_EN | Enables the checksum generation for the transmit payload (long packet only). 0x0: Disabled. The value 0x00 is used. 0x1: Enabled. The Check-sum value is calculated by HW. | RW | 0x0 |
| 6 | BTA_EN | Send the bus turn around to the peripheral. It can be used when the automatic mode is enabled (BTA_SHORT_EN=1 or/and BTA_LONG_EN=1). In that case only one BTA is sent to the peripheral. The manual mode allows users to define for which packets, the turn around is required for example getting acknowledge from the peripheral. 0x0: READS: BTA generation is completed. It is reset by HW when it is completed. WRITES: Cancellation of the BTA generation (not guarantee since it could already on going, must not be used). 0x1: READS: BTA generation has been requested by user (it could be on going but not completed). WRITES: Request for BTA generation. | RW | 0x0 |
| 5 | TX_FIFO_NOT_EMPTY | FIFO status 0x0: The TX FIFO is empty (the FIFO does not contain any data for the VC) 0x1: The TX FIFO is not empty (the FIFO contains at least one byte for the VC) | R | 0x0 |
| 4 | MODE | Selection of the mode 0x0: Command mode. 0x1: Video mode. | RW | 0x0 |
| 3 | BTA_LONG_EN | Enables the automatic bus turn-around after completion of each long packet transmission. 0x0: Disabled 0x1: Enabled | RW | 0x0 |
| 2 | BTA_SHORT_EN | Enables the automatic bus turn-around after completion of each short packet transmission. 0x0: Disabled 0x1: Enabled | RW | 0x0 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|---|------|-------|
| 1 | SOURCE | <p>Selection of the source between L4 interconnect slave port and video port. This bit is ignored by hardware when video mode is selected.</p> <p>0x0: All the data are provided by the L4 interconnect slave port. Any transfer on the video port is ignored for this VC.</p> <p>0x1: If MODE=VIDEO_MODE, any data received on the video port (pixels and enabled synchronization events using DSI_CTRL[17] VP_HSYNC_START, DSI_CTRL[18] VP_HSYNC_END, DSI_CTRL[15] VP_VSYNC_START, DSI_CTRL[16] VP_VSYNC_END,) are sent on the VC (only one VC can be associated with the video port, the software must ensure that no more than one VC is enabled with the video port as the main source for data). If MODE=COMMAND_MODE, the VP_STALL signal is used by the protocol engine to indicate when new data are required. The synchronization signals are not generated by the display controller. Regardless of the MODE, no data can be provided on the L4 interconnect slave port.</p> | RW | 0x0 |
| 0 | VC_EN | <p>Enables the VC.</p> <p>0x0: Disabled. The VC must be disabled for any register change in the DSI_VCn_XXX registers the corresponding VC ID.</p> <p>0x1: Enabled. No change is allowed to the VC registers (except for setting the bit fields/registers: DSI_VCn_CTRL[6] BTA_EN, DSI_VCn_TE[15:0] TE_SIZE, DSI_VCn_TE[31] TE_START, DSI_VCn_LONG_XXX, DSI_VCn_SHORT_XXX, DSI_VCn_IRQXXX registers).</p> | RW | 0x0 |

| TE_START | TE_EN | RESERVED | | | | | | TE_SIZE | | | | | | | | | | | | | | | | | | | | | | | |

| Bits | Field Name | Description | Type | Reset |
|-------|------------|---|------|----------|
| 31 | TE_START | Manual control of the start of the transfer. Users can use the TE interrupt to determine that the TE trigger has been received before setting the TE_START bit field. It is not mandatory to use the TE interrupt. 0x0: Indicates the end of the transfer. The bit can be used to cancel the transfer if not already started. The FIFO must be flushed by software to ensure it contains no remaining data. 0x1: Starts the transfer of the data. The size is defined in TE_SIZE. The bit field is set until the transfer completes. It is reset by hardware when the transfer completes. | RW | 0 |
| 30 | TE_EN | Tearing effect control 0x0: Disables the automatic transfer of the data using the TE trigger as a synchronization event. The interruption is used to know when the TE trigger is received. The hardware resets the bit field when the transfer completes(TE_SIZE=0). 0x1: Enables the automatic transfer of the data using the TE trigger as a synchronization event. | RW | 0 |
| 29:24 | RESERVED | Write 0s for future compatibility. Reads returns 0. | RW | 0x0000 |
| 23:0 | TE_SIZE | Defines the number of bytes (payload data excluding the check-sum) to be sent. Users must perform the write into the DSI_VCn_LONG_PACKET_HEADER register before sending data from the DSI_VCn_LONG_PACKET_PAYLOAD register. The register value is decremented for every byte of the DSI link that is sent. At the end of the transfer (TE_SIZE = 0), the TE_EN bit field is reset by hardware. The DMA_request is asserted when the trigger is received in order to receive data in the TX FIFO. It must not be used until all data (TE_SIZE) have been received in the FIFO. | RW | 0x000000 |

| Bits | Field Name | Description | Type | Reset |
|------|-----------------------|---|------|----------|
| 31:9 | RESERVED | Write 0s for future compatibility. Reads returns 0. | RW | 0x000000 |
| 8 | PP_BUSY_CHANGE_IRQ | Video port ping-pong buffer busy status. 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset. | RW | 0 |
| 7 | FIFO_TX_UDF_IRQ | FIFO underflow status. The FIFO used on the slave port for buffering the data received on the OCP slave port for the VC has underflowed which means that the data for the current packet have not been received in time since the transfer of the packet are already started (transfer started since the packet size is bigger than space allocated in the FIFO). 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset. | RW | 0x0 |
| 6 | ECC_NO_CORRECTION_IRQ | ECC error status (short and long packets). No correction of the header because of more than 1-bit error. 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset. | RW | 0x0 |
| 5 | BTA_IRQ | Virtual channel - BTA status. 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset. | RW | 0x0 |
| 4 | FIFO_RX_OVF_IRQ | FIFO overflow error status. The FIFO used on the slave port for buffering the data received on the DSI link for the VC has overflowed. 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset. | RW | 0x0 |

| Bits | Field Name | Description | Type | Reset |
|------|--------------------|--|------|-------|
| 3 | FIFO_TX_OVF_IRQ | FIFO overflow error status. The FIFO used on the slave port for buffering the data received on the OCP slave port for the VC has overflowed. 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset. | RW | 0x0 |
| 2 | PACKET_SENT_IRQ | Indicates that a packet has been sent. It is used when BTA manual mode is used. 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset. | RW | 0x0 |
| 1 | ECC_CORRECTION_IRQ | Virtual channel - ECC has been used to do the correction of the only 1-bit error status (short and long packet only). 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset. | RW | 0x0 |
| 0 | CS_IRQ | Virtual channel - Check-Sum mismatch status. 0x0: READS: Event is false. WRITES: Status bit unchanged. 0x1: READS: Event is true (pending). WRITES: Status bit is reset. | RW | 0x0 |

Timers

This chapter describes the timer modules.

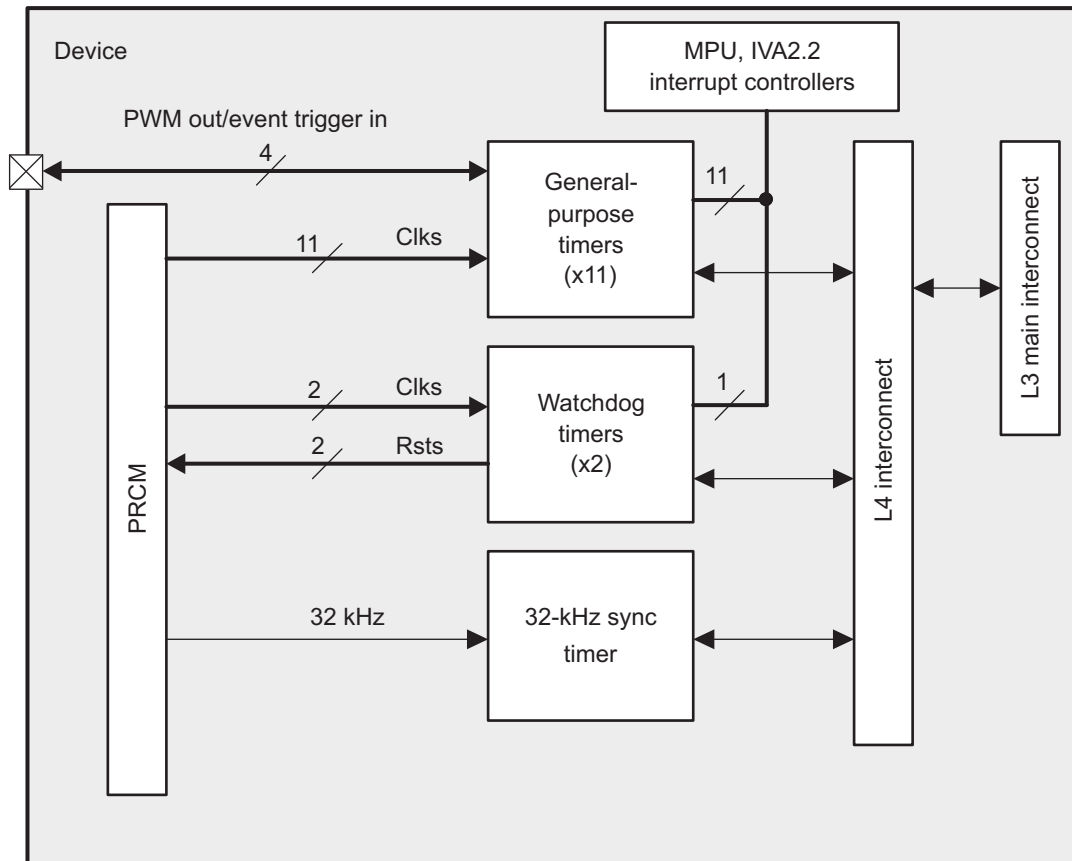

NOTE: Some features may not be available or supported in your particular device. For more information, see Chapter 1, the Device Family section, and your device-specific data manual.

| Topic | Page |
|---|------|
| 13.1 Timers Overview | 1618 |
| 13.2 General-Purpose Timers | 1619 |
| 13.3 General-Purpose Timers Register Manual | 1640 |
| 13.4 Watchdog Timers | 1663 |
| 13.5 Watchdog Timer Register Manual | 1672 |
| 13.6 32-kHz Synchronized Timer | 1680 |
| 13.7 32-kHz Sync Timer Register Manual | 1682 |

13.1 Timers Overview

The device includes several types of timers used by the system software, including 11 general-purpose timers (GP timers), 2 watchdog timers (WDTs), a 32-kHz synchronized timer. Figure 13-1 shows the counters in the device in a high-level block diagram.

Figure 13-1. Timers

PU108-027

The 2 WDTs are clocked with 32-kHz clocks. The 32-kHz synchronized timer, which is reset only at power up, provides the operating system with a stable timing source that stores the relative time since the last power cycle of the product. Finally, 11 GP timers, which are useful simply as basic timers, are included to generate time-stamp-based interrupts to the system software or to use as a source of pulse-width modulation (PWM) signals.

13.2 General-Purpose Timers

13.2.1 GP Timers Overview

The device has 11 GP timers: GPTIMER1 through GPTIMER11.

Each timer can be clocked from either the system clock (12, 13, 16.8, 19.2, 26, or 38.4 MHz) or the 32-kHz clock. The selection of the clock source is made at the power, reset, clock management (PRCM) module level. For more information, see [Section 13.2.3.1, Clocking, Reset, and Power-Management Scheme](#).

GPTIMER1 has its GPT1_EVENT_CAPTURE pin tied to the 32-kHz clock and can be used to gauge the system clock input; it detects its frequency among 12, 13, 16.8, 19.2, 26, or 38.4 MHz.

Each timer can provide an interrupt to the microprocessor unit (MPU) subsystem. In addition, GPTIMER5 through GPTIMER8 also have interrupts connected to the IVA2.2 subsystem.

GPTIMER1, GPTIMER2, and GPTIMER10 include specific functions to generate accurate tick interrupts to the operating system. GPTIMER8 through GPTIMER11 are connected to external pins by their PWM output or their event capture input pin (for external timer triggering). [Figure 13-2](#) shows an overview of the GP timers.

Figure 13-2. GP Timers Overview

13.2.1.1 GP Timers Features

The following are the main features of the GP timers controllers:

- L4 slave interface support:

- 32-bit data bus width
- 32-/16-bit access supported
- 8-bit access not supported
- 10-bit address bus width
- Burst mode not supported
- Write nonposted transaction mode supported
- Interrupts generated on overflow, compare, and capture
- Free-running 32-bit upward counter
- Compare and capture modes
- Autoreload mode
- Start/stop mode
- Programmable divider clock source (2^n with $n = [0:8]$)
- Dedicated input trigger for capture mode and dedicated output trigger/PWM signal
- Dedicated output signal for general-purpose using GPTi_GPOCFG signal
- On-the-fly read/write register (while counting)
- 1-ms tick with 32,768 Hz functional clock generated (only GPTIMER1, GPTIMER2, and GPTIMER10)

13.2.2 GP Timers Environment

13.2.2.1 GP Timers External System Interface

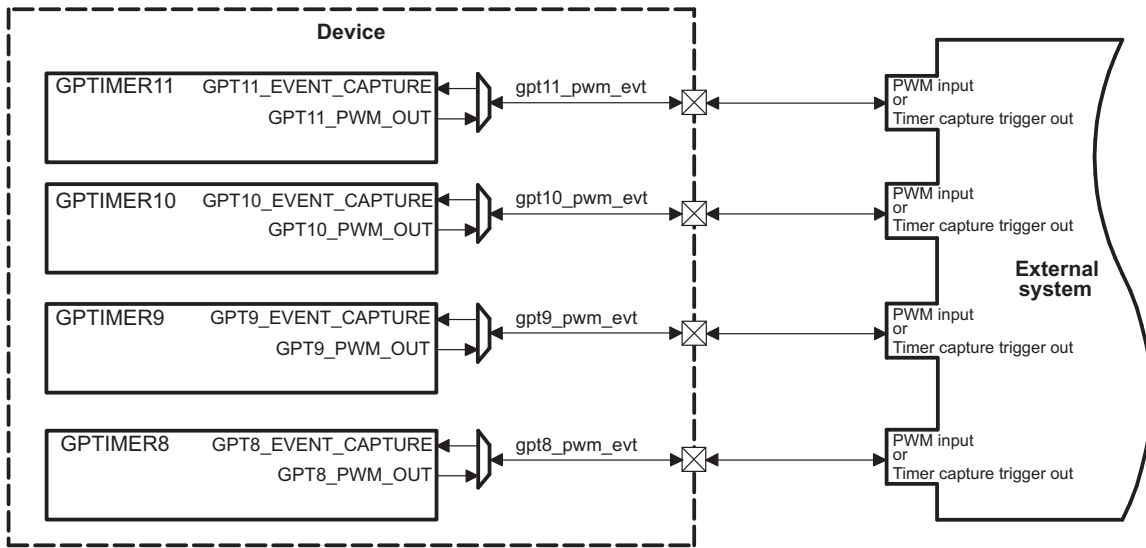

Four of the 11 GP timers can send or receive stimulus to/from the external (off-chip) system. In the device, however, only GPTIMER8 through GPTIMER11 are configured to output a PWM pulse or receive an external event signal used as a trigger to capture the current timer count. GPTIMER1 is also configured to receive an event trigger input (GPT1_EVENT_CAPTURE) tied to the internal 32-kHz clock. This event signal gauges the system clock input; it detects its frequency among 12, 13, 16.8, 19.2, 26, or 38.4 MHz.

Figure 13-3 shows the external system interface for the GP timers, and Table 13-1 describes the GP timer inputs and outputs.

NOTE: Software must ensure that MUX mode is configured to select the `gpt_x_pwm_evt` (where $x = 8$ to 11) signal on only one pad. Other pad(s) on which the same signal is multiplexed must be configured in safe mode or non-gptimer mode to avoid two different pads driving the same signal

For more information about the `gpt_8_pwm_evt` through `gpt11_pwm_evt` I/O pad configuration, see [Chapter 6, System Control Module](#).

Figure 13-3. GP Timers External System Interface

PU108-003

Table 13-1. Input/Output Description

| Pin Name | Type ⁽¹⁾ | Reset Value | Signal Name | Description |
|---------------|---------------------|-------------|--------------------------------------|--|
| gpt8_pwm_evt | I/O | 0 | GPT8_EVENT_CAPTURE GPT8_PWM_OUT | GPTIMER8 trigger input/ PWM output |
| gpt9_pwm_evt | I/O | 0 | GPT9_EVENT_CAPTURE GPT9_PWM_OUT | GPTIMER9 trigger input/ PWM output |
| gpt10_pwm_evt | I/O | 0 | GPT10_EVENT_CAPTURE GPT10_PWM_OUT | GPTIMER10 trigger input/ PWM output |
| gpt11_pwm_evt | I/O | 0 | GPT11_EVENT_CAPTURE GPT11_PWM_OUT | GPTIMER11 trigger input/ PWM output |

⁽¹⁾ When configured for that function; I = input, O = output

NOTE: The event trigger input (GPTi_EVENT_CAPTURE) for GPTIMER2 through GPTIMER7 is internally tied low, and the PWM output (GPTi_PWM_OUT) is not connected.

13.2.3 GP Timers Integration

Figure 13-4 shows the GP timer integration in the device.

Figure 13-4. GP Timer Integration

13.2.3.1 Clocking, Reset, and Power-Management Scheme

13.2.3.1.1 Clock Management

There are two clock domains in the GP timers:

- Functional clock domain: GPTi_FCLK is the GP timer functional clock. It is used to clock the GP timer internal logic.
- Interface clock domain: GPTi_ICLK is the GP timer interface clock. It is used to synchronize the GP timer L4 port to the L4 interconnect. All accesses from the interconnect are synchronous to GPTi_ICLK.

Table 13-2 lists the source clocks for each GP timer in the device. For more information on clock control and domains, see *Power, Reset, and Clock Management*.

Table 13-2. Clock, Power, and Reset Domains for GP Timers

| Timer | Interface Clock | Functional Clock | Power Domain |
|------------------------------|-----------------|--------------------------------------|--------------|
| GPTIMER1 | WKUP_L4_ICLK | GPT1_FCLK | WKUP |
| GPTIMER2 through GPTIMER9 | PER_L4_ICLK | GPTx_ALWON_FCLK (x = 2 through 9) | PER |
| GPTIMER10 and 11 | CORE_L4_ICLK | GPTx_FCLK (x = 10 or 11) | CORE |

GP timers can be selected as the source of GPT_i_FCLK (32-kHz clock or 12, 13, 16.8, 19.2, 26, or 38.4 MHz) at the PRCM level in the corresponding registers. For more information, see , *Power, Reset, and Clock Management*. [Table 13-3](#) lists the GP timer PRCM clock selection bits.

Table 13-3. GP Timer PRCM Clock Selection Bits

| Name | Associated PRCM Clock Output | Selection Bit |
|---------------|------------------------------|---|
| GPT1_FCLK | GPT1_FCLK | PRCM.CM_CLKSEL_WKUP[0] CLKSEL_GPT1 |
| GPT[2:9]_FCLK | GPT[2:9]_ALWON_FCLK | PRCM.CM_CLKSEL_PER [0:7] CLKSEL_GPT[2:9] |
| GPT10_FCLK | GPT10_FCLK | PRCM.CM_CLKSEL_CORE [6] CLKSEL_GPT10 |
| GPT11_FCLK | GPT11_FCLK | PRCM.CM_CLKSEL_CORE [7] CLKSEL_GPT11 |

From a global system power-management perspective, when one or both of the GP timer clocks is no longer required, the GP timers can be deactivated at the PRCM level in the corresponding registers. [Table 13-4](#) lists the GP timer PRCM clock control bits.

Table 13-4. GP Timer PRCM Clock Control Bits

| Name | Associated PRCM Clock Output | Enable Bit | Autoidle Bit |
|---------------|------------------------------|--|---|
| GPT1_FCLK | GPT1_FCLK | PRCM.CM_FCLKEN_WKUP[0] EN_GPT1 bit | N/A |
| GPT[2:9]_FCLK | GPT[2:9]_ALWON_FCLK | PRCM.CM_FCLKEN_PER [3:10] EN_GPT[2:9] bit | N/A |
| GPT10_FCLK | GPT10_FCLK | PRCM.CM_FCLKEN1_CORE [11] EN_GPT10 bit | N/A |
| GPT11_FCLK | GPT11_FCLK | PRCM.CM_FCLKEN1_CORE [12] EN_GPT11 bit | N/A |
| GPT1_ICLK | WKUP_L4_ICLK | PRCM.CM_ICLKEN_WKUP[0] EN_GPT1 bit | PRCM.CM_AUTOIDLE_WKUP[0] AUTO_GPT1 bit |
| GPT[2:9]_ICLK | PER_L4_ICLK | PRCM.CM_ICLKEN_PER[3:10] EN_GPT[2:9] bit | PRCM.CM_AUTOIDLE_PER[3:10] AUTO_GPT[2:9] bit |
| GPT10_ICLK | CORE_L4_ICLK | PRCM.CM_ICLKEN1_CORE[11] EN_GPT10 bit | PRCM.CM_AUTOIDLE1_CORE[11] AUTO_GPT10 bit |
| GPT11_ICLK | | PRCM.CM_ICLKEN1_CORE[12] EN_GPT11 bit | PRCM.CM_AUTOIDLE1_CORE[12] AUTO_GPT11 bit |

NOTE:

- The PRCM function clock outputs are gated at the PRCM level, assuming all the modules that share it are disabled in the corresponding register. Disabling GP timers is a necessary but not sufficient action. The clock is effectively out when all PRCM conditions are fulfilled. For the other actions to be taken, see , *Power, Reset, and Clock Management*.
- The PRCM interface clock outputs are gated at the PRCM level, assuming all the modules that share it are disabled in the corresponding register. Disabling GP timers is a necessary but not sufficient action. The clock is effectively out when all PRCM conditions are fulfilled. For the other actions to be taken, see , *Power, Reset, and Clock Management*.
- The PRCM AUTOIDLE bits are used to link/unlink the GP timers from the clock domain transitions related to the GPTi_ICLK clocks.
- For further details about source clock gating and domain transitions, see , *Power, Reset, and Clock Management*.

GP timer modules also have an internal bit, GPTi.TIOCP_CFG[0] AUTOIDLE. The GP timer AUTOIDLE bit is used to apply an internal interface clock gating strategy.

At the PRCM level, when all conditions to shut off the PRCM functional or interface output clocks are met (see , *Power, Reset, and Clock Management*, for details), the PRCM automatically launches a hardware handshake protocol to ensure the GP timer is ready to have its clocks switched off. Namely, the PRCM asserts an IDLE request to the GP timer.

Although this handshake is a hardware function and is out of software control, the way the GP timer acknowledges the PRCM IDLE request is configurable through the GPTi.TIOCP_CFG[4:3] IDLEMODE bit. [Table 13-5](#) lists the IDLEMODE settings and the related acknowledgement modes.

Table 13-5. IDLEMODE Settings

| IDLEMODE Value | Selected Mode | Description |
|----------------|---------------|---|
| 00 | Force-idle | The GP timer acknowledges unconditionally the IDLE request from the PRCM module, regardless of its internal operations. This mode must be used carefully, because it does not prevent the loss of data when the clock is switched off. |
| 01 | No-idle | The GP timer never acknowledges an IDLE request from the PRCM module. This mode is safe from a module point of view, because it ensures that the clocks remain active. It is not efficient from a power-saving perspective, however, because it does not allow the PRCM output clock to be shut off and thus the power domain to be set to a lower power state. |
| 10 | Smart-idle | The GP timer acknowledges the IDLE request, basing its decision on its internal activity. The acknowledge signal is asserted only when all pending transactions and IRQ requests are treated. This is the best approach for efficient system power management. |
| 11 | Reserved | |

When configured in smart-idle mode, the GP timer also offers an additional granularity on GPTi_FCLK and GPTi_ICLK gating. The GPTi.TIOCP_CFG[9:8] CLOCKACTIVITY bit field is used to determine which clock will be shut down (GPTi_FCLK, GPTi_ICLK, neither of them, or both of them).

The CLOCKACTIVITY setting is used internally to the GP timer to determine the part of the module on which the conditions to acknowledge the PRCM IDLE request will be tested. For example, if GPTi_FCLK is not to be shut down on a PRCM IDLE request, the GP timer considers only GPTi_ICLK and the associated pending activities before acknowledging the request.

Some GP timer features are associated with GPTi_ICLK and others are associated with GPTi_FCLK. Using the CLOCKACTIVITY setting along with the smart-idle mode ensures that the features associated with the clock that will remain active are always enabled, even if the GP timer acknowledges an IDLE request.

Table 13-6 lists the CLOCKACTIVITY settings and the associated features.

Table 13-6. CLOCKACTIVITY Settings

| CLOCKACTIVITY Value | GPTi_ICLK Effects | GPTi_FCLK Effects | Description | Associated Features |
|---------------------|-------------------|-------------------|---|---|
| 00 | OFF | OFF | Both GPTi_ICLK and GPTi_FCLK are considered for generating the acknowledge. This setting also means both GPTi_FCLK and GPTi_ICLK are likely to be shut down on PRCM IDLE request. | The idle acknowledge signal is asserted when there are no pending activities on the functional clock domain (improved latency in assertion of idle acknowledge). The wake-up capability of the GP timer is disabled. |
| 01 | ON | OFF | GPTi_ICLK is not shut down on PRCM IDLE request; only GPTi_FCLK is affected. | |
| 10 | OFF | ON | GPTi_FCLK is not shut down on PRCM IDLE request; only GPTi_ICLK is affected. | The idle acknowledge signal is asserted when there are no pending activities on the interface clock domain, without evaluating the pending activities on the functional clock domain (the GP timer enters into sleep mode, and if a pending interrupt event is finished during idle mode, the wake-up signal is asserted). The wake-up signal is enabled. |
| 11 | ON | ON | None of the clocks are shut down. Therefore, the GP timer can potentially acknowledge the IDLE request without checking the internal functionalities linked to its clocks. | |

CAUTION

The PRCM module does not have any hardware means to read the CLOCKACTIVITY settings. The software must ensure consistent programming between the GP timer CLOCKACTIVITY and the PRCM functional clock and interface clock control bits. If the GP timer is disabled in both CM_FCLKEN and CM_ICLKEN PRCM registers while CLOCKACTIVITY is set to 11, nothing prevents the PRCM module from asserting its IDLE request, which is acknowledged regardless of the features associated with the GP timer clocks. This can lead to unpredictable behavior.

13.2.3.1.2 Wake-Up Capability

If the GPTi.TIOCP_CFG[4:3] IDLEMODE bit field sets the smart-idle mode, the timer module evaluates its internal capability to have the interface clock switched off. When there is no more internal activity (no pending interrupt sources: match, overflow, or timer capture events), the idle acknowledge signal is asserted and the timer enters into sleep mode, ready to issue a wake-up request. This wake-up request is sent only if the GPTi.TIOCP_CFG[2] ENAWAKEUP bit enables the timer wake-up capability.

Figure 13-5 shows the wake-up request generation. For more information on the GP timer clock control, see Section 13.2.3.1.1, *Clock Management*.

Figure 13-5. Wake-Up Request Generation

PU108-005

The timer wake-up enable register (GPTi.TWER) allows masking the expected source of the wake-up event that generates a wake-up request. The GPTi.TWER register is programmed synchronously with the interface clock before the PRCM module sends an idle mode request. The expected source of the wake-up event is an overflow (GPTi.TCRR), a timer match (the compare result of GPTi.TCRR and GPTi.TMAR matches the counter value), and a timer capture (an external pulse transition of the correct polarity is detected on the GPTi_EVENT_CAPTURE).

When the wake-up event is issued, the associated interrupt status bit is set in the timer status register (GPTi.TISR). The pending wake-up event is reset when the set status bit is overwritten by 1.

NOTE: The status bit must be reset to re-enter idle mode.

13.2.3.1.3 Reset and Power Management

GPTIMER1 belongs to the WKUP power domain. As part of that domain, this GP timer is sensitive to a WKUP_RST signal issued by the PRCM module. For further details about the WKUP power domain implementation and the WKUP_RST signal, see , *Power, Reset, and Clock Management*.

GPTIMER2 through GPTIMER9 belong to the PER power domain. As part of that domain, these GP timers are sensitive to a PER_RST signal issued by the PRCM module. For further details about the PER power domain implementation and the PER_RST signal, see , *Power, Reset, Clock Management*.

GPTIMER10 and GPTIMER11 belong to the CORE power domain. As part of that domain, these GP timers are sensitive to a CORE_RST signal issued by the PRCM module. For further details about the CORE power domain implementation and the CORE_RST signal, see , *Power, Reset, and Clock Management*.

13.2.3.2 Software Reset

Two bit fields (GPTi.TIOCP_CFG[1] SOFTRESET and GPTi.TSICR[1] SFT) can generate a software reset of the GP timer. For both of these bits, all read accesses return 0.

The GPTi.TIOCP_CFG[1] SOFTRESET bit allows resetting the functional and interface domains. The GPTi.TSICR[1] SFT bit allows resetting the functional part of the GP timer.

Before accessing or using the GP timer, the local host must ensure that both internal resets are released by reading the GPTi.TISTAT[0] RESETDONE bit. This bit field monitors the internal reset status.

13.2.3.3 GP Timer Interrupts

Table 13-7 lists the interrupt mapping from the 12 GP timers to the three internal processors.

Table 13-7. Timer Interrupt Names and Processor IRQ Mapping

| Timer | Interrupt Name | Mapping | Comments |
|-----------|----------------|-------------|---|
| GPTIMER 1 | GPT1_IRQ | M_IRQ_37 | GPTIMER1 interrupt to MPU |
| GPTIMER2 | GPT2_IRQ | M_IRQ_38 | GPTIMER2 interrupt to MPU |
| GPTIMER3 | GPT3_IRQ | M_IRQ_39 | GPTIMER3 interrupt to MPU |
| GPTIMER4 | GPT4_IRQ | M_IRQ_40 | GPTIMER4 interrupt to MPU |
| GPTIMER5 | GPT5_IRQ | M_IRQ_41 | GPTIMER5 interrupt to MPU |
| GPTIMER6 | GPT6_IRQ | IVA2_IRQ[6] | GPTIMER5 interrupt to IVA2.2 |
| | | M_IRQ_42 | GPTIMER6 interrupt to MPU |
| | | IVA2_IRQ[7] | GPTIMER6 interrupt to IVA2.2 |
| GPTIMER7 | GPT7_IRQ | MD_IRQ_6 | GPTIMER6 interrupt to modem subsystem (D2D) |
| | | M_IRQ_43 | GPTIMER7 interrupt to MPU |
| | | IVA2_IRQ[8] | GPTIMER7 interrupt to IVA2.2 |
| GPTIMER8 | GPT8_IRQ | MD_IRQ_7 | GPTIMER7 interrupt to modem subsystem (D2D) |
| | | M_IRQ_44 | GPTIMER8 interrupt to MPU |
| | | IVA2_IRQ[9] | GPTIMER8 interrupt to IVA2.2 |
| GPTIMER9 | GPT9_IRQ | MD_IRQ_8 | GPTIMER8 interrupt to modem subsystem (D2D) |
| | | M_IRQ_45 | GPTIMER9 interrupt to MPU |
| GPTIMER10 | GPT10_IRQ | MD_IRQ_9 | GPTIMER9 interrupt to modem subsystem (D2D) |
| | | M_IRQ_46 | GPTIMER10 interrupt to MPU |
| GPTIMER11 | GPT11_IRQ | M_IRQ_47 | GPTIMER11 interrupt to MPU |

The timer can issue an overflow interrupt, a timer match interrupt, and a timer capture interrupt. Each internal interrupt source can be independently enabled/disabled in the interrupt enable register (GPTi.TIER). When the interrupt event is issued, the associated interrupt status bit is set in the timer status register (GPTi.TISR). The pending interrupt event is reset when the set status bit is overwritten by a1.

13.2.4 GP Timers Functional Description

Each GP timer contains a free-running upward counter with autoreload capability on overflow. The timer counter can be read and written on-the-fly (while counting). Each GP timer includes compare logic to allow an interrupt event on a programmable counter matching value. A dedicated output signal can be pulsed or toggled on either an overflow or a match event. This offers time-stamp trigger signaling or PWM signal sources. A dedicated input signal can be used to trigger an automatic timer counter capture or an interrupt event on a programmable input signal transition type. A programmable clock divider (prescaler) allows reduction of the timer input clock frequency. All internal timer interrupt sources are merged into one module interrupt line and one wake-up line. Each internal interrupt source can be independently enabled/disabled with a dedicated bit of the GPTi.TIER register for the interrupt features and a dedicated bit of the GPTi.TWER register for the wakeup. In addition, GPTIMER1, GPTIMER2, and GPTIMER10 have implemented a mechanism to generate an accurate tick interrupt.

For each GP timer implemented in the device, there are two possible clock sources:

- 32-kHz clock
- System clock

Selection of the input clock source is done in the registers in the PRCM configuration (see [Section 13.2.1, GP Timer Overview](#)).

Each GP timer supports three functional modes:

- Timer mode
- Capture mode
- Compare mode

By default, after core reset, the capture and compare modes are disabled.

13.2.4.1 GP Timers Block Diagram

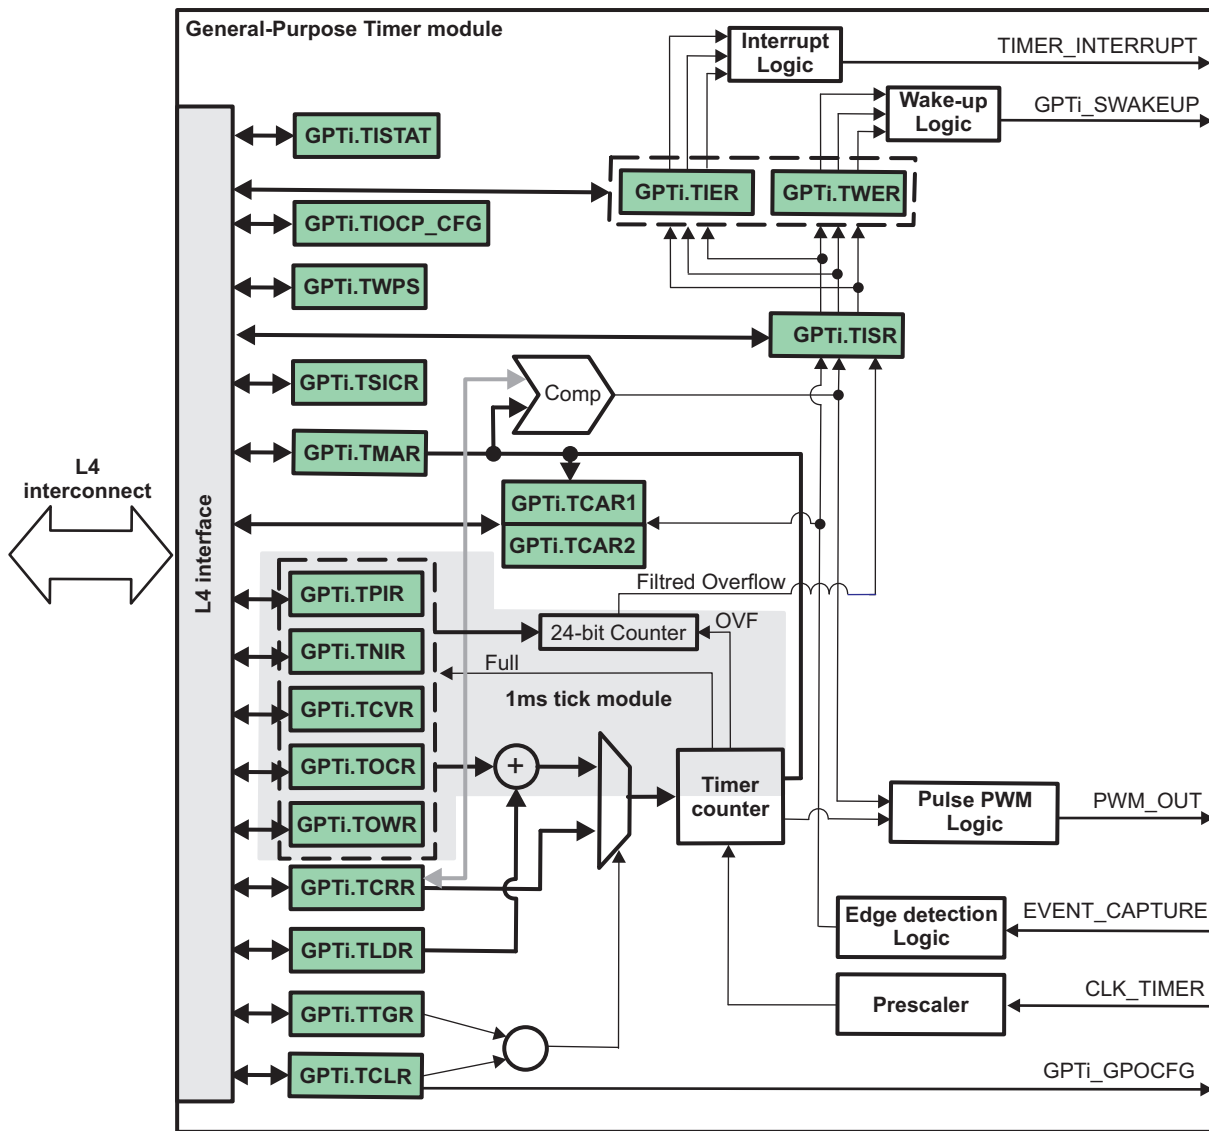

[Figure 13-6](#) shows the block diagram of common GP timers, and [Figure 13-7](#) shows the block diagram of GP timers with 1-ms tick generation module.

Figure 13-6. Block Diagram of GPTIMER3 through GPTIMER9 and GPTIMER11

PU108-006

Figure 13-7. Block Diagram of GPTIMER1, GPTIMER2, and GPTIMER10

PU108-007

13.2.4.2 Timer Mode Functionality

The timer is an upward counter that can be started and stopped at any time through the timer control register (GPTi.TCLR[0] ST bit). The timer counter register (GPTi.TCRR) can be loaded when stopped or on-the-fly (while counting). GPTn.TCRR can be loaded directly by a GPTi.TCRR write access with a new timer value. The GPTi.TCRR register can also be loaded by the value held in the timer load register GPTi.TLDR by a trigger register (GPTi.TTGR) write access. The GPTi.TCRR loading is done regardless of the GPTi.TTGR written value. The timer counter register GPTi.TCRR value can be read when stopped or captured on-the-fly by a GPTi.TCRR read access. The timer is stopped and the counter value is set to 0 when the module reset is asserted. The timer is maintained at stop after the reset is released.

In one-shot mode (the GPTi.TCLR[1] AR bit set to 0), the counter is stopped after counting overflow occurs (the counter value remains at 0).

When the autoreload mode is enabled (the GPTi.TCLR[1] AR bit set to 1), the GPTi.TCRR register is reloaded with the timer load register (GPTi.TLDR) value after a counting overflow occurs.

CAUTION

Do not put the overflow value (0xFFFFFFFF) in the GPTi.TLDR register because it can lead to undesired results.

An interrupt can be issued on overflow if the overflow interrupt enable bit is set in the timer interrupt enable register (GPTi.TIER[1] OVF_IT_ENA bit set to 1), the interrupt is enabled after 10 * GPTi.ICLK clock cycles. A dedicated output pin (timer PWM) can be programmed in GPTi.TCLR[12] through GPTi.TCLR[11:10] (PT and TRG bits) to generate one positive pulse (prescaler duration) or to invert the current value (toggle mode) when an overflow occurs. The GPTi.TCLR[12] PT bit selects pulse/toggle modulation (GPTi.TCLR[11:10] TRG bit field select trigger mode).

Figure 13-8 shows the GPTi.TCRR timing value.

Figure 13-8. GPTi.TCRR Timing Value

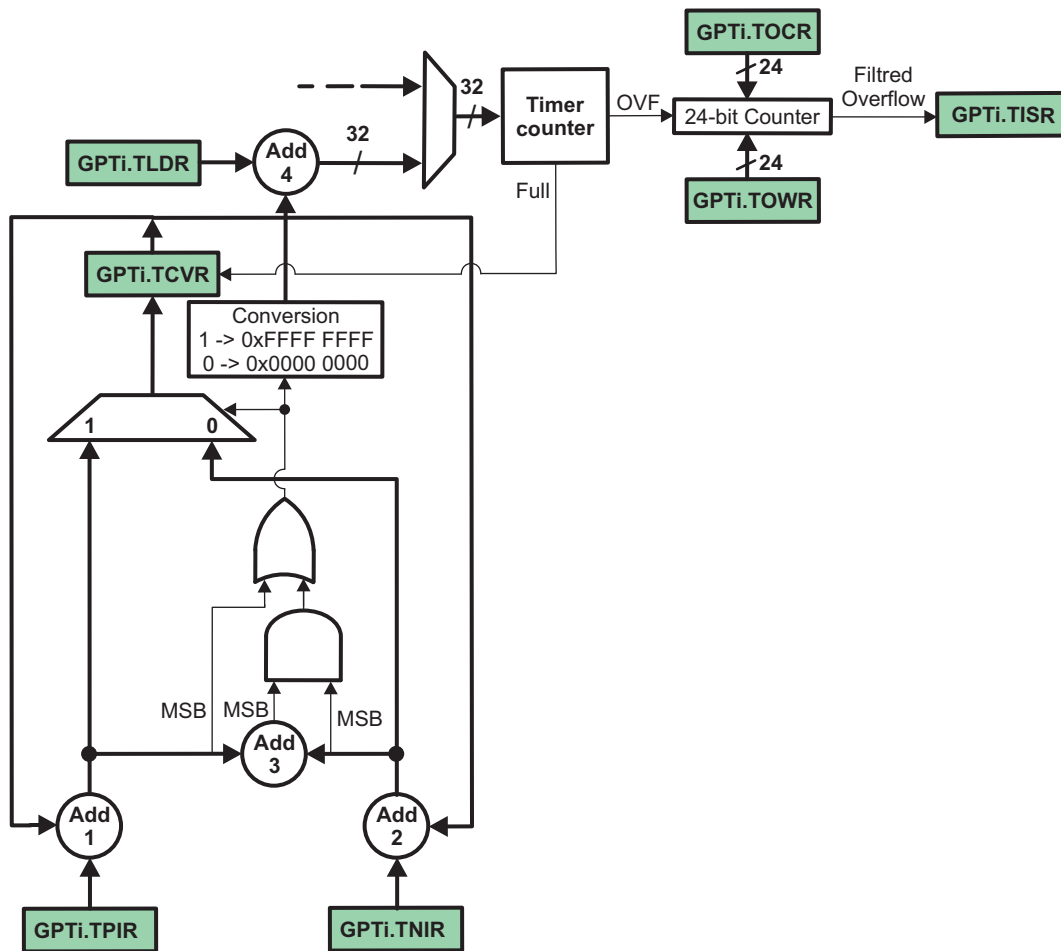

13.2.4.2.1 1-ms Tick Generation (Only GPTIMER1, GPTIMER2, and GPTIMER10)

Because the timer input clock is 32,768 Hz, the interrupt period is not exactly 1 ms. If the clock counts up to 32, it obtains a 0.977-ms period; if it counts up to 33, it obtains a 1.007-ms period. For large granularity, the error is cumulative and can generate important deviations to the standard value.

To minimize the error between a true 1-ms tick and the tick generated by the 32,768 Hz timer, the sequencing of periods less than 1 ms and periods greater than 1 ms must be shuffled. An additional 1-ms block is used to correct this error. Refer to Figure 13-9.

In this implementation, the increment sequencing is automatically managed by the timer to minimize the error. The user must define only the value of the timer positive increment register (GPTi.TPIR[31:0] POSITIVE_INC_VALUE bit field) and the timer negative increment register (GPTi.TNIR[31:0] NEGATIVE_INC_VALUE bit field). An automatic adaptation mechanism is used to simplify the programming model.

Figure 13-9. Block Diagram of the 1-ms Tick Module

PU108-009

The GPTi.TPIR, GPTi.TNIR, and GPTi.TCVR registers and adders Add1, Add2, and Add3 are used to define whether the next value loaded in the timer counter register (GPTi.TCRR[31:0] TIMER_COUNTER bit field) is the value of the GPTi.TLDR[31:0] LOAD_VALUE bit field (period less than 1 ms) or the value of GPTi.TLDR[31:0] LOAD_VALUE - 1 (period greater than 1 ms).

Table 13-8 lists the value loaded in the GPTi.TCRR register according to the sign of the result of Add1, Add2, and Add3.

MSB = 0: Positive value, MSB = 1: Negative value

Table 13-8. Value Loaded in GPTi.TCRR to Generate 1-ms Tick

| Add1 MSB | Add2 MSB | Add3 MSB | Value of GPTi.TCRR Register |
|----------|----------|----------|--------------------------------------|
| 0 | 0 | 0 | GPTi.TLDR[31:0] LOAD_VALUE bit field |
| 0 | 0 | 1 | GPTi.TLDR[31:0] LOAD_VALUE bit field |
| 0 | 1 | 0 | GPTi.TLDR[31:0] LOAD_VALUE bit field |
| 0 | 1 | 1 | GPTi.TLDR[31:0] LOAD_VALUE - 1 |
| 1 | 0 | 0 | N/A |
| 1 | 0 | 1 | N/A |
| 1 | 1 | 0 | GPTi.TLDR[31:0] LOAD_VALUE - 1 |
| 1 | 1 | 1 | GPTi.TLDR[31:0] LOAD_VALUE - 1 |

The values of the GPTi.TPIR and GPTi.TNIR registers are calculated using the following formula:

- Positive increment value = (INTEGER[Fclk * Ttick] + 1) * 1e6) - (Fclk * Ttick * 1e6)
- Negative increment value = (INTEGER[Fclk * Ttick] * 1e6) - (Fclk * Ttick * 1e6)

NOTE: Fclk clock frequency (kHz)

Ttick tick period (ms)

The timer overflow counter register (GPTi.TOCR) and the timer overflow wrapping register (GPTi.TOWR) are used to filter interrupts. When the timer overflows, it increments the 24-bit TOCR register. When the 24-bit TOCR register values match the value in the 24-bit TOWR register and the timer overflow is asserted, the TOCR register is reset and an interrupt is generated to the TISR register.

With the conversion block in reset state (the positive increment register, negative increment register, and counter value register are zeroed), the programming model and the behavior of GPTIMER1, GPTIMER2, and GPTIMER10 remain unchanged.

For 1-ms tick with a 32,768-Hz clock:

- GPTi.TPIR[31:0] POSITIVE_INC_VALUE = 232000
- GPTi.TNIR[31:0] NEGATIVE_INC_VALUE = -768000
- GPTi.TLDR[31:0] LOAD_VALUE = 0xFFFFFEE0

NOTE: Any value of the tick period can be generated with the appropriate value of the GPTi.TPIR, GPTi.TNIR, and GPTi.TLDR registers.

By default, the GPTi.TPIR, GPTi.TNIR, GPTi.TCVR, GPTi.TOCR, and GPTi.TOWR registers and the associated logic are in reset mode (all 0s) and have no action on the programming model.

13.2.4.3 Capture Mode Functionality

When a transition is detected on the module input pin (EVENT_CAPTURE), the timer value in the GPTi.TCRR register can be captured and saved in the GPTi.TCAR1 or GPTi.TCAR2 register function of the mode selected in the GPTi.TCLR[13] CAPT_MODE bit. The edge detection circuitry monitors transitions on the input pin (EVENT_CAPTURE).

The rising edge, falling edge, or both, can be selected in the GPTi.TCLR[9:8] TCM field to trigger the timer counter capture. The module sets the GPTi.TISR[2] TCAR_IT_FLAG bit when an active edge is detected, and at the same time, the counter value GPTi.TCRR is stored in timer capture register GPTi.TCAR1 or GPTi.TCAR2, as follows:

- If the GPTi.TCLR[13] CAPT_MODE bit is 0, then on the first enabled capture event the value of the counter register is saved in the GPTi.TCAR1 register, and all the next events are ignored (no update on the GPTi.TCAR1 register and no interrupt triggering) until the detection logic is reset or the GPTi.TISR[2] TCAR_IT_FLAG bit is cleared by writing 1 in it.
- If the GPTi.TCLR[13] CAPT_MODE bit is 1, then on the first enabled capture event the value of the counter register is saved in the GPTi.TCAR1 register, and on the second enabled capture event, the value of the counter register is saved in the GPTi.TCAR2 register. If a capture interrupt is enabled, the interrupt triggers on the second event capture. All other events are ignored (no update on GPTi.TCAR1/GPTi.TCAR2 and no interrupt triggering) until the detection logic is reset or GPTi.TISR[2] TCAR_IT_FLAG bit is cleared by writing 1 in it. This mechanism is useful for period calculation of a clock, if that clock is connected to the EVENT_CAPTURE input pin.

The edge detection logic is reset (a new capture is enabled) when the active capture interrupt is served the GPTi.TISR[2] TCAR_IT_FLAG bit (previously 1) is cleared by writing 1 to it or when the edge detection mode bits (the GPTi.TCLR[9:8] TCM field) are changed from no-capture mode detection to any other mode. The timer functional clock (input to prescaler) is used to sample the input pin (EVENT_CAPTURE). An input negative or positive pulse can be detected when the pulse time is greater than the functional clock period. An interrupt is issued on edge detection if the capture interrupt enable bit is set in the GPTi.TIER[2] TCAR_IT_ENA bit. See the examples in Figure 13-10 and Figure 13-11.

In [Figure 13-10](#), the GPTi.TCLR[9:8] TCM value is 0b01, and GPTi.TCLR[13] CAPT_MODE is 0. Only the rising edge of EVENT_CAPTURE triggers a capture in the GPTi.TCAR1 and GPTi.TCAR2 registers, and only the GPTi.TCAR1 register updates.

Figure 13-10. Capture Wave Example for GPTi.TCLR[13] CAPT_MODE = 0

PU108-010

In [Figure 13-11](#), the GPTi.TCLR[9:8] TCM value is 0b01, and GPTi.TCLR[13] CAPT_MODE is 1. Only the rising edge of EVENT_CAPTURE triggers a capture in the GPTi.TCAR1 register on the first enabled event, and the GPTi.TCAR2 register updates on the second enabled event.

Figure 13-11. Capture Wave Example for GPTi.TCLR[13] CAPT_MODE = 1

PU108-011

13.2.4.4 Compare Mode Functionality

When the compare enable register GPTi.TCLR[6] CE bit is set to 1, the timer value (GPTi.TCRR[31:0] TIMER_COUNTER field) is continuously compared to the value held in the timer match register (GPTi.TMAR). The GPTi.TMAR[31:0] COMPARE_VALUE value can be loaded at any time (timer counting or stopped). When the GPTi.TCRR and the GPTi.TMAR values match, an interrupt is issued, if the GPTi.TIER[0] MAT_IT_ENA bit is set.

The dedicated output pin (timer PWM) can be programmed in the GPTi.TCLR[12] PT bit through the GPTi.TCLR[11:10] TRG field to generate one positive pulse (timer clock duration) or to invert the current value (toggle mode) when an overflow or a match occurs.

13.2.4.5 Prescaler Functionality

A prescaler can be used to divide the timer counter input clock frequency. The prescaler is enabled when the GPTi.TCLR[5] PRE bit is set. The GPTi.TCLR[4:2] PTV field sets the second prescaler ratio. The prescaler counter is reset when the timer counter is stopped or reloaded on-the-fly.

Table 13-9 lists the prescaler/timer reload values versus contexts.

Table 13-9. Prescaler/Timer Reload Values Versus Contexts

| Context | Prescaler | Timer Counter |
|----------------------------------|-----------|-----------------|
| Overflow (when autoreload is on) | Reset | GPTi.TLDR[31:0] |
| TCRR write | Reset | GPTi.TCRR[31:0] |
| TTGR write | Reset | GPTi.TLDR[31:0] |
| Stop | Reset | Frozen |

13.2.4.6 Pulse-Width Modulation

The timer can be configured to provide a programmable PWM output. The timer PWM output pin can be configured to toggle on an event. The GPTi.TCLR[11:10] TRG field determines on which register value the PWM pin toggles. Either overflow alone or both overflow and match can be selected to toggle the timer PWM pin when a compare condition occurs.

CAUTION

In toggle mode when GPTi.TCLR[11:10] TRG = 0x2 (overflow and match), the first event that will toggle the PWM line is an overflow event. If a match event occurs first, it will not toggle the PWM line. Figure 13-13 illustrates those.

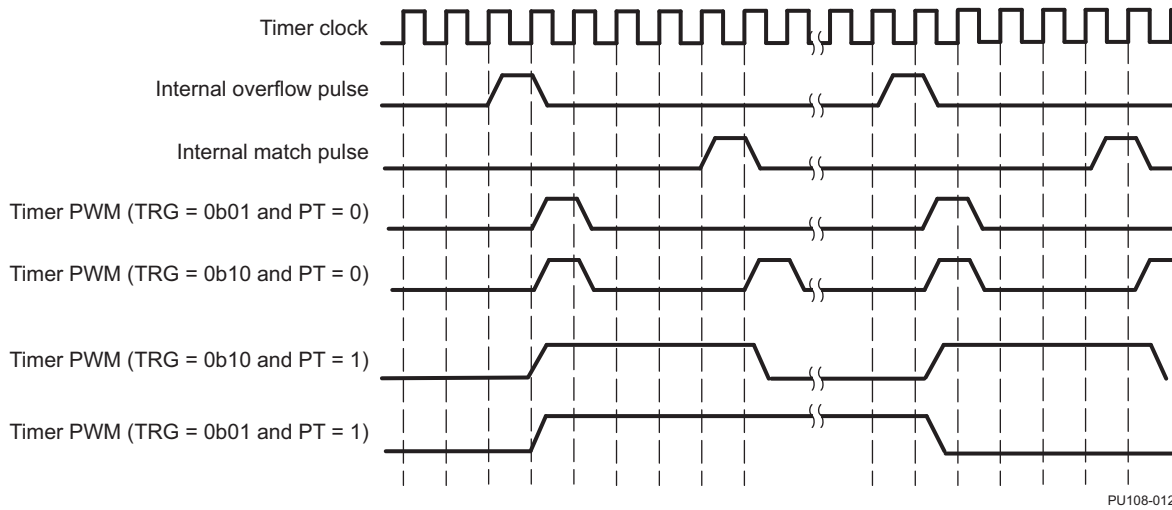

The GPTi.TCLR[7] SCPWM bit can be programmed to set or clear the timer PWM output signal only while the counter is stopped or the trigger is off. This allows setting the output pin to a known state before modulation starts. Modulation synchronously stops when the GPTi.TCLR[11:10] TRG field is cleared and overflow occurs. This allows fixing a deterministic state of the output pin when modulation stops.

In Figure 13-12, the internal overflow pulse is set each time (0xFFFF FFFF - GPTi.TLDR[31:0] LOAD_VALUE + 1) the value is reached, and the internal match pulse is set when the counter reaches the GPTi.TMAR register value. According to the value of the GPTi.TCLR[12] PT and GPTi.TCLR[11:10] TRG bits, the timer provides pulse or PWM event on the output pin (timer PWM).

The GPTi.TLDR and GPTi.TMAR registers must keep values smaller than the overflow value (0xFFFF FFFF) by at least two units. In case the PWM trigger events are both overflow and match, the difference between the values kept in the GPTi.TMAR register and the value in the GPTi.TLDR register must be at least two units. When match event is used, the compare mode GPTi.TCLR[6] CE bit must be set.

In Figure 13-12, the GPTi.TCLR[7] SCPWM bit is set to 0. In Figure 13-13, the GPTi.TCLR[7] SCPWM bit is set to 1. To obtain the desired wave form, start the counter at 0xFFFF FFFE value (to ensure an overflow first) or adjust the line polarity (GPTi.TCLR[7] SCPWM bit).

Figure 13-12. Timing Diagram of PWM With GPTi.TCLR[7] SCPWM Bit = 0

PU108-012

Figure 13-13. Timing Diagram of PWM With GPTi.TCLR[7] SCPWM Bit = 1

PU108-013

13.2.4.7 Timer Counting Rate

The timer rate is defined by the following values:

- Value of the prescaler fields (GPTi.TCLR[5] PRE bit and GPTi.TCLR[4:2] PTV field)
- Value loaded into the timer load register (GPTi.TLDR)

Table 13-10 lists prescaler clock ratio values.

Table 13-10. Prescaler Clock Ratio Values

| GPTi.TCLR[5] PRE | GPTi.TCLR[4:2] PTV | Divisor (PS) |
|------------------|--------------------|--------------|
| 0 | X | 1 |
| 1 | 0 | 2 |
| 1 | 1 | 4 |
| 1 | 2 | 8 |
| 1 | 3 | 16 |
| 1 | 4 | 32 |

Table 13-10. Prescaler Clock Ratio Values (continued)

| GPTi.TCLR[5] PRE | GPTi.TCLR[4:2] PTV | Divisor (PS) |
|------------------|--------------------|--------------|
| 1 | 5 | 64 |
| 1 | 6 | 128 |
| 1 | 7 | 256 |

Thus, the timer overflow-rate is expressed as:

$$\text{OVF_Rate} = (0xFFFF\ FFFF - \text{GPTn.TLDR} + 1) * (\text{timer-functional clock period}) * \text{PS}$$

With (timer-functional clock period) = 1 / (timer-functional clock frequency) and PS = $2^{(\text{PTV} + 1)}$ if prescaler is enabled, or PS = 1 if prescaler is disabled.

CAUTION

Internal resynchronization causes any write to the GPTn.TCLR[1] ST bit to have some latency before the register is updated:

2.5 * functional clock cycles write_GPTn.TCLR_latency 3.5 * functional clock cycles

Remember to take this latency into account whenever the timer must be started or stopped by a software change to the GPTn.TCLR[1] ST bit.

CAUTION

- In the non-PWM mode, GTPi.TLDR must be maintained at less than or equal to 0xFFFF FFFE.
- In the PWM mode, GTPi.TLDR must be maintained at less than or equal to 0xFFFF FFFD.

For example, with a timer clock input of 32 kHz and a GPTn.TCLR[5] PRE field equal to 0, the timer output period is as listed in [Table 13-11](#).

Table 13-11. Value and Corresponding Interrupt Period

| GPTi.TLDR[31:0] LOAD_VALUE | Interrupt Period |
|----------------------------|------------------|
| 0x0000 0000 | 39 h |
| 0xFFFF 0000 | 2.1 s |
| 0xFFFF FFF0 | 524 μ s |
| 0xFFFF FFFE | 65.5 μ s |

13.2.5 Timer Under Emulation

During emulation mode, the timer continues to run according to the value of the GPTi.TIOCP_CFG[5] EMUFREE bit.

If the GPTi.TIOCP_CFG[5] EMUFREE bit is set to 1, timer execution is not stopped in emulation mode and the interrupt is still generated when overflow or match is reached.

If the GPTi.TIOCP_CFG[5] EMUFREE bit is set to 0, the prescaler and timer are frozen and both resume on exit from emulation mode. The asynchronous external input pin (gpti_pwm_evt, with i=[9:12]) is internally synchronized on two timer-clock rising edges.

13.2.6 Accessing GP Timer Registers

All accesses are nonposted until software reconfiguration.

All registers are 32 bits wide, accessible through the L4 interface with 16-bit or 32-bit access (read/write).

Any 16-bit write access must be least-significant bit (LSB) first, and the second write access must be most-significant bit (MSB). Write operations to the GP timer registers (GPTi.TIDR, GPTi.TIOCP_CFG, GPTi.TISR, GPTi.TIER, GPTi.TWER, and GPTi.TSICR) can skip the MSB access if it is not necessary to update the 16 MSBs of the register.

Write operations to any functional register (GPTi.TCLR, GPTi.TCRR, GPTi.TLDR, GPTi.TTGR, and GPTi.TMAR, and GPTi.TPIR, GPTi.TNIR, GPTi.TCVR, GPTi.TOCR, and GPTi.TOWR for GPTIMER1, GPTIMER2, and GPTIMER10) must be complete (the MSB must be written even if the MSB data is not used).

13.2.6.1 Writing to Timer Registers

The host uses the L4 interface to write the following registers synchronously with the timer interface clock:

- GPTi.TLDR
- GPTi.TCRR
- GPTi.TIER
- GPTi.TISR
- GPTi.TCLR
- GPTi.TIOCP_CFG
- GPTi.TWER
- GPTi.TTGR
- GPTi.TSICR
- GPTi.TMAR

GPTIMER1, GPTIMER2, and GPTIMER10 also have the following registers:

- GPTi.TPIR
- GPTi.TNIR
- GPTi.TCVR
- GPTi.TOCR
- GPTi.TOWR

In 16-bit access mode, the 16 LSBs must be written before writing to the 16 MSBs.

13.2.6.1.1 Write Posting Synchronization Mode

This mode is used if the GPTi.TSICR[2] POSTED bit is set to 1.

This mode uses a posted write scheme to update any internal register (GPTi.TCLR, GPTi.TCRR, GPTi.TLDR, GPTi.TTGR, GPTi.TMAR, and GPTi.TPIR, GPTi.TNIR, GPTi.TCVR, GPTi.TOCR, and GPTi.TOWR for GPTIMER1, GPTIMER2, and GPTIMER10). Therefore, the write transaction is immediately acknowledged on the L4 interface, although the effective write operation occurs later, because of a resynchronization in the timer clock domain. The advantage is that neither the interconnect nor the device that requested the write transaction is stalled.

For each register, a status bit is provided in the timer write-posted status register GPTi.TWPS. In this mode, it is mandatory that the software checks this status bit prior to any write access. In case a write is attempted to a register with a previous access pending, the previous access is discarded without notice.

The timer module updates the timer counter register value synchronously with the L4 clock. Consequently, any read access to the timer counter register GPTi.TCRR does not add any resynchronization latency; the current value is always available.

If a write access is pending for a register, reading from this register does not yield a correct result. Software synchronization must be used to avoid incorrect results.

The drawback of this automatic update mechanism is that it assumes a given relationship between the timer interface frequency and the timer clock frequency.

Functional frequency range: $\text{freq}(\text{timer clock}) < \text{freq}(\text{L4 interface clock})/4$

13.2.6.1.2 Write Nonposting Synchronization Mode

This mode is used if the GPTi.TSICR[2] POSTED bit is set to 0.

This mode uses a nonposted write scheme to update any internal register. Therefore, the write transaction is not acknowledged on the L4 interface until the effective write operation occurs after the resynchronization in the timer functional clock domain. The drawback is that both the interconnect and the device that requested the write transaction are stalled during this period.

The same full resynchronization scheme is used for a read transaction, and the same stall period applies. A register read following a write to the same register is always coherent.

This mode is functional regardless of the ratio between the L4 interface frequency and the timer clock frequency.

13.2.6.2 Reading From Timer Counter Registers

In 16-bit access mode, reading the 16 LSBs from the timer counter registers (GPTi.TCRR, GPTi.TCAR1, and GPTi.TCAR2) captures the current timer counter value. This must be followed by reading the 16MSBs.

IVA2.2 subsystem 16-bit accesses can be interleaved with MPU subsystem 32-bit accesses.

NOTE: LSB/MSB accesses cannot be interleaved (that is, the sequence LSB register 1, LSB register 2, MSB register 1, MSB register 2 is not supported).

13.3 General-Purpose Timers Register Manual

13.3.1 GP Timer Register Map

13.3.1.1 Instance Summary

Table 13-12 lists the base address and block size for the GP timer module instances. All timers are memory mapped to the L4 peripheral bus memory space.

Table 13-12. GP Timer Instance Summary

| Module Name | Base Address | Size |
|-------------|--------------|----------|
| GPTIMER1 | 0x4831 8000 | 4K bytes |
| GPTIMER2 | 0x4903 2000 | 4K bytes |
| GPTIMER3 | 0x4903 4000 | 4K bytes |
| GPTIMER4 | 0x4903 6000 | 4K bytes |
| GPTIMER5 | 0x4903 8000 | 4K bytes |
| GPTIMER6 | 0x4903 A000 | 4K bytes |
| GPTIMER7 | 0x4903 C000 | 4K bytes |
| GPTIMER8 | 0x4903 E000 | 4K bytes |
| GPTIMER9 | 0x4904 0000 | 4K bytes |
| GPTIMER10 | 0x4808 6000 | 4K bytes |
| GPTIMER11 | 0x4808 8000 | 4K bytes |

13.3.2 GP Timer Register Mapping Summary

CAUTION

The GP timer registers are limited to 32-bit and 16-bit data accesses; 8-bit access is not allowed and can corrupt the register content.

Table 13-13 through Table 13-15 provide the register summary and associated offset addresses for the 11 GP timer internal registers. (Example: The physical address for the **TCLR** register of GPTIMER8 is 0x4903 E024.)

Table 13-13. GPTIMER1 to GPTIMER4 Register Summary

| 5 | EMUFREE | Emulation mode 0x0: Timer counter frozen in emulation 0x1: Timer counter free-running in emulation | RW | 0 |
| 4:3 | IDLEMODE | Power management, req/ack control 0x0: Force-idle. An idle request is acknowledged unconditionally. 0x1: No-idle. An idle request is never acknowledged. 0x2: Smart-idle. Acknowledgement to an idle request is given based on the internal activity of the module. 0x3: Reserved. Do not use. | RW | 0x0 |
| 2 | ENAWAKEUP | Wake-up feature global control 0x0: No wake-up line assertion in idle mode 0x1: Wake-up line assertion enabled in smart-idle mode | RW | 0 |
| 1 | SOFTRESET | Software reset. This bit is automatically reset by the hardware. During reads, it always returns 0. 0x0: Normal mode 0x1: The module is reset. | RW | 0 |
| 0 | AUTOIDLE | Internal L4 interface clock gating strategy 0x0: L4 interface clock is free-running. 0x1: Automatic L4 interface clock gating strategy is applied, based on the L4 interface activity. | | 0 |

13.4 Watchdog Timers

13.4.1 WDTs Overview

The device includes two instances of the 32-bit WDT: WDT2 and WDT3. Figure 13-14 shows how each timer is connected in the device.

NOTE: WDTi (where i is the watchdog timer instance: i = 2 or 3) stands for the following:

- WDT2: Watchdog timer 2, also called MPU watchdog timer
- WDT3: Watchdog timer 3, also called IVA2 watchdog timer

Each WDT is an upward counter capable of generating both a pulse on the reset pin and an interrupt to the device system modules following an overflow condition. The MPU WDT serves resets to the PRCM module (its interrupt outputs are unused), and the IVA2 WDT serves watchdog interrupts to the MPU (its reset outputs are unused).

The WDTs can be accessed, loaded, and cleared by registers through the L4 interface. The MPU and IVA2 WDTs have the 32-kHz clock for their timer clock input.

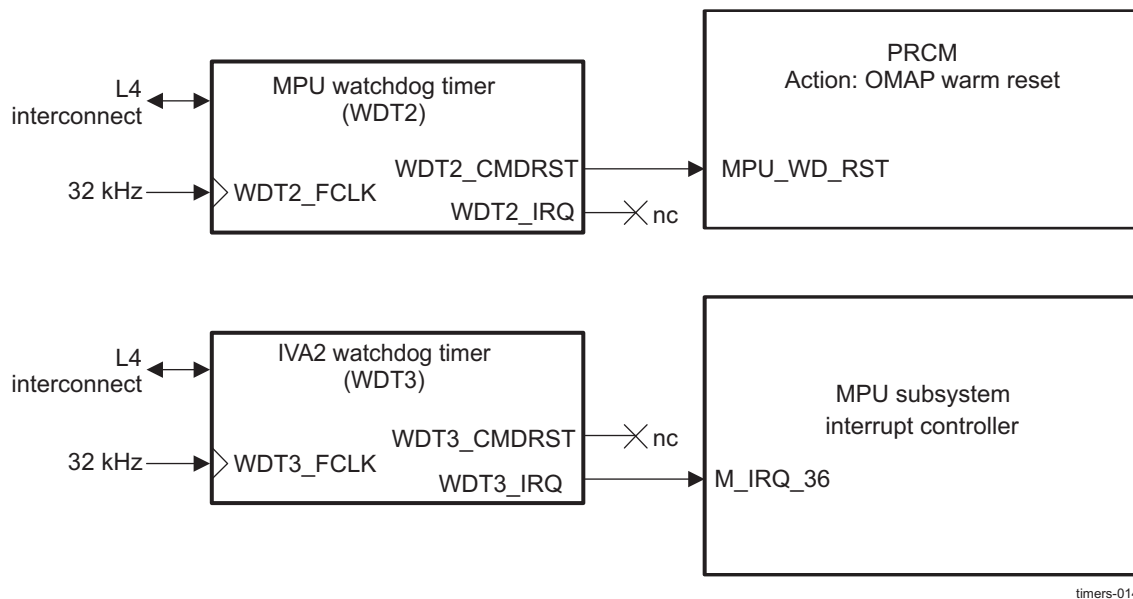

The MPU WDT directly generates a warm reset condition on overflow. The IVA2 WDT generates an MPU interrupt condition on overflow, which can be used by the application software via the PRCM to indirectly trigger a reset condition (that is, to the IVA2 subsystem).

The MPU WDT connects to a single target agent port on the L4 interconnect.

Table 13-56. WD Timers Default State for GP and EMU devices

| Timer | Device | | | |
|---------------|---------|-------------|---------|-------------|
| | EMU | | GP | |
| MPU WDTIMER2 | Enabled | Running | Enabled | Running |
| IVA2 WDTIMER3 | Enabled | NOT Running | Enabled | NOT Running |

Figure 13-14. WDTs Block Diagram

13.4.1.1 WDT Features

The following are the main features of the WDT controllers:

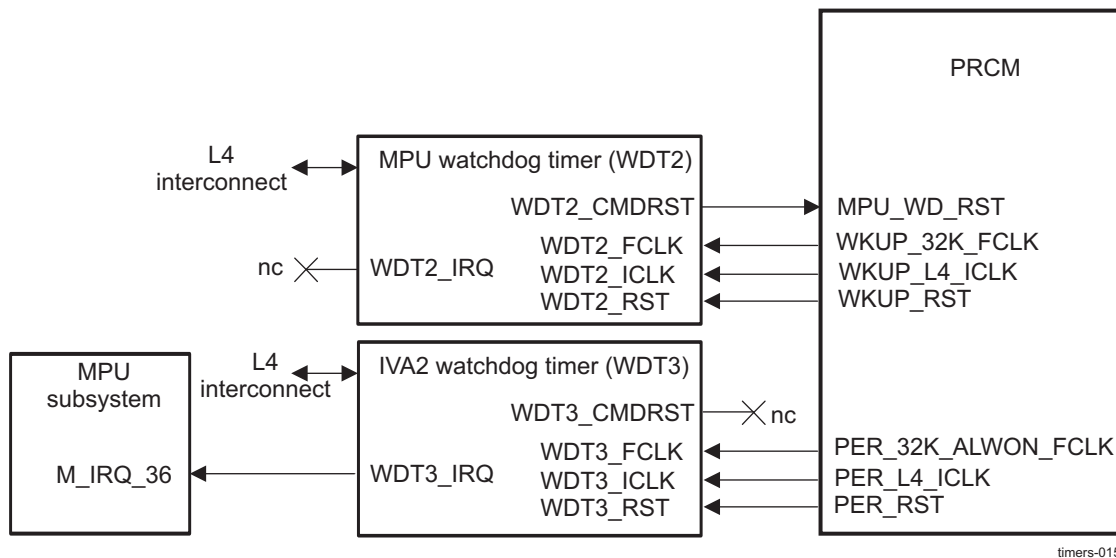

- L4 slave interface support:
 - 32-bit data bus width

- 32-/16-bit access supported
- 8-bit access not supported
- 11-bit address bus width
- Burst mode not supported
- Write nonposted transaction mode only
- Free-running 32-bit upward counter
- Programmable divider clock source (2^n with $n=[0:7]$)
- On-the-fly read/write register (while counting)
- Subset programming model of the GP timer
- WDTs are reset either on power-on or after a warm reset.
- Reset or interrupt actions when a timer overflow condition occurs
- WDT generates either a reset or an interrupt in its hardware integration (WDT2, or WDT3).

13.4.2 WDT Integration

Figure 13-15 shows the integration of the WDT in the device.

Figure 13-15. WDT Integration

13.4.2.1 Clocking, Reset, and Power-Management Scheme

13.4.2.1.1 Clock Management

There are two clock domains in the WDTs:

- Functional clock domain: WDT_i_FCLK is the WDT functional clock. It is used to clock the WDT internal logic.
- Interface clock domain: WDT_i_ICLK is the WDT interface clock. It is used to synchronize the WDT L4 port to the L4 interconnect. All accesses from the interconnect are synchronous to WDT_i_ICLK .

Table 13-57 lists the the source clocks for each WDT in the device. For more information on clock control and domains, see , *Power, Reset, and Clock Management*.

Table 13-57. Clock, Power, and Reset Domains for WDTs

| Timer | Interface Clock | Functional Clock | Power Domain |
|----------|-----------------|--------------------|--------------|
| MPU WDT | WKUP_L4_ICLK | WKUP_32K_FCLK | WKUP |
| IVA2 WDT | PER_L4_ICLK | PER_32K_ALWON_FCLK | PER |

From a global system power-management perspective, when one or both of the WDT clocks is no longer required, the WDTs can be deactivated at the PRCM level in the corresponding registers. [Table 13-58](#) lists the WDT PRCM clock control bits.

Table 13-58. WDT PRCM Clock Control Bits

| Name | Associated PRCM Clock Output | Enable Bit | Autoidle Bit |
|-----------|------------------------------|---------------------------------------|---|
| WDT2_FCLK | WKUP_32K_FCLK | PRCM.CM_FCLKEN_WKUP[5] EN_WDT2 bit | N/A |
| WDT3_FCLK | PER_32K_ALWON_FCLK | PRCM.CM_FCLKEN_PER[12] EN_WDT3 bit | N/A |
| WDT2_ICLK | WKUP_L4_ICLK | PRCM.CM_ICLKEN_WKUP[5] EN_WDT2 bit | PRCM.CM_AUTOIDLE_WKUP[5] AUTO_WDT2 bit |
| WDT3_ICLK | PER_L4_ICLK | PRCM.CM_ICLKEN_PER[12] EN_WDT3 bit | PRCM.CM_AUTOIDLE_PER[12] AUTO_WDT3 bit |

NOTE:

- The PRCM function clock outputs are gated at the PRCM level, assuming the modules that share it have been disabled in the corresponding register. Disabling the WDTs is a necessary but not sufficient action. The clock is effectively out when all PRCM conditions are fulfilled. For the other actions to be taken, see , *Power, Reset, and Clock Management*.
- The PRCM interface clock outputs are gated at the PRCM level, assuming the modules that share it have been disabled in the corresponding register. Disabling the WDTs is a necessary but not sufficient condition. The clock is effectively out when all PRCM conditions are fulfilled. For the other actions to be taken, see , *Power, Reset, and Clock Management*.
- The PRCM AUTOIDLE bits are used to link/unlink the WDTs from the clock domain transitions related to the GPTi_ICLK clocks.
- For further details about source clocks gating and domain transitions, see , *Power, Reset, and Clock Management*.

At the PRCM level, when the conditions to shut off the PRCM functional or interface output clocks are met (see , *Power, Reset, and Clock Management*, for details), the PRCM automatically launches a hardware handshake protocol to ensure the WDT is ready to have its clocks switched off. Namely, the PRCM module asserts an IDLE request to the WDT.

Although this handshake is a hardware function and out of software control, the way the WDT acknowledges the PRCM IDLE request is configurable through the WDTi.WD_SYSCONFIG[4:3] IDLEMODE bit. [Table 13-59](#) lists the IDLEMODE settings and the related acknowledgement modes.

Table 13-59. IDLEMODE Settings

| IDLEMODE Value | Selected Mode | Description |
|----------------|---------------|---|
| 00 | Force-idle | The WDT acknowledges unconditionally the IDLE request from the PRCM module, regardless of its internal operations. This mode must be used carefully, because it does not prevent loss of data when the clock is switched off. |
| 01 | No-idle | The WDT never acknowledges an IDLE request from the PRCM module. This mode is safe from a module point of view, because it ensures the clocks remain active; it is not efficient from a power-saving perspective, however, because it does not allow the PRCM output clock to be shut off and thus the power domain to be set to a lower power state. |
| 10 | Smart-idle | The WDT acknowledges the IDLE request, basing its decision on its internal activity. The acknowledge signal is asserted only when all pending transactions and IRQs requests are treated. This is the best approach for efficient system power management. |
| 11 | Reserved | |

When configured in smart-idle mode, the WDT also offers an additional granularity on WDTi_FCLK and WDTi_ICLK gating. The WDTi.WD_SYSCONFIG[9:8] CLOCKACTIVITY bit field is used to determine which clock will be shut down (WDTi_FCLK, WDTi_ICLK, neither of them, or both of them).

The CLOCKACTIVITY setting is used internally to the WDT to determine the part of the module on which the conditions to acknowledge the PRCM IDLE request will be tested. For example, if WDTi_FCLK is not to be shut down on a PRCM IDLE request, the WDT considers only WDTi_ICLK and the associated pending activities before acknowledging the request.

Some WDT features are associated with WDTi_ICLK, and others are associated with WDTi_FCLK. Using the CLOCKACTIVITY setting along with the smart-idle mode ensures that the features associated with the clock that will remain active are always enabled, even if the WDT acknowledges an IDLE request.

Table 13-60 lists the CLOCKACTIVITY settings.

Table 13-60. CLOCKACTIVITY Settings

| CLOCKACTIVITY Value | WDTi_ICLK Effects | WDTi_FCLK Effects | Description |
|---------------------|-------------------|-------------------|---|
| 00 | OFF | OFF | Both WDTi_ICLK and WDTi_FCLK are considered for generating the acknowledge. This setting also means both WDTi_FCLK and WDTi_ICLK are likely to be shut down on a PRCM IDLE request. |
| 01 | OFF | ON | WDTi_FCLK is not shut down on a PRCM IDLE request; only WDTi_ICLK is concerned. |
| 10 | ON | OFF | WDTi_ICLK is not shut down on a PRCM IDLE request; only WDTi_FCLK is concerned. |
| 11 | ON | ON | None of the clocks are shut down. Therefore, the WDT can potentially acknowledge the IDLE request without checking the internal functionalities linked to its clocks. |

CAUTION

The PRCM module does *not* have any hardware means to read the CLOCKACTIVITY settings. The software must ensure consistent programming between the WDT CLOCKACTIVITY and the PRCM functional clock and interface clock control bits. If the WDT is disabled in both the CM_FCLKEN and CM_ICLKEN PRCM registers while CLOCKACTIVITY is set to 11, nothing prevents the PRCM module from asserting its IDLE request, which is acknowledged regardless of the features associated with the WDT clocks. This can lead to unpredictable behavior.

13.4.2.1.2 Reset and Power Management

The MPU WDT (WDT2) belong to the WKUP power domain. As part of that domain, this WDT is sensitive to a WKUP_RST signal issued by the PRCM module. For further details about the WKUP power domain implementation and WKUP_RST signal, see , *Power, Reset, and Clock Management*.

The IVA WDT (WDT3) belongs to the PER power domain. As part of that domain, WDT3 is sensitive to the PER_RST signal issued by the PRCM module. For further details about the PER power domain implementation and PER_RST signal, see , *Power, Reset, and Clock Management*.

NOTE: WDT2 is reset on power-on or after a warm reset, and then it starts counting.

WDT3 is reset either on power-on or after a warm reset, and then it doesn't start counting.

13.4.2.2 Interrupts

Table 13-61 shows interrupt mapping from the three WDTs to the MPU.

Table 13-61. WDT Interrupt Names and Processor IRQ Mapping

| Timer | Interrupt Name | Mapping | Comments |
|----------|----------------|---------------|-------------------|
| MPU WDT | WDT2_IRQ | Not connected | |
| IVA2 WDT | WDT3_IRQ | M_IRQ_36 | IVA2 WDT overflow |

13.4.3 WDTs Functional Description

13.4.3.1 General WDT Operation

The WDTs are based on an upward 32-bit counter coupled with a prescaler. The counter overflow is signaled through two independent signals: a simple reset signal and an interrupt signal, both active low. The use of these signals depends on whether they are connected or not. For this information, see [Figure 13-14](#). The interrupt generation mechanism is controlled through the WDTi.WIER and WDTi.WISR registers.

The prescaler ratio can be set between 1 and 128 by accessing the WDTi.WCLR[4:2] PTV and WDTi.WCLR[5] PRE fields of the watchdog control register (WDTi.WCLR).

The current timer value can be accessed on-the-fly by reading the WDT counter register (WDTi.WCRR), modified by accessing the WDT load register (WDTi.WLDR) (no on-the-fly update), or reloaded by following a specific reload sequence on the WDT trigger register (WDTi.WTGR). A start/stop sequence applied to the WDT start/stop register (WDTi.WSPR) can start and stop the WDT.

Figure 13-16. 32-Bit WDT Functional Block Diagram

timers-016

13.4.3.2 Reset Context

After reset, the WDTs are enabled. [Table 13-62](#) lists the default reset values of the three WDT load registers (WDTi.WLDR) and prescaler ratios (WDTi.WCLR[4:2] PTV field). To get these values, software must read the corresponding WDTi.WCLR[4:2] PTV fields and the 32-bit register to retrieve the static configuration of the module.

Table 13-62. Count and Prescaler Default Reset Values

| Timer | WLDR Reset Value | PTV Reset Value |
|-----------------|------------------|-----------------|
| OMAP WDT (WDT2) | 0xFFFB 0000 | 0 |
| IVA2 WDT (WDT3) | 0xFFFB 0000 | 0 |

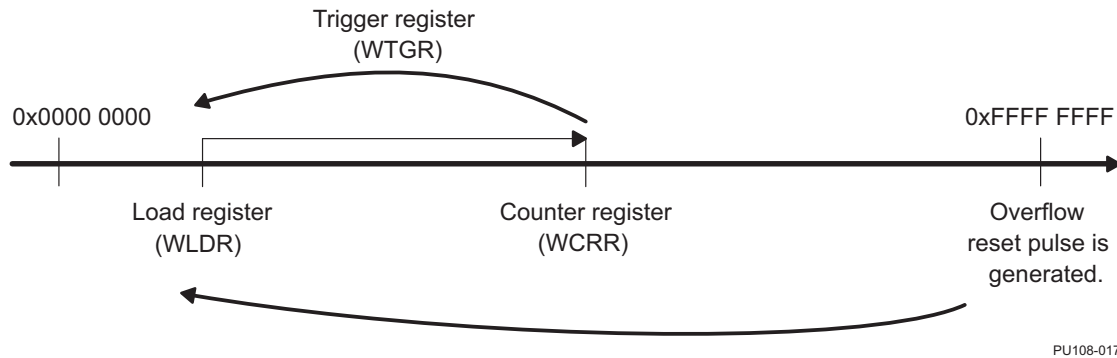

13.4.3.3 Overflow/Reset Generation

When the WDT counter register (WDTi.WCRR) overflows, an active-low reset pulse is generated to the PRCM module. This pulse is one prescaled timer clock cycle wide and occurs at the same time as the timer counter overflow.

After reset generation, the counter is automatically reloaded with the value stored in the watchdog load register (WDTi.WLDR) and the prescaler is reset (the prescaler ratio remains unchanged). Then, after the reset pulse output has been generated, the timer counter begins incrementing again.

Figure 13-17 shows a general functional view of the WDT.

Figure 13-17. WDT General Functional View

13.4.3.4 Prescaler Value/Timer Reset Frequency

Each WDT is composed of a prescaler stage and a timer counter.

The timer rate is defined by the following values:

- Value of the prescaler fields (the WDTi.WCLR[5] PRE bit and the WDTi.WCLR[4:2] PTV field)
- Value loaded into the timer load register (WDTi.WLDR)

The prescaler stage is clocked with the timer clock and acts as a clock divider for the timer counter stage. The ratio is managed by accessing the ratio definition field (the WDTi.WCLR[4:2] PTV field) and is enabled with the WDTi.WCLR[5] PRE bit.

Table 13-63 lists the prescaler clock ratio values.

Table 13-63. Prescaler Clock Ratios

| PRE Bit (in WDTi.WCLR Register) | PTV Bits (in WDTi.WCLR Register) | Clock Divider (PS) |
|---------------------------------|----------------------------------|--------------------|
| 0 | X | 1 |
| 1 | 0 | 1 |
| 1 | 1 | 2 |
| 1 | 2 | 4 |
| 1 | 3 | 8 |
| 1 | 4 | 16 |
| 1 | 5 | 32 |
| 1 | 6 | 64 |
| 1 | 7 | 128 |

The watchdog timer overflow rate is expressed by: $OVF_Rate = (0xFFFF\ FFFF - WDTn.WLDR + 1) * (wd\text{-}functional\ clock\ period) * PS$

With $wd\text{-}functional\ clock\ period = 1 / (wd\text{-}functional\ clock\ frequency)$ and $PS = 2^{(PTV)}$.

CAUTION

Internal resynchronization causes any software write to `GPTn.WSPR` to have some latency before `WSPR` is updated with the programmed value:

$1.5 * functional\ clock\ cycles \leq write_WSPR_latency \leq 2.5 * functional\ clock\ cycles$

Remember to take this latency into account whenever the watchdog must be started or stopped.

For example, for a timer clock input of 32 kHz with a prescaler ratio value of 0x1 (clock divided by 2) and `WDTi.WCLR[5] PRE` bit = 1 (clock divider enabled), the reset period is as listed in [Table 13-64](#).

Table 13-64. Reset Period Examples

| WDTi.WLDR Value | Reset Period |
|-----------------|--------------|
| 0x0000 0000 | 74 h 56 min |
| 0xFFFF 0000 | 4 s |
| 0xFFFF FFF0 | 1 ms |
| 0xFFFF FFFF | 62.5 us |

CAUTION

- Ensure that the reloaded value allows the correct operation of the application. When a WDT is enabled, the software must periodically trigger a reload before the counter overflows. Hence, the `WDTi.WLDR[31:0]` value must be chosen according to the ongoing activity preceding the watchdog reload.
- Due to design reasons, `WDTi.WLDR[31:0] = 0xFFFF FFFF` is a special case, although such a `WDTi.WLDR` value is meaningless. When `WDTi.WLDR` is programmed with the overflow value, a triggering event generates a reset/interrupt one functional clock cycle later, even if the WDT is stopped.

[Table 13-65](#) lists the default reset periods for the WDTs.

Table 13-65. Default WDT Time Periods

| WDTs | Clock Source | Default Reset Period |
|----------------|--------------|----------------------|
| OMAP/IVA2 WDTs | 32 kHz | 10 s |

13.4.3.5 Triggering a Timer Reload

To reload the timer counter and reset the prescaler before reaching overflow, a reload command is executed by accessing the WDT trigger register (`WDTi.WTGR`) using a specific reload sequence.

The specific reload sequence is performed whenever the written value on the WDT trigger register (`WDTi.WTGR`) differs from its previous value. In this case, reload is executed in the same way as an overflow autoreload, but without a reset pulse generation.

The timer counter is loaded with the WDT load register value (the `WDTi.WLDR[31:0] TIMER_LOAD` field), and the prescaler is reset.

13.4.3.6 Start/Stop Sequence for WDTs (Using WDTi.WSPR Register)

To start/stop a WDT, access must be made through the start/stop register (WDTi.WSPR) using a specific sequence.

To disable the timer, follow this sequence:

1. Write 0xFFFF AAAA in WDTi.WSPR.
2. Write 0xFFFF 5555 in WDTi.WSPR.

To enable the timer, follow this sequence:

1. Write 0xFFFF BBBB in WDTi.WSPR.
2. Write 0xFFFF 4444 in WDTi.WSPR.

All other write sequences on WDTi.WSPR have no effect on the start/stop feature of the module.

13.4.3.7 Modifying Timer Count/Load Values and Prescaler Setting

To modify the timer counter value (WDTi.WCRR), prescaler ratio (the WDTi.WCLR[4:2] PTV field), or load value (the WDTi.WLDR[31:0] TIMER_LOAD field), the WDT must be disabled by using the start/stop sequence (the WDTi.WSPR register).

After a write access, the load register value and prescaler ratio registers are updated immediately, but new values are considered only after the next consecutive counter overflow or after a new trigger command (WDTi.WTGR).

13.4.3.8 Watchdog Counter Register Access Restriction (WDTi.WCRR Register)

Because the WDTi.WCRR register is directly related to the timer counter value and is updated on the timer clock (WDTi_FCLK), a 32-bit shadow register is implemented to read a coherent value of the WDTi.WCRR register. The shadow register is updated by a 16-bit LSB read command.

NOTE: Although the L4 clock (WDTi_ICLK) is completely asynchronous with the timer clock (WDTi_FCLK), some synchronization is done to ensure that the WDTi.WCRR value is not read while it is being incremented.

When 32-bit read access is performed, the shadow register is not updated. Read access is made directly from the accessed register.

To ensure that a coherent value is read inside WDTi.WCRR, the first read access is to the lower 16 bits (offset = 0x08), followed by read access to the upper 16 bits (offset = 0x0A).

13.4.3.9 WDT Interrupt Generation

The WDT issues an overflow interrupt if this interrupt is enabled in the WDT interrupt enable register (WDTi.WIER[0] OVF_IT_ENA = 1). When the overflow occurs, the interrupt status bit (the WDTi.WISR[0] OVF_IT_FLAG bit) is set to 1. The output interrupt line (WDTi_IRQ) is asserted (active low) when both status (OVF_IT_FLAG) and enable (OVF_IT_ENA) flags are set to 1; the order is not relevant. Writing 1 in the enable bit (the status is already set at 1) also triggers the interrupt in the normal order (enable first, status after). The pending interrupt event is cleared when the set status bit is overwritten by a value of 1 by a write command in the WDTi.WISR register. Reading the WDTi.WISR register and writing the value back allows a fast acknowledge interrupt process.

NOTE: Writing 0 in the WDTi.WISR[0] OVF_IT_FLAG bit has no effect on it.

Because the interrupt event is generated on the functional clock domain (WDTi_FCLK), during the interrupt status register (WDTi.WISR) update, the two clock domains are resynchronized.

13.4.3.10 WDT Under Emulation

During emulation mode, the WDT can/cannot continue running, according on the value of the WDTi.WD_SYSCONFIG[5] EMUFREE bit of the system configuration register (WDTi.WD_SYSCONFIG).

- When EMUFREE is 1, WDT execution is not stopped and a reset pulse is still generated when overflow is reached.
- When EMUFREE is 0, the counters (prescaler/timer) are frozen and incrementation restarts after exiting from emulation mode.

13.5 Watchdog Timer Register Manual

All registers are 32 bits wide and are accessible through the L4 interface with 16-bit or 32-bit access (read/write).

13.5.1 Instance Summary

Table 13-66 lists the base address and address space for the WDT module instances. All timers are memory mapped to the L4 peripheral bus memory space.

Table 13-66. WDT Instance Summary

| Module Name | Base Address | Size |
|-------------|--------------|----------|
| WDTIMER2 | 0x4831 4000 | 4K bytes |
| WDTIMER3 | 0x4903 0000 | 4K bytes |

13.5.2 WDT Register Mapping Summary

CAUTION

The WDT registers are limited to 32-bit and 16-bit data accesses; 8-bit access is not allowed and can corrupt register content.

Table 13-67 lists the WDT2 registers and Table 13-68 lists the WDT3 registers.

Table 13-67. WDTIMER2 Register Summary

13.6 32-kHz Synchronized Timer

13.6.1 32-kHz Sync Timer Functional Description

The 32-kHz sync timer is a 32-bit counter, clocked by the falling edge of the 32-kHz system clock. It is reset while the external asynchronous power-up reset (`sys_nrespwron`) primary I/O is active (main device reset). When `sys_nrespwron` is released (on the rising edge of `sys_nrespwron`), after three 32-kHz clock periods, the counter starts counting up from the reset value of the counter register on the falling edge of the 32-kHz system clock. After reaching its highest value, the counter wraps back to 0 and starts counting again. [Figure 13-18](#) shows the block diagram of the 32-kHz sync timer.

NOTE: `sys_nrespwron` is an active low I/O.

Figure 13-18. 32-kHz Sync Timer Block Diagram

13.6.1.1 Reading the 32-kHz Sync Timer

The sync counter register is 32 bits wide and for correct count capture must be accessed as 16-bit LSB access first and two 16-bit MSB access last. Internal synchronization logic allows reading of the counter value while the counter is running. The time latency to read the counter is one L4 interconnect clock period.

13.6.1.2 32-kHz Sync Timer Features

The following are the main features of the 32-kHz sync timer controller:

- L4 slave interface support:
 - 32-bit data bus width
 - 32-/16-bit access supported
 - 8-bit access not supported
 - 16-bit address bus width
 - Burst mode not supported
 - Write nonposted transaction mode supported
- Only read operations are supported on the module registers; no write operation is supported (no error/no action on write).
- Free-running 32-bit upward counter
- Start and keep counting after power-on reset
- Automatic roll over to 0, highest value reached (0xFFFF FFFF)
- On-the-fly read (while counting)

13.6.2 32-kHz Sync Timer Environment

The sync timer is accessible only through the L4 interface.

13.6.3 32-kHz Sync Timer Integration

13.6.3.1 Clocking, Reset, and Power-Management Scheme

[Table 13-91](#) lists the power and reset domain and the source clock for the 32-kHz sync timer in the device. For more information on power, reset, and clock control and domains, see [Power, Reset, and Clock Management](#).

Table 13-91. Clock, Power, and Reset Domains for 32-kHz Sync Timer

| Timer | Source Clock | Interface Clock | Clock and Power Domain | Reset Domain |
|-------------------|--------------|-----------------|------------------------|--------------------------|
| 32-kHz sync timer | sys_32k | 32KSYNC_ICLK | WKUP | SYNCT_RST ⁽¹⁾ |

13.6.3.2 Interrupts

The 32-kHz sync timer has no interrupt outputs.

13.6.3.3 Sync Timer 32k and MSuspend Signal

By default, the Sync Timer 32k is not stopped when the MPU or DSP is in *halt*. To activate its sensitivity to the MSuspend signal, the CONTROL.CONTROL_MSUSPEND_2[29:27] SyncTMMsctrl bit has been added to the system control module.

13.7 32-kHz Sync Timer Register Manual

13.7.1 32-kHz Sync Timer Instance Summary

Table 13-92 lists the base address and block size for the 32-kHz sync timer. It is memory mapped to the L4 peripheral bus memory space.

Table 13-92. 32-kHz Sync Timer Instance Summary

| Module Name | Base Address | Size |
|-------------------|--------------|----------|
| 32-kHz Sync Timer | 0x4832 0000 | 4K bytes |

13.7.2 32-kHz Sync Timer Register Mapping Summary

CAUTION

The 32-kHz sync timer registers are limited to 32-bit and 16-bit data accesses; 8-bit access is not allowed and can corrupt the register content.

Table 13-93 lists the 32-kHz sync timer registers. Table 13-94 through Table 13-98 describe the register bits.

Table 13-93. 32-kHz Sync Timer Register Summary

UART/IrDA/CIR Module

This chapter describes the function, operation, and configuration of the universal asynchronous receiver/transmitter (UART)/infrared data association (IrDA)/consumer infrared (CIR) module.

NOTE: Some features may not be available or supported in your particular device. For more information, see Chapter 1, the *Device Family* section, and your device-specific data manual.

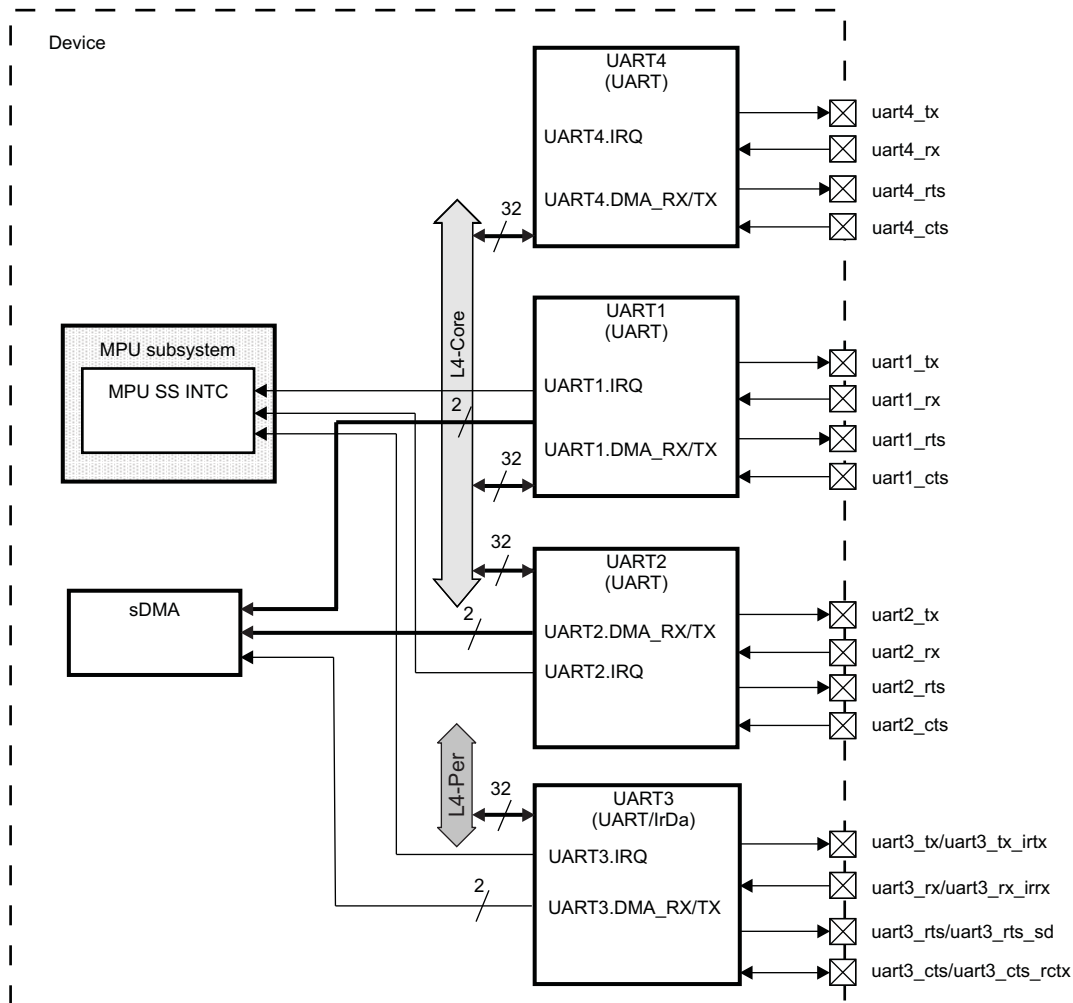

| Topic | Page |
|--|------|
| 14.1 UART/IrDA/CIR Overview | 1686 |
| 14.2 UART/IrDA/CIR Environment | 1689 |
| 14.3 UART/IrDA/CIR Integration | 1702 |
| 14.4 UART/IrDA/CIR Functional Description | 1706 |
| 14.5 UART/IrDA/CIR Basic Programming Model | 1735 |
| 14.6 UART/IrDA/CIR Registers | 1743 |

14.1 UART/IrDA/CIR Overview

The processor contains three universal asynchronous receiver/transmitter (UART) devices controlled by the microprocessor unit (MPU) (see Figure 14-1):

- Three UART-only modules, UART1, UART2 and UART4 are pinned out for use as UART devices only. UART1, UART2 and UART3 must be programmed by setting the UARTi.MDR1_REG[2:0] MODE_SELECT field to one of the three UART operating modes.
- UART3, which adds infrared communication support, is pinned out for use as a UART, infrared data association (IrDA), or consumer infrared (CIR) device, and can be programmed to any available operating mode.

Figure 14-1. UART Module

14.1.1 UART Features

The UARTs (UART1, UART2, UART3, and UART4 when in UART mode) include the following key features:

- 16C750 compatibility
- 64-byte FIFO for receiver and 64-byte FIFO for transmitter
- Programmable interrupt trigger levels for FIFOs
- Baud generation based on programmable divisors N (N = 1...16,384) operating from a fixed functional clock of 48 MHz

Oversampling is programmed by software as 16 or 13; thus, the baud rate computation is either:

- Baud rate = (functional clock/16)/N
- Baud rate = (functional clock/13)/N

This software programming mode enables higher baud rates with the same error amount without changing the clock source:

- Break character detection and generation
- Configurable data format
 - Data bit: 5, 6, 7, or 8 bits
 - Parity bit: Even, odd, none
 - Stop-bit: 1, 1.5, 2 bit(s)
- Flow control: Hardware (RTS/CTS) or software (XON/XOFF)

The UART clocks are connected to produce a baud rate of up to 3.6M bits/s. [Table 14-1](#) lists the supported baud rates, the requested divisor, and the corresponding error versus the standard baud rate.

Table 14-1. UART Mode Baud Rates, Divisor Values, and Error Rates

| Baud Rate | Oversampling | Divisor | Error (%) |
|-----------|--------------|---------|-----------|
| 300 | 16 | 10000 | 0 |
| 600 | 16 | 5000 | 0 |
| 1200 | 16 | 2500 | 0 |
| 2400 | 16 | 1250 | 0 |
| 4800 | 16 | 625 | 0 |
| 9600 | 16 | 312 | 0.16 |
| 14,400 | 16 | 208 | 0.16 |
| 19,200 | 16 | 156 | 0.16 |
| 28,800 | 16 | 704 | 0.16 |
| 38,400 | 16 | 78 | 0.16 |
| 57,600 | 16 | 52 | 0.16 |
| 115,200 | 16 | 26 | 0.16 |
| 230,400 | 16 | 13 | 0.16 |
| 460,800 | 13 | 8 | 0.16 |
| 921,600 | 13 | 4 | 0.16 |
| 1,843,200 | 13 | 2 | 0.16 |
| 3,000,000 | 16 | 1 | 0 |
| 3,686,400 | 13 | 1 | 0.16 |

NOTE: The maximum baud rate required of the module does not depend on the change of OPP.

14.1.2 IrDA Features

The IrDA (UART3 only) includes the following key features:

- Support of IrDA 1.4 slow infrared (SIR), medium infrared (MIR), and fast infrared (FIR) communications
 - Frame formatting: Addition of variable beginning-of-frame (xBOF) characters and end-of-frame (EOF) characters
 - Uplink/downlink cyclic redundancy check (CRC) generation/detection
 - Asynchronous transparency (automatic insertion of break character)
 - Eight-entry status FIFO (with selectable trigger levels) to monitor frame length and frame errors
 - Framing error, CRC error, illegal symbol (FIR), and abort pattern (SIR, MIR) detection

[Table 14-2](#) lists the supported baud rates, the requested divisor, and the corresponding error versus the standard baud rate.

Table 14-2. UART IrDA Mode Baud Rates, Divisor Values, and Error Rates

| Baud Rate | IR Mode | Encoding | Divisor | Error (%) |
|-----------|---------|----------------------|---------|-----------|
| 2400 | SIR | 3/16 | 1250 | 0 |
| 9600 | SIR | 3/16 | 312 | 0.16 |
| 19,200 | SIR | 3/16 | 156 | 0.16 |
| 38,400 | SIR | 3/16 | 78 | 0.16 |
| 57,600 | SIR | 3/16 | 52 | 0.16 |
| 115,200 | SIR | 3/16 | 26 | 0.16 |
| 576,000 | MIR | 1/4 | 2 | 0 |
| 1,152,000 | MIR | 1/4 | 1 | 0 |
| 4,000,000 | FIR | 4 PPM ⁽¹⁾ | 1 | 0 |

⁽¹⁾ PPM = pulse-position-modulation

14.1.3 CIR Features

The CIR mode uses a variable pulse-width modulation (PWM) technique (based on multiples of a programmable t period) to encompass the various formats of infrared encoding for remote-control applications. The CIR logic transmits data packets based on a user-definable frame structure and packet content.

The CIR (UART3 only) includes the following key features to provide CIR support for remote control applications:

- Transmit mode only (receive mode is not supported)
- Free data format (supports any remote-control private standards)
- Selectable bit rate
- Configurable carrier frequency
- 1/2, 5/12, 1/3, or 1/4 carrier duty cycle

14.2 UART/IrDA/CIR Environment

This section describes the UART/IrDA/CIR connection with an external device.

14.2.1 System Using UART Communication with Hardware Handshake

UART1, UART2, or UART3 can be connected easily to the UART port of an external IC (see [Figure 14-2](#)).

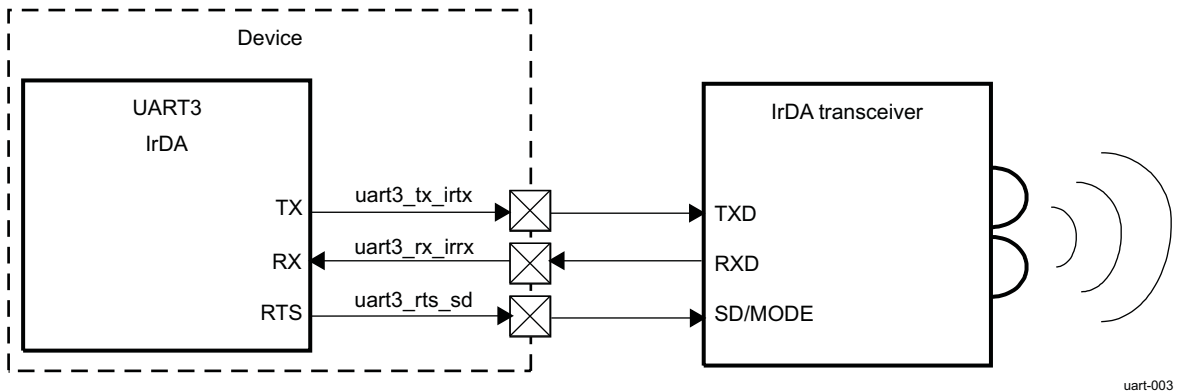

Figure 14-2. UART Mode Bus System Overview

14.2.2 System using IrDA Communication Protocol

As [Figure 14-3](#) shows, UART3 can be connected to an external infrared transceiver in the IrDA modes (FIR, SIR, and MIR).

Figure 14-3. IrDA System Overview

14.2.3 System using CIR Communication Protocol with Remote Control

UART3 can be connected to an external Infrared transceiver in CIR mode (see [Figure 14-4](#)).

Figure 14-4. CIR System Overview

108-004

14.2.4 UART Interface Description

14.2.4.1 UART Interface Description

Table 14-3 describes the UART interface.

Table 14-3. UART I/O Pin Description

| Signal | I/O ⁽¹⁾ | Description | Reset |
|---------------------------|--------------------|--------------------|---------|
| UART Modem Signals | | | |
| uarti_rx | I | Serial data input | Unknown |
| uarti_tx | O | Serial data output | 0 |
| uarti_cts | I | Clear to send | 0 |
| uarti_rts | O | Request to send | 0 |

Because this pin is active high in the IrDA mode and the output is muxed, this pin is set to low on reset (when UARTi.MDR1_REG[2:0] is set to 0x7) and takes the defined inactive level of that signal corresponding to when and how UARTi.MDR1_REG is programmed; that is, the output is 1 (inactive for UART modem modes) and 0 (inactive for IrDA modes).

Active-low modem status signal. Reading the UARTi.MSR_REG[4] NCTS_STS bit checks the condition of uarti_cts. Reading the UARTi.MSR_REG[0] CTS_STS bit checks a change of state of uarti_cts since the last read of the modem status register. The auto-nCTS mode uses uarti_cts to control the transmitter.

When active (low), the module is ready to receive data. Setting the UARTi.MCR_REG[1] RTS bit activates uarti_rts, which becomes inactive as the result of a module reset, loopback mode, or clearing the UARTi.MCR_REG[1] RTS bit. In auto-RTS mode, uarti_rts becomes inactive as a result of the receiver threshold logic.

⁽¹⁾ I = Input, O = Output

14.2.4.2 UART Protocol and Data Format

The UART device operates in three modes:

- UART 16x mode ($\leq 230.4\text{K}$ bits/s)
- UART 16x mode with autobauding (≥ 1200 bits/s and $\leq 115.2\text{K}$ bits/s)
- UART 13x mode ($\geq 460.8\text{K}$ bits/s)

CAUTION

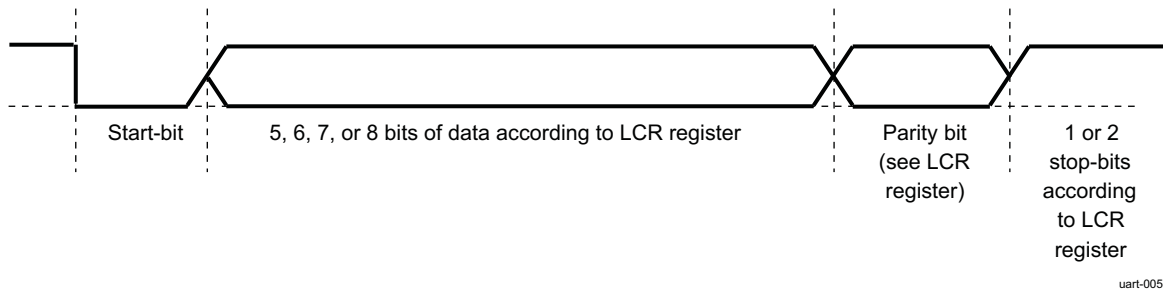

To be used as a UART, the operating mode must be programmed appropriately in the UARTi.MDR1_REG[2:0] MODE_SELECT field to select the UART, IrDA, or CIR mode.

The UART uses a wired interface for serial communication with a remote device.

The UART module is functionally compatible with the TL16C750 UART and earlier designs such as the TL16C550.

Figure 14-5 shows the UART frame data format.

Figure 14-5. UART Frame Data Format

uart-005

14.2.5 IrDA Functional Interfaces

14.2.5.1 UART3 Interface Description

Table 14-4 describes the UART3 interface.

Table 14-4. UART3 I/O Description

| Signal | I/O ⁽¹⁾ | Description | Reset |
|---------------------|--------------------|--|---------|
| IrDA Signals | | | |
| uart3_rx_irrx | I | Serial data input | Unknown |
| uart3_tx_irtx | O | Serial data output in IrDA modes (SIR, MIR, and FIR). In other modes, this pin is set to the reset value (inactive state). | 0 |
| uart3_rts_sd | O | SD mode is used to configure the transceivers. The SD pinout is an inverted value of the UART3.ACREG_REG[6] SD_MOD bit. | 1 |

⁽¹⁾ I = Input, O = Output

14.2.5.2 IrDA Protocol and Data Format

14.2.5.2.1 SIR Mode

In SIR mode, data is transferred between the MPU and peripheral devices at speeds of up to 115,200 baud. A SIR transmit frame begins with start flags (a single 0xC0, a multiple 0xC0, or a single 0xC0 preceded by a number of 0xFF flags), is followed by frame data and a CRC-16, and ends with a stop flag (0xC1).

The bit format for a single word uses 1 start bit, 8 data bits, and 1 stop bit, and is unaffected by the use and settings of the UART3.LCR_REG register.

The UART3.BLR_REG[6] XBOF_TYPE bit selects whether the 0xC0 or 0xFF start patterns are used when multiple start flags are required.

The SIR transmit state-machine attaches start flags, CRC-16, and stop flags, and checks the outgoing data to establish whether data transparency is required.

SIR transparency is carried out if the outgoing data between the start and stop flags contains 0xC0, 0xC1, or 0x7D. If one of these start flags is about to be transmitted, the SIR state-machine first sends an escape character (0x7D), then inverts the fifth bit of the real data to be sent, and sends this data immediately after the 0x7D character.

The SIR receive state-machine recovers the receive clock, removes the start flags and any transparency from the incoming data, and determines the frame boundary with reception of the stop flag. The SIR state-machine also checks for errors, such as a frame abort (0x7D character followed immediately by a 0xC1 stop flag without transparency), a CRC error, and a frame-length error. At the end of a frame reception, the MPU reads the line status register (UART3.LSR_REG) to find possible errors of the received frame.

NOTE: Data can be transferred both ways by the module, but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware. See the UART3.ACREG_REG[5] DIS_IR_RX bit description. This applies to all three modes: SIR, MIR, and FIR.

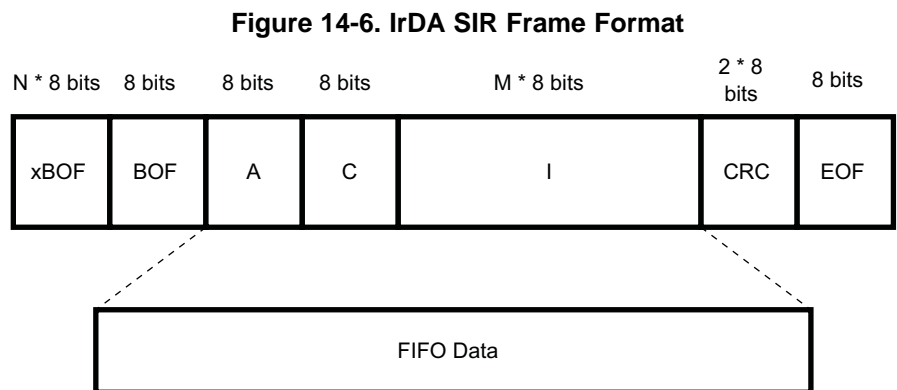

Infrared output in SIR mode can be either 1.6-us or 3/16th encoding, selected by the UART3.ACREG_REG[7] PULSE_TYPE bit. In 1.6-us encoding, the infrared pulse width is 1.6 μ s; and in 3/16th encoding, the infrared pulse width is 3/16th of a bit duration (1/ baud rate).

The transmitting device must send at least two start flags at the start of each frame for back-to-back frames.

NOTE: Reception supports variable-length stop-bits.

14.2.5.2.1.1 Frame Format

Figure 14-6 shows the IrDA SIR frame format.

uart-006

The CRC is applied on the address (A), control ©), and information (I) bytes.

NOTE: The two words of CRC are written to the FIFO in reception.

14.2.5.2.1.2 Asynchronous Transparency

Before transmitting a byte, the UART IrDA controller examines each byte of the payload and the CRC field (between BOF and EOF). For each byte equal to 0xC0 (BOF), 0xC1 (EOF), or 0x7D (control escape), the controller performs certain tasks:

- In transmission:
 - Inserts a control escape (CE) byte preceding the byte
 - Complements bit 5 of the byte (that is, exclusive ORs the byte with 0x20)

The byte sent for the CRC computation is the initial byte written in the TX FIFO (before the XOR with

0x20).

- In reception:

For the A, C, I, CRC field:

- Compares the byte with the CE byte; if they are not equal, sends the byte to the CRC detector and stores it in the RX FIFO
- If the byte is equal to the CE byte, discards the CE byte
- Complements bit 5 of the byte following the CE
- Sends the complemented byte to the CRC detector and stores it in the RX FIFO

14.2.5.2.1.3 Abort Sequence

The transmitter can decide to prematurely close a frame. The transmitter aborts by sending the following sequence: 0x7DC1. The abort pattern closes the frame without a CRC field or an ending flag.

The receiver treats a frame as an aborted frame when a 0x7D character followed immediately by a 0xC1 character is received without transparency.

14.2.5.2.1.4 Pulse Shaping

The SIR mode supports both the 3/16th and the 1.6- μ s pulse duration methods. The UART3.ACREG_REG[7] PULSE_TYPE bit selects the pulse width method in transmit mode.

14.2.5.2.1.5 Encoder

Serial data from the transmit state-machine is encoded to transmit data to the optoelectronics. While the TX FIFO output is high, the `uart3_tx_irtx` line is always low, and the counter used to form a pulse on `uart3_tx_irtx` is cleared continuously.

After the TX FIFO output resets to 0, `uart3_tx_irtx` rises on the falling edge of the 7th 16XCLK. On the falling edge of the 10th 16XCLK pulse, `uart3_tx_irtx` falls, creating a three-clock-wide pulse. While the TX FIFO output stays low, a pulse is transmitted during the 7th to the 10th clock of each 16-clock bit cycle.

Figure 14-7 shows the IrDA SIR encoding mechanism.

Figure 14-7. IrDA SIR Encoding Mechanism

14.2.5.2.1.6 Decoder

After reset, the RX FIFO input is high and the 4-bit counter is cleared. When a rising edge is detected on RX, the RX FIFO input falls on the next rising edge of 16XCLK with sufficient setup time. The RX FIFO input stays low for 16 cycles (16XCLK) and then returns to high as required by the IrDA specification. As long as no pulses (rising edges) are detected on the RX, the RX FIFO input remains high.

Figure 14-8 shows the IrDA SIR decoding mechanism.

Figure 14-8. IrDA SIR Decoding Mechanism

Data can be transferred both ways by the module, but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware. The operation of the `uart3_rx_irrx` input can be disabled using the `UART3.ACREG_REG[5]` `DIS_IR_RX` bit. Furthermore, the `UART3.MDR2_REG[6]` `IRRXINVERT` bit can invert the signal from the transceiver (RXD) pin to the IRRX logic inside the UART. This inversion is performed by default.

14.2.5.2.1.7 IR Address Checking

In all IR modes, when address checking is enabled by setting `EFR_REG[1:0]` (see [Table 14-5](#)), only frames intended for the device are written to the RX FIFO. This is to avoid receiving frames not meant for this device in a multipoint infrared environment. To program two frame addresses that the UART3 receives in IrDA mode, use the `UART3.XON1_ADDR1_REG[7:0]` field and the `UART3.XON2_ADDR2_REG[7:0]` field.

Table 14-5. EFR_REG[0-1] IR Address Checking Options

| EFR_REG[1] | EFR_REG[0] | IR Address Checking |
|------------|------------|--|
| 0 | 0 | All address-checking operations disabled |
| 0 | 1 | Only address 1 checking enabled |
| 1 | 0 | Only address 2 checking enabled |
| 1 | 1 | All address-checking operations enabled |

14.2.5.2.2 SIR Free Format Mode

To allow complete software flexibility when transmitting and receiving infrared data packets, the SIR free format (FF) mode is a subfunction of the existing SIR mode; all frames going to and from the FIFO buffers are untouched with respect to appending and removing control characters and CRC values.

This mode corresponds to a UART mode with a pulse modulation of 3/16 of baud rate pulse width.

For example, a normal SIR packet has BOF control and CRC error-checking data appended (transmitting) or removed (receiving) from the data going to and from the FIFOs.

[Figure 14-9](#) shows the SIR free format mode.

Figure 14-9. SIR Free Format Mode

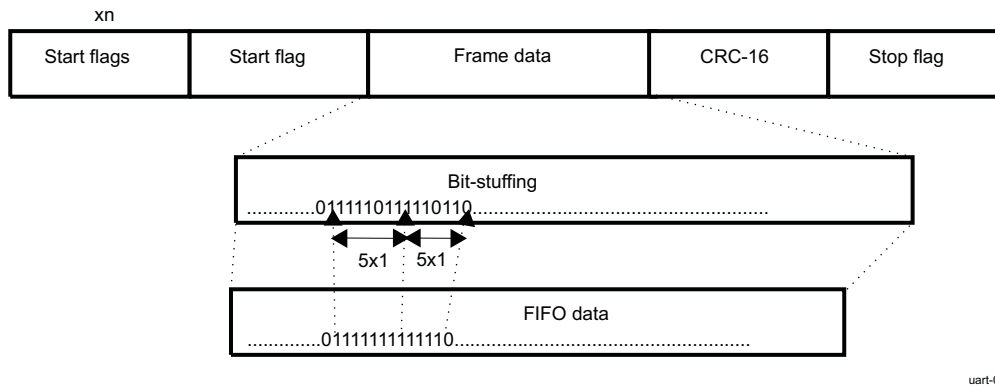

In the SIR free format mode, the MPU software must construct (that is, encode and decode) the entire FIFO data packet.

14.2.5.2.3 MIR Mode

In MIR mode, data is transferred between the MPU and the peripheral devices at 0.576 or 1.152M bits/s speed. A MIR transmit frame starts with start flags (at least two), followed by a frame data, CRC-16, and ends with a stop flag (see Figure 14-10).

Figure 14-10. MIR Transmit Frame Format

On transmit, the MIR state-machine attaches start flags, CRC-16, and stop flags, as in SIR mode. All fields are transmitted least-significant bit (LSB) of each byte first.

Contrary to SIR mode:

- The state-machine looks for consecutive 1s in the frame data and automatically inserts 0 after five consecutive 1s (this is called bit-stuffing).
- 0x7E is used for both start and stop flags (unambiguously, not data, because of bit-stuffing).
- Abort sequence requires a minimum of seven consecutive 1s (unambiguously, not data, because of bit stuffing).
- Back-to-back frames are allowed with three or more stop flags in between. If two consecutive frames are not back to back, the gap between the last stop flag of the first frame and the start flag of the second frame must be separated by at least seven bit durations.

On receive, the MIR receive state-machine recovers the receive clock, removes the start flags, destuffs the incoming data, and determines the frame boundary with reception of the stop flag. The state-machine also checks for errors, such as frame abort, CRC error, and frame-length error. At the end of a frame reception, the MPU reads the line status register (UART3.LSR_REG) to detect possible errors of the received frame.

Data can be transferred both ways by the module, but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware.

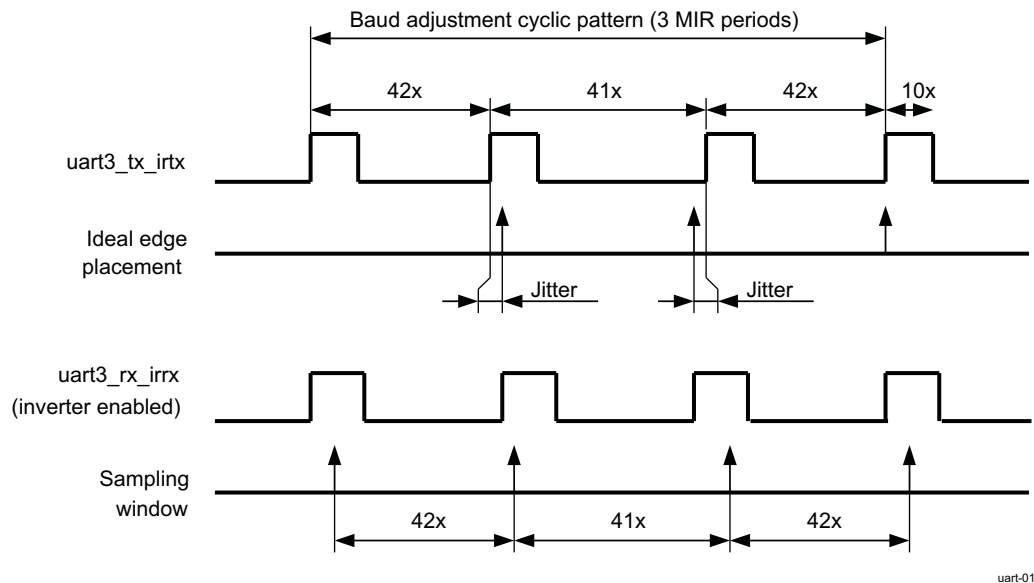

14.2.5.2.3.1 MIR Encoder/Decoder

To meet the MIR baud rate tolerance of ± 0.1 percent with a 48-MHz clock input, a 42-41-42 encoding/decoding adjustment is performed. The reference start point is the first start flag, and the 42-41-42 cyclic pattern is repeated until the stop flag is sent or detected.

The jitter created this way is within MIR tolerances. The pulse width is not exactly 1/4, but it is within the tolerances defined by the IrDA specifications.

Figure 14-11 shows the MIR baud rate adjustment mechanism.

Figure 14-11. MIR Baud Rate Adjustment Mechanism

14.2.5.2.3.2 SIP Generation

In the MIR and FIR operation modes, the transmitter must send a serial infrared interaction pulse (SIP) at least once every 500 ms. The SIP informs slow devices (operating in SIR mode) that the medium is currently occupied.

Figure 14-12 shows the SIP.

Figure 14-12. SIP

14.2.5.2.4 FIR Mode

In FIR mode, data is transferred between the MPU and the peripheral devices at 4M bits/s. A FIR transmit frame starts with a preamble that is followed by a start flag, frame data, CRC-32, and ends with a stop flag.

Table 14-6 shows the FIR transmit frame format.

Table 14-6. FIR Transmit Frame Format

| | | | | |
|-------------------|------------|------------|--------|-----------|
| Preamble (16x) | Start flag | Frame data | CRC-32 | Stop flag |
|-------------------|------------|------------|--------|-----------|

On transmit, the FIR transmit state-machine attaches the preamble, start flag, CRC-32, and stop flag. An abort sequence requires at least two transmissions of 0000. Back-to-back frames are allowed, but each frame must be complete.

The state-machine also encodes the transmit data into 4-PPM format (see [Table 14-7](#)) and generates the SIP (see [Section 14.2.5.2.3.2, SIP Generation](#)).

Table 14-7. 4-PPM Format

| Data Bit Pair (Bin) | 4-PPM Data Symbol (Bin) |
|---------------------|-------------------------|
| 00 | 1000 |
| 01 | 0100 |
| 10 | 0010 |
| 11 | 0001 |

The four symbols described in [Table 14-7](#) are the legal encoded data symbols. All other combinations are illegal for encoding data. Some of these illegal symbols are used in the definition of the preamble, start flag, and stop flag because they are unambiguously not data (see [Table 14-8](#)).

Table 14-8. FIR Preamble, Start Flag, and Stop Flag

| Frame Part | Transmitted Frame (Bin) |
|------------|---|
| Preamble | 1000 0000 1010 1000 (16 repeated transmissions) |
| Start Flag | 0000 1100 0000 1100 0110 0000 0110 0000 |
| Stop Flag | 0000 1100 0000 1100 0000 0110 0000 0110 |

All fields are transmitted the LSBs of each byte first (see [Table 14-9](#)).

Table 14-9. FIR Data Byte Transmission Order Example

| Data Byte (Hex) | Data Byte Pair (Bin) | 4-PPM Data Symbol (Bin) | Transmission Order |
|-----------------|----------------------|-------------------------|--------------------|
| 0x0B | 00 | 1000 | 4 |
| | 00 | 1000 | 3 |
| | 10 | 0010 | 2 |
| | 11 | 0001 | 1 |

On receive, the FIR receive state-machine recovers the receive clock, removes the preamble and the start flag, decodes the 4-PPM incoming data, and determines the frame boundary with reception of the stop flag. The state-machine also checks for errors, such as illegal symbol, CRC error, and frame-length error. At the end of a frame reception, the MPU reads the line status register (UART3.LSR_REG) to detect possible errors of the received frame.

Data can be transferred both ways by the module, but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware.

14.2.6 CIR Functional Interfaces

14.2.6.1 CIR Interface Description

Table 14-10 describes the CIR interface.

Table 14-10. CIR I/O Description

| Signal | I/O ⁽¹⁾ | Description | Reset |
|--------------------|--------------------|--|---------|
| CIR Signals | | | |
| uart3_rx_irrx | I | Serial data input | Unknown |
| uart3_cts_rctx | O | Serial data output in CIR mode. In other modes, this pin is set to the reset value (inactive state). | 0 |
| uart3_rts_sd | O | SD mode is used to configure the transceivers. The SD pinout is an inverted value of the UART3.ACREG_REG[6] SD_MOD bit. | 1 |

⁽¹⁾ I = Input, O = Output

14.2.6.2 CIR Protocol and Data Format

In the CIR mode, the infrared operation functions as a programmable (universal) remote control.

The CIR mode uses a variable PWM technique (based on multiples of a programmable t period) to encompass the various formats of infrared encoding for remote control applications. The CIR logic transmits data packets based on the user-defined frame structure and packet content.

14.2.6.2.1 Carrier Modulation

Each modulated pulse that constitutes a digit is a train of on/off pulses (see Figure 14-13).

Figure 14-13. CIR Pulse Modulation

14.2.6.2.2 Pulse Duty Cycle

The programmer can choose between four possible duty cycles for modulation pulses by setting the appropriate value in the UART3.MDR2_REG[5:4] CIR_PULSE_MODE field (1/4, 1/3, 5/12, or 1/2).

Figure 14-14 shows the CIR modulation duty cycles.

Figure 14-14. CIR Modulation Duty Cycle

The transmission logic ensures that all pulses are transmitted completely (that is, no cutoff during transmission). Furthermore, while transmitting continuous bytes back-to-back, no delay is inserted between 2 transmitted bytes. Thus, software must handle the delay between consecutively transmitted bytes if the receiving end needs it.

14.2.6.2.3 Consumer IR Encoding/Decoding

There are two methods of encoding for remote control applications. The first method uses time-extended bit forms (a variable pulse distance, or duration, in which the difference between a logic 1 and logic 0 is the length of the pulse width).

The second encoding method uses a biphase in which the encoding of the logic 0 and logic 1 is in the change of signal level from 1 to 0 or 0 to 1, respectively. Japanese manufacturers favor pulse duration encoding; European manufacturers favor biphase encoding.

The CIR mode uses a completely flexible free-format encoding in which the TX FIFO is transmitted as a modulated pulse with duration T.

Similarly, 0 is transmitted as a blank duration T. The MPU constructs and deciphers the protocol of the data. For example, the RC-5 protocol using Manchester encoding can be emulated as using a 01 pair for 1 and a 10 pair for 0 (see Figure 14-15.).

Figure 14-15. RC-5 Bit Encoding

Because the CIR mode logic does not impose a fixed format for infrared packets of data, the MPU software can define the format using simple data structures that are then modulated into an industry standard, such as RC-5 or SIRC. To send a sequence of 0101 in RC-5, the MPU software must write an 8-bit binary character of 10011001 to the data FIFO of the UART.

For SIRC, the modulation length (that is, multiples of T) is the method used to distinguish between 1 and 0. The following SIRC digits show the difference in encoding between this and, for example, RC-5. The pulse width is extended for one digit.

Figure 14-16 shows SIRC bit encoding.

Figure 14-16. SIRC Bit Encoding

To construct comprehensive packets constituting remote-control commands, the MPU software must combine a number of 8-bit data characters in a sequence that follows one of the universally accepted formats.

Figure 14-17 shows a standard RC-5 frame as detected by the UART3 in CIR mode (the SIRC format follows this). Each field in RC-5 can be considered as two T pulses (digital bits) from the TX and RX FIFOs.

Figure 14-17. RC-5 Standard Packet Format

uart-018

Where:

- S1, S2: Start bits (always 1)
- T: Toggle bit
- A4..A0: Address (or system) bits
- C5..C0: Command bits

The toggle bit T changes when a new command is transmitted to detect when the same key is pressed twice (effectively receiving the same data from the host consecutively). A brief delay in the transmission of the same command is detected by the use of the toggle bit because a code is sent while the MPU transmits characters to the UART for transmission. The address bits define the machine or device for which the infrared transmission is intended, and the command defines the operation.

To accommodate an extended RC-5 format, the S2 bit is replaced by an additional command bit (C6) that allows the command range to increase to 7 bits. This format is known as the extended RC-5 format.

SIRC encoding uses the duration of modulation for mark and space; therefore, the duration of data bits inside the standard frame length varies.

Figure 14-18 shows the packet format and bit encoding. As Figure 14-19 shows, 1 start bit of 2 ms and control codes are followed by data that constitute the entire frame.

Figure 14-18. SIRC Packet Format

uart-019

NOTE: The encoding must take a standard duration, but the contents of the data can vary. This implies that the control software for emitting and receiving data packets must exercise a scheme of interpacket delay, where the emission of successive packets can be done only after a real-time delay has expired.

Figure 14-19. SIRC Bit Transmission Example

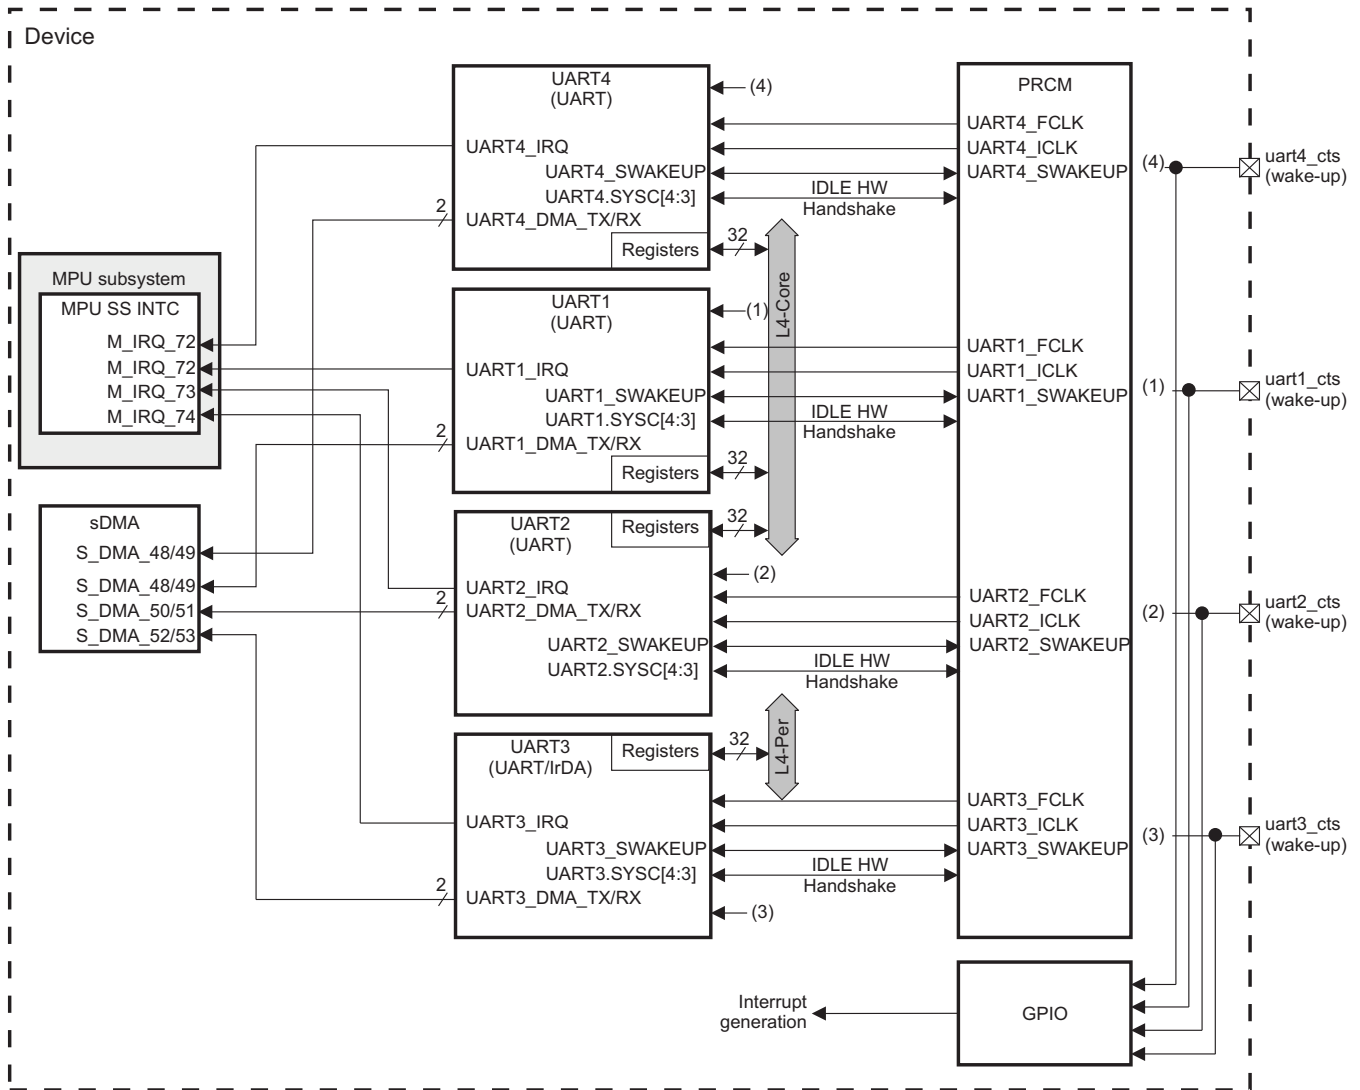

uart-020

This document does not describe all encoding methods and techniques; the preceding information shows the considerations required to employ different encoding methods for different industry-standard protocols. See industry-standard documentation for specific methods of encoding and protocol usage.

14.3 UART/IrDA/CIR Integration

Figure 14-20 shows the internal connections with related modules for UART functions.

Figure 14-20. UART Functional Integration

14.3.1 Clocking, Reset, and Power-Management Scheme

14.3.1.1 Clocking

Each UART uses a 48-MHz functional clock for its logic and the generation of external interface signals. Each UART uses an interface clock for register accesses. The power, reset, and clock management (PRCM) module generates and controls all these clocks (for more information, see the *Power, Reset, and Clock Management* chapter).

Table 14-11 describes the UART clocks.

Table 14-11. UART Clocks

| Clock Type | Frequency | Name | Comments |
|------------------|---------------|------------|---|
| UART1 | | | |
| Functional clock | CORE_48M_FCLK | UART1_FCLK | Source and gating is the PRCM module. Enable/disable this clock with the PRCM.CM_FCLKEN1_CORE[13] EN_UART1 bit. |
| Interface clock | CORE_L4_ICLK | UART1_ICLK | Source and gating is the PRCM module. Enable/disable this clock with the PRCM.CM_ICLKEN1_CORE[13] EN_UART1 bit. Enable/disable auto-idle for this clock with the PRCM.CM_AUTOIDLE1_CORE[13] AUTO_UART1 bit. |
| UART2 | | | |
| Functional clock | CORE_48M_FCLK | UART2_FCLK | Source and gating is the PRCM module. Enable/disable this clock with the PRCM.CM_FCLKEN1_CORE[14] EN_UART2 bit. |
| Interface clock | CORE_L4_ICLK | UART2_ICLK | Source and gating is the PRCM module. Enable/disable this clock with the PRCM.CM_ICLKEN1_CORE[14] EN_UART2 bit. Enable/disable auto-idle for this clock with the PRCM.CM_AUTOIDLE1_CORE[14] AUTO_UART2 bit. |
| UART3 | | | |
| Functional clock | PER_48M_FCLK | UART3_FCLK | Source and gating is the PRCM module. Enable/disable this clock with the PRCM.CM_FCLKEN_PER[11] EN_UART3 bit. |
| Interface clock | PER_L4_ICLK | UART3_ICLK | Source and gating is the PRCM module. Enable/disable this clock with the PRCM.CM_ICLKEN_PER[11] EN_UART3 bit. Enable/disable auto-idle for this clock with the PRCM.CM_AUTOIDLE_PER[11] AUTO_UART3 bit. |
| UART4 | | | |
| Functional clock | CORE_48M_FCLK | UART4_FCLK | Source and gating is the PRCM module. Enable/disable this clock with the PRCM.CM_FCLKEN1_CORE[23] EN_UART4 bit. |
| Interface clock | CORE_L4_ICLK | UART4_ICLK | Source and gating is the PRCM module. Enable/disable this clock with the PRCM.CM_ICLKEN1_CORE[23] EN_UART1 bit. Enable/disable auto-idle for this clock with the PRCM.CM_AUTOIDLE1_CORE[23] AUTO_UART1 bit. |

The idle and wake-up processes use a handshake protocol between the PRCM module and the UARTs (for a description of the protocol, see the *Power, Reset, and Clock Management* chapter). The UARTi.SYSC_REG[4:3] IDLEMODE field controls the UART idle mode.

14.3.1.2 Hardware Reset

Table 14-12 lists the UART reset domain.

Table 14-12. Reset Domain

| Peripherals | Reset Domain |
|-------------|--------------|
| UART1 | CORE_RST |
| UART2 | CORE_RST |
| UART3 | PER_RST |
| UART4 | CORE_RST |

14.3.1.3 Software Reset

The UARTi.SYSC_REG[1] SOFTRESET bit controls the software reset; writing 1 to this bit triggers a software-reset functionally equivalent to hardware reset.

14.3.2 Hardware Requests

14.3.2.1 Interrupts

Table 14-13 describes the UART interrupt mappings.

Table 14-13. Interrupt Mapping to MPU Subsystem

| IRQ | Source | Description |
|----------|-----------|--------------------------------|
| M_IRQ_72 | UART1_IRQ | UART module 1 interrupt to MPU |
| M_IRQ_73 | UART2_IRQ | UART module 2 interrupt to MPU |
| M_IRQ_74 | UART3_IRQ | UART module 3 interrupt to MPU |
| M_IRQ_84 | UART4_IRQ | UART module 4 interrupt to MPU |

14.3.2.2 DMA Requests

Table 14-14 describes the UART DMA requests.

Table 14-14. UART DMA Requests to System DMA

| DMA ⁽¹⁾ | Source | Description |
|--------------------|--------------|--------------------------------|
| S_DMA_48 | UART1_DMA_TX | UART module 1 transmit request |
| S_DMA_49 | UART1_DMA_RX | UART module 1 receive request |
| S_DMA_50 | UART2_DMA_TX | UART module 2 transmit request |
| S_DMA_51 | UART2_DMA_RX | UART module 2 receive request |
| S_DMA_52 | UART3_DMA_TX | UART module 3 transmit request |
| S_DMA_53 | UART3_DMA_RX | UART module 3 receive request |
| S_DMA_54 | UART4_DMA_TX | UART module 4 transmit request |
| S_DMA_55 | UART4_DMA_RX | UART module 4 receive request |

⁽¹⁾ This table assumes that DMA mode 1 is used.

14.3.2.3 Wake-up Request

The UART can wake up the system on different events (see [Section 14.6, UART/IrDA/CIR Registers](#)).

One important wake-up generation is event detection on the uarti_cts pin when the system is idle. The uarti_cts pin uses an asynchronous path to transmit the wake-up request to the system (PRCM), which enables wake-up capabilities to be active even if all module clocks are off (see [Table 14-15](#)).

Table 14-15. Wake-Up Requests from PRCM

| Wake-Up Pin | PRCM Input | Description |
|-------------|---------------|--|
| uart1_cts | UART1_SWAKEUP | Wake UART1 (system wake-up capabilities) |
| uart2_cts | UART2_SWAKEUP | Wake UART2 (system wake-up capabilities) |
| uart3_cts | UART3_SWAKEUP | Wake UART3 (system wake-up capabilities) |

CAUTION

UARTs are not in the WAKEUP power domain, which implies limitations on wake-up capability. If the CORE power domain is off, UART1 and UART2 cannot wake up the system, because power is not supplied. If the PER power domain is off, UART3 cannot wake up the system, because power is not supplied. In these cases, a GPIO multiplexed on the uarti_cts pin can be used to capture the event and wake up the system. Software must enable this strategy, if required. See the *General-Purpose Interface* chapter for a full description of this mechanism.

14.4 UART/IrDA/CIR Functional Description

14.4.1 UART/IrDA/CIR Block Description

The UART/IrDA/CIR module can be divided into three main blocks:

- FIFO management
- Mode selection
- Protocol formatting

FIFO management is common to all functions and enables the transmission and reception of data from the host processor point of view.

There are two mode selections:

- Function mode selection: Route the data to the chosen functionality (UART, IrDA, or CIR) and enable the mechanism corresponding to the chosen functionality.
- Register mode selection, which enables conditional access to registers

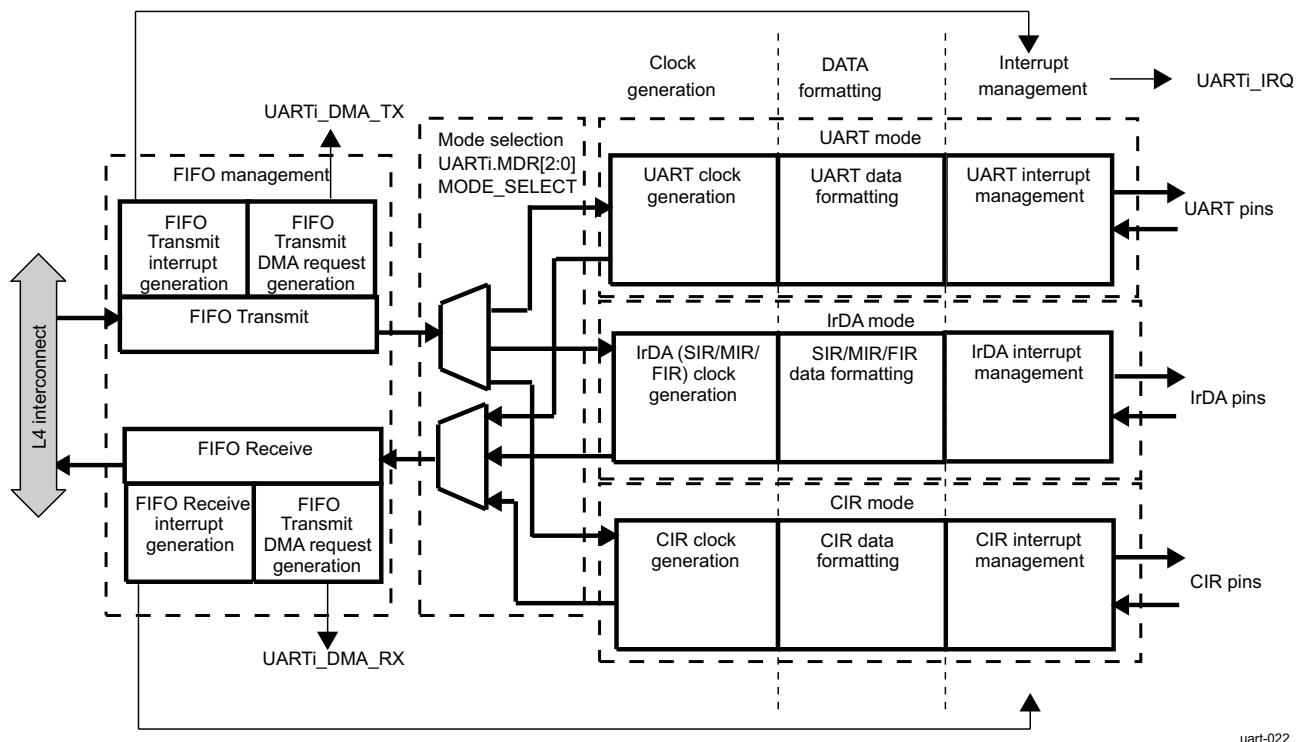

Protocol formatting has three subcategories:

- Clock generation: The 48-MHz input clock generates all necessary clocks.
- Data formatting: Each function uses its own state-machine, which assumes the transition between FIFO data and frame data.
- Interrupt management: Different interrupt types are generated depending on the chosen function.

In parallel with these functional blocks, a power-saving strategy exists for each function.

Figure 14-21 is the UART/IrDA/CIR block diagram.

Figure 14-21. UART/IrDA/CIR Block Diagram

uart-022

14.4.2 FIFO Management

The FIFO is accessed by reading/writing the UARTi.RHR_REG and UARTi.THR_REG registers.

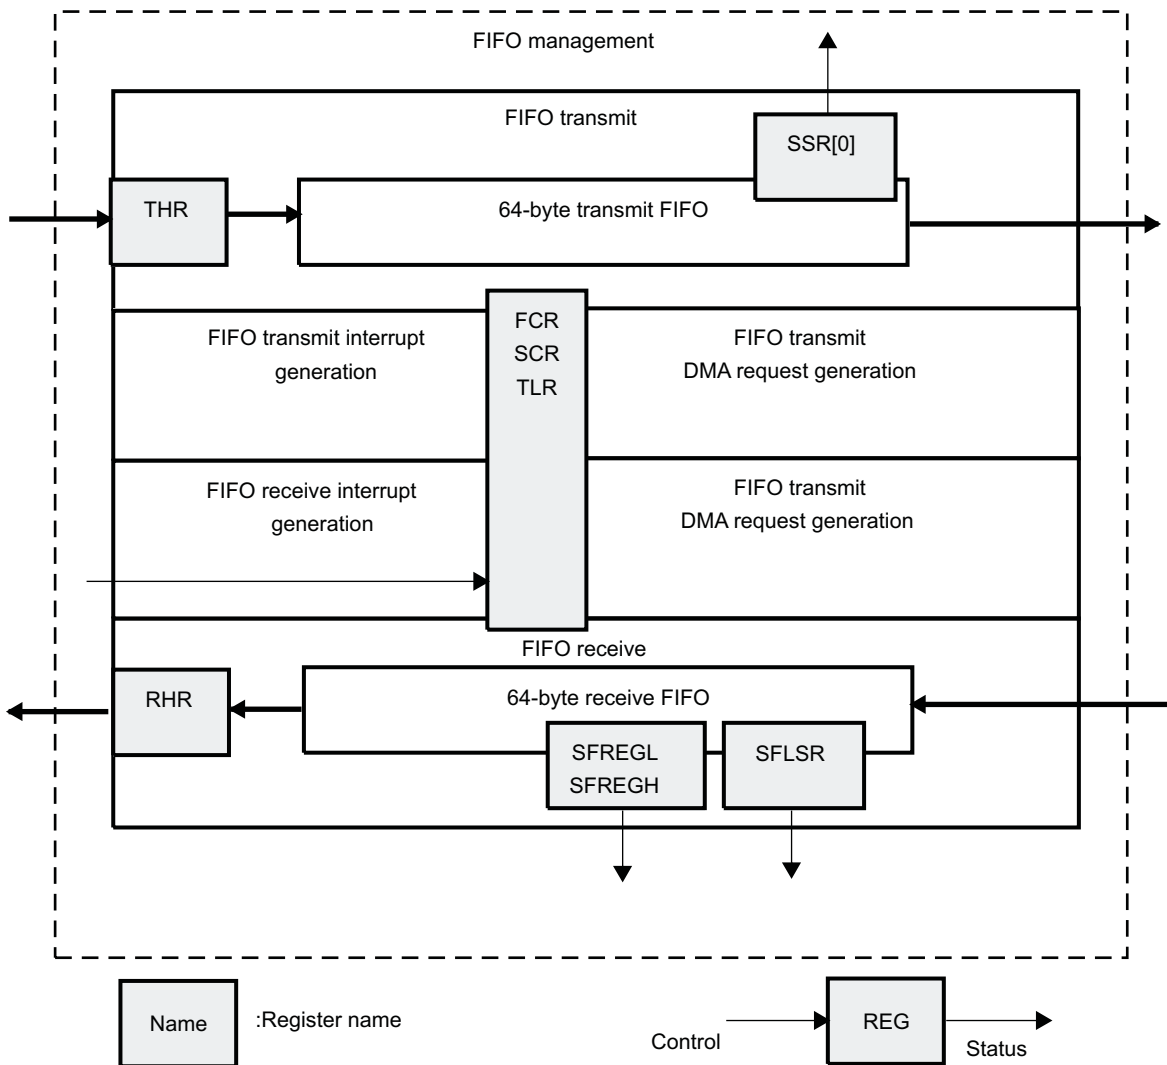

Parameters are controlled using the FIFO control register (UARTi.FCR_REG) and supplementary control register (UARTi.SCR_REG). Reading the UARTi.SSR_REG[0] TX_FIFO_FULL bit at 1 means the FIFO is full.

The UARTi.TLR_REG register controls the FIFO trigger level, which enables the DMA and interrupt generation. After reset, both transmitter and receiver FIFOs are disabled; so, in effect, the trigger level is the default value of 1 byte. Figure 14-22 shows the FIFO management registers.

NOTE: Data in the UARTi.RHR_REG register is not overwritten when an overflow occurs.

NOTE: The UARTi.SFLSR_REG, UARTi.SFREGL_REG, and UARTi.SFREGH_REG status registers are used in IrDA mode only. For use, see Section 14.4.4.2.3, IrDA Data Formatting.

Figure 14-22. FIFO Management Registers

uart-023

14.4.2.1 FIFO Trigger

14.4.2.1.1 Transmit FIFO Trigger

Table 14-16 summarizes the transmit FIFO trigger level settings.

Table 14-16. TX FIFO Trigger Level Setting Summary

| SCR_REG[6] | TLR_REG[3:0] | TX FIFO Trigger Level |
|------------|--------------|---|
| 0 | = 0x0 | Defined by the UARTi.FCR_REG[5:4] TX_FIFO_TRIG field (8,16, 32, or 56 spaces) |
| 0 | ≠ 0x0 | Defined by the UARTi.TLR_REG[3:0] TX_FIFO_TRIG_DMA field (from 4 to 60 spaces with a granularity of 4 spaces) |
| 1 | Value | Defined by the concatenated value of TX_FIFO_TRIG_DMA and TX_FIFO_TRIG (from 1 to 63 spaces with a granularity of 1 space) Note: The combination of TX_FIFO_TRIG_DMA = 0x0 and TX_FIFO_TRIG = 0x0 (all zeros) is not supported (minimum of one space required). All zeros result in unpredictable behavior. |

14.4.2.1.2 Receive FIFO Trigger

Table 14-17 summarizes the receive FIFO trigger level settings.

Table 14-17. RX FIFO Trigger Level Setting Summary

| SCR_REG[7] | TLR_REG[7:4] | RX FIFO Trigger Level |
|------------|--------------|---|
| 0 | = 0x0 | Defined by the UARTi.FCR_REG[7:6] RX_FIFO_TRIG field (8,16, 56, or 60 characters) |
| 0 | ≠ 0x0 | Defined by UARTi.TLR_REG[7:4] RX_FIFO_TRIG_DMA field (from 4 to 60 characters with a granularity of 4 characters) |
| 1 | Value | Defined by the concatenated value of RX_FIFO_TRIG_DMA and RX_FIFO_TRIG (from 1 to 63 characters with a granularity of 1 character). Note: The combination of RX_FIFO_TRIG_DMA = 0x0 and RX_FIFO_TRIG = 0x0 (all zeros) is not supported (minimum 1 character required). All zeros result in unpredictable behavior. |

The receive threshold is programmed using the UARTi.TCR_REG[7:4] RX_FIFO_TRIG_START and UARTi.TCR_REG[3:0] RX_FIFO_TRIG_HALT fields.

- Trigger levels from 0 to 60 bytes are available with a granularity of four. (Trigger level = 4 x [4-bit register value])
- To ensure correct device operation, ensure that RX_FIFO_TRIG_HALT > RX_FIFO_TRIG when auto-RTS is enabled.
- In the FIFO interrupt mode with flow control, ensure that the trigger level to HALT transmission is greater than or equal to the receive FIFO trigger level (either the UARTi.TCR_REG[7:4] RX_FIFO_TRIG_START field or the UARTi.FCR_REG[7:6] RX_FIFO_TRIG field); otherwise, FIFO operation stalls. In the FIFO DMA mode with flow control, this concept does not exist, because a DMA request is sent when a byte is received.

14.4.2.2 FIFO Interrupt Mode

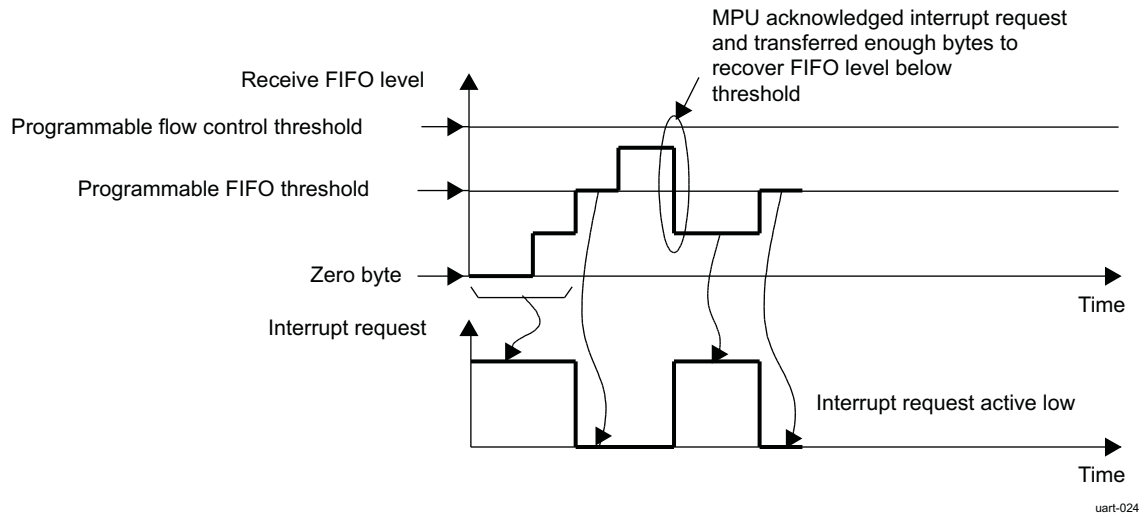

In the FIFO interrupt mode (the FIFO control register UARTi.FCR_REG[0] FIFO_EN bit is set to 1 and relevant interrupts are enabled by the UARTi.IER_REG register), an interrupt signal informs the processor of the status of the receiver and transmitter. These interrupts are raised when the receive/transmit FIFO threshold (the UARTi.TLR_REG[7:4] RX_FIFO_TRIG_DMA and UARTi.TLR_REG[3:0] TX_FIFO_TRIG_DMA fields or the UARTi.FCR_REG[7:6] RX_FIFO_TRIG and UARTi.FCR_REG[5:4] TX_FIFO_TRIG fields, respectively) is reached.

The interrupt signals instruct the MPU to transfer data to the destination (from the UART module in receive mode and/or from any source to the UART FIFO in transmit mode).

When the UART flow control is enabled with the interrupt capabilities, the UART flow control FIFO threshold (UARTi.TCR_REG[3:0] RX_FIFO_TRIG_HALT field) must be greater than or equal to the receive FIFO threshold.

Figure 14-23 shows the generation of the receive FIFO interrupt request.

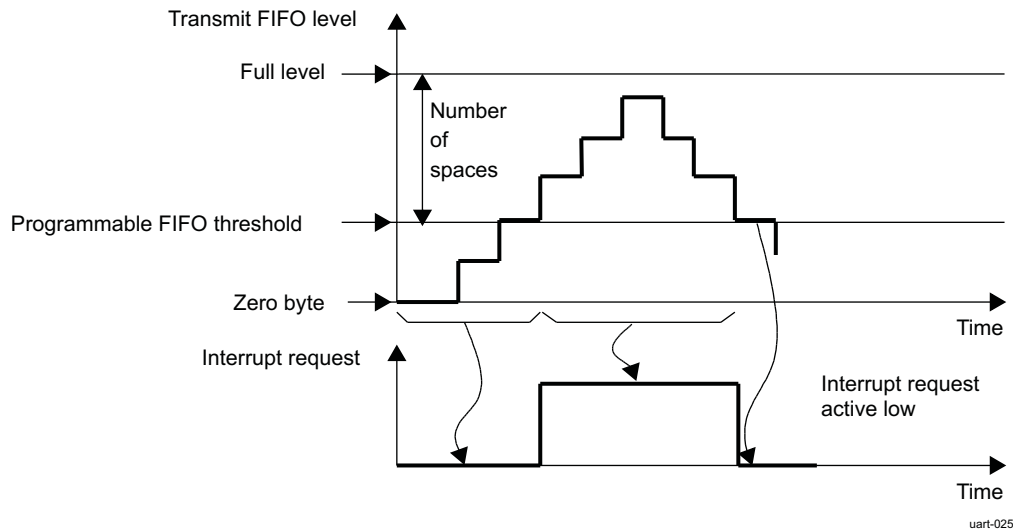

Figure 14-23. Receive FIFO Interrupt Request Generation

In receive mode, no interrupt is generated until the receive FIFO reaches its threshold. Once low, the interrupt can be deasserted only when the MPU has handled enough bytes to make the FIFO level below threshold. The flow control threshold is set at a higher value than the FIFO threshold.

Figure 14-24 shows the generation of the transmit FIFO interrupt request.

Figure 14-24. Transmit FIFO Interrupt Request Generation

In transmit mode, an interrupt request is automatically asserted when the TX FIFO is empty. This request is deasserted when the TX FIFO crosses the threshold level. The interrupt line is deasserted until a sufficient number of elements is transmitted to go below the TX FIFO threshold.

14.4.2.3 FIFO Polled Mode Operation

In the FIFO polled mode (the UARTi.FCR_REG[0] FIFO_EN bit is set to 0 and the relevant interrupts are disabled by the UARTi.IER_REG register), the status of the receiver and transmitter can be checked by polling the line status register (UARTi.LSR_REG).

This mode is an alternative to the FIFO interrupt mode of operation in which the status of the receiver and transmitter is automatically determined by sending interrupts to the MPU.

14.4.2.4 FIFO DMA Mode Operation

Although DMA operation includes four modes (DMA modes 0/1/2/3), the information in [Table 14-14](#) assumes that mode 1 is used. (Mode 2 and mode 3 are legacy modes that use only one DMA request for each module.)

In mode 2, the remaining DMA request is used for RX. In mode 3, the remaining DMA request is used for TX.

The DMA requests in mode 2 and mode 3 use S_DMA_48, S_DMA_50, and S_DMA_52/D_DMA_10. S_DMA_49, S_DMA_51, and S_DMA_53/D_DMA_11 are not used by the module in mode 2 and mode 3 and can be selected as follows:

- When the UARTi.SCR_REG[0] DMA_MODE_CTL bit is set to 0, setting the UARTi.FCR_REG[3] DMA_MODE bit to 0 enables DMA mode 0. Setting the DMA_MODE bit to 1 enables DMA mode 1.
- When the DMA_MODE_CTL bit is set to 1, the UARTi.FCR_REG[2:1] DMA_MODE_2 field determines DMA mode 0 to 3 based on the supplementary control register (SCR_REG) description.

For example:

- If no DMA operation is desired, set the DMA_MODE_CTL bit to 1 and the DMA_MODE_2 field to 0x0. (The DMA_MODE bit is discarded.)
- If DMA mode 1 is desired, set either the DMA_MODE_CTL bit to 0 and the DMA_MODE bit to 1, or set the DMA_MODE_CTL bit to 1 and the DMA_MODE_2 field to 01. (The DMA_MODE bit is discarded.)

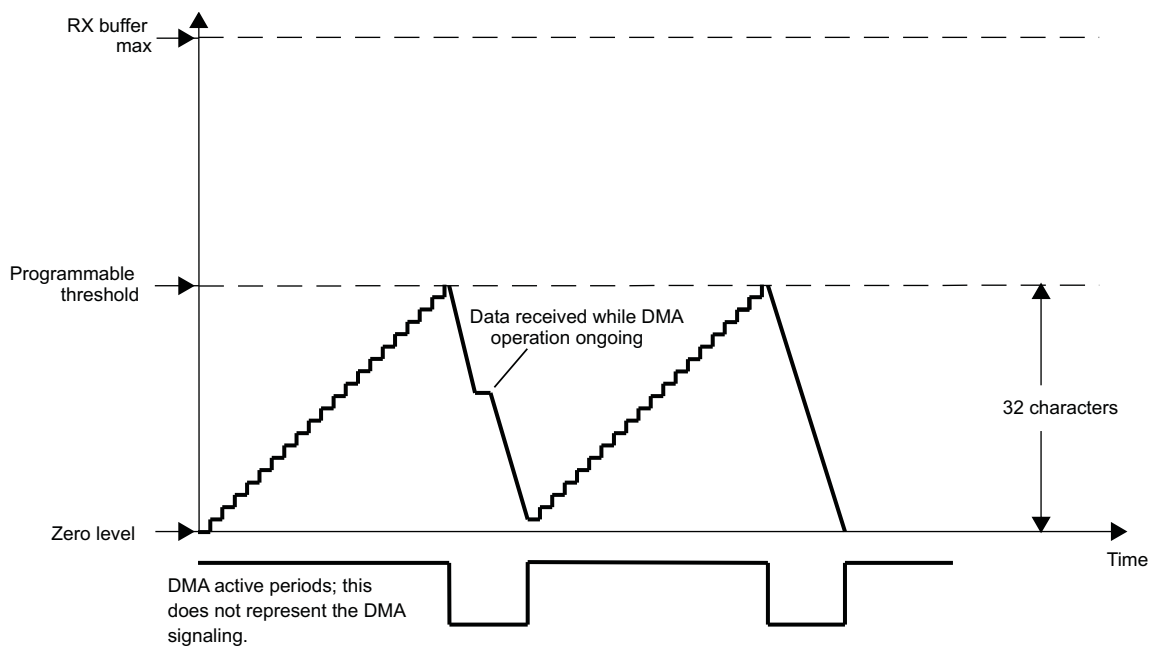

If the FIFOs are disabled (the UARTi.FCR_REG[0] FIFO_EN bit = 0), the DMA occurs in single-character transfers.

When DMA mode 0 is programmed, the signals associated with DMA operation are not active.

14.4.2.4.1 DMA Transfers (DMA Mode 1, 2, or 3)

[Figure 14-25](#) through [Figure 14-28](#) show the supported DMA operations.

Figure 14-25. Receive FIFO DMA Request Generation (32 Characters)

uart-026

In receive mode, a DMA request is generated when the receive FIFO reaches its threshold level defined in the trigger level register (UARTi.TLR_REG). This request is deasserted when the number of bytes defined by the threshold level is read by the system DMA (sDMA).

In transmit mode, a DMA request is automatically asserted when the transmit FIFO is empty. This request is deasserted when the number of bytes defined by the number of spaces in the trigger level register (UARTi.TLR_REG) is written by the sDMA. If an insufficient number of characters is written, the DMA request stays active.

Figure 14-26. Transmit FIFO DMA Request Generation (56 Spaces)

uart-027

The DMA request is again asserted if the FIFO can receive the number of bytes defined by the UARTi.TLR_REG register.

The threshold can be programmed in a number of ways. Figure 14-26 shows a DMA transfer operating with a space setting of 56 that can arise from using the auto settings in the UARTi.FCR_REG[5:4] TX_FIFO_TRIG field or the UARTi.TLR_REG[3:0] TX_FIFO_TRIG_DMA field concatenated with the TX_FIFO_TRIG field.

The setting of 56 spaces in the UART/IrDA/CIR module must correlate with the settings of the sDMA so that the buffer does not overflow (program the DMA request size of the local host controller to be equal to the number of spaces value in the UART/IrDA/CIR module).

Figure 14-27 shows an example with eight spaces to show the buffer level crossing the space threshold. Again, the local host DMA controller settings must correspond to that of the UART/IrDA/CIR module.

Figure 14-27. Transmit FIFO DMA Request Generation (8 Spaces)

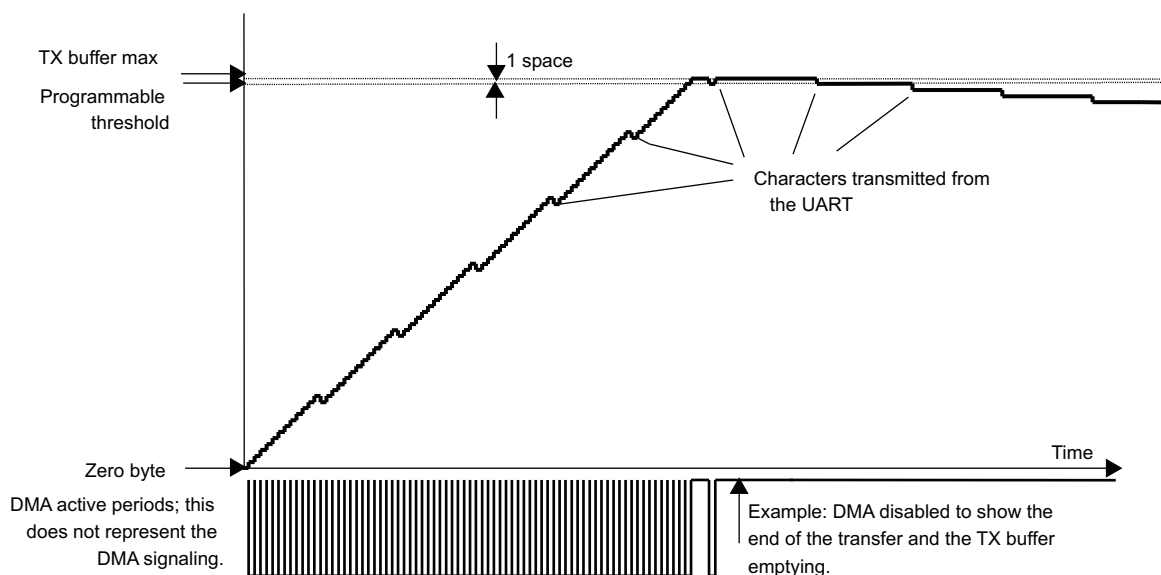

uart-028

The final example shows the setting of one space that uses the DMA for each transfer of one character to the transmit buffer (see Figure 14-28). The buffer is filled at a faster rate than the baud rate at which data is transmitted to the TX pin. Eventually, the buffer is completely full and the DMA operations stop transferring data to the transmit buffer.

On two occasions the buffer holds the maximum amount of data words; shortly after this, the DMA is disabled to show the slower transmission of the data words to the TX pin. Eventually, the buffer is emptied at the rate specified by the baud rate settings of the UARTi.DLL_REG and the UARTi.DLH_REG registers.

Again, the DMA settings must correspond to the system local host DMA controller settings to ensure correct operation of this logic.

Figure 14-28. Transmit FIFO DMA Request Generation (1 Space)

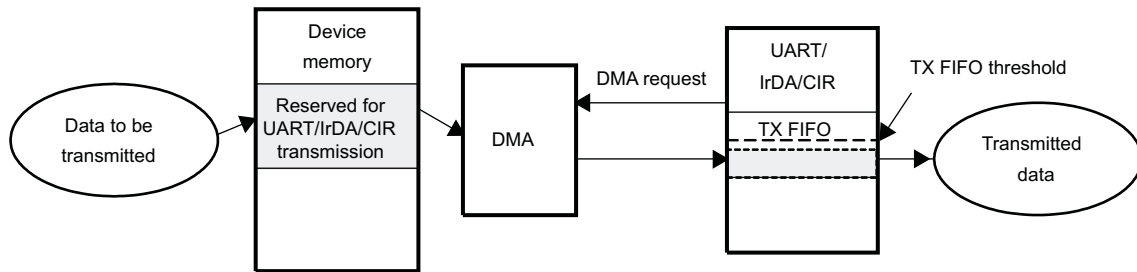

uart-029

14.4.2.4.2 DMA Transmission

Figure 14-29 shows the DMA transmission process.

Figure 14-29. Transmission Process

uart-030

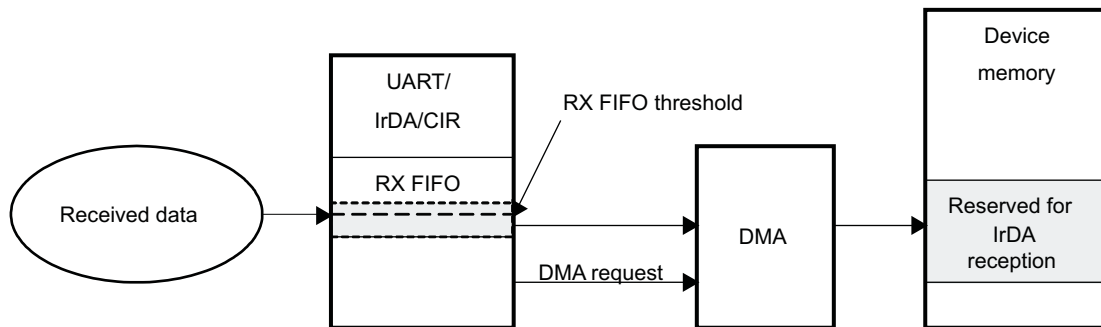

- Data to be transmitted are put in the device's memory reserved for UART/IrDA/CIR transmission by the DMA:
 - Until the TX FIFO trigger level is not reached, a DMA request is generated.
 - An element (1 byte) is transferred from the SDRAM to the TX FIFO at each DMA request (DMA element synchronization).
- Data in the TX FIFO are automatically transmitted.
- The end of the transmission is signaled by the UARTi.THR_REG empty (TX FIFO empty).

NOTE: In IrDA mode, the transmission is not ended immediately after the TX FIFO empties, at which point there are still the last data byte, the CRC field, and the stop flag to be transmitted; thus, the end of transmission is a few milliseconds after the UARTi.THR_REG register empties.

14.4.2.4.3 DMA Reception

Figure 14-30 shows the DMA reception process.

Figure 14-30. Reception Process

uart-031

1. Enable the reception.
2. Received data are put in the RX FIFO.
3. Data are transferred from the RX FIFO to the device memory by the DMA.
 - At each received byte, the RX FIFO trigger level (one character) is reached and a DMA request is generated.
 - An element (1 byte) is transferred from the RX FIFO to the SDRAM at each DMA request (DMA element synchronization).
4. The end of the reception is signaled by the EOF interrupt.

14.4.3 Mode Selection

14.4.3.1 Register Access Modes

14.4.3.1.1 Operational Mode and Configuration Modes

Register access depends on the register access mode, although register access modes are not correlated to functional mode selection. Three different modes are available:

- Operational mode
- Configuration mode A
- Configuration mode B

Operational mode is the selected mode when the function is active; serial data transfer can be performed in this mode.

Both configuration mode A and configuration mode B are used during module initialization steps. These modes enable access to configuration registers, which are hidden in the operational mode. The modes are used when the module is inactive (no serial data transfer processed) and only in the initialization step or reconfiguration of the module.

The value of the UARTi.LCR_REG register determines the register access mode (see [Table 14-18](#)).

Table 14-18. UART/IrDA/CIR Register Access Mode Programming (Using LCR_REG)

| Mode | Condition |
|----------------------|---|
| Configuration_mode_A | LCR_REG[7] = 0x1 and LCR_REG[7:0]! = 0xBF |
| Configuration_mode_B | LCR_REG[7] = 0x1 and LCR_REG[7:0] = 0xBF |
| Operational_mode | LCR_REG[7] = 0x0 |

14.4.3.1.2 Register Access Submode

In each access register mode (operational mode or configuration mode A/B), some register accesses are conditional to the programming of a submode (MSR_SPR, TCR_TLR, and XOFF). These registers are identified in [Section 14.6, UART/IrDA/CIR Registers](#).

[Table 14-19](#) through [Table 14-21](#) summarize the register access submodes.

Table 14-19. Sub-Configuration_Mode_A Mode Summary

| Mode | Condition |
|---------|--|
| MSR_SPR | (EFR_REG[4] = 0x0 or MCR_REG[6] = 0x0) |
| TCR_TLR | EFR_REG[4] = 0x1 and MCR_REG[6] = 0x1 |

Table 14-20. Sub-Configuration_Mode_B Mode Summary

| Mode | Condition |
|---------|--|
| TCR_TLR | EFR_REG[4] = 0x1 and MCR_REG[6] = 0x1 |
| XOFF | (EFR_REG[4] = 0x0 or MCR_REG[6] = 0x0) |

Table 14-21. Sub-Operational_Mode Mode Summary

| Mode | Condition |
|---------|---------------------------------------|
| MSR_SPR | EFR_REG[4] = 0x0 or MCR_REG[6] = 0x0) |
| TCR_TLR | EFR_REG[4] = 0x1 and MCR_REG[6] = 0x1 |

14.4.3.1.3 Registers Available for the Register Access Modes

[Table 14-22](#) lists the names of the register hits in each access register mode. Gray-shaded registers do not depend on the register access mode (available in all modes).

Table 14-22. UART/IrDA/CIR Register Access Mode Overview

| Address Offset | Registers | | | | | |
|-------------------|--|--|--|--|--|--|
| | Configuration_Mode_A | | Configuration_Mode_B | | Operational_Mode | |

⁽¹⁾ if MSR_SPR mode is active (see [Section 14.4.3.1.2, Register Access Submode](#))

⁽²⁾ if TCR_TLR mode is active (see [Section 14.4.3.1.2, Register Access Submode](#))

⁽³⁾ if XOFF mode is active (see [Section 14.4.3.1.2, Register Access Submode](#))

14.4.3.2 UART/IrDA (SIR, MIR, FIR)/CIR Mode Selection

To select a mode, set the UARTi.MDR1_REG[2:0] MODE_SELECT field (see [Table 14-23](#)).

Table 14-23. UART Mode Selection

| Value | Mode |
|-------|-----------------------|
| 0x0: | UART 16x mode |
| 0x1: | SIR mode (UART3 only) |
| 0x2: | UART 16x auto-baud |
| 0x3: | UART 13x mode |
| 0x4: | MIR mode (UART3 only) |
| 0x5: | FIR mode (UART3 only) |
| 0x6: | CIR mode (UART3 only) |

MODE_SELECT is effective when the module is in operational mode (see [Section 14.4.3.1](#), *Register Access Modes*).

14.4.3.2.1 Registers Available for the UART Function

Only the registers listed in [Table 14-24](#) are used for the UART function.

Table 14-24. UART Mode Register Overview^{(1) (2)}

| Address Offset | Registers | | | | | |
|-------------------|----------------------|-----------------|----------------------|-------------------|------------------|-----------------|

⁽¹⁾ REGISTER_NAME(UART) notation indicates that the register exists for other functions (IrDA or CIR), but fields have different meanings for other functions (described separately in [Section 14.6, UART/IrDA/CIR Registers](#)).

⁽²⁾ REGISTER_NAME[m:n] notation indicates that only register bits numbered m to n apply to the UART function.

14.4.4 Protocol Formatting

14.4.4.1 UART Mode

14.4.4.1.1 UART Clock Generation: Baud Rate Generation

The UART function contains a programmable baud generator and a set of fixed divisors that divide the 48-MHz clock input down to the expected baud rate.

Figure 14-31 shows the baud rate generator and associated controls.

uart-032

CAUTION

It is mandatory that MODE_SELECT = DISABLE (UARTi.MDR1_REG[2:0] = 0x7) before initializing or modifying clock parameter controls (UARTi.DLH_REG, UARTi.DLL_REG). Failure to observe this rule can result in unpredictable module behavior.

14.4.4.1.2 Choosing the Appropriate Divisor Value

Two divisor values are:

- UART 16x mode: Divisor value = Operating frequency/(16x baud rate)
- UART 13x mode: Divisor value = Operating frequency/(13x baud rate)

Table 14-27 describes the UART baud rate settings.

Table 14-27. UART Baud Rate Settings (48-MHz Clock)

| Baud Rate | Baud Multiple | DLH, DLL (Decimal) | DLH, DLL (Hex) | Actual Baud Rate | Error (%) |
|------------|---------------|--------------------|----------------|------------------|-----------|
| 0.3 Kbps | 16x | 10000 | 0x27, 0x10 | 0.3 Kbps | 0 |
| 0.6 Kbps | 16x | 5000 | 0x13, 0x88 | 0.6 Kbps | 0 |
| 1.2 Kbps | 16x | 2500 | 0x09, 0xC4 | 1.2 Kbps | 0 |
| 2.4 Kbps | 16x | 1250 | 0x04, 0xE2 | 2.4 Kbps | 0 |
| 4.8 Kbps | 16x | 625 | 0x02, 0x71 | 4.8 Kbps | 0 |
| 9.6 Kbps | 16x | 312 | 0x01, 0x38 | 9.6153 Kbps | +0.16 |
| 14.4 Kbps | 16x | 208 | 0x00, 0xD0 | 14.423 Kbps | +0.16 |
| 19.2 Kbps | 16x | 156 | 0x00, 0x9C | 19.231 Kbps | +0.16 |
| 28.8 Kbps | 16x | 104 | 0x00, 0x68 | 28.846 Kbps | +0.16 |
| 38.4 Kbps | 16x | 78 | 0x00, 0x4E | 38.462 Kbps | +0.16 |
| 57.6 Kbps | 16x | 52 | 0x00, 0x34 | 57.692 Kbps | +0.16 |
| 115.2 Kbps | 16x | 26 | 0x00, 0x1A | 115.38 Kbps | +0.16 |

Table 14-27. UART Baud Rate Settings (48-MHz Clock) (continued)

| Baud Rate | Baud Multiple | DLH, DLL (Decimal) | DLH, DLL (Hex) | Actual Baud Rate | Error (%) |
|-------------|---------------|--------------------|----------------|------------------|-----------|
| 230.4 Kbps | 16x | 13 | 0x00, 0x0D | 230.77 Kbps | +0.16 |
| 460.8 Kbps | 13x | 8 | 0x00, 0x08 | 461.54 Kbps | +0.16 |
| 921.6 Kbps | 13x | 4 | 0x00, 0x04 | 923.08 Kbps | +0.16 |
| 1.843 Mbps | 13x | 2 | 0x00, 0x02 | 1.846 Mbps | +0.16 |
| 3.6884 Mbps | 13x | 1 | 0x00, 0x01 | 3.6923 Mbps | +0.16 |

14.4.4.1.3 UART Data Formatting

The UART module can use hardware flow control to manage transmission/reception. Hardware flow control significantly reduces software overhead and increases system efficiency by automatically controlling serial data flow using the RTS output and CTS input signals.

The UART module is enhanced with the autobauding function. In control mode, autobauding allows the speed, the number of bits per character, and the parity selected to be set automatically.

14.4.4.1.3.1 Frame Formatting

When autobauding is not used, frame format attributes must be defined in the UARTi.LCR_REG register. Character length is specified using the UARTi.LCR_REG[1:0] CHAR_LENGTH field.

The number of stop bits is specified using the UARTi.LCR_REG[2] NB_STOP register bit.

The parity bit is programmed using the UARTi.LCR_REG[5:3] PARITY_EN, PARITY_TYPE_1, and PARITY_TYPE_2 register bits (see [Table 14-28](#)).

Table 14-28. UART Parity Bit Encoding

| PARITY_EN | PARITY_TYPE1 | PARITY_TYPE2 | Parity |
|-----------|--------------|--------------|-------------|
| 0 | N/A | N/A | No parity |
| 1 | 0 | 0 | Odd parity |
| 1 | 1 | 0 | Even parity |
| 1 | 0 | 1 | Forced 1 |
| 1 | 1 | 1 | Forced 0 |

14.4.4.1.3.2 Hardware Flow Control

Hardware flow control is composed of auto-CTS and auto-RTS. Auto-CTS and auto-RTS can be enabled/disabled independently by programming the UARTi.EFR_REG[7:6] AUTO_CTS_EN and AUTO_RTS_EN bits, respectively.

With auto-CTS, uarti_cts must be active before the module can transmit data.

Auto-RTS activates the uarti_rts output only when there is enough room in the RX FIFO to receive data. It deactivates the uarti_rts output when the RX FIFO is sufficiently full. The HALT and RESTORE trigger levels in the UARTi.TCR_REG register determine the levels at which uarti_rts is activated/deactivated.

If both auto-CTS and auto-RTS are enabled, data transmission does not occur unless the receiver FIFO has empty space. Thus, overrun errors are eliminated during hardware flow control. If auto-CTS and auto-RTS are not enabled, overrun errors occur if the transmit data rate exceeds the receive FIFO latency.

- **Auto-RTS**

Auto-RTS data flow control originates in the receiver block. The receiver FIFO trigger levels used in auto-RTS are stored in the UARTi.TCR_REG register. uarti_rts is active if the RX FIFO level is below the HALT trigger level in the UARTi.TCR_REG[3:0] RX_FIFO_TRIG_HALT field. When the receiver FIFO HALT trigger level is reached, uarti_rts is deasserted. The sending device (for example, another UART) might send an additional byte after the trigger level is reached because it might not recognize the deassertion of RTS until it begins sending the additional byte.

uarti_rts is automatically reasserted when the receiver FIFO reaches the RESUME trigger level

programmed by the UARTi.TCR_REG[7:4] RX_FIFO_TRIG_START field. This reassertion requests the sending device to resume transmission.

In this case, uarti_rts is an active-low signal.

- **Auto-CTS**

The transmitter circuitry checks uarti_cts before sending the next data byte. When uarti_cts is active, the transmitter sends the next byte. To stop the transmitter from sending the next byte, uarti_cts must be deasserted before the middle of the last stop bit currently sent.

The auto-CTS function reduces interrupts to the host system. When auto-CTS flow control is enabled, the uarti_cts state changes do not have to trigger host interrupts because the device automatically controls its own transmitter. Without auto-CTS, the transmitter sends any data present in the transmit FIFO, and a receiver overrun error can result.

In this case, uarti_cts is an active-low signal.

14.4.4.1.3.3 Software Flow Control

Software flow control is enabled through the enhanced feature register (UARTi.EFR_REG) and the modem control register (UARTi.MCR_REG). Different combinations of software flow control can be enabled by setting different combinations of UARTi.EFR_REG[3:0] (see [Table 14-29](#)).

Two other enhanced features relate to software flow control:

- XON any function (UARTi.MCR_REG[5]): Operation resumes after receiving any character after recognition of the XOFF character.

NOTE: The XON-any character is written into the RX FIFO even if it is a software flow character.

- Special character (UARTi.EFR_REG[5]): Incoming data is compared to XOFF2. When the special character is detected, the XOFF interrupt (UARTi.IIR_REG[4]) is set, but it does not halt transmission. The XOFF interrupt is cleared by a read of UARTi.IIR_REG. The special character is transferred to the RX FIFO.

Table 14-29. EFR_REG[0-3] Software Flow Control Options

| Bit 3 | Bit 2 | Bit 1 | Bit 0 | Tx, Rx Software Flow Controls |
|-------|-------|-------|-------|---|
| 0 | 0 | X | X | No transmit flow control |
| 1 | 0 | X | X | Transmit XON1, XOFF1 |
| 0 | 1 | X | X | Transmit XON2, XOFF2 |
| 1 | 1 | X | X | Transmit XON1, XON2: XOFF1, XOFF2 ⁽¹⁾ |
| X | X | 0 | 0 | No receive flow control |
| X | X | 1 | 0 | Receiver compares XON1, XOFF1 |
| X | X | 0 | 1 | Receiver compares XON2, XOFF2 |
| X | X | 1 | 1 | Receiver compares XON1, XON2: XOFF1, XOFF2 ⁽¹⁾ |

⁽¹⁾ In these cases, the XON1 and XON2 characters or the XOFF1 and XOFF2 characters must be transmitted/received sequentially with XON1/XOFF1 followed by XON2/XOFF2.

XON1 is defined in the UARTi.XON1_ADDR1_REG[7:0] XON_WORD1 field, XON2 is defined in UARTi.XON2_ADDR2_REG[7:0] XON_WORD2.

XOFF1 is defined in the UARTi.XOFF1_REG[7:0] XOFF_WORD1 field, XOFF2 is defined in UARTi.XOFF2_REG[7:0] XOFF_WORD2.

14.4.4.1.3.3.1 Receive (RX)

When software flow control operation is enabled, the UART compares incoming data with XOFF1/2 programmed characters (in certain cases, XOFF1 and XOFF2 must be received sequentially). When the correct XOFF characters are received, transmission stops after transmission of the current character is complete. XOFF detection also sets UARTi.IIR_REG[4] (if enabled by UARTi.IER_REG[5]) and causes the interrupt line to go low.

To resume transmission, an XON1/2 character must be received (in certain cases, XON1 and XON2 must be received sequentially). When the correct XON characters are received, UARTi.IIR_REG[4] is cleared and the XOFF interrupt disappears.

NOTE: When a parity, framing, or break error occurs while receiving a software flow control character, this character is treated as normal data and is written to the RX FIFO.

When XON-any and special character detect are disabled and software flow control is enabled, no valid XON or XOFF characters are written to the RX FIFO. For example, when UARTi.EFR_REG[1:0] = 0x2, if XON1 and XOFF1 characters are received, they do not get written to the RX FIFO.

When pairs of software flow characters are programmed to be received sequentially (UARTi.EFR_REG[1:0] = 0x3), the software flow characters are not written to the RX FIFO if they are received sequentially. However, received XON1/XOFF1 characters must be written to the RX FIFO if the subsequent character is not XON2/XOFF2.

14.4.4.1.3.3.2 Transmit (TX)

XOFF1: Two characters are transmitted when the RX FIFO passes the trigger level programmed by UARTi.TCR_REG[3:0].

XON1: Two characters are transmitted when the RX FIFO reaches the trigger level programmed by UARTi.TCR_REG[7:4].

NOTE: If software flow control is disabled after an XOFF character is sent, the module transmits XON characters automatically to enable normal transmission to proceed.

The transmission of XOFF(s)/XON(s) follows the same protocol as transmission of an ordinary byte from the TX FIFO. This means that even if the word length is set to 5, 6, or 7 characters, the 5, 6, or 7 LSBs of XOFF1/2 and XON1/2 are transmitted. The 5, 6, or 7 bits of a character are seldom transmitted, but this function is included to maintain compatibility with earlier designs.

It is assumed that software flow control and hardware flow control are never enabled simultaneously.

14.4.4.1.3.4 Autobauding Modes

In autobauding mode, the UART can extract transfer characteristics (speed, length, and parity) from an AT command (ASCII code). These characteristics are used to receive data after an “at” (AT) and to send data.

The valid AT commands follow:

| | | |
|----|------|------|
| AT | DATA | <CR> |
| at | DATA | <CR> |
| A/ | | |
| a/ | | |

A line break during the acquisition of the sequence AT is not recognized, and echo functionality is not implemented in hardware.

A/ and a/ are not used to extract characteristics, but they must be recognized because of their special meaning. Either A/ or a/ is used to instruct the software to repeat the last received AT command; therefore, an a/ always follows an AT, and transfer characteristics are not expected to change between an AT and an a/.

When a valid AT is received, AT and all subsequent data, including the final <CR> (0x0D), are saved to RX FIFO. The autobaud state-machine waits for the next valid AT command. If an a/ (A/) is received, the a/ (A/) is saved into RX FIFO and the state-machine waits for the next valid AT command.

On the first successful detection of the baud rate, the UART activates an interrupt to signify that the AT (upper or lower case) sequence is detected. The UARTi.UASR_REG register reflects the correct settings for the baud rate detected. The interrupt activity can continue in this fashion when a subsequent character is received. Therefore, it is recommended that the software enable the RHR interrupt when using the autobaud mode.

The following settings are detected in autobaud mode with a module clock of 48 MHz:

- Speed: 115.2k baud, 57.6k baud, 38.4k baud, 28.8k baud, 19.2k baud, 14.4k baud, 9.6k baud, 4.8k baud, 2.4k baud, or 1.2k baud
- Length: 7 or 8 bits
- Parity: Odd, even, or space

NOTE: The combination of 7-bit character + space parity is not supported.

Autobauding mode is selected when the UARTi.MDR1_REG[2:0] MODE_SELECT field is set to 0x2. In the UART autobauding mode, UARTi.DLL_REG, UARTi.DLH_REG, UARTi.LCR_REG[5:0] settings are not used; instead, UASR_REG is updated with the configuration detected by the autobauding logic.

UASR_REG Autobauding Status Register Use

This register is used to set up transmission according to the characteristics of the previous reception instead of the UARTi.LCR_REG, UARTi.DLL_REG, and UARTi.DLH_REG registers when the UART is in autobauding mode.

To reset the autobauding hardware (to start a new AT detection) or to set the UART in standard mode (no autobaud), the UARTi.MDR1_REG[2:0] MODE_SELECT field must be set to reset state (0x7) and then to the UART in autobauding mode (0x2) or to the UART in standard mode (0x0).

Use limitation:

- Only 7- and 8-bit characters (5- and 6-bit not supported)
- 7-bit character with space parity not supported
- Baud rate between 1,200 and 115,200 bps (10 possibilities)

14.4.4.1.3.5 Error Detection

When the UARTi.LSR_REG register is read, UARTi.LSR_REG[4:2] reflects the error bits (BI: break condition, FE: framing error, PE: parity error) of the character at the top of the RX FIFO (next character to be read). Therefore, reading the UARTi.LSR_REG register and then reading the UARTi.RHR_REG register identifies errors in a character.

Reading the UARTi.RHR_REG register updates the BI, FE, and PE bits (see [Table 14-30](#) for the UART mode interrupts).

The UARTi.LSR_REG [7] RX_FIFO_STS bit is set when there is an error in the RX FIFO and is cleared only when no errors remain in the RX FIFO.

NOTE: Reading UARTi.LSR_REG does not cause an increment of the RX FIFO read pointer. The RX FIFO read pointer is incremented by reading UARTi.RHR_REG.

Reading UARTi.LSR_REG clears the OE bit if it is set (see [Table 14-30](#) for the UART mode interrupts).

14.4.4.1.3.6 Overrun During Receive

Overrun during receive occurs if the RX state-machine tries to write data into the RX FIFO when it is already full. When overrun occurs, the device interrupts the MPU with UARTi.IIR_REG[5:1] IT_TYPE = 0x3 (receiver line status error) and discards the remaining portion of the frame.

Overrun also causes an internal flag to be set, which disables further reception. Before the next frame can be received, the system (MPU) must:

- Reset the RX FIFO
- Read the UARTi.RESUME_REG register (which clears the internal flag)

14.4.4.1.3.7 Time-Out and Break Conditions

14.4.4.1.3.7.1 Time-Out Counter

An RX idle condition is detected when the receiver line (uarti_rx) is high for a time equivalent to 4x programmed word length + 12 bits. uarti_rx is sampled midway through each bit.

For sleep mode, the counter is reset when there is activity on uarti_rx.

For the time-out interrupt, the counter counts only when there is data in the RX FIFO, and the count is reset when there is activity on uarti_rx or when the UARTi.RHR_REG is read.

14.4.4.1.3.7.2 Break Condition

When a break condition occurs, uarti_tx is pulled low. A break condition is activated by setting the UARTi.LCR_REG[6] BREAK_EN bit. The break condition is not aligned on word stream (that is, a break condition can occur in the middle of a character). The only way to send a break condition on a full character is as follows:

1. Reset the transmit FIFO (if enabled).
2. Wait for the transmit shift register to empty (UARTi.LSR_REG[6] TX_SR_E = 1).
3. Take a guard time according to stop-bit definition.
4. Set the BREAK_EN bit to 1.

The break condition is asserted while the BREAK_EN bit is set to 1.

The time-out counter and break condition apply only to UART modem operation and not to IrDA/CIR mode operation.

14.4.4.1.4 UART Mode Interrupt Management

The UART mode includes seven possible interrupts prioritized to six levels.

When an interrupt is generated, the interrupt identification register (UARTi.IIR_REG) sets the UARTi.IIR_REG[0] IT_PENDING bit to 0 to indicate that an interrupt is pending, and provides the type of interrupt through UARTi.IIR_REG[5:1]. [Table 14-30](#) summarizes the interrupt control functions.

Table 14-30. UART Mode Interrupts

| IIR_REG[5:0] | Priority Level | Interrupt Type | Interrupt Source | Interrupt Reset Method |
|--------------|----------------|--|---|--|
| 000001 | None | None | None | None |
| 000110 | 1 | Receiver line status | OE, FE, PE, or BI errors occur in characters in the RX FIFO. | FE, PE, BI: Read RHR_REG. OE: Read LSR_REG. |
| 001100 | 2 | RX time-out | Stale data in RX FIFO | Read RHR_REG. |
| 000100 | 2 | RHR interrupt | DRDY (data ready) (FIFO disable) | Read RHR_REG until interrupt condition disappears. |
| | | | RX FIFO above trigger level (FIFO enable) | |
| 000010 | 3 | THR interrupt | TFE (THR_REG empty) (FIFO disable) | Write to THR_REG until interrupt condition disappears. |
| | | | TX FIFO below trigger level (FIFO enable) | |
| 000000 | 4 | Modem status | See the MSR_REG register. | Read MSR_REG. |
| 010000 | 5 | XOFF interrupt/special character interrupt | Receive XOFF characters/special character | Receive XON character(s), if XOFF interrupt/read of IIR_REG, if special character interrupt. |
| 100000 | 6 | CTS, RTS | RTS pin or CTS pin change state from active (low) to inactive (high). | Read IIR_REG. |

For the receiver-line status interrupt, the RX_FIFO_STS bit (UARTi.LSR_REG[7]) generates the interrupt.

For the XOFF interrupt, if an XOFF flow character detection caused the interrupt, the interrupt is cleared by an XON flow character detection. If special character detection caused the interrupt, the interrupt is cleared by a read of the UARTi.IIR_REG register.

14.4.4.1.4.1 Wake-Up Interrupt

Wake-up interrupt is a special interrupt that is not designed the same way as other interrupts. This interrupt is enabled when the UARTi.SCR_REG[4] RX_CTS_WU_EN bit is set to 1. The UARTi.IIR_REG register is not modified when it occurs; the UART3.SSR_REG[1] RX_CTS_WU_STS bit must be checked to detect a wake-up event.

When a wake-up interrupt occurs, the only way to clear it is to reset the UARTi.SCR_REG[4] RX_CTS_WU_EN bit. This bit must be re-enabled (set to 1) after the current wake-up interrupt event is processed to detect the next incoming wake-up event.

14.4.4.2 IrDA Mode (UART3 Only)

14.4.4.2.1 IrDA Clock Generation: Baud Generator

The IrDA function contains a programmable baud generator and a set of fixed dividers that divide the 48-MHz clock input down to the expected baud rate.

Figure 14-32 shows the baud rate generator and associated controls.

Figure 14-32. Baud Rate Generator

uart-033

CAUTION

Before trying to initialize or modify clock parameter controls (UARTi.DLH_REG, UARTi.DLL_REG), it is mandatory to set MODE_SELECT=DISABLE (UARTi.MDR1_REG[2:0]=0x7).

Failure to observe this rule can result in unpredictable module behavior.

14.4.4.2.2 Choosing the Appropriate Divisor Value

- SIR mode: Divisor value = Operating frequency/(16x baud rate)
- MIR mode: Divisor value = Operating frequency/(41x/42x baud rate)
- FIR mode: Divisor value = None

Table 14-31 lists the IrDA baud rate settings.

Table 14-31. IrDA Baud Rates Settings

| Baud Rate | IR Mode | Baud Multiple | Encoding | DLH, DLL (Decimal) | Actual Baud Rate | Error (%)\$ | Source Jitter (%) | Pulse duration |
|------------|---------|---------------|----------|--------------------|----------------------------|-------------|-------------------|----------------|
| 2.4 Kbps | SIR | 16x | 3/16 | 1250 | 2.4 Kbps | 0 | 0 | 78.1 μ s |
| 9.6 Kbps | SIR | 16x | 3/16 | 312 | 9.6153 Kbps | +0.16 | 0 | 19.5 μ s |
| 19.2 Kbps | SIR | 16x | 3/16 | 156 | 19.231 Kbps | +0.16 | 0 | 9.75 μ s |
| 38.4 Kbps | SIR | 16x | 3/16 | 78 | 38.462 Kbps | +0.16 | 0 | 4.87 μ s |
| 57.6 Kbps | SIR | 16x | 3/16 | 52 | 57.692 Kbps | +0.16 | 0 | 3.25 μ s |
| 115.2 Kbps | SIR | 16x | 3/16 | 26 | 115.38 Kbps | +0.16 | 0 | 1.62 μ s |
| 0.576 Mbps | MIR | 41x/42x | 1/4 | 2 | 0.5756 Mbps ⁽¹⁾ | 0 | +1.63/- 0.80 | 416 ns |
| 1.152 Mbps | MIR | 41x/42x | 1/4 | 1 | 1.1511 Mbps ⁽¹⁾ | 0 | +1.63/- 0.80 | 208 ns |
| 4 Mbps | FIR | 6x | 4 PPM | - | 4 Mbps | 0 | 0 | 125 ns |

⁽¹⁾ Average value

NOTE: Baud rate error and source jitter table values do not include 48-MHz reference clock error and jitter.

14.4.4.2.3 IrDA Data Formatting

The methods described in this section apply to all IrDA modes (SIR, MIR, and FIR).

14.4.4.2.3.1 IRRX Polarity Control

The UART3.MDR2_REG[6] IRRXINVERT bit provides the flexibility to invert the uart3_rx_irrx pin in the UART module to ensure that the protocol at the output of the transceiver module has the same polarity at module level. By default, the uart3_rx_irrx pin is inverted because most transceivers invert the IR receive pin.

14.4.4.2.3.2 IrDA Reception Control

Data can be transferred both ways by the module, but when the device is transmitting, the IR RX circuitry is automatically disabled by hardware.

Operation of the uart3_rx_irrx input can be disabled by the UART3.ACREG_REG[5] DIS_IR_RX bit.

14.4.4.2.3.3 IR Address Checking

In all IR modes, when address checking is enabled, only frames intended for the device are written to the RX FIFO. This restriction avoids receiving frames not meant for this device in a multipoint infrared environment. It is possible to program two frame addresses that the UART IrDA receives with the UART3.XON1_ADDR1_REG[7:0] XON_WORD1 and UART3.XON2_ADDR2_REG[7:0] XON_WORD2 fields.

Setting the EFR_REG[0] bit to 1 selects address1 checking. Setting the EFR_REG[1] bit to 1 selects address2 checking. Setting the EFR_REG[1:0] bit to 0 disables all address checking operations. If both bits are set, the incoming frame is checked for both private and public addresses.

If address checking is disabled, all received frames write to the reception FIFO.

14.4.4.2.3.4 Frame Closing

A transmission frame can be correctly terminated in two ways:

- **Frame-length method:** The frame-length method is selected by setting the UART3.MDR1_REG[7] FRAME_END_MODE bit to 0. The MPU writes the frame-length value to the UART3.TXFLH_REG and UART3.TXFLR_REG registers. The device automatically attaches end flags to the frame when the number of bytes transmitted equals the frame-length value.
- **Set-EOT bit method:** The set-EOT bit method is selected by setting the FRAME_END_MODE bit to 1. The MPU writes 1 to the UART3.ACREG_REG[0] EOT bit just before it writes the last byte to the TX FIFO. When the MPU writes the last byte to the TX FIFO, the device internally sets the tag bit for that character in the TX FIFO. As the TX state-machine reads data from the TX FIFO, it uses this tag-bit information to attach end flags and correctly terminate the frame.

14.4.4.2.3.5 Store and Controlled Transmission

In store and controlled transmission (SCT) mode, the MPU starts writing data to the TX FIFO. Then, after writing a part of a frame (for a bigger frame) or a whole frame (a small frame; that is, a supervisory frame), the MPU writes 1 to the UART3.ACREG_REG[2] SCTX_EN bit (deferred TX start) to start transmission.

SCT mode is enabled by setting the UART3.MDR1_REG[5] SCT bit to 1. This transmission method is different from the normal mode, in which data transmission starts immediately after data is written to the TX FIFO. SCT mode is useful for sending short frames without TX underrun.

14.4.4.2.3.6 Error Detection

When the UART3.LSR_REG register is read, the UART3.LSR_REG[4:2] field reflects the error bits [FL, CRC, ABORT] of the frame at the top of the STATUS FIFO (the next frame status to be read).

The error is triggered by an interrupt (see [Table 14-32](#) for IrDA mode interrupts). STATUS FIFO must be read until empty (a maximum of eight reads is required).

14.4.4.2.3.7 Underrun During Transmission

Underrun during transmission occurs when the TX FIFO is empty before the end of the frame is transmitted. When underrun occurs, the device closes the frame with end flags but attaches an incorrect CRC value. The receiving device detects a CRC error and discards the frame; it can then ask for a retransmission.

Underrun also causes an internal flag to be set, which disables additional transmissions. Before the next frame can be transmitted, the system (MPU) must:

- Reset the TX FIFO.
- Read the UART3.RESUME_REG register (which clears the internal flag).

This functionality can be disabled by the UART3.ACREG_REG[4] DIS_TX_UNDERRUN bit, compensated by the extension of the stop bit in transmission if the TX FIFO is empty.

14.4.4.2.3.8 **Overrun During Receive**

Overrun during receive for the IrDA mode has the same functionality as that for the UART mode (see [Section 14.4.4.1.3.6, Overrun During Receive](#)).

14.4.4.2.3.9 **Status FIFO**

In IrDA modes, a status FIFO records the received frame status. When a complete frame is received, the length of the frame and the error bits associated with the frame are written to the status FIFO.

Reading UART3.SFREGH_REG[3:0] (MSB) and UART3.SFREGL_REG[3:0] (LSB) obtains the frame length. The frame error status is read in the UART3.SFLSR_REG register. Reading the UART3.SFLSR_REG register increments the status FIFO read pointer. The status FIFO is eight entries deep and, therefore, can hold the status of eight frames.

The MPU uses the frame-length information to locate the frame boundary in the received frame data. The MPU can screen bad frames using the error status information and can later request the sender to resend only the bad frames.

This status FIFO can be used effectively in DMA mode because the MPU must be interrupted only when the programmed status FIFO trigger level is reached, not each time a frame is received.

14.4.4.2.4 **SIR Mode DATA Formatting**

This section provides specific instructions for SIR mode programming.

14.4.4.2.4.1 **Abort Sequence**

When the transmitter prematurely closes a frame, it sends the following sequence to abort: 0x7DC1. The abort pattern closes the frame without a CRC field or an ending flag.

A transmission frame can be aborted by setting the UART3.ACREG_REG[1] ABORT_EN bit to 1.

When this bit is set to 1, 0x7D and 0xC1 are transmitted and the frame is not terminated with CRC or stop flags.

The receiver treats a frame as an aborted frame when a 0x7D character followed immediately by a 0xC1 character is received without transparency.

CAUTION

When the transmit FIFO is not empty and the UART3.MDR1_REG[5] SCT bit is set to 1, the UART IrDA starts a new transfer with data of a previous frame when the abort frame is sent. Therefore, TX FIFO must be reset before sending an abort frame.

14.4.4.2.4.2 **Pulse Shaping**

The SIR mode supports both the 3/16th or the 1.6- μ s pulse duration methods. The UART3.ACREG_REG[7] PULSE_TYPE bit selects the pulse width method in the transmit mode.

14.4.4.2.4.3 **SIR Free Format Programming**

The SIR FF mode is selected by setting the module in the UART mode (UART3.MDR1_REG[2:0] MODE_SELECT = 0x0) and the UART3.MDR2_REG[3] UART_PULSE bit to 1 to allow pulse shaping.

Because the bit format remains the same, some UART mode configuration registers must be set at specific values:

- UART3.LCR_REG[1:0] CHAR_LENGTH field = 0x3 (8 data bits)
- UART3.LCR_REG[2] NB_STOP bit = 0x0 (1 stop-bit)
- UART3.LCR_REG[3] PARITY_EN bit = 0x0 (no parity)

The UART mode interrupts are used for the SIR FF mode, but many of them are not relevant (XOFF, RTS, CTS, modem status register, etc.).

14.4.4.2.5 MIR and FIR Mode Data Formatting

This section describes common instructions for FIR and MIR mode programming.

At the end of a frame reception, the MPU reads the line status register (UART3.LSR_REG) to detect possible errors in the received frame.

When the UART3.MDR1_REG[6] SIP_MODE bit is set to 1, the TX state-machine always sends one SIP at the end of a transmission frame. However, when the SIP_MODE bit is set to 0, SIP transmission depends on the UART3.ACREG_REG[3] SEND_SIP bit.

The system (MPU) can set the SEND_SIP bit at least once every 500 ms. The advantage of this approach over the default approach is that the TX state-machine does not have to send the SIP at the end of each frame, which can reduce the overhead required.

14.4.4.2.6 IrDA Mode Interrupt Management

14.4.4.2.6.1 IrDA Interrupts

The IrDA function generates interrupts. All interrupts can be enabled/disabled by writing to the appropriate bit in the interrupt enable register (UART3.IER_REG). The interrupt status of the device can be checked at any time by reading the interrupt identification register (UART3.IIR_REG).

The UART, IrDA, and CIR modes have different interrupts in the UART/IrDA/CIR module and, therefore, different UART3.IER_REG and UART3.IIR_REG mappings, depending on the selected mode.

The IrDA modes have eight possible interrupts (see [Table 14-32](#)). The interrupt line is activated when any of the eight interrupts is generated (there is no priority).

Table 14-32. IrDA Mode Interrupts

| IIR_REG Bit | Interrupt Type | Interrupt Source | Interrupt Reset Method |
|-------------|--------------------------------|---|--|
| 0 | RHR interrupt | DRDY (data ready) (FIFO disable) RX FIFO above trigger level (FIFO enable) | Read RHR_REG until interrupt condition disappears. |
| 1 | THR interrupt | TFE (THR_REG empty) (FIFO disable) TX FIFO below trigger level (FIFO enable) | Write to THR_REG until interrupt condition disappears. |
| 2 | Last byte in RX FIFO | Last byte of frame in RX FIFO is available to be read at the RHR port. | Read RHR_REG. |
| 3 | RX overrun | Write to RHR_REG when RX FIFO full. | Read RESUME_REG register. |
| 4 | Status FIFO interrupt | Status FIFO triggers level reached. | Read STATUS FIFO. |
| 5 | TX status | 1. THR_REG empty before EOF sent. Last bit of transmission of the IrDA frame occurred, but with an underrun error. OR 2. Transmission of the last bit of the IrDA frame completed successfully. | 1. Read RESUME_REG register. OR 2. Read IIR_REG. |
| 6 | Receiver line status interrupt | CRC, ABORT, or frame-length error is written into STATUS FIFO. | Read STATUS FIFO (read until empty - maximum of eight reads required). |
| 7 | Received EOF | Received end-of-frame. | Read IIR_REG. |

14.4.4.2.6.2 Wake-Up Interrupts

The wake-up interrupt for the IrDA mode has the same functionality as that for the UART mode (see [Section 14.4.4.1.4.1, Wake-Up Interrupt](#)).

CAUTION

Wake-up interface implementation in this mode is based on the UARTi_SIDLEACK low-to-high transition instead of the UARTi_SIDLEACK state.

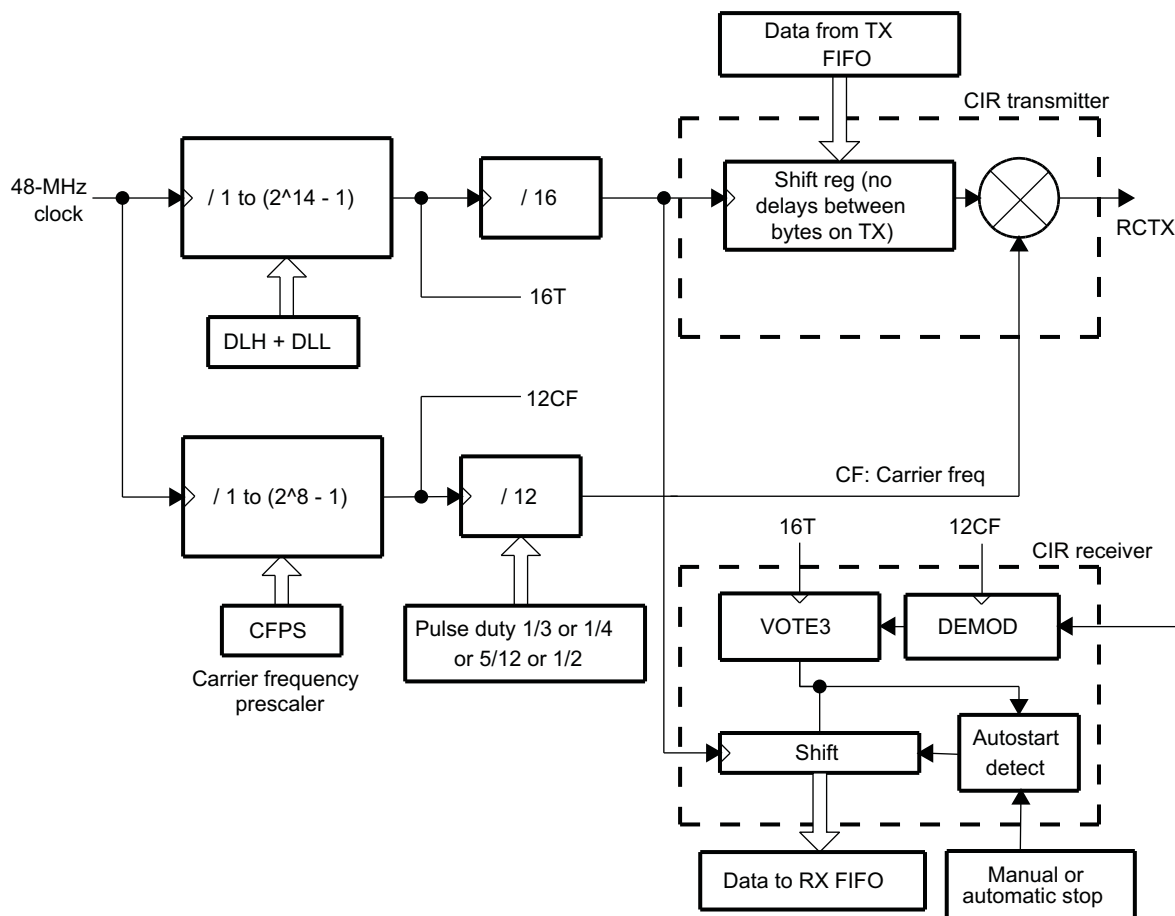

This does not ensure wake-up event generation as expected when configured in smart-idle mode and the system wakes up for a short period.

14.4.4.3 CIR Mode (UART3 Only)

14.4.4.3.1 CIR Mode Clock Generation

Depending on the encoding method (variable pulse distance/biphase), the MPU must develop a data structure that combines 1 and 0 with a t period to encode the complete frame to transmit. This can then be transmitted to the infrared output with a modulation method, as shown in [Figure 14-33](#).

Figure 14-33. CIR Mode Block Components

uart-034

Based on the requested modulation frequency, the UART3.CFPS_REG register must be set with the correct dividing value to provide the more accurate pulse frequency:

$$\text{Dividing value} = (\text{FCLK}/12)/\text{MODfreq}$$

Where:

FCLK = System clock frequency (48 MHz)

12 = Real value of baud multiple

MODfreq = Effective frequency of the modulation (MHz)

Example: For a targeted modulation frequency of 36 kHz, the CFPS_REG value must be set to 111 (decimal), which provides a modulation frequency of 36.04 kHz.

NOTE: The UART3.CFPS_REG register starts with a reset value of 105 (decimal), which translates to a frequency of 38.1 kHz.

The duty cycle of these pulses is user-defined by the pulse duty register bits in the UART3.MDR2_REG configuration register. [Table 14-33](#) shows the duty cycle.

Table 14-33. Duty Cycle

| MDR2_REG[5:4] | Duty Cycle (High Level) |
|---------------|-------------------------|
| 00 | 1/4 |
| 01 | 1/3 |
| 10 | 5/12 |
| 11 | 1/2 |

14.4.4.3.2 CIR Data Formatting

The methods described in this section apply to all CIR modes.

14.4.4.3.2.1 IRRX Polarity Control

The IRRX polarity control for the CIR mode has the same functionality as that for the IrDA mode (see [Section 14.4.4.2.3.1, IRRX Polarity Control](#)).

14.4.4.3.2.2 CIR Transmission

In transmission, the MPU software must exercise an element of real-time control to transmit data packets, each of which must be emitted at a constant delay from the start bits of each individual packet. Thus, when sending a series of packets, the packet-to-packet delay must respect a specific delay. Two methods can be used to control this delay:

- Filling the TX FIFO with a number of zero bits that are transmitted with a t period
- Using an external system timer to control the delay either between each start-of-frame or between the end of a frame and the start of the next one. This can be performed by:
 - Controlling the start of the frame using the UART3.MDR1_REG[5] SCT bit and UART3.ACREG_REG[2] SCTX_EN bit, depending on the timer status
 - Using the UART3.IIR_REG[5] TX_STATUS_IT interrupt to preload the next frame in the TX FIFO and to control the start of the timer (in case of control delay between the end of a frame and the start of the next frame).

NOTE: There's a limitation when receiving data in UART CIR mode. The consumer IR transceivers on the market have a common characteristic that shrinks the hold time of the received modulation pulse. The UART filtering schema on receiving is based on the same encoding mechanism used in transmission.

Consider the following scenario:

- shift register period : 0.9 μ s
- modulation frequency : 36 kHz
- duty cycle : 1/4 of a modulation frequency period

So the data sent in those conditions would look like 7 μ s pulses within 28 μ s period. The UART expects to receive similar incoming data on receive, but available transceiver timing characteristics typically send 2 μ s modulated pulses. Those will be filtered out and RX FIFO will not receive any data.

The transmission of data in UART CIR mode is not affected by this limitation.

14.4.4.3.3 CIR Mode Interrupt Management

14.4.4.3.3.1 CIR Interrupts

The CIR function generates interrupts that can be enabled/disabled by writing to the appropriate bit in the interrupt enable register (UART3.IER_REG). The interrupt status of the device can be checked at any time by reading the interrupt identification register (UART3.IIR_REG).

The UART, IrDA, and CIR modes have different interrupts in the UART/IrDA/CIR module and, therefore, different UART3.IER_REG and UART3.IIR_REG mappings, depending on the selected mode.

Table 14-34 lists the interrupt modes to be maintained. In CIR mode, the sole purpose of the UART3.IIR_REG[5] bit is to indicate that the last bit of infrared data was passed to the uart3_cts_rctx pin.

Table 14-34. CIR Mode Interrupts

| IIR_REG Bit Number | Interrupt Type | Interrupt Source | Interrupt Reset Method |
|--------------------|------------------|---|--|
| 0 | N/A for CIR mode | N/A for CIR mode | N/A for CIR mode |
| 1 | THR interrupt | TFE (THR_REG empty) (FIFO disable) TX FIFO below trigger level (FIFO enable) | Write to THR_REG until interrupt condition disappears. |
| 2:4 | N/A for CIR mode | N/A for CIR mode | N/A for CIR mode |
| 5 | TX status | Transmission of the last bit of the frame is completed successfully. | Read IIR_REG. |
| 6:7 | N/A for CIR mode | N/A for CIR mode | N/A for CIR mode |

14.4.4.3.3.2 Wake-Up Interrupts

The wake-up interrupt for the IrDA mode has the same functionality as that for the UART mode (see Section 14.4.4.1.4.1, *Wake-Up Interrupt*).

14.4.5 Power Management

14.4.5.1 UART Mode Power Management

14.4.5.1.1 Module Power Saving

In UART modes, sleep mode is enabled by setting the UARTi.IER_REG[4] SLEEP_MODE bit to 1 (when the UARTi.EFR_REG[4] ENHANCED_EN bit is set to 1).

Sleep mode is entered when all the following conditions exist:

- The serial data input line, `uarti_rx`, is idle.
- The TX FIFO and TX shift register are empty.
- The RX FIFO is empty.
- No interrupts are pending except THR interrupts.

Sleep mode is a good way to lower power consumption of the UART, but this state can be achieved only when the UART is set in modem mode. Therefore, even if the UART has no functional key role, it must be initialized in a functional mode to take advantage of sleep mode.

In sleep mode, the module clock and baud rate clock are stopped internally. Because most registers are clocked using these clocks, this greatly reduces power consumption. The module wakes up when a change is detected on the `uarti_rx` line, when data is written to the TX FIFO, and when there is a change in the state of the modem input pins.

An interrupt can be generated on a wake-up event by setting the `UARTi.SCR_REG[4] RX_CTS_WU_EN` bit to 1. See [Section 14.4.4.1.4.1, Wake-Up Interrupt](#), to understand how to manage the interrupt.

NOTE: There must be no writing to the divisor latches, `UARTi.DLL_REG` and `UARTi.DLH_REG`, to set the baud clock, `BCLK`, while in sleep mode. It is advisable to disable sleep mode using the `UARTi.IER_REG[4] SLEEP_MODE` bit before writing to the `UARTi.DLL_REG` register or the `UARTi.DLH_REG` register.

14.4.5.1.2 System Power Saving

Sleep and auto-idle modes are embedded power-saving features. At the system level, power-reduction techniques can be applied by shutting down certain internal clock and power domains of the device.

The UART supports an idle req/idle ack handshaking protocol. This protocol is used at the system level to shut down clocks of the UART in a clean and controlled manner and to switch the UART from interrupt-generation mode to wake-up generation mode for unmasked events (see the `UARTi.SYSC_REG[2] ENAWAKEUP` bit and the `UARTi.WER_REG` register).

For more information, see the *Power, Reset, and Clock Management* chapter.

14.4.5.2 IrDA Mode Power Management (UART3 Only)

14.4.5.2.1 Module Power Saving

In IrDA modes, sleep mode is enabled by setting the `UART3.MDR[3] IR_SLEEP` bit to 1.

Sleep mode is entered when all the following conditions exist:

- The serial data input line, `uart3.rx_irrx`, is idle.
- The TX FIFO and TX shift register are empty.
- The RX FIFO is empty.
- No interrupts are pending except THR interrupts.

The module wakes up when a change is detected on the `uart3_rx_irrx` line or when data is written to the TX FIFO.

14.4.5.2.2 System Power Saving

System power saving for the IrDA mode has the same functionality as that for the UART mode (see [Section 14.4.5.1.2, System Power Saving](#)).

14.4.5.3 CIR Mode Power Management (UART3 Only)

14.4.5.3.1 Module Power Saving

Module power saving for the CIR mode has the same functionality as that for the IrDA mode (see [Section 14.4.5.2.1, Module Power Saving](#)).

14.4.5.3.2 System Power Saving

System power saving for the CIR mode has the same functionality as that for the UART mode (see [Section 14.4.5.2.2, System Power Saving](#)).

14.5 UART/IrDA/CIR Basic Programming Model

14.5.1 UART Programming Model

14.5.1.1 Quick Start

This section outlines the procedure for operating the UART module with FIFO and DMA or interrupts. This 3-part procedure ensures the quick start of the UART module. It does not cover every UART module feature.

The first programming model covers software reset of the module. The second programming model deals with FIFO and DMA configuration. The last programming model deals with protocol, baud rate and interrupt configuration.

NOTE: Each programming model can be used independently of the other two; for instance, reconfiguring the FIFOs and DMA settings only.

Each programming model can be executed starting from any UART register access mode (register modes, submodes, and other register dependencies). However, if the UART register access mode is known before executing the programming model, some steps that enable or restore register access are optional. For more information see [Section 14.4.3.1, Register Access Modes](#).

14.5.1.1.1 Software Reset

To clear the UART registers, perform the following steps:

1. Initiate a software reset:
Set the UARTi.SYSC_REG[1] SOFTRESET bit to 1.
2. Wait for the end of the reset operation:
Poll the UARTi.SYSS_REG[0] RESETDONE bit until it equals 1.

14.5.1.1.2 FIFOs and DMA Settings

To enable and configure the receive and transmit FIFOs and program the DMA mode, perform the following steps:

1. Switch to register configuration mode B to access the UARTi.EFR_REG register:
 - (a) Save the current UARTi.LCR_REG value.
 - (b) Set UARTi.LCR_REG to 0x00BF.
2. Enable register submode TCR_TLR to access UARTi.TLR_REG (part 1 of 2):
 - (a) Save the UARTi.EFR_REG[4] ENHANCED_EN value.
 - (b) Set the UARTi.EFR_REG[4] ENHANCED_EN bit to 1.
3. Switch to register configuration mode A to access the UARTi.MCR_REG register:
Set UARTi.LCR_REG to 0x0080.
4. Enable register submode TCR_TLR to access UARTi.TLR_REG (part 2 of 2):
 - (a) Save the UARTi.MCR_REG[6] TCR_TLR value.
 - (b) Set the UARTi.MCR_REG[6] TCR_TLR bit to 1.
5. Enable FIFO, load the new FIFO triggers (part 1 of 3) and the new DMA mode (part 1 of 2):
Set the following bits to the desired values:
 - UARTi.FCR_REG[7:6] RX_FIFO_TRIG
 - UARTi.FCR_REG[5:4] TX_FIFO_TRIG
 - UARTi.FCR_REG[3] DMA_MODE
 - UARTi.FCR_REG[0] FIFO_ENABLE (0: Disable the FIFO/1: Enable the FIFO)

NOTE: The UARTi.FCR_REG register is not readable.

6. Switch to register configuration mode B to access the UARTi.EFR_REG register:
Set UARTi.LCR_REG to 0x00BF.
7. Load the new FIFO triggers (part 2 of 3):
Set the following bits to the desired values:
 - UARTi.TLR_REG[7:4] RX_FIFO_TRIG_DMA
 - UARTi.TLR_REG[3:0] TX_FIFO_TRIG_DMA
8. Load the new FIFO triggers (part 3 of 3) and the new DMA mode (part 2 of 2):
Set the following bits to the desired values:
 - UARTi.SCR_REG[7] RX_TRIG_GRANU1
 - UARTi.SCR_REG[6] TX_TRIG_GRANU1
 - UARTi.SCR_REG[2:1] DMA_MODE_2
 - UARTi.SCR_REG[0] DMA_MODE_CTL
9. Restore the UARTi.EFR_REG[4] ENHANCED_EN value saved in Step 2a.
10. Switch to register configuration mode A to access the UARTi.MCR_REG register:
Set UARTi.LCR_REG to 0x0080.
11. Restore the UARTi.MCR_REG[6] TCR_TLR value saved in Step 4a.
12. Restore the UARTi.LCR_REG value saved in Step 1a.

Triggers are used to generate interrupt and DMA requests. See [Section 14.4.2.1.1, Transmit FIFO Trigger](#), to choose the following values:

- UARTi.FCR_REG[5:4] TX_FIFO_TRIG
- UARTi.TLR_REG[3:0] TX_FIFO_TRIG_DMA
- UARTi.SCR_REG[6] TX_TRIG_GRANU1

Triggers are used to generate interrupt and DMA requests. See [Section 14.4.2.1.2, Receive FIFO Trigger](#), to choose the following values:

- UARTi.FCR_REG[7:6] RX_FIFO_TRIG
- UARTi.TLR_REG[7:4] RX_FIFO_TRIG_DMA
- UARTi.SCR_REG[7] RX_TRIG_GRANU1

DMA mode enables the different DMA requests. See [Section 14.4.2.4, FIFO DMA Mode Operation](#), to choose the following values:

- UARTi.FCR_REG[3] DMA_MODE
- UARTi.SCR_REG[2:1] DMA_MODE_2
- UARTi.SCR_REG[0] DMA_MODE_CTL

14.5.1.1.3 Protocol, Baud Rate, and Interrupt Settings

To program the protocol, baud rate and interrupt settings, perform the following steps:

1. Disable UART to access UARTi.DLL_REG and UARTi.DLH_REG:
Set UARTi.MDR1_REG[2:0] MODE_SELECT to 0x7.
2. Switch to register configuration mode B to access the UARTi.EFR_REG register:
Set UARTi.LCR_REG to 0x00BF.
3. Enable access to UARTi.IER_REG[7:4]:
 - (a) Save the UARTi.EFR_REG[4] ENHANCED_EN value.
 - (b) Set the UARTi.EFR_REG[4] ENHANCED_EN bit to 1.
4. Switch to register operational mode to access the UARTi.IER_REG register:
Set UARTi.LCR_REG to 0x0000.
5. Clear the UARTi.IER_REG (UARTi.IER_REG[4] SLEEP_MODE bit to 0 to change UARTi.DLL_REG and UARTi.DLH_REG). Set UARTi.IER_REG to 0x0000.
6. Switch to register configuration mode B to access the UARTi.DLL_REG and UARTi.DLH_REG registers:
Set UARTi.LCR_REG to 0x00BF.

7. Load the new divisor value:
Set the UARTi.DLL_REG[7:0] CLOCK_LSB and UARTi.DLH_REG[5:0] CLOCK_MSB fields to the desired value.
 8. Switch to register operational mode to access the UARTi.IER_REG register:
Set UARTi.LCR_REG to 0x0000.
 9. Load the new interrupt configuration.(0: Disable the interrupt/1: Enable the interrupt):
Set the following bits to the desired values:
 - UARTi.IER_REG[7] CTS_IT
 - UARTi.IER_REG[6] RTS_IT
 - UARTi.IER_REG[5] XOFF_IT
 - UARTi.IER_REG[4] SLEEP_MODE
 - UARTi.IER_REG[3] MODEM_STS_IT
 - UARTi.IER_REG[2] LINE_STS_IT
 - UARTi.IER_REG[1] THR_IT
 - UARTi.IER_REG[0] RHR_IT
 10. Switch to register configuration mode B to access the UARTi.EFR_REG register:
Set UARTi.LCR_REG to 0x00BF.
 11. Restore the UARTi.EFR_REG[4] ENHANCED_EN value saved in Step 3a.
 12. Load the new protocol formatting (parity, stop bit, char length) and switch to register operational mode:
Set UARTi.LCR_REG[7] DIV_EN to 0.
Set UARTi.LCR_REG[6] BREAK_EN to 0.
Set the following bits to the desired values:
 - UARTi.LCR_REG[5] PARITY_TYPE_2
 - UARTi.LCR_REG[4] PARITY_TYPE_1
 - UARTi.LCR_REG[3] PARITY_EN
 - UARTi.LCR_REG[2] NB_STOP
 - UARTi.LCR_REG[1:0] CHAR_LENGTH
 13. Load the new UART mode:
Set UARTi.MDR1_REG[2:0] MODE_SELECT to the desired value.
- See [Section 14.4.4.1.2, Choosing the Appropriate Divisor Value](#), to choose the following values:
- UARTi.DLL_REG[7:0] CLOCK_LSB
 - UARTi.DLH_REG[5:0] CLOCK_MSB
 - UARTi.MDR1_REG[2:0] MODE_SELECT
- See [Section 14.4.4.1.3.1, Frame Formatting](#), to choose the following values:
- UARTi.LCR_REG[5] PARITY_TYPE_2
 - UARTi.LCR_REG[4] PARITY_TYPE_1
 - UARTi.LCR_REG[3] PARITY_EN
 - UARTi.LCR_REG[2] NB_STOP
 - UARTi.LCR_REG[1:0] CHAR_LENGTH

14.5.1.2 Hardware and Software Flow Control Configuration

This section outlines the programming steps to enable and configure hardware and software flow control. Hardware and software flow control cannot be used at the same time.

NOTE: Each programming model can be executed starting from any UART register access mode (register modes, submodes, and other register dependencies). However, if the UART register access mode is known before executing the programming model, some steps that enable or restore register access are optional. For more information, see [Section 14.4.3.1, Register Access Modes](#).

14.5.1.2.1 Hardware Flow Control Configuration

To enable and configure hardware flow control, perform the following procedure:

1. Switch to register configuration mode A to access the UARTi.MCR_REG register:
 - (a) Save the current UARTi.LCR_REG.
 - (b) Set UARTi.LCR_REG to 0x0080.
 2. Enable register submode TCR_TLR to access UARTi.TCR_REG (part 1 of 2):
 - (a) Save the UARTi.MCR_REG[6] TCR_TLR value.
 - (b) Set UARTi.MCR_REG[6] TCR_TLR = 1.
 3. Switch to register configuration mode B to access the UARTi.EFR_REG register:
Set UARTi.LCR_REG to 0x00BF.
 4. Enable register submode TCR_TLR to access the UARTi.TCR_REG register (part 2 of 2):
 - (a) Save the UARTi.EFR_REG[4] ENHANCED_EN value.
 - (b) Set the UARTi.EFR_REG[4] ENHANCED_EN bit to 1.
 5. Load the new start and halt trigger values for hardware flow control:
Set the following bits to the desired values:
 - UARTi.TCR_REG[7:4] AUTO_RTS_START
 - UARTi.TCR_REG[3:0] AUTO_RTS_HALT
 6. Enable or disable receive and transmit hardware flow control mode and restore the UARTi.EFR_REG[4] ENHANCED_EN value saved in Step 4a.
Set the following bits to the desired values:
 - UARTi.EFR_REG[7] AUTO_CTS_EN (0: Disable/1: Enable)
 - UARTi.EFR_REG[6] AUTO_RTS_EN (0: Disable/1: Enable)
 Restore UARTi.EFR_REG[4] ENHANCED_EN to the saved value.
 7. Switch to register configuration mode A to access UARTi.MCR_REG:
Set UARTi.LCR_REG to 0x0080.
 8. Restore the UARTi.MCR_REG[6] TCR_TLR value saved in Step 2a.
 9. Restore the UARTi.LCR_REG value saved in Step 1a.
- See [Section 14.4.4.1.3.2, Hardware Flow Control](#), to choose the following values:
- UARTi.EFR_REG[7] AUTO_CTS_EN
 - UARTi.EFR_REG[6] AUTO_RTS_EN
 - UARTi.TCR_REG[7:4] AUTO_RTS_START
 - UARTi.TCR_REG[3:0] AUTO_RTS_HALT

14.5.1.2.2 Software Flow Control Configuration

To enable and configure software flow control, perform the following procedure:

1. Switch to register configuration mode B to access the UARTi.EFR_REG register.
 - (a) Save the current UARTi.LCR_REG.
 - (b) Set UARTi.LCR_REG to 0x00BF.
2. Enable register submode XOFF to access the UARTi.XOFF1_REG and UARTi.XOFF2_REG registers:

- (a) Save the UARTi.EFR_REG[4] ENHANCED_EN value.
 - (b) Set the UARTi.EFR_REG[4] ENHANCED_EN bit to 0.
 3. Load the new software flow control characters:
Set the following bits to the desired values:
 - UARTi.XON1_ADDR1_REG[7:0] XON_WORD1
 - UARTi.XON2_ADDR2_REG[7:0] XON_WORD2
 - UARTi.XOFF1_REG[7:0] XOFF_WORD1
 - UARTi.XOFF2_REG[7:0] XOFF_WORD2
 4. Enable access to UARTi.MCR_REG[7:5] and enable register submode TCR_TLR to access UARTi.TCR_REG (part 1 of 2):
Set the UARTi.EFR_REG[4] ENHANCED_EN bit to 1.
 5. Switch to register configuration mode A to access the UARTi.MCR_REG register:
Set UARTi.LCR_REG to 0x0080.
 6. Enable register submode TCR_TLR to access UARTi.TCR_REG (part 2 of 2) and enable or disable XON any function:
 - (a) Save the UARTi.MCR_REG[6] TCR_TLR value.
 - (b) Set the UARTi.MCR_REG[6] TCR_TLR to 1.
Set UARTi.MCR_REG[5] XON_EN to the desired value (0: Disable/1: Enable).
 7. Switch to register configuration mode B to access the UARTi.EFR_REG register:
Set UARTi.LCR_REG to 0x00BF.
 8. Load the new start and halt trigger values for software flow control:
Set the following bits to the desired values:
 - UARTi.TCR_REG[7:4] AUTO_RTS_START
 - UARTi.TCR_REG[3:0] AUTO_RTS_HALT
 9. Enable or disable special char function and load the new software flow control mode and restore the UARTi.EFR_REG[4] ENHANCED_EN value saved in Step 2a:
Set the following bits to the desired values:
 - UARTi.EFR_REG[5] SPEC_CHAR (0: Disable/1: Enable)
 - UARTi.EFR_REG[3:0] SW_FLOW_CONTROL
 Restore UARTi.EFR_REG[4] ENHANCED_EN to the saved value.
 10. Switch to register configuration mode A to access the UARTi.MCR_REG register:
Set UARTi.LCR_REG to 0x0080.
 11. Restore the UARTi.MCR_REG[6] TCR_TLR value saved in Step 6a.
 12. Restore the UARTi.LCR_REG value saved in Step 1a.
- See [Section 14.4.4.1.3.3](#), *Software Flow Control*, to choose the following values:
- UARTi.EFR_REG[5] SPEC_CHAR
 - UARTi.EFR_REG[3:0] SW_FLOW_CONTROL
 - UARTi.TCR_REG[7:4] AUTO_RTS_START
 - UARTi.TCR_REG[3:0] AUTO_RTS_HALT
 - UARTi.XON1_ADDR1_REG[7:0] XON_WORD1
 - UARTi.XON2_ADDR2_REG[7:0] XON_WORD2
 - UARTi.XOFF1_REG[7:0] XOFF_WORD1
 - UARTi.XOFF2_REG[7:0] XOFF_WORD2

14.5.2 IrDA Programming Model (UART3 Only)

14.5.2.1 SIR Mode

14.5.2.1.1 Receive

The following programming model explains how to program the module in order to receive IrDA frame with parity forced to '1', baud rate = 112.5Kbs, FIFOs disable, 2 stop bits, 8 bits word length

1. **Disable UART before accessing UARTi.DLL_REG and UARTi.DLH_REG:**
Set UARTi.MDR1_REG[2:0] MODE_SELECT to 0x7.
2. **Grant access to DLL_REG and DLH_REG (LCR_REG[7] DIV_EN = 0x1)**
UART3.LCR_REG = 0x80 (Note: Data format is unaffected by the use and settings of the UART3.LCR_REG register in IrDA mode)
3. **Load the new baud rate (115.2Kbs)**
UART3.DLL_REG = 0x1A
UART3.DLH_REG = 0x00
4. **Set SIR Mode**
UART3.MDR1_REG[2:0] MODE_SELECT = 0x1
5. **Disable access to DLL_REG and DLH_REG and Switch to register operational mode**
UART3.LCR_REG = 0x00
6. **Optional: Enable RHR interrupt**
UART3.IER_REG[0] RHR_IT = 0x1

14.5.2.1.2 Transmit

The following programming model explains how to program the module in order to transmit IrDA 6 bytes frame with no parity, baud rate = 112.5Kbs, FIFOs disable, 3/16 encoding, 2 stop bits, 7 bits word length

1. **Disable UART before accessing UARTi.DLL_REG and UARTi.DLH_REG:**
Set UARTi.MDR1_REG[2:0] MODE_SELECT to 0x7.
2. **Grant access to EFR_REG**
UART3.LCR_REG = 0xBF
3. **Enable the enhanced features (EFR_REG[4] ENAHNCED_EN = 0x1)**
UART3.EFR_REG = 0x10
4. **Grant access to DLL_REG and DLH_REG (LCR_REG[7] DIV_EN = 0x1)**
UART3.LCR_REG = 0x80 (Note: Data format is unaffected by the use and settings of the UART3.LCR_REG register in IrDA mode)
5. **Load the new baud rate (115.2Kbs)**
UART3.DLL_REG = 0x1A
UART3.DLH_REG = 0x00
6. **Set SIR Mode (MDR1_REG[2:0] MODE_SELECT = 0x1)**
UART3.MDR1_REG = 0x01
7. **Disable access to DLL_REG and DLH_REG and Switch to register operational mode**
UART3.LCR_REG = 0x00
8. **Force DTR output to active**
UART3.MCR_REG[0] DTR = 0x1
9. **Optional: Enable THR interrupt**
UART3.IER_REG[1] THR_IT = 0x1
10. **Set transmit frame length to 6 bytes**
UART3.TXFLL_REG = 0x06
11. **Set 7 starts of frame transmission**
UART3.EBLR_REG = 0x08
12. **Optional: Set SIR pulse width to be 1.6 us**
UART3.ACREG_REG[7] PULSE_TYPE = 0x1
13. **Load THR_REG with the desired data to be transmitted**

14.5.2.2 MIR Mode

14.5.2.2.1 Receive

The following programming model explains how to program the module in order to receive IrDA frame with no parity, baud rate = 1.152Mbs, FIFOs disable

1. **Disable UART before accessing UARTi.DLL_REG and UARTi.DLH_REG:**
Set UARTi.MDR1_REG[2:0] MODE_SELECT to 0x7.
2. **Grant access to DLL_REG and DLH_REG (LCR_REG[7] DIV_EN = 0x1)**
UART3.LCR_REG = 0x80 (Note: Data format is unaffected by the use and settings of the UART3.LCR_REG register in IrDA mode)
3. **Load the new baud rate (1.152Mbs)**
UART3.DLL_REG = 0x01
UART3.DLH_REG = 0x00
4. **Set MIR Mode**
UART3.MDR1_REG[2:0] MODE_SELECT = 0x4
5. **Disable access to DLL_REG and DLH_REG and Switch to register operational mode**
UART3.LCR_REG = 0x00
6. **Force DTR output to active (MCR_REG[0] DTR = 0x1)**
Force RTS output to active (MCR_REG[1] RTS = 0x1)
UART3.MCR_REG = 0x3
7. **Optional: Enable RHR interrupt**
UART3.IER_REG[0] RHR_IT = 0x1

14.5.2.2.2 Transmit

The following programming model explains how to program the module in order to transmit IrDA 60 bytes frame with no parity, baud rate = 1.152Mbs, FIFOs disable

1. **Disable UART before accessing UARTi.DLL_REG and UARTi.DLH_REG:**
Set UARTi.MDR1_REG[2:0] MODE_SELECT to 0x7.
2. **Grant access to DLL_REG and DLH_REG (LCR_REG[7] DIV_EN = 0x1)**
UART3.LCR_REG = 0x80 (Note: Data format is unaffected by the use and settings of the UART3.LCR_REG register in IrDA mode)
3. **Load the new baud rate (1.152Mbs)**
UART3.DLL_REG = 0x01
UART3.DLH_REG = 0x00
4. **Set MIR Mode**
UART3.MDR1_REG[2:0] MODE_SELECT = 0x4
5. **Disable access to DLL_REG and DLH_REG and Switch to register operational mode**
UART3.LCR_REG = 0x00
6. **Force DTR output to active**
UART3.MCR_REG[0] DTR = 0x1
7. **Optional: Enable THR interrupt**
UART3.IER_REG[1] THR_IT = 0x1
8. **Set frame length to 60 bytes**
UART3.TXFLL_REG = 0x3C
9. **Optional: Transmit 8 additional starts of frame (MIR mode requires 2 starts anyway)**
UART3.EBLR_REG = 0x08
10. **SIP will be send at the end of transmission**
UART3.ACREG_REG[3] = 0x1
11. **Load THR_REG with the desired data to be transmitted**

14.5.2.3 FIR Mode

14.5.2.3.1 Receive

The following programming model explains how to program the module to receive IrDA frame with no parity, baud rate = 4M bits/s, FIFOs enable, 8-bit word length.

1. **Disable UART before accessing UARTi.DLL_REG and UARTi.DLH_REG:**
Set UARTi.MDR1_REG[2:0] MODE_SELECT to 0x7.
2. **Grant access to DLL_REG and DLH_REG (LCR_REG[7] DIV_EN = 0x1)**
UART3.LCR_REG = 0x80 (Note: Data format is unaffected by the use and settings of the UART3.LCR_REG register in IrDA mode.)
3. **FIFO clear and enable**
FCR_REG = 0x7 (Tx/Rx FIFO trigger : FCR_REG[7:6] & FCR_REG[5:4])
LCR_REG[7]=0
4. **Set FIR Mode**
UART3.MDR1_REG[2:0] MODE_SELECT = 0x5
5. **Set frame length**
RXFLL_REG = 0xA (Data + CRC + STO)
6. **Disable access to DLL_REG and DLH_REG and switch to register operational mode**
UART3.LCR_REG[7] DIV_EN = 0x0.
7. **Optional: Enable RHR interrupt**
UART3.IER_REG[0] RHR_IT = 0x1.

14.5.2.3.2 Transmit

The following programming model explains how to program the module to transmit IrDA 4 bytes frame with no parity, baud rate = 4M bits/s, FIFOs enable, 8-bit word length.

1. **Disable UART before accessing UARTi.DLL_REG and UARTi.DLH_REG:**
Set MDR1_REG[2:0] MODE_SELECT = 0x7).
2. **Grant access to EFR_REG**
UART3.LCR_REG = 0xBF
3. **Enable the enhanced features (EFR_REG[4] ENAHNCED_EN = 0x1)**
UART3.EFR_REG = 0x10.
4. **FIFO clear and enable**
FCR_REG = 0x7 (Tx/Rx FIFO trigger: FCR_REG[7:6] and FCR_REG[5:4])
LCR_REG[7]=0
5. **Set FIR mode and enable auto-SIP mode**
MDR1_REG = 0x45
6. **Set Frame Length**
TXFLL_REG = 0x4
TXFLH_REG = 0x0
RXFLL_REG = 0xA (Data + CRC + STO)
RXFLH_REG = 0x0
7. **Force DTR output to active**
UART3.MCR_REG[0] DTR = 0x1
8. **Optional: Enable THR interrupt**
UART3.IER_REG[1] THR_IT = 0x1
9. **Load THR_REG with the desired data to be transmitted**

14.6 UART/IrDA/CIR Registers

Table 14-35 shows the base address and address space for the UART/IrDA/CIR module instances.

Table 14-35. Instance Summary

| Module Name | Base Address | Size |
|-----------------------|--------------|---------|
| UART1 (UART only) | 0x4806 A000 | 1K byte |
| UART2 (UART only) | 0x4806 C000 | 1K byte |
| UART3 (UART/IrDA/CIR) | 0x4902 0000 | 1K byte |
| UART4 | 0x4809 E000 | 1K byte |

14.6.1 UART/IrDA/CIR Register Mapping Summary

This section provides information about the UART/IrDA/CIR module instance in the device. Each register in the module instance is described separately in this section. This module has multiple modes.

Table 14-36 summarizes register access for different modes.

Table 14-36. UART Mode Overview

| Address Offset | Registers | | | | | |
|-------------------|--|--|---|--|--|--|
| | Configuration_Mode_A | | Configuration_Mode_B | | Operational_Mode | |
| | Read | Write | Read | Write | Read | Write |
| 0x000 | DLL_REG | DLL_REG | DLL_REG | DLL_REG | RHR_REG | THR_REG |
| 0x004 | DLH_REG | DLH_REG | DLH_REG | DLH_REG | IER_REG | IER_REG |
| 0x008 | IIR_REG | FCR_REG | EFR_REG | EFR_REG | IIR_REG | FCR_REG |

14.6.2 UART/IrDA/CIR Register Descriptions

14.6.2.1 DLL_REG

Table 14-50. DLL_REG

| | | | |
|-------------------------|---|-----------------|-------|
| Address Offset | 0x000 | | |
| Physical Address | 0x4806 A000 | Instance | UART1 |
| | 0x4806 C000 | | UART2 |
| | 0x4902 0000 | | UART3 |
| | 0x4809 E000 | | UART4 |
| Description | Divisor latches low This register, with DLH_REG, stores the 14-bit divisor for generation of the baud clock in the baud rate generator. DLH_REG stores the most-significant part of the divisor. DLL_REG stores the least-significant part of the divisor. Note: DLL_REG and DLH_REG can be written to only before sleep mode is enabled (before IER_REG[4] is set). | | |
| Type | RW | | |

| | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|---|---|-----------|---|---|---|---|---|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Reserved | | | | | | | | CLOCK_LSB | | | | | | | |

| Bits | Field Name | Description | Type | Reset |
|------|------------|------------------------------------|------|-------|
| 15:8 | Reserved | Read returns 0x00. | R | 0x00 |
| 7:0 | CLOCK_LSB | Stores the 8-bit LSB divisor value | RW | 0x00 |

14.6.2.2 RHR_REG
Table 14-51. RHR_REG

| | | | |
|-------------------------|--|-----------------|-------|
| Address Offset | 0x000 | | |
| Physical Address | 0x4806 A000 | Instance | UART1 |
| | 0x4806 C000 | | UART2 |
| | 0x4902 0000 | | UART3 |
| | 0x4809 E000 | | UART4 |
| Description | Receive holding register The receiver section consists of the receiver holding register (RHR_REG) and the receiver shift register. The RHR_REG is actually a 64-byte FIFO. The receiver shift register receives serial data from RX input. The data is converted to parallel data and moved to the RHR_REG. If the FIFO is disabled, location zero of the FIFO is used to store the single data character. Note: If an overflow occurs the data in the RHR_REG is not overwritten. | | |
| Type | R | | |

| | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|---|---|-----|---|---|---|---|---|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Reserved | | | | | | | | RHR | | | | | | | |

| Bits | Field Name | Description | Type | Reset |
|------|------------|--------------------------|------|-------|
| 15:8 | Reserved | Read returns 0x00. | R | 0x00 |
| 7:0 | RHR | Receive holding register | R | 0x– |

14.6.2.3 THR_REG
Table 14-52. THR_REG

| | | | |
|-------------------------|---|-----------------|-------|
| Address Offset | 0x000 | | |
| Physical Address | 0x4806 A000 | Instance | UART1 |
| | 0x4806 C000 | | UART2 |
| | 0x4902 0000 | | UART3 |
| | 0x4809 E000 | | UART4 |
| Description | Transmit holding register The transmitter section consists of the transmit holding register (THR_REG) and the transmit shift register. The transmit holding register is a 64-byte FIFO. The MPU writes data to the THR_REG. The data is placed in the transmit shift register where it is shifted out serially on the TX output. If the FIFO is disabled, location zero of the FIFO is used to store the data. | | |
| Type | W | | |

| | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|---|---|-----|---|---|---|---|---|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Reserved | | | | | | | | THR | | | | | | | |

| Bits | Field Name | Description | Type | Reset |
|------|------------|---------------------------------|------|-------|
| 15:8 | Reserved | Write has no functional effect. | W | 0x00 |
| 7:0 | THR | Transmit holding register | W | 0x– |

14.6.2.4 IER_REG

Table 14-53. IER_REG

| | | | |
|-------------------------|---------------------------|-----------------|-------|
| Address Offset | 0x004 | | |
| Physical Address | 0x4806 A004 | Instance | UART1 |
| | 0x4806 C004 | | UART2 |
| | 0x4902 0004 | | UART3 |
| | 0x4809 E000 | | UART4 |
| Description | Interrupt enable register | | |
| Type | RW | | |

14.6.2.4.1 UART Bitfield Details

| | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|---|---|--------|--------|---------|------------|--------------|-------------|--------|--------|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Reserved | | | | | | | | CTS_IT | RTS_IT | XOFF_IT | SLEEP_MODE | MODEM_STS_IT | LINE_STS_IT | THR_IT | RHR_IT |

| Bits | Field Name | Description | Type | Reset |
|------|--------------|---|------|-------|
| 15:8 | Reserved | Read returns 0x00. Write has no functional effect. | RW | 0x00 |
| 7 | CTS_IT | Can be written only when EFR_REG[4] = 1 0x0: Disables the nCTS interrupt 0x1: Enables the nCTS interrupt | RW | 0 |
| 6 | RTS_IT | Can be written only when EFR_REG[4] = 1 0x0: Disables the interrupt 0x1: Enables the nRTS interrupt | RW | 0 |
| 5 | XOFF_IT | Can be written only when EFR_REG[4] = 1 0x0: Disables the XOFF interrupt 0x1: Enables the XOFF interrupt | RW | 0 |
| 4 | SLEEP_MODE | Can be only written when EFR_REG[4] = 1 0x0: Disables sleep mode 0x1: Enables sleep mode (stop baud rate clock when the module is inactive) | RW | 0 |
| 3 | MODEM_STS_IT | 0x0: Disables the modem status register interrupt 0x1: Enables the modem status register interrupt | RW | 0 |
| 2 | LINE_STS_IT | 0x0: Disables the receiver line status interrupt 0x1: Enables the receiver line status interrupt | RW | 0 |
| 1 | THR_IT | 0x0: Disables the THR interrupt 0x1: Enables the THR interrupt | RW | 0 |
| 0 | RHR_IT | 0x0: Disables the RHR interrupt and time out interrupt. 0x1: Enables the RHR interrupt and time out interrupt. | RW | 0 |

14.6.2.4.2 IrDA Bitfield Details

| | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|---|---|--------|---------------|--------------|------------------|---------------|-----------------|--------|--------|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Reserved | | | | | | | | EOF_IT | LINE_STS_IT_I | TX_STATUS_IT | STS_FIFO_TRIG_IT | RX_OVERRUN_IT | LAST_RX_BYTE_IT | THR_IT | RHR_IT |

| Bits | Field Name | Description | Type | Reset |
|------|------------------|--|------|-------|
| 15:8 | Reserved | Read returns 0. Write has no functional effect. | RW | 0x00 |
| 7 | EOF_IT | 0x0: Disables the received EOF interrupt 0x1: Enables the received EOF interrupt | | |
| 6 | LINE_STS_IT_I | 0x0: Disables the receiver line status interrupt 0x1: Enables the receiver line status interrupt | RW | 0 |
| 5 | TX_STATUS_IT | TX_STATUS_IT interrupt reflects two possible conditions. The MDR2_REG[0] must be read to determine the status in the event of this interrupt. 0x0: Disables the TX status interrupt 0x1: Enables the TX status interrupt | RW | 0 |
| 4 | STS_FIFO_TRIG_IT | 0x0: Disables status FIFO trigger level interrupt 0x1: Enables status FIFO trigger level interrupt. | RW | 0 |
| 3 | RX_OVERRUN_IT | 0x0: Disables the RX overrun interrupt 0x1: Enables the RX overrun interrupt | RW | 0 |
| 2 | LAST_RX_BYTE_IT | 0x0: Disables the last byte of frame in RX FIFO interrupt 0x1: Enables the last byte of frame in RX FIFO interrupt | RW | 0 |
| 1 | THR_IT | 0x0: Disables the THR interrupt 0x1: Enables the THR interrupt | RW | 0 |
| 0 | RHR_IT | 0x0: Disables the RHR interrupt 0x1: Enables the RHR interrupt | RW | 0 |

14.6.2.4.3 CIR Bitfield Details

| | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|---|---|--------------|----------|---|---|---|--------|----------|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Reserved | | | | | | | | TX_STATUS_IT | Reserved | | | | THR_IT | Reserved | |

| Bits | Field Name | Description | Type | Reset |
|------|--------------|--|------|-------|
| 15:6 | Reserved | Read returns 0x00. Write has no functional effect. | RW | 0x00 |
| 5 | TX_STATUS_IT | In IR-CIR mode, contrary to the IR-IrDA mode, the TX_STATUS_IT has only one meaning corresponding to the case MDR2_REG[0] = 0. | RW | 0 |
| 4:2 | Reserved | Read returns 0. Write has no functional effect. | R | 0 |
| 1 | THR_IT | 0x0: Disables the THR interrupt 0x1: Enables the THR interrupt | RW | 0 |
| 0 | Reserved | Reserved | R | 0 |

14.6.2.5 DLH_REG
Table 14-54. DLH_REG

| | | | |
|-------------------------|--|-----------------|-------|
| Address Offset | 0x004 | | |
| Physical Address | 0x4806 A004 | Instance | UART1 |
| | 0x4806 C004 | | UART2 |
| | 0x4902 0004 | | UART3 |
| | 0x4809 E000 | | UART4 |
| Description | Divisor latches high This register, with DLL_REG, stores the 14-bit divisor for generation of the baud clock in the baud rate generator. DLH_REG stores the most-significant part of the divisor. DLL_REG stores the least-significant part of the divisor. Note: DLL_REG and DLH_REG can be written to only before sleep mode is enabled (before IER_REG[4] is set). | | |
| Type | RW | | |

| | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|---|---|----------|---|-----------|---|---|---|---|---|

| | 0x4809 E000 | | UART4 |
| Description | Enhanced feature register | | |
| | This register enables or disables enhanced features. Most enhanced functions apply only to UART modes, but EFR_REG[4] enables write accesses to FCR_REG[5:4], the TX trigger level, which is also used in IrDA modes. | | |
| Type | RW | | |

| | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|---|---|-------------|-------------|-----------|-------------|-----------------|---|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Reserved | | | | | | | | AUTO_CTS_EN | AUTO_RTS_EN | SPEC_CHAR | ENHANCED_EN | SW_FLOW_CONTROL | | | |

| Bits | Field Name | Description | Type | Reset |
|------|-----------------|--|------|-------|
| 15:8 | Reserved | Read returns 0x00. | R | 0x00 |
| 7 | AUTO_CTS_EN | Auto-CTS enable bit (UART mode only) 0x0: Normal operation 0x1: Auto-CTS flow control is enabled; transmission is halted when the nCTS pin is high (inactive). | RW | 0 |
| 6 | AUTO_RTS_EN | Auto-RTS enable bit (UART mode only) 0x0: Normal operation 0x1: Auto-RTS flow control is enabled; nRTS pin goes high (inactive) when the receiver FIFO HALT trigger level, TCR_REG[3:0], is reached and goes low (active) when the receiver FIFO RESTORE transmission trigger level is reached. | RW | 0 |
| 5 | SPEC_CHAR | (UART mode only) Special character detect 0x0: Normal operation 0x1: Special character detect enable. Received data is compared with XOFF2 data. If a match occurs, the received data is transferred to RX FIFO and IIR_REG bit 4 is set to 1 to indicate that a special character was detected. | RW | 0 |
| 4 | ENHANCED_EN | Enhanced functions write enable bit 0x0: Disables writing to IER_REG bits [7:4], FCR_REG bits [5:4], and MCR_REG bits [7:5] 0x1: Enables writing to IER_REG bits [7:4], FCR_REG bits [5:4], and MCR_REG bits [7:5] | RW | 0 |
| 3:0 | SW_FLOW_CONTROL | Combinations of software flow control can be selected by programming bit [3:0]. See Table 14-29 . In IrDA mode, bits [1:0] select IR address to check. See Section 14.2.5.2.1.7, IR Address Checking . | RW | 0x0 |

14.6.2.9 LCR_REG

Table 14-58. LCR_REG

| | | | |
|-------------------------|---|-----------------|-------|
| Address Offset | 0x00C | Instance | UART1 |
| Physical Address | 0x4806 A00C | | UART2 |
| | 0x4806 C00C | | UART3 |
| | 0x4902 000C | | UART4 |
| | 0x4809 E000 | | |
| Description | Line control register | | |
| | LCR_REG[6:0] define parameters of the transmission and reception for UART mode. LCR_REG[7] is used to put the module in operational mode or Configuration_Mode_A/B. | | |
| Type | RW | | |

| | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|---|---|--------|----------|--------------|--------------|-----------|---------|-------------|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Reserved | | | | | | | | DIV_EN | BREAK_EN | PARITY_TYPE2 | PARITY_TYPE1 | PARITY_EN | NB_STOP | CHAR_LENGTH | |

| Bits | Field Name | Description | Type | Reset |
|------|--------------|--|------|-------|
| 15:8 | Reserved | Read returns 0x00 | R | 0x00 |
| 7 | DIV_EN | 0x0: Operational mode 0x1: Divisor latch enable; put the module in Configuration_Mode_A/B. Allows access to DLL_REG, DLH_REG, and other registers (see Section 14.6.1, UART/IrDA/CIR Register Mapping Summary). Configuration_Mode_B: LCR_REG[7:0] = 0xBF Else, Configuration_Mode_A | RW | 0 |
| 6 | BREAK_EN | Break control bit. UART mode only. Note: When LCR_REG[6] is set to 1, the TX line is forced to 0 and remains in this state as long as LCR_REG[6] = 1. 0x0: Normal operating condition 0x1: Forces the transmitter output to go low to alert the communication terminal. TX line is forced to 0 and remains in this state while BREAK_EN = 1. | RW | 0 |
| 5 | PARITY_TYPE2 | Selects the forced parity format (if LCR_REG[3] = 1). UART mode only. If LCR_REG[5] = 1 and LCR_REG[4] = 0, the parity bit is forced to 1 in the transmitted and received data. If LCR_REG[5] = 1 and LCR_REG[4] = 1, the parity bit is forced to 0 in the transmitted and received data. | RW | 0 |
| 4 | PARITY_TYPE1 | UART mode only 0x0: Odd parity is generated (if LCR_REG[3] = 1). 0x1: Even parity is generated (if LCR_REG[3] = 1). | RW | 0 |
| 3 | PARITY_EN | UART mode only 0x0: No parity 0x1: A parity bit is generated during transmission, and the receiver checks for received parity. | RW | 0 |
| 2 | NB_STOP | Specifies the number of stop bits. UART mode only. 0x0: 1 stop bit (word length = 5, 6, 7, 8) 0x1: 1.5 stop bits (word length = 5) 1 - 2 stop bits (word length = 6, 7, 8) | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|-------------|-------------------|--|-------------|--------------|
| 1:0 | CHAR_LENGTH | Specifies the word length to be transmitted or received. UART mode only. 0x0: 5 bits 0x1: 6 bits 0x2: 7 bits 0x3: 8 bits | RW | 0x0 |

14.6.2.10 MCR_REG

Table 14-59. MCR_REG

| | | | |
|-------------------------|---|-----------------|-------|
| Address Offset | 0x010 | | |
| Physical Address | 0x4806 A010 | Instance | UART1 |
| | 0x4806 C010 | | UART2 |
| | 0x4902 0010 | | UART3 |
| | 0x4809 E000 | | UART4 |
| Description | Modem control register | | |
| | MCR_REG[3:0] controls the interface with the modem, data set, or peripheral device that is emulating the modem. | | |
| Type | RW | | |

| | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|---|---|----------|---------|--------|-------------|-----------|-----------|-----|-----|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Reserved | | | | | | | | Reserved | TCR_TLR | XON_EN | LOOPBACK_EN | CD_STS_CH | RI_STS_CH | RTS | DTR |

| Bits | Field Name | Description | Type | Reset |
|------|-------------|--|------|-------|
| 15:8 | Reserved | Read returns 0x00. | R | 0x00 |
| 7 | Reserved | Read returns 0. Write has no functional effect. | RW | 0 |
| 6 | TCR_TLR | Can be written only when EFR_REG[4] ENHANCED_EN = 1 0x0: No action 0x1: Enables access to the TCR_REG and TLR_REG registers | RW | 0 |
| 5 | XON_EN | Can be written only when EFR_REG[4] ENHANCED_EN = 1 0x0: Disable XON any function 0x1: Enable XON any function | RW | 0 |
| 4 | LOOPBACK_EN | 0x0: Normal operating mode 0x1: Enable local loopback mode (internal). In this mode, the MCR_REG[3:0] signals are looped back into MSR_REG[7:4]. The transmit output is looped back to the receive input internally. | RW | 0 |
| 3 | CD_STS_CH | 0x0: In loopback, forces nDCD input high and IRQ outputs to INACTIVE state. 0x1: In loopback, forces nDCD input low and IRQ outputs to INACTIVE state. | RW | 0 |
| 2 | RI_STS_CH | 0x0: In loopback, forces nRI input inactive (high). 0x1: In loopback, forces nRI input active (low). | RW | 0 |
| 1 | RTS | In loop back, controls MSR_REG[4]. If auto-RTS is enabled, the nRTS output is controlled by hardware flow control. 0x0: Force nRTS output to inactive (high). 0x1: Force nRTS output to active (low). | RW | 0 |
| 0 | DTR | 0x0: Force DTR output (used in loop back mode) to inactive (high). 0x1: Force DTR output (used in loop back mode) to active (low). | RW | 0 |

14.6.2.11 XON1_ADDR1_REG
Table 14-60. XON1_ADDR1_REG

| | | | |
|-------------------------|---|-----------------|-------|
| Address Offset | 0x010 | | |
| Physical Address | 0x4806 A010 | Instance | UART1 |
| | 0x4806 C010 | | UART2 |
| | 0x4902 0010 | | UART3 |
| | 0x4809 E000 | | UART4 |
| Description | UART mode: XON1 character, IrDA mode: ADDR1 address | | |
| Type | RW | | |

| | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|---|---|-----------|---|---|---|---|---|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Reserved | | | | | | | | XON_WORD1 | | | | | | | |

| Bits | Field Name | Description | Type | Reset |
|------|------------|---|------|-------|
| 15:8 | Reserved | Read returns 0x00 | R | 0x00 |
| 7:0 | XON_WORD1 | Used to store the 8-bit XON1 character in UART modes and ADDR1 address 1 for IrDA modes | RW | 0x00 |

14.6.2.12 LSR_REG

Table 14-61. LSR_REG

| | | | |
|-------------------------|----------------------|-----------------|-------|
| Address Offset | 0x014 | | |
| Physical Address | 0x4806 A014 | Instance | UART1 |
| | 0x4806 C014 | | UART2 |
| | 0x4902 0014 | | UART3 |
| | 0x4809 E000 | | UART4 |
| Description | Line status register | | |
| Type | R | | |

14.6.2.12.1 UART Bitfield Details

| | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|---|---|-------------|---------|-----------|-------|-------|-------|-------|-----------|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Reserved | | | | | | | | RX_FIFO_STS | TX_SR_E | TX_FIFO_E | RX_BI | RX_FE | RX_PE | RX_OE | RX_FIFO_E |

| Bits | Field Name | Description | Type | Reset |
|------|-------------|---|------|-------|
| 15:8 | Reserved | Read returns 0x00. | R | 0x00 |
| 7 | RX_FIFO_STS | 0x0: Normal operation 0x1: At least one parity error, framing error, or break indication in the RX FIFO. Bit 7 is cleared when no errors are present in the RX FIFO. | R | 0 |
| 6 | TX_SR_E | 0x0: Transmitter hold (TX FIFO) and shift registers are not empty. 0x1: Transmitter hold (TX FIFO) and shift registers are empty | R | 1 |
| 5 | TX_FIFO_E | 0x0: Transmit hold register (TX FIFO) is not empty. 0x1: Transmit hold register (TX FIFO) is empty. The transmission is not necessarily complete. | R | 1 |
| 4 | RX_BI | 0x0: No break condition 0x1: A break was detected while the data being read from the RX FIFO was being received (RX input was low for one character + 1 bit time frame). | R | 0 |
| 3 | RX_FE | 0x0: No framing error in data being read from RX FIFO 0x1: Framing error occurred in data being read from RX FIFO (received data did not have a valid stop bit). | R | 0 |
| 2 | RX_PE | 0x0: No parity error in data being read from RX FIFO 0x1: Parity error in data being read from RX FIFO | R | 0 |
| 1 | RX_OE | 0x0: No overrun error 0x1: Overrun error occurred. Set when the character held in the receive shift register is not transferred to the RX FIFO. This case occurs only when receive FIFO is full. | R | 0 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|---|------|-------|
| 0 | RX_FIFO_E | 0x0: No data in the receive FIFO 0x1: At least one data character in the RX FIFO | R | 0 |

14.6.2.12.2 IrDA Bitfield Details

| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|----------|----|----|----|----|----|---|---|-----------|--------------|--------------|----------------|-------|-----|------------|-----------|
| Reserved | | | | | | | | THR_EMPTY | STS_FIFO_FUL | RX_LAST_BYTE | FRAME_TOO_LONG | ABORT | CRC | STS_FIFO_E | RX_FIFO_E |

| Bits | Field Name | Description | Type | Reset |
|------|----------------|---|------|-------|
| 15:8 | Reserved | Read returns 0x00. | R | 0x00 |
| 7 | THR_EMPTY | 0x0: Transmit holding register (TX FIFO) is not empty. 0x1: Transmit hold register (TX FIFO) is empty. The transmission is not necessarily complete. | R | 0 |
| 6 | STS_FIFO_FUL | 0x0: Status FIFO not full 0x1: Status FIFO full | R | 1 |
| 5 | RX_LAST_BYTE | Receive last byte 0x0: The RX FIFO (RHR_REG) does not contain the last byte of the frame to be read. 0x1: The RX FIFO (RHR_REG) contains the last byte of the frame to be read. This bit is set only when the last byte of a frame is available to be read. It is used to determine the frame boundary. It is cleared on a single read of the LSR_REG register. | R | 1 |
| 4 | FRAME_TOO_LONG | Frame too long 0x0: No frame-too-long error in frame 0x1: Frame-too-long error in the frame at the top of the STATUS FIFO (next character to be read). This bit is set to 1 when a frame exceeding the maximum length (set by RXFLH_REG and RXFLR_REG registers) is received. When this error is detected, current frame reception is terminated. Reception is stopped until the next START flag is detected. | R | 0 |
| 3 | ABORT | 0x0: No abort pattern error in frame 0x1: Abort pattern received. SIR and MIR: abort pattern. FIR: Illegal symbol. | R | 0 |
| 2 | CRC | 0x0: No CRC error in frame 0x1: CRC error in the frame at the top of the STATUS FIFO (next character to be read) | R | 0 |
| 1 | STS_FIFO_E | 0x0: Status FIFO not empty 0x1: Status FIFO empty | R | 0 |
| 0 | RX_FIFO_E | | R | 1 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|---|------|-------|
| | | 0x0: At least one data character in the RX FIFO | | |
| | | 0x1: No data in the receive FIFO | | |

14.6.2.12.3 CIR Bitfield Details

| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 | |

| Bits | Field Name | Description | Type | Reset |
|------|--------------------|---|------|-------|
| 15:8 | Reserved | Read returns 0x00. | R | 0x00 |
| 7:4 | RX_FIFO_TRIG_START | RX FIFO trigger level to RESTORE transmission (0 to 60) | RW | 0x0 |
| 3:0 | RX_FIFO_TRIG_HALT | RX FIFO trigger level to HALT transmission (0 to 60) | RW | 0xF |

14.6.2.16 MSR_REG
Table 14-65. MSR_REG

| | | | |
|-------------------------|---|-----------------|-------|
| Address Offset | 0x018 | | |
| Physical Address | 0x4806 A018 | Instance | UART1 |
| | 0x4806 C018 | | UART2 |
| | 0x4902 0018 | | UART3 |
| | 0x4809 E000 | | UART4 |
| Description | Modem status register. UART mode only. This register provides information about the current state of the control lines from the modem, data set, or peripheral device to the MPU. It also indicates when a control input from the modem changes state. | | |
| Type | R | | |

| | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|---|---|---------|---------|----------|----------|---------|--------|---------|---------|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Reserved | | | | | | | | NCD_STS | NRI_STS | NDSR_STS | NCTS_STS | DCD_STS | RI_STS | DSR_STS | CTS_STS |

| Bits | Field Name | Description | Type | Reset |
|------|------------|---|------|-------|
| 15:8 | Reserved | Read returns 0x00. | R | 0x00 |
| 7 | NCD_STS | In loopback mode, it is equivalent to MCR_REG[3]. | R | - |
| 6 | NRI_STS | This bit is the complement of the nRI input. In loopback mode, it is equivalent to MCR_REG[2]. | R | - |
| 5 | NDSR_STS | In loopback mode, it is equivalent to MCR_REG[0]. | R | - |
| 4 | NCTS_STS | This bit is the complement of the nCTS input. In loopback mode, it is equivalent to MCR_REG[1]. | R | - |
| 3 | DCD_STS | Indicates that MCR_REG[3] in loopback changed. Cleared on a read. | R | 0 |
| 2 | RI_STS | Indicates that nRI input (or MCR_REG[2] in loopback) changed state from low to high. Cleared on a read. | R | 0 |
| 1 | DSR_STS | 0x1: Indicates that MCR_REG[0] in loopback changed state. Cleared on a read. | R | 0 |
| 0 | CTS_STS | 0x1: Indicates that nCTS input (or MCR_REG[1] in loopback) changed state. Cleared on a read. | R | 0 |

14.6.2.17 SPR_REG

Table 14-66. SPR_REG

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|--|--|---------------------|----|----|----|---|---|----------|-----------------|-------|---|---|---|---|-------------|--------------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|----------|--|--|--|--|--|--|--|----------|--|--|--|--|--|--|--|

| Bits | Field Name | Description | Type | Reset |
|------|------------------|-----------------------------|------|-------|
| 15:8 | Reserved | Read returns 0x00. | R | 0x00 |
| 7:4 | RX_FIFO_TRIG_DMA | Receive FIFO trigger level | RW | 0x0 |
| 3:0 | TX_FIFO_TRIG_DMA | Transmit FIFO trigger level | RW | 0x0 |

14.6.2.20 MDR1_REG

Table 14-69. MDR1_REG

| | | | |
|-------------------------|---|-----------------|-------|
| Address Offset | 0x020 | | |
| Physical Address | 0x4806 A020 | Instance | UART1 |
| | 0x4806 C020 | | UART2 |
| | 0x4902 0020 | | UART3 |
| | 0x4809 E000 | | UART4 |
| Description | Mode definition register 1. The mode of operation can be programmed by writing to MDR1_REG[2:0]; therefore, the MDR1_REG must be programmed on startup after configuration of the configuration registers (DLL_REG, DLH_REG, LCR_REG). The value of MDR1_REG[2:0] must not be changed again during normal operation. | | |
| Type | RW | | |

| | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|---|---|----------------|----------|-----|----------|----------|-------------|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Reserved | | | | | | | | FRAME_END_MODE | SIP_MODE | SCT | SET_TXIR | IR_SLEEP | MODE_SELECT | | |

| Bits | Field Name | Description | Type | Reset |
|------|----------------|---|------|-------|
| 15:8 | Reserved | Read returns 0x00. | R | 0x00 |
| 7 | FRAME_END_MODE | IrDA mode only 0x0: Frame-length method 0x1: Set EOT bit method | RW | 0 |
| 6 | SIP_MODE | MIR/FIR modes only. IrDA only. 0x0: Manual SIP mode: SIP is generated with the control of ACREG_REG[3]. 0x1: Automatic SIP mode: SIP is generated after each transmission. | RW | 0 |
| 5 | SCT | Store and control the transmission. 0x0: Starts the infrared transmission when a value is written to THR_REG 0x1: Starts the infrared transmission with the control of ACREG_REG[2] Note: Before starting any transmission, there must be no reception ongoing. | RW | 0 |
| 4 | SET_TXIR | Used to configure the infrared transceiver. IrDA only. 0x0: No action 0x1: IRTX pin output is forced high. | RW | 0 |
| 3 | IR_SLEEP | 0x0: IrDA/CIR sleep mode disabled 0x1: IrDA/CIR sleep mode enabled | RW | 0 |
| 2:0 | MODE_SELECT | UART-IrDA-CIR mode selection 0x0: UART 16x mode 0x1: SIR mode 0x2: UART 16x auto-baud 0x3: UART 13x mode | RW | 0x7 |

| Bits | Field Name | Description | Type | Reset |
|-------------|-------------------|-------------------------|-------------|--------------|
| 0x4: | | MIR mode | | |
| 0x5: | | FIR mode | | |
| 0x6: | | CIR mode | | |
| 0x7: | | Disable (default state) | | |

14.6.2.21 MDR2_REG

Table 14-70. MDR2_REG

| | | | |
|-------------------------|--|-----------------|-------|
| Address Offset | 0x024 | | |
| Physical Address | 0x4806 A024 | Instance | UART1 |
| | 0x4806 C024 | | UART2 |
| | 0x4902 0024 | | UART3 |
| | 0x4809 E000 | | UART4 |
| Description | Mode definition register 2 IR-IrDA and IR-CIR modes only MDR2_REG[0] describes the status of the interrupt in IIR_REG[5]. The IRTX_UNDERRUN bit must be read after an IIR_REG[5] TX_STATUS_IT interrupt occurs. The bits [2:1] of this register set the trigger level for the frame status FIFO (8 entries) and must be programmed before the mode is programmed in MDR1_REG[2:0]. | | |
| Type | RW | | |

| | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|---|---|----------|------------|----------------|------------|---------------|---------------|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Reserved | | | | | | | | Reserved | IRRXINVERT | CIR_PULSE_MODE | UART_PULSE | STS_FIFO_TRIG | IRTX_UNDERRUN | | |

| Bits | Field Name | Description | Type | Reset |
|------|----------------|---|------|-------|
| 15:8 | Reserved | Read returns 0x00. | R | 0x00 |
| 7 | Reserved | | R | 0 |
| 6 | IRRXINVERT | Only for IR mode (IrDA and CIR). Invert RX pin in the module before the voting or sampling system logic of the infrared block. This does not affect the RX path in UART modem modes. 0x0: Inversion is performed. 0x1: No inversion is performed. | RW | 0 |
| 5:4 | CIR_PULSE_MODE | CIR pulse modulation definition. Defines high level of the pulse width associated with a digit: 0x0: Pulse width of 3 from 12 cycles 0x1: Pulse width of 4 from 12 cycles 0x2: Pulse width of 5 from 12 cycles 0x3: Pulse width of 6 from 12 cycles | RW | 0x00 |
| 3 | UART_PULSE | UART mode only. Used to allow pulse shaping in UART mode. 0x0: Normal UART mode 0x1: UART mode with pulse shaping | RW | 0 |
| 2:1 | STS_FIFO_TRIG | Only for IR-IrDA mode Frame status FIFO threshold select: 0x0: 1 entry 0x1: 4 entries 0x2: 7 entries 0x3: 8 entries | RW | 0x00 |
| 0 | IRTX_UNDERRUN | IrDA transmission status interrupt. When the IIR_REG[5] interrupt occurs, the meaning of the interrupt is: 0x0: The last bit of the frame was transmitted successfully without error. | R | 0 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|---|------|-------|
| 0x1: | | An underrun occurred. The last bit of the frame was transmitted but with an underrun error. The bit is reset to 0 when the RESUME_REG register is read. | | |

14.6.2.22 TXFLL_REG

Table 14-71. TXFLL_REG

| | | | |
|-------------------------|---|-----------------|-------|
| Address Offset | 0x028 | | |
| Physical Address | 0x4806 A028 | Instance | UART1 |
| | 0x4806 C028 | | UART2 |
| | 0x4902 0028 | | UART3 |
| | 0x4809 E000 | | UART4 |
| Description | Transmit frame length register low IrDA modes only The registers TXFLL_REG and TXFLH_REG hold the 13-bit transmit frame length (expressed in bytes). TXFLL_REG holds the LSBs and TXFLH_REG holds the MSBs. The frame length value is used if the frame length method of frame closing is used. | | |
| Type | W | | |

| | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|---|---|-------|---|---|---|---|---|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Reserved | | | | | | | | TXFLL | | | | | | | |

| Bits | Field Name | Description | Type | Reset |
|------|------------|---|------|-------|
| 15:8 | Reserved | Write has no functional effect. | W | 0x00 |
| 7:0 | TXFLL | LSB register used to specify the frame length | W | 0x00 |

14.6.2.23 SFLSR_REG
Table 14-72. SFLSR_REG

| | | | |
|-------------------------|---|-----------------|-------|
| Address Offset | 0x028 | | |
| Physical Address | 0x4806 A028 | Instance | UART1 |
| | 0x4806 C028 | | UART2 |
| | 0x4902 0028 | | UART3 |
| | 0x4809 E000 | | UART4 |
| Description | Status FIFO line status register IrDA modes only Reading this register effectively reads frame status information from the status FIFO (this register does not physically exist). Reading this register increments the status FIFO read pointer (SFREGL_REG and SFREGH_REG must be read first). | | |
| Type | R | | |

| | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|---|---|----------|---|---|----------|-----------|--------------|-----------|----------|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Reserved | | | | | | | | Reserved | | | OE_ERROR | FTL_ERROR | ABORT_DETECT | CRC_ERROR | Reserved |

| Bits | Field Name | Description | Type | Reset |
|------|--------------|---|------|-------|
| 15:8 | Reserved | Read returns 0x00. | R | 0x00 |
| 7:5 | Reserved | | R | 0x0 |
| 4 | OE_ERROR | 0x1: Overrun error in RX FIFO when frame at top of RX FIFO was received. Top of RX FIFO = next frame to be read from RX FIFO. | R | - |
| 3 | FTL_ERROR | Frame-too-long error 0x1: Frame-length too long error in frame at top of RX FIFO | R | - |
| 2 | ABORT_DETECT | 0x1: Abort pattern detected in frame at top of RX FIFO 0x1: CRC error in frame at top of RX FIFO | R | - |
| 1 | CRC_ERROR | | R | - |
| 0 | Reserved | Read returns 0. | R | 0 |

14.6.2.24 RESUME_REG
Table 14-73. RESUME_REG

| | | | |
|-------------------------|--|-----------------|-------|
| Address Offset | 0x02C | | |
| Physical Address | 0x4806 A02C | Instance | UART1 |
| | 0x4806 C02C | | UART2 |
| | 0x4902 002C | | UART3 |
| | 0x4809 E000 | | UART4 |
| Description | IR-IrDA and IR-CIR modes only This register is used to clear internal flags, which halt transmission/reception when an underrun/overrun error occurs. Reading this register resumes the halted operation. This register does not physically exist and always reads as 0x00. | | |
| Type | R | | |

| | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|---|---|--------|---|---|---|---|---|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Reserved | | | | | | | | RESUME | | | | | | | |

| Bits | Field Name | Description | Type | Reset |
|------|------------|------------------------------------|------|-------|
| 15:8 | Reserved | Read returns 0x00 | R | 0x00 |
| 7:0 | RESUME | Dummy read to restart the TX or RX | R | 0x00 |

14.6.2.25 TXFLH_REG
Table 14-74. TXFLH_REG

|------|------------|---|------|-------|
| 15:8 | Reserved | Read returns 0x00. | R | 0x00 |
| 7:5 | Reserved | | R | 0x0 |
| 4:0 | TXFLH | MSB register used to specify the frame length | W | 0x00 |

14.6.2.26 RXFLL_REG
Table 14-75. RXFLL_REG

| | | | |
|-------------------------|---|-----------------|-------|
| Address Offset | 0x030 | | |
| Physical Address | 0x4806 A030 | Instance | UART1 |
| | 0x4806 C030 | | UART2 |
| | 0x4902 0030 | | UART3 |
| | 0x4809 E000 | | UART4 |
| Description | Received frame length register low IrDA modes only The registers RXFLL_REG and RXFLH_REG hold the 12-bit receive maximum frame length. RXFLL_REG holds the LSBs, and RXFLH_REG holds the MSBs. If the intended maximum receive frame length is n bytes, program RXFLL_REG and RXFLH_REG to be n + 3 in SIR or MIR modes and n + 6 in FIR mode (+3 and +6 are the result of frame format with CRC and stop flag; two bytes are associated with the FIR stop flag). | | |
| Type | W | | |

| | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|---|---|-------|---|---|---|---|---|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|--|------|-------|
| 15:8 | Reserved | Write has no functional effect. | W | 0x00 |
| 7:0 | RXFLL | LSB register used to specify the frame length in reception | W | 0x00 |

14.6.2.27 SFREGL_REG
Table 14-76. SFREGL_REG

| | | | |
|-------------------------|---|-----------------|-------|
| Address Offset | 0x030 | | |
| Physical Address | 0x4806 A030 | Instance | UART1 |
| | 0x4806 C030 | | UART2 |
| | 0x4902 0030 | | UART3 |
| | 0x4809 E000 | | UART4 |
| Description | Status FIFO register low | | |
| | IrDA modes only | | |
| | The frame lengths of received frames are written into the status FIFO. This information can be read by reading the SFREGL_REG and SFREGH_REG registers (these registers do not physically exist). The LSBs are read from SFREGL_REG, and the MSBs are read from SFREGH_REG. Reading these registers does not alter the status FIFO read pointer. These registers must be read before the pointer is incremented by reading the SFLSR_REG. | | |
| Type | R | | |

| | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|---|---|--------|---|---|---|---|---|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

| 15:8 | Reserved | Read returns 0x00. | R | 0x00 |
| 7 | STS_FIFO_RESET | Status FIFO reset. This bit is self-clearing. | RW | 0 |
| 6 | XBOF_TYPE | SIR xBOF select 0x0: 0xFF 0x1: 0xC0 | RW | 1 |
| 5:0 | Reserved | Read returns 0x00. | R | 0x00 |

14.6.2.31 UASR_REG
Table 14-80. UASR_REG

| | | | |
|-------------------------|--|-----------------|-------|
| Address Offset | 0x038 | | |
| Physical Address | 0x4806 A038 | Instance | UART1 |
| | 0x4806 C038 | | UART2 |
| | 0x4902 0038 | | UART3 |
| | 0x4809 E000 | | UART4 |
| Description | UART autobauding status register UART autobauding mode only This status register returns the speed, the number of bits by characters, and the type of parity in UART autobauding mode. In autobauding mode, the input frequency of the UART modem must be fixed to 48 MHz. Any other module clock frequency results in incorrect baud rate recognition. | | |

| | 0x4809 E000 | | UART4 |
| Description | Auxiliary control register | | |
| | IrDA-CIR mode only | | |
| Type | RW | | |

| | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|---|---|------------|--------|-----------|-----------------|----------|---------|----------|--------|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Reserved | | | | | | | | PULSE_TYPE | SD_MOD | DIS_IR_RX | DIS_TX_UNDERRUN | SEND_SIP | SCTX_EN | ABORT_EN | EOT_EN |

| Bits | Field Name | Description | Type | Reset |
|------|-----------------|---|------|-------|
| 15:8 | Reserved | Read returns 0x00. | R | 0x00 |
| 7 | PULSE_TYPE | SIR pulse-width select: 0x0: 3/16 of baud-rate pulse width 0x1: 1.6 μ s | RW | 0 |
| 6 | SD_MOD | Primary output used to configure transceivers. Connected to the SD/MODE input pin of IrDA transceivers. 0x0: SD pin is set to high. 0x1: SD pin is set to low. | RW | 0 |
| 5 | DIS_IR_RX | 0x0: Normal operation (RX input automatically disabled during transmit, but enabled outside of transmit operation). 0x1: Disables RX input (permanent state; independent of transmit) | RW | 0 |
| 4 | DIS_TX_UNDERRUN | 0x0: Long stop bits cannot be transmitted. TX underrun is enabled. 0x1: Long stop bits can be transmitted. TX underrun is disabled. | RW | 0 |
| 3 | SEND_SIP | MIR/FIR modes only. Send serial infrared interaction pulse (SIP). If this bit is set during an MIR/FIR transmission, the SIP is sent at the end of it. This bit is automatically cleared at the end of the SIP transmission. 0x0: No action 0x1: Send SIP pulse. | RW | 0 |
| 2 | SCTX_EN | Store and control TX start. When MDR1_REG[5] = 1 and the MPU writes 1 to this bit, the TX state-machine starts frame transmission. This bit is self-clearing. | RW | 0 |
| 1 | ABORT_EN | Frame abort. The MPU can intentionally abort transmission of a frame by writing 1 to this bit. Neither the end flag nor the CRC bits are appended to the frame. | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|---|------|-------|
| 0 | EOT_EN | EOT (end-of-transmission) bit. The MPU writes 1 to this bit just before it writes the last byte to the TX FIFO in the set-EOT bit frame-closing method. This bit is automatically cleared when the MPU writes to the THR_REG (TX FIFO). | RW | 0 |

| | 0x4809 E000 | | UART4 |
| Description | BOF length register. | | |
| | IR-IrDA mode only | | |
| | In IR-IrDA SIR operation, this register specifies the number of BOF + xBOFs to transmit. Value set into this register must consider the BOF character; therefore, to send only one BOF with no XBOF, this register must be set to 1. To send one BOF with N XBOF, this register must be set to N + 1. Furthermore, the value 0 sends 1 BOF plus 255 XBOF. | | |
| | In IR-IrDA MIR mode, this register specifies the number of additional start flags (MIR protocol mandates a minimum of 2 start flags). | | |
| Type | RW | | |

| | 0x4902 005C | | UART3 |
| | 0x4809 E000 | | UART4 |
| Description | Wake-up enable register The UART wake-up enable register is used to mask and unmask a UART event that subsequently notifies the system. An event is any activity in the logic that can cause an interrupt and/ or an activity that requires the system to wake up. Even if wakeup is disabled for certain events, if these events are also an interrupt to the UART, the UART still registers the interrupt as such. | | |

This chapter describes the four high-speed I²C controller modules.

NOTE: Some features may not be available or supported in your particular device. For more information, see Chapter 1, the Device Family section, and your device-specific data manual.

15.1 High-Speed I²C Controller Overview

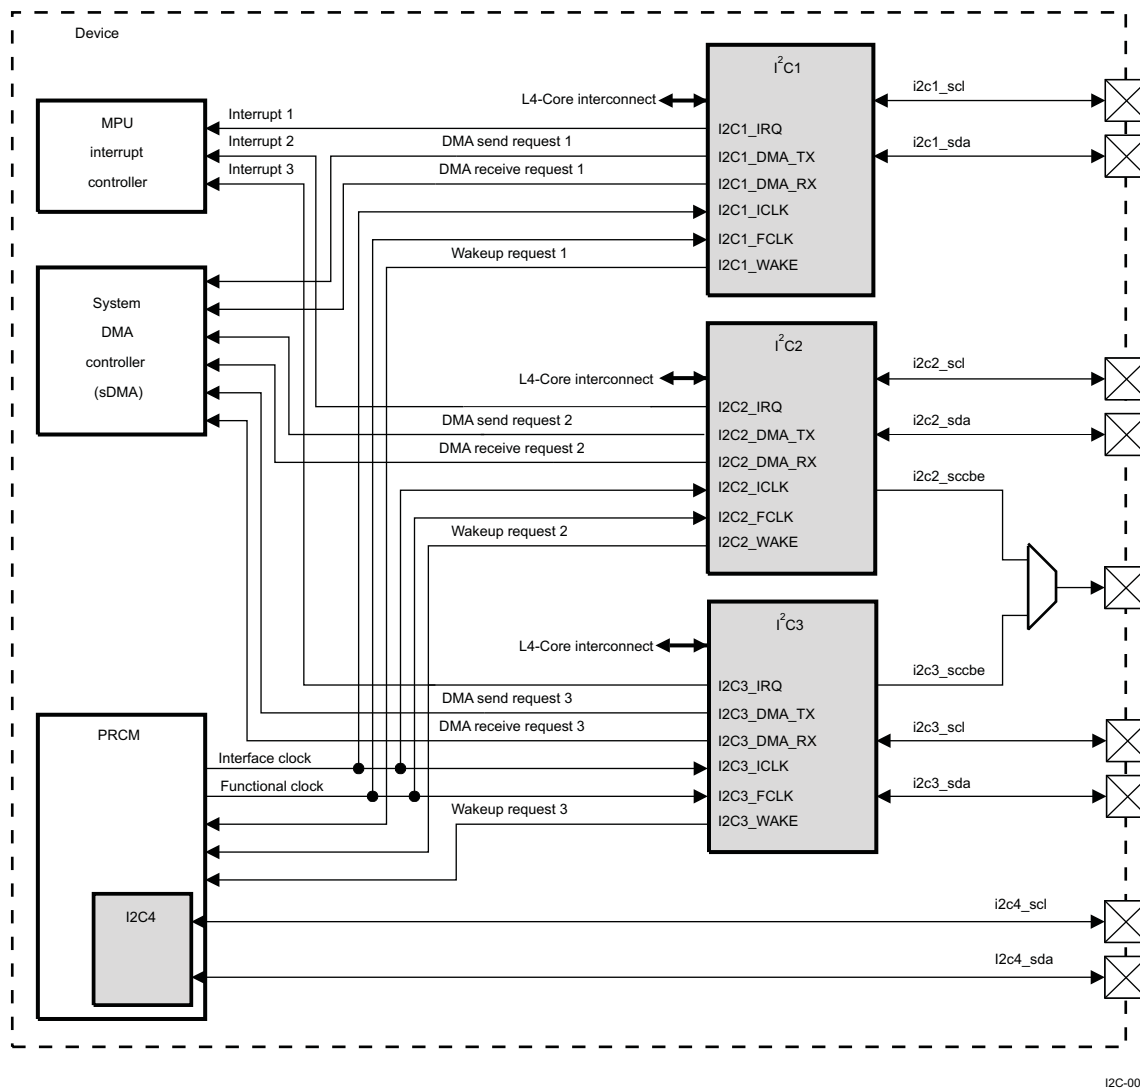

The device contains three multimaster high-speed (HS) inter-integrated circuit (I²C) controllers (I2Ci modules, where i = 1, 2, 3), each of which provides an interface between a local host (LH), such as the MPU subsystem, and any I²C-bus-compatible device that connects through the I²C serial bus. External components attached to the I²C bus can serially transmit/receive up to 8 bits of data to/from the LH device through the 2-wire I²C interface.

Each multimaster HS I²C controller can be configured to act like a slave or master I²C-compatible device. Moreover, each multimaster HS I²C controller can be configured in serial camera control bus (SCCB) mode (the SCCB is a serial bus developed by Omnivision Technologies, Inc.) to act as a master on a 2-wire SCCB bus. Only multimaster HS I²C controllers I2C2 and I2C3 can be configured in SCCB mode to act as a master device on a 3-wire SCCB bus.

The device contains an additional master transmitter HS I²C interface (I2C4) in the power, reset, and clock management (PRCM) module to perform dynamic voltage control and power sequencing. Texas Instruments provides a global solution with the device connected to power chips.

Figure 15-1 shows the HS I²C controllers in the device.

Figure 15-1. HS I²C Controllers

The three multimaster HS I²C controllers have the following features:

- Compliance with Philips I²C specification version 2.1

- Support for standard mode (up to 100K bits/s) and fast mode (up to 400K bits/s)
- Support for HS mode for transfer up to 3.4M bits/s
- Support for 3-wire/2-wire SCCB master mode for I2C2 and I2C3 modules, 2-wire SCCB master mode for I2C1 module, up to 100K bits/s
- 7-bit and 10-bit device addressing modes
- General call
- Start/restart/stop
- Multimaster transmitter/slave receiver mode
- Multimaster receiver/slave transmitter mode
- Combined master transmit/receive and receive/transmit mode
- Built-in FIFO for buffered read or write
 - 8 bytes for I2C1 and I2C2
 - 64 bytes for I2C3
- Module enable/disable capability
- Programmable clock generation
- 8-bit-wide data access
- Low-power consumption design
- Two DMA channels
- Wide interrupt capability

The master transmitter HS I²C controller I2C4 has the following features:

- Support of HS and fast modes
- 7-bit addressing mode only
- Master transmitter mode only
- Start/restart/stop

NOTE: The I2C4 clock frequency in HS mode is equal to the SYS_CLK clock frequency divided by 15.

NOTE: Before using HS I²C mode, determine that the target device supports this mode.

15.2 High-Speed $\mathcal{I}^2\mathcal{C}$ Controller Environment

15.2.1 Multimaster HS \mathcal{P} C Controllers in $\mathcal{I}^2\mathcal{C}$ Mode

Figure 15-2 shows the multimaster HS $\mathcal{I}^2\mathcal{C}$ controllers and their related connections with $\mathcal{I}^2\mathcal{C}$ -compliant devices in $\mathcal{I}^2\mathcal{C}$ mode.

Figure 15-2. Multimaster HS $\mathcal{I}^2\mathcal{C}$ Controllers and Typical Connections to $\mathcal{I}^2\mathcal{C}$ Devices

15.2.1.1 Multimaster HS $\mathcal{I}^2\mathcal{C}$ Controller Pins for Typical Connections in $\mathcal{I}^2\mathcal{C}$ Mode

Figure 15-3 shows the multimaster HS $\mathcal{I}^2\mathcal{C}$ controller pins used for typical connections with $\mathcal{I}^2\mathcal{C}$ devices.

Figure 15-3. Multimaster HS $\mathcal{I}^2\mathcal{C}$ Controller Interface Signals in $\mathcal{I}^2\mathcal{C}$ Mode

15.2.1.2 $\mathcal{I}^2\mathcal{C}$ Interface Typical Connections

Table 15-1 lists the pins associated with the $\mathcal{I}^2\mathcal{C}$ interface.

Table 15-1. Input/Output

| Signal | I/O ⁽¹⁾ | Description | Reset Value |
|----------|--------------------|--|-------------|
| i2ci_scl | I/O(OD) | $\mathcal{I}^2\mathcal{C}$ serial clock line ⁽²⁾ . Open-drain output buffer. Requires external pullup resistor (R_p). | Hi-Z |
| i2ci_sda | I/O(OD) | $\mathcal{I}^2\mathcal{C}$ serial data line. Open-drain output buffer. Requires external R_p . | Hi-Z |

⁽¹⁾ I = Input; O = Output; OD = Open Drain; Hi-Z = High Impedance

⁽²⁾ This signal is also used as re-timing input.

15.2.1.3 I²C Typical Connection Protocol and Data Format

15.2.1.3.1 Serial Data Format

The I²C controller operates in 8-bit word data format (byte write access supported for the last access). Each byte transmitted or received on the serial data line (i2ci_sda) is 8 bits long. The number of bytes that can be transmitted or received is not restricted. The data is transferred with the most-significant bit (MSB) first. In receiver mode, each byte is followed by an acknowledge bit from the I²C. Figure 15-4 shows a typical I²C communication format.

Figure 15-4. I²C Data Transfer

15.2.1.3.2 Data Validity

The data on the serial data line must be stable during the high period of the clock i2ci_scl. The high and low states of the data line can change only when the clock signal on the serial clock line is low.

Figure 15-5 is an example of data validity requirements.

Figure 15-5. Bit Transfer on the I²C Bus

15.2.1.3.3 Start and Stop Conditions

The I²C module generates start (S) and stop (P) conditions when it is configured as a master.

- An S condition is a high-to-low transition on the i2ci_sda line while i2ci_scl is high.
- A P condition is a low-to-high transition on the i2ci_sda line while i2ci_scl is high.

The bus is considered busy after the S condition (the I2Ci.I2C_STAT[12] BB bit is 1 to indicate that the bus is busy) and free after the P condition (the I2Ci.I2C_STAT[12] BB bit is 0 to indicate that the bus is free).

Figure 15-6 shows the waveforms that occur during an S and a P condition.

Figure 15-6. S and P Condition Events

15.2.1.3.4 Addressing

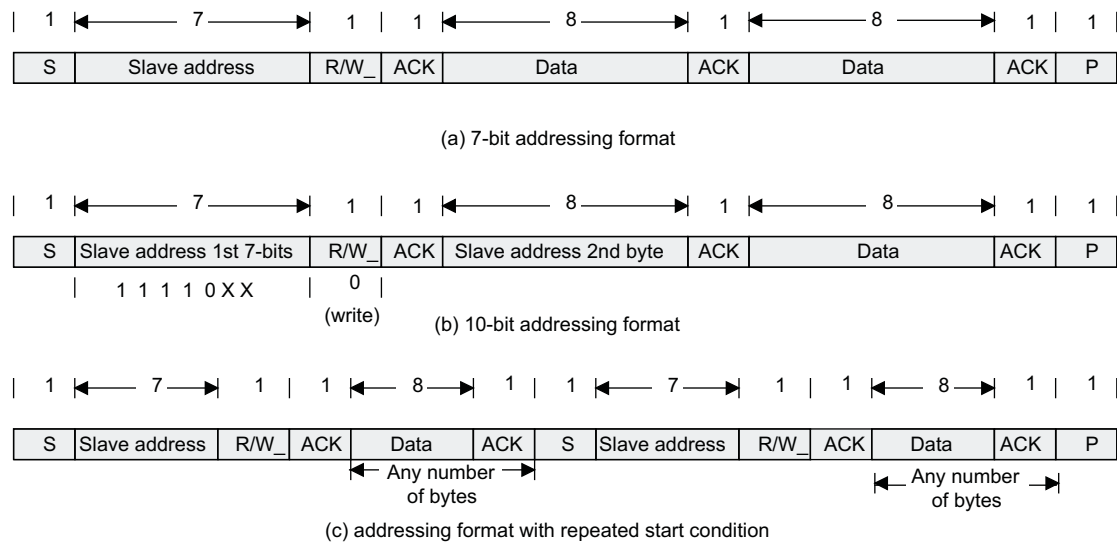

The I²C module supports two data formats in fast/standard (F/S) and HS modes:

- 7-bit/10-bit addressing format
- 7-bit/10-bit addressing format with repeated start (Sr) condition

15.2.1.3.4.1 Data Transfer Format in F/S Mode

Figure 15-7 shows the I²C data transfer format in F/S mode.

Figure 15-7. I²C Data Transfer Formats in F/S Mode

I2C-007

The first word after a S condition consists of 8 bits. In acknowledge mode, an extra dedicated acknowledgment bit is inserted after each byte.

In addressing formats with 7-bit addresses, the first byte is composed of 7 MSB slave address bits and 1 least-significant bit (LSB) R/W_ bit.

The LSB R/W_ bit of the address byte indicates the transmission direction of the data bytes that follow it. If R/W_ is 0, the master writes data to the selected slave; if it is 1, the master reads data from the slave.

In addressing formats with 10-bit addresses, the structure of the first byte is 11110XXY, where XX is the two MSBs of the 10-bit addresses, and Y is the R/W_ bit. If the R/W_ bit is 0, the next byte contains the last 8 bits of the slave address. If the R/W_ bit is 1, the next byte contains data transmitted from the slave to the master.

15.2.1.3.4.2 Data Transfer Format in HS Mode

Figure 15-8 shows the I²C data transfer format in HS mode.

Figure 15-8. I²C Data Transfers in HS Mode

I2C-008

Each multimaster HS I²C controller module can also operate in HS mode. In this case, after the S condition, the module, which is in F/S mode, writes the master code address (000001XXX, where XXX is the variable portion of the master code) on the bus. No device connected on the same bus acknowledges this address. The module switches the clock to the HS clock and after an Sr condition, and sends the slave address and the data, as shown in Figure 15-8.

NOTE: For more information, see *I²C Bus Specification v2.1*, January 2000.

15.2.1.3.5 Master Transmitter

In master transmitter mode, data assembled in one of the previously described data formats is shifted out on serial data line i2ci_sda in synchronization with the self-generated clock pulses on serial clock line i2ci_scl. When the intervention of the processor is required (I2Ci.I2C_STAT[10] XUDF bit) after a byte is transmitted, the clock pulses are inhibited and the serial clock line is held low.

15.2.1.3.6 Master Receiver

Master receiver mode can be entered only from master transmitter mode. With any of the address formats (a), (b), or (c) (see Figure 15-7), if R/W_ is high, the module enters master receiver mode after the slave address byte and bit R/W_ are transmitted. Serial data bits received on bus line i2ci_sda are shifted in synchronization with the self-generated clock pulses on i2ci_scl. When the intervention of the processor is required (I2Ci.I2C_STAT[11] ROVR bit) after a byte is transmitted, the clock pulses are inhibited and the serial clock line is held low. At the end of a transfer, a P condition is generated.

15.2.1.3.7 Slave Transmitter

Slave transmitter mode can be entered only from slave receiver mode. With any of the address formats (a), (b), or (c) (see Figure 15-7), slave transmitter mode is entered if the slave address byte is the same as its own address, and when the R/W_ bit transmitted by the master transmitter is high. The slave transmitter shifts the serial data out on data line i2ci_sda in synchronization with the clock pulses generated by the master device. It does not generate the clock, but it can hold clock line i2ci_scl low when intervention of the LH is required (the I2Ci.I2C_STAT[10] XUDF bit).

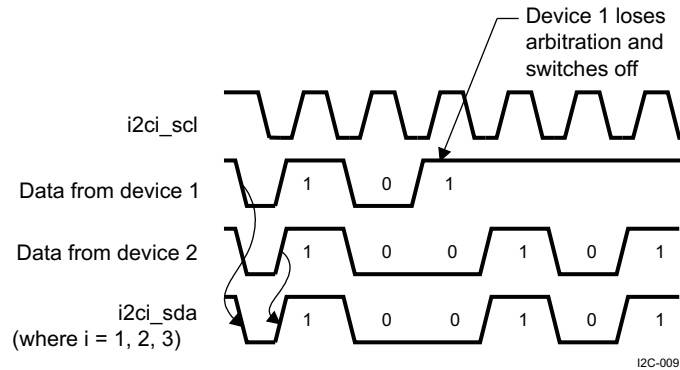

15.2.1.3.8 Slave Receiver

In slave receiver mode, serial data bits received on bus line i2ci_sda are shifted in in synchronization with the clock pulses on i2ci_scl generated by the master device. The slave receiver does not generate the clock, but it can hold the serial clock line low when intervention of the LH is required (the I2Ci.I2C_STAT[11] ROVR bit) after a byte is received.

15.2.1.3.9 Bus Arbitration

If two or more master transmitters start a transmission on the same bus simultaneously, an arbitration procedure is invoked. This arbitration procedure uses the data presented on the serial bus by the competing transmitters. When a transmitter senses that a high signal it has presented on the bus has been overruled by a low signal, it switches to slave receiver mode, sets the arbitration lost flag (I2Ci.I2C_STAT[0] AL bit), and generates the arbitration lost interrupt. Figure 15-9 shows arbitration between two devices. The arbitration procedure gives priority to the device that transmits the serial data stream with the lowest binary value. If two or more devices send identical first bytes, arbitration continues on the subsequent bytes.

Figure 15-9. Arbitration Between Master Transmitters

15.2.1.3.10 I²C Clock Generation and Synchronization

Under normal conditions, only one master device generates the clock signal i2ci_scl. During arbitration, however, there are two or more master devices, and the clock must be synchronized so that the data output can be compared. The wired-AND property of the clock line means that the device that first generates a low period of the clock line overrules the other devices. At this high-low transition, the clock generators of the other devices are forced to start generating their own low periods. The clock line is then held low by the device with the longest low period, while the other devices that finish their low periods must wait for the clock line to be released before starting their high periods. A synchronized signal on the clock line is thus obtained, where the slowest device determines the length of the low period and the fastest device determines the length of the high period.

If a device pulls down the clock line for a longer time, all clock generators must enter the wait state. In this way, a slave can slow down a fast master, and the slow device can create enough time to store a received byte or prepare a byte to be transmitted. Figure 15-10 shows clock synchronization.

Figure 15-10. Synchronization of I²C Clock Generators

15.2.2 Multimaster High-Speed I²C Controllers in SCCB Mode

The SCCB is a 3-wire serial bus developed by Omnivision Technologies, Inc. The SCCB can also operate in a modified 2-wire serial mode. For details, see the SCCB specifications version 2.1 document at http://www.ovt.com/pdfs/ds_note.pdf.

The multimaster HS I²C controllers support the 2-wire SCCB protocol in master mode. Only the I2C2 and I2C3 modules support the 3-wire SCCB protocol in master mode.

Figure 15-11 shows the multimaster HS I²C controllers and their related connections with 3-wire or 2-wire SCCB-compliant devices.

Figure 15-11. Multimaster HS I²C Controllers and Typical Connections to SCCB Devices

(a) Typical connection with 3-wire SCCB devices

(b) Typical connection with 2-wire SCCB devices

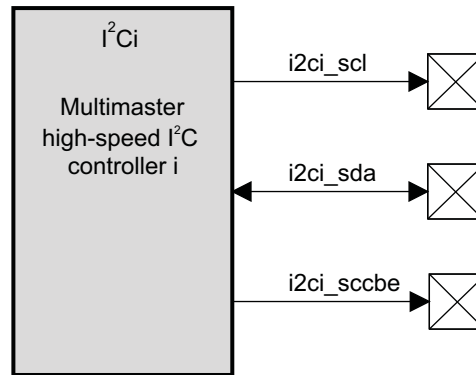

I2C-011

NOTE: Only one 2-wire SCCB slave device can be connected to the 2-wire SCCB bus.

15.2.2.1 Multimaster HS I²C Controller Pins for Typical Connections in SCCB Mode

Figure 15-12 shows the multimaster HS I²C controller pins used for typical connections with 3-wire or 2-wire SCCB devices.

Figure 15-12. Multimaster HS I²C Controller Interface Signals in SCCB Mode

(where i = 1, 2, 3 and i2ci_sccb_e is not available for I2C1)

I2C-012

15.2.2.2 SCCB Interface Typical Connections

Table 15-2 lists the pins associated with the SCCB interface.

Table 15-2. Input/Output

| Signal | I/O ⁽¹⁾ | Description | Reset Value | I2Ci.I2C_CON[15] I2C_EN bit = 0 |
|----------------------------|--------------------|--|-------------|------------------------------------|
| i2ci_scl | O | SCCB serial clock line ⁽²⁾ . Standard CMOS output buffer. | Hi-Z | High |
| i2ci_sda | I/O(OD) | SCCB serial data line. Standard CMOS 3-state output buffer. Requires external conflict-protection resistor for each slave device connected to the bus. | Hi-Z | Hi-Z |
| i2ci_sccb_e ⁽³⁾ | O | SCCB enable line. Standard CMOS output buffer. | High | High |

⁽¹⁾ I = Input; O = Output; OD = Open Drain; Hi-Z = High Impedance

⁽²⁾ This output signal is also used as re-timing input.

⁽³⁾ This signal is used for the 3-wire SCCB protocol only.

NOTE: Because they share the same ball, the i2c2_sccb_e and i2c3_sccb_e signals are not available at the same time. For detailed information about pin configuration, see Chapter 6, System Control Module.

The I2C1 module does not provide any i2c1_sccb_e signal at the chip boundary of the device; thus, this module does not support the 3-wire SCCB protocol

15.2.2.3 SCCB Typical Connection Protocol and Data Format

15.2.2.3.1 Serial Transmission Timing Diagram

Figure 15-13 is the timing diagram of the 3-wire SCCB data transmission.

Figure 15-13. 3-wire SCCB Transmission Timing Diagram

NOTE: When operating in 2-wire SCCB mode, the i2ci_sccbce signal is not used by the 2-wire SCCB-compliant slave device attached to the 2-wire SCCB bus.

15.2.2.3.2 SCCB Transmission Data Formats

Figure 15-14 describes the data format of the three kinds of transmission.

Figure 15-14. SCCB Transmission Data Formats

R/W: 0 = Write, 1 = Read

X: don't care

NA: ninth bit of a read phase. This bit must be set to 1 by the master device.

I2C-014

The basic element of a data transmission is a phase. A phase contains 9 bits, which consist of an 8-bit sequential data transmission followed by a ninth bit. The ninth bit is a don't-care bit (X) or an NA bit, depending on whether the data transmission is a write or a read. The maximum number of phases that can be included in a transmission is three. The MSB is always asserted first for each phase.

A data transmission is one of three types:

- **3-phase write transmission:** The 3-phase write transmission cycle (see (a) of [Figure 15-14](#)) is a full write operation in which the master can write 1 byte of data to a specific slave(s). The 7-bit slave address in the ID value identifies the specific slave that the master intends to access. The subaddress identifies the register location of the specified slave. The write data contains 8-bit data that the master intends to write over the content of this specific address. The ninth bit of each of the three phases is a don't-care bit (X bit).
- **2-phase write transmission:** The 2-phase write transmission cycle is followed by a 2-phase read transmission cycle (see below). The purpose of issuing a 2-phase write transmission cycle (see (b) of [Figure 15-14](#)) is to identify the subaddress of some specific slave from which the master intends to read data for the following 2-phase read transmission cycle. The ninth bit of each phase is a don't-care bit (X bit).
- **2-phase read transmission:** Either a 3-phase or a 2-phase write transmission cycle must be asserted ahead of a 2-phase read transmission cycle. The 2-phase read transmission cycle (see (c) of [Figure 15-14](#)) has no ability to identify the subaddress. The 2-phase write transmission cycle contains read data of 8 bits and a ninth don't-care bit or NA bit. The master must drive the NA bit at logical 1.

In each transmission type, phase 1 (7-bit slave address of the ID value) is asserted by the master to identify the selected slave to which the data is read or written. Each slave has a unique 7-bit slave address. The 7-bit slave address of the ID value comprises 7 bits, from bit 7 to bit 1, that can identify up to 128 slaves. The eighth bit, bit 0, is the read/write selector bit that specifies the transmission direction of the current cycle. A logical 0 represents a write cycle and a logical 1 represents a read cycle. The ninth bit of phase 1 is a don't-care bit (X bit).

Phase 2 (subaddress/read data) is asserted by the master (subaddress) or the slave(s) (read data). A phase 2 transmission asserted by the master identifies the subaddress of the slave(s) the master intends to access. A phase 2 transmission asserted by the slave(s) indicates the read data that the master will receive. The slave(s) recognize the subaddress of this read data according to the previous 3-phase or 2-phase write transmission cycle. The ninth bit is defined as a don't-care bit (X bit) when the master asserts phase 2. The ninth bit is defined as an NA bit when the slave(s) asserts the phase 2 transmission. The master is responsible for a logical 1 during the period of the NA bit.

Phase 3 (write data) is asserted only by the master. This phase contains the data the master intends to write to the slave(s). Because the master asserts the transmission, the ninth bit of the phase 3 transmission is defined as a don't-care bit (X bit).

NOTE: A multimaster HS I²C controller configured in SCCB mode can perform two operations:

- Writing a single byte to an SCCB slave device by using the 3-phase write transmission cycle
 - Reading a single byte from an SCCB slave device by using the 2-phase write transmission cycle followed by the 2-phase read transmission cycle
-

15.2.3 High-Speed I²C Controller for Communication With Power Chip(s)

The master transmitter HS I²C controller I2C4 interfaces between the and external power chip(s) for voltage control. This module is always configured as an I²C master transmitter; it does not support the SCCB protocol. For a definition of master transmitter mode, see [Section 15.2.1.3.5, Master Transmitter](#).

[Figure 15-15](#) shows a typical connection between the master transmitter HS I²C controller I2C4 of the device and external power chip(s).

Figure 15-15. Typical Connection Between the HS I²C Controller and Power Chip(s)

I2C-015

15.2.3.1 HS I²C Controller I2C4 Pins for Typical Connections

Figure 15-16 shows the HS I²C controller I2C4 pins used for typical connections with power chips.

Figure 15-16. HS I²C Controller I2C4 Interface Signals

I2C-016

15.2.3.2 HS I²C Controller I2C4 Interface Typical Connections

Table 15-3 lists the pins associated with the I²C interface of the HS I²C controller I2C4 of the device.

Table 15-3. Input/Output Description

| Signal | I/O ⁽¹⁾ | Description | Reset Value |
|----------|--------------------|---|-------------|
| i2c4_scl | I/O(OD) | I ² C serial clock line ⁽²⁾ . Open-drain output buffer. Requires external Rp. | Hi-Z |
| i2c4_sda | I/O(OD) | I ² C serial data line. Open-drain output buffer. Requires external Rp. | Hi-Z |

⁽¹⁾ I = Input; O = Output; OD = Open Drain; Hi-Z = High Impedance

⁽²⁾ This signal is also used as re-timing input.

NOTE: The I2C4 clock frequency in HS mode is equal to the SYS_CLK clock frequency divided by 15.

15.2.3.3 I²C Typical Connections Protocol and Data Format for I2C4

15.2.3.3.1 Serial Data Format

The serial data format is the same as described in [Section 15.2.1.3.1, Serial Data Format](#).

15.2.3.3.2 Data Validity

The data validity is the same as described in [Section 15.2.1.3.2, Data Validity](#).

15.2.3.3.3 S and P Conditions

The S and stop P conditions are the same as described in [Section 15.2.1.3.3, Start and Stop Conditions](#).

15.2.3.3.4 Addressing

The master transmitter HS I²C controller I2C4 supports only the 7-bit addressing mode. For each frame, the master writes the 8-bit value (DATA) in the register specified by the 8-bit register address (RA) of the slave addressed by the slave address (SA).

15.2.3.3.4.1 Data Transfer Format in F/S Mode

[Figure 15-17](#) shows the I²C data transfer format in F/S mode for the I2C4 module.

Figure 15-17. I²C Data Transfer Format in F/S Mode for the I2C4 Module

I2C-017

15.2.3.3.4.2 Data Transfer Format in HS Mode

[Figure 15-18](#) shows the I²C data transfer format in HS mode for the I2C4 module.

I2C-018

15.3 High-Speed I²C Controller Integration

Figure 15-19 shows the integration of the four HS I²C controllers in the device.

Figure 15-19. HS I²C Controller Integration

15.3.1 Clocking, Reset, and Power-Management Scheme

15.3.1.1 Clocks

15.3.1.1.1 Module Clocks

Each multimaster HS I²C controller is clocked with an independent functional clock of 96 MHz (I2Ci_FCLK) and an interface clock (I2Ci_ICLK) for interfacing with the L4-Core interconnect. These clocks are provided by the PRCM module.

The SYS_CLK clock provided by the clock generator of the PRCM module is connected to the functional and interface clocks of the HS I²C controller I2C4. For detailed information about the module clocking, see *Power, Reset, and Clock Management*.

The interface clock can be enabled or disabled for each multimaster HS I²C controller by setting the following bits in the PRCM module:

- PRCM.CM_ICLKEN1_CORE[15] EN_I2C1 bit for the I2C1 module

- PRCM.CM_ICLKEN1_CORE[16] EN_I2C2 bit for the I2C2 module
- PRCM.CM_ICLKEN1_CORE[17] EN_I2C3 bit for the I2C3 module

The functional clock can be enabled or disabled for each multimaster HS I²C controller by setting the following bits in the PRCM module:

- PRCM.CM_FCLKEN1_CORE[15] EN_I2C1 bit for the I2C1 module
- PRCM.CM_FCLKEN1_CORE[16] EN_I2C2 bit for the I2C2 module
- PRCM.CM_FCLKEN1_CORE[17] EN_I2C3 bit for the I2C3 module

The functional clock is processed by a prescaler block to produce the internal sampling clock. This clock is generated by the I²C prescaler block. The prescaler block consists of the I2Ci.I2C_PSC[7:0] PSC bit field (where i = 1, 2, 3) that is used to divide down the functional clock to obtain an internal sampling clock with a frequency value of I2Ci_FCLK/(I2Ci.I2C_PSC[7:0] PSC bit field value + 1, where i = 1, 2, 3).

NOTE: The I2C4.I2C_PSC[7:0] PSC bit field of the I2C4 module is not accessible by software. For details about the bit rates available for the I2C4 module, see [Section 15.4.7](#).

15.3.1.2 Power Management

15.3.1.2.1 Module Power Saving

This section describes power-saving techniques for the multimaster HS I²C controllers. To conserve power, when no activity is detected on the L4-Core interconnect interface of the module, each of these modules supports an automatic idle mode that is enabled or disabled by setting the I2Ci.I2C_SYSC[0] AUTOIDLE bit.

When this bit is asserted (set to 1), if no activity is detected on the L4-Core interface, the automatic idle mode is enabled and the interface clock I2Ci_ICLK is disabled internally to the module, thus reducing power consumption.

When new activity is detected on the L4-Core interconnect interface of the module, the clock restarts with no latency penalty. After reset, the automatic idle mode is disabled; thus, this mode must be enabled by software for reduced power consumption.

15.3.1.2.2 System Power Management

As part of the system-wide power-management scheme, each multimaster HS I²C controller supports a communication protocol with the PRCM module to request the module to enter a low-power mode. When a module acknowledges a low-power mode request from the PRCM module, the interface and/or the functional clocks are gated off at the PRCM clock generator. Because the clocks are disabled at the source, the low-power mode offers lower power consumption than the internal clock autogating method used by local power management.

The PRCM.CM_ICLKEN1_CORE[15] EN_I2C1, PRCM.CM_ICLKEN1_CORE[16] EN_I2C2, and PRCM.CM_ICLKEN1_CORE[17] EN_I2C3 bits in the PRCM module control the interface clocks of the I2C1, I2C2, and I2C3 modules, respectively.

The PRCM.CM_FCLKEN1_CORE[15] EN_I2C1, PRCM.CM_FCLKEN1_CORE[16] EN_I2C2, and PRCM.CM_FCLKEN1_CORE[17] EN_I2C3 bits in the PRCM module control the functional clocks of the I2C1, I2C2, and I2C3 modules, respectively.

For details about clock enabling/disabling in the PRCM module, see [Power, Reset, and Clock Management](#).

Each multimaster HS I²C controller can be configured through the I2Ci.I2C_SYSC[4:3] IDLEMODE bit field as one of the following acknowledgment modes:

- Force-idle mode (I2Ci.I2C_SYSC[4:3] IDLEMODE bit field = b00): The module immediately enters idle mode on receiving a low-power-mode request from the PRCM module. In this mode, the software must ensure that there are no asserted output interrupts before requesting this mode to go to idle state.
- No-idle mode (I2Ci.I2C_SYSC[4:3] IDLEMODE bit field = b01): The module never enters idle mode.
- Smart-idle mode (I2Ci.I2C_SYSC[4:3] IDLEMODE bit field = b10): After receiving a low-power-mode request from the PRCM module, the module enters idle mode only after all asserted output interrupts are acknowledged and there is no pending internal event.

NOTE: The value I2Ci.I2C_SYSC[4:3] IDLEMODE bit field = b11 must not be used.

Table 15-4 describes the multimaster HS I²C controller power management modes.

Table 15-4. Multimaster HS I²C Controller Power Management Modes

| Power management mode requested by the PRCM module | I2Ci.I2C_SYSC[4:3] IDLEMODE bit field value (where i = 1, 2, 3) |
|--|---|
| Force-idle | b00 |
| No-idle | b01 |
| Smart-idle | b10 |
| Reserved (not used) | b11 |

The PRCM module gates the interface and/or the functional clocks after receiving the acknowledgment of the I2Ci module (where i = 1, 2, 3). The I2Ci.I2C_SYSC[9:8] CLOCKACTIVITY bit field indicates the state of the interface and functional clocks of the module when in idle mode. Table 15-5 lists the value of the I2Ci.I2C_SYSC[9:8] CLOCKACTIVITY bit field and indicates the state of the interface and functional clocks at the PRCM clock generator output in idle mode.

Table 15-5. State of the Interface and Functional Clocks When the Module is in Idle Mode

| I2Ci.I2C_SYSC[9:8] CLOCKACTIVITY bit field value (where i = 1, 2, 3) | Functional Clock | Interface Clock |
|--|------------------|-----------------|
| b00 | OFF | OFF |
| b01 | OFF | ON |
| b10 | ON | OFF |
| b11 | ON | ON |

NOTE: The PRCM.CM_AUTOIDLE1_CORE[15] AUTO_I2C1, PRCM.CM_AUTOIDLE1_CORE[16] AUTO_I2C2, and PRCM.CM_AUTOIDLE1[17] AUTO_I2C3 bits control, for each multimaster HS I²C controller, whether the L4-Core interconnect interface clock is enabled or disabled in synchronization with the CORE power domain state transition (see , *Power, Reset, and Clock Management*).

NOTE: The voltage controller, in which the HS I²C controller I2C4 is implemented, has no idle request/acknowledge mechanism. The idle modes for the voltage controller are directly managed by the PRM module. For details, see , *Power, Reset, and Clock Management*.

15.3.1.2.3 Wake-Up Capability

Each multimaster HS I²C controller I2Ci can wake up the system by generating a wake-up request through the I2Ci_WAKE signal connected to the PRCM module.

The wake-up request is composed of the merge of all wake-up events. Each wake-up event can be separately enabled or disabled by setting the corresponding bit in the I2Ci.I2C_WE register.

The global wake-up capability of the module can be enabled or disabled by setting the I2Ci.I2C_SYSC[2] ENAWAKEUP bit (1: enabled, 0: disabled).

Figure 15-20 shows the wake-up generation flow.

Figure 15-20. Wake-up Generation Flow

Table 15-6 lists all wake-up events with the corresponding enable/disable bit in the I2Ci.I2C_WE register.

Table 15-6. Wake-up Events

| Wake-up Event Name | Supported Configuration Mode | Enable/Disable bit ⁽¹⁾ | Event Generated When: |
|--------------------------|--|-----------------------------------|---|
| AL event | I ² C mode only | I2Ci.I2C_WE[0] AL_WE | The I2Ci module in the device loses the arbitration of the I ² C bus in master transmitter mode. |
| NACK event | I ² C mode only | I2Ci.I2C_WE[1] NACK_WE | A nonacknowledgment has been generated on the I ² C bus, indicating a transmission error. |
| ARDY event | I ² C receive mode and SCCB read mode | I2Ci.I2C_WE[2] ARDY_WE | The current transaction is finished and the module registers can be accessed. |
| DRDY event | I ² C and SCCB modes | I2Ci.I2C_WE[3] DRDY_WE | The TX FIFO needs some data to be transferred or the RX FIFO must be read. |
| GC event | I ² C mode only | I2Ci.I2C_WE[5] GC_WE | A general call is received on the I ² C bus. |
| STC event ⁽²⁾ | I ² C mode only | I2Ci.I2C_WE[6] STC_WE | A start (S) condition is detected on the I ² C bus. ⁽³⁾ |
| BF event | I ² C and SCCB modes | I2Ci.I2C_WE[8] BF_WE | The bus is free and the LH can initiate its own transfer. |
| AAS event | I ² C mode only | I2Ci.I2C_WE[9] AAS_WE | An external master I ² C device addresses the module of the device to inform the LH that it can check which of its own addresses was used by the external master I ² C device to access the module of the device. |

⁽¹⁾ To enable the corresponding wake-up event generation, set the bit to 1. To disable the corresponding wake-up event generation, set the bit to 0.

⁽²⁾ Wake-up event asynchronously detected.

⁽³⁾ This event must not be enabled if the functional clock cannot be disabled.

Table 15-6. Wake-up Events (continued)

| Wake-up Event Name | Supported Configuration Mode | Enable/Disable bit ⁽¹⁾ | Event Generated When: |
|--------------------|--|-----------------------------------|--|
| RDR event | I ² C receive mode only | I2Ci.I2C_WE[13] RDR_WE | The module, configured as a receiver, has detected a stop (P) condition on the I ² C bus and the RX FIFO threshold (I2Ci.I2C_BUF[13:8] RTRSH field value + 1) is not reached and the RX FIFO is not empty. This allows the module to inform the LH that it can check the amount of data to be transferred from the RX FIFO. |
| XDR event | I ² C master transmit mode only | I2Ci.I2C_WE[14] XDR_WE | The TXFIFO level is below the threshold (I2Ci.I2C_BUF[5:0] XTRSH field value + 1) and the amount of data left to be transferred is less than this threshold. This allows the module to inform the LH that it can check the amount of data to be written to the TX FIFO. |

NOTE: With the exception of the STC event, the functional clock must be active for wake-up event detection to occur. The HS I²C controller I2C4 has no wake-up capability.

15.3.1.3 Resets

15.3.1.3.1 Hardware Reset

The three multimaster HS I²C controllers receive their reset signal CORE_RST (the reset signal of the CORE power domain) from the PRCM module.

The master transmitter HS I²C controller I2C4 gets its reset signal PRM_RSTPWON from the reset manager in the PRCM module.

15.3.1.3.2 Software Reset

Each multimaster HS I²C controller supports the software reset by accessing the I2Ci.I2C_SYSC[1] SRST bit (1: reset, 0: normal mode).

The software reset status can be checked by accessing the I2Ci.I2C_SYSS[0] RDONE bit (1: reset is done, 0: reset is ongoing).

To do a software reset, the following steps must be done:

1. Ensure that the module is disabled (clear the I2Ci.I2C_CON[15] I2C_EN bit to 0).
2. Set the I2Ci.I2C_SYSC[1] SRST bit to 1.
3. Enable the module by setting I2Ci.I2C_CON[15] I2C_EN bit to 1.
4. Check the I2Ci.I2C_SYSS[0] RDONE bit until it is set to 1 to indicate the software reset is complete.

NOTE: The I2Ci.I2C_CON[15] I2C_EN bit can hold the functional clock domain of the multimaster HS I²C controller in reset after the device reset has been released. When the system bus reset is removed, this bit remains cleared. The functional part of the I²C controller is held in reset state while this bit is 0, and all configuration registers can be accessed.

The I2Ci.I2C_CON[15] I2C_EN bit must be set to 1 to enable the functional part of the I²C controller.

The I2Ci.I2C_SYSS[0] RDONE bit is asserted only after the module is enabled by setting the I2Ci.I2C_CON[15] I2C_EN bit to 1.

15.3.1.4 Power Domain

The three multimaster HS I²C controllers are connected to the CORE power domain, whereas the HS I²C controller I2C4 belongs to the WKUP power domain.

15.3.2 Hardware Requests

15.3.2.1 DMA Requests

Each multimaster HS I²C controller can generate two DMA requests to the system DMA (sDMA) controller. [Table 15-7](#) lists the DMA requests with mapping on the sDMA controller.

Table 15-7. Multimaster HS I²C Controller DMA Requests

| Name | Source | Destination (sDMA controller) | Description |
|-------------|--------|-------------------------------|--|
| I2C1_DMA_TX | I2C1 | S_DMA_26 | I2C1 DMA write request to inform the sDMA to write new data in the I2C1.I2C_DATA[7:0] register |
| I2C1_DMA_RX | I2C1 | S_DMA_27 | I2C1 DMA read request to inform the sDMA to read the data in the I2C1.I2C_DATA[7:0] register |
| I2C2_DMA_TX | I2C2 | S_DMA_28 | I2C2 DMA write request to inform the sDMA to write new data in the I2C2.I2C_DATA[7:0] register |
| I2C2_DMA_RX | I2C2 | S_DMA_29 | I2C2 DMA read request to inform the sDMA to read the data in the I2C2.I2C_DATA[7:0] register |
| I2C3_DMA_TX | I2C3 | S_DMA_24 | I2C3 DMA write request to inform the sDMA to write new data in the I2C3.I2C_DATA[7:0] register |
| I2C3_DMA_RX | I2C3 | S_DMA_25 | I2C3 DMA read request to inform the sDMA to read the data in the I2C3.I2C_DATA[7:0] register |

NOTE: The HS I²C controller I2C4 does not generate any DMA request.

15.3.2.2 Interrupt Requests

Each multimaster HS I²C controller can generate an interrupt I2Ci_IRQ to the MPU subsystem. [Table 15-8](#) lists the interrupt requests with the mapping on the MPU interrupt controller.

Table 15-8. Multimaster HS I²C Controller Interrupt Requests

| Name | Source | Destination (MPU interrupt controller) |
|----------|--------|--|
| I2C1_IRQ | I2C1 | M_IRQ_56 |
| I2C2_IRQ | I2C2 | M_IRQ_57 |
| I2C3_IRQ | I2C3 | M_IRQ_61 |

An event can generate an interrupt request when the corresponding mask bit in the I2Ci.I2C_IE register is set to 1. [Table 15-9](#) summarizes the events causing the generation of an interrupt request.

Table 15-9. Multimaster HS I²C Controller Interrupt Events

| Event name | Supported configuration mode | Status bit | Mask bit | This event happens when: |
|------------|------------------------------|------------------------|------------------------|--|
| AL event | I ² C mode only | I2Ci.I2C_STAT [0] AL | I2Ci.I2C_IE[0] AL_IE | Two or more I ² C master devices initiate a transfer and the I ² C module I2Ci in the device loses arbitration of the I ² C bus. |
| NACK event | I ² C mode only | I2Ci.I2C_STAT [1] NACK | I2Ci.I2C_IE[1] NACK_IE | A nonacknowledgment has been received. In master mode, the transfer is automatically ended by generating a stop condition on the bus. The I2Ci.I2C_CON[1] STP, I2Ci.I2C_CON[10] MST and I2Ci.I2C_CON[9] TRX bits are automatically cleared to 0 (slave receiver mode). TX and RX FIFOs must be cleared (I2Ci.I2C_BUF[6] TXFIFO_CLR and I2Ci.I2C_BUF[14] RXFIFO_CLR bits set to 1). |

Table 15-9. Multimaster HS I²C Controller Interrupt Events (continued)

| Event name | Supported configuration mode | Status bit | Mask bit | This event happens when: |
|------------|--|-----------------------|------------------------|---|
| ARDY event | I ² C and SCCB modes | I2Ci.I2C_STAT[2] ARDY | I2Ci.I2C_IE[2] ARDY_IE | One of the following cases occurs: <ul style="list-style-type: none"> In I²C master receiver mode, the I2Ci.I2C_CON[1] STP bit is set to 1, the I2Ci.I2C_CNT[15:0] DCOUNT field value is 0, and the RX FIFO is empty. In I²C master transmitter mode, the I2Ci.I2C_CON[1] STP bit is set to 1 and the I2Ci.I2C_CNT[15:0] DCOUNT field value is 0. In I²C master transmitter mode, the I2Ci.I2C_CON[1] STP bit is cleared to 0 and the I2Ci.I2C_CNT[15:0] DCOUNT field value passed 0. In I²C master receiver mode, the I2Ci.I2C_CON[1] STP bit is set to 1, the I2Ci.I2C_CNT[15:0] DCOUNT field value passed 0, and the RX FIFO is empty. In I²C slave transmitter mode, a stop or start (S) condition is received from the external I²C master device. In I²C slave receiver mode, a stop or start (S) condition is received from the external I²C master device and the RX FIFO is empty. In SCCB master transmitter or receiver mode, a stop (P) condition is detected. |
| RRDY event | I ² C receive mode and SCCB read mode | I2Ci.I2C_STAT[3] RRDY | I2Ci.I2C_IE[3] RRDY_IE | The RX FIFO level is above the threshold (I2Ci.I2C_BUF[13:8] RTRSH field value + 1). |
| XRDY event | I ² C transmit mode and SCCB write mode | I2Ci.I2C_STAT[4] XRDY | I2Ci.I2C_IE[4] XRDY_IE | The module requires new data to be served. A master transmitter module requests new data when the TX FIFO level is below the threshold (I2Ci.I2C_BUF[5:0] XTRSH field value + 1) and the required amount of data to be transmitted specified by the I2Ci.I2C_BUFSTAT[5:0] TXSTAT field is greater than the threshold. A slave transmitter requests new data when the TX FIFO is below the threshold (if the I2Ci.I2C_BUF[5:0] XTRSH field value is greater than 1), or when there is a read request from the external master device (for each acknowledge received from the master) when the I2Ci.I2C_BUF[5:0] XTRSH field value is 1. |
| GC event | I ² C mode only | I2Ci.I2C_STAT[5] GC | I2Ci.I2C_IE[5] GC_IE | The module detects a general call on the I ² C bus (all bits of the address cleared to 0). |
| STC event | I ² C mode only | I2Ci.I2C_STAT[6] STC | I2Ci.I2C_IE[6] STC_IE | The module is in idle mode and a start (S) condition is asynchronously detected on the I ² C bus and signaled with a wakeup. When the active mode is restored and the interrupt generated, this bit indicates the reason for the wakeup. See ⁽¹⁾ . |
| AERR event | I ² C and SCCB modes | I2Ci.I2C_STAT[7] AERR | I2Ci.I2C_IE[7] AERR_IE | A write access to the I2Ci.I2C_DATA register by the LH through the L4-Core interconnect is performed while the TX FIFO is full or a read access to the I2Ci.I2C_DATA register by the LH through the L4-Core interconnect is performed while the RX FIFO is empty. When the RX FIFO is empty, the read of the RX FIFO returns the previous read data value. When the TX FIFO is full, a write in the TX FIFO is ignored. |
| BF event | I ² C and SCCB modes | I2Ci.I2C_STAT[8] BF | I2Ci.I2C_IE[8] BF_IE | The I ² C bus becomes free (after a transfer is ended on the bus and a stop (P) condition is detected). |
| AAS event | I ² C mode only | I2Ci.I2C_STAT[9] AAS | I2Ci.I2C_IE[9] AAS_IE | The module has recognized its own slave address or an alternate Own Address, or a general call (all address bits cleared to 0). |

⁽¹⁾ The interrupt request generation on an STC event must be enabled only if the module is configured to allow the possibility of switching off the functional clock while in idle state (the I2Ci.I2C_SYSC[9:8] CLOCKACTIVITY field set to b00 or b01). The first transfer (corresponding to the detected start (S) condition) is lost, and is used only to restore the active mode of the module. On the I²C bus, the external master that generated the transfer detects this behavior as a nonacknowledge to the address phase and may possibly restart the transfer.

Table 15-9. Multimaster HS I²C Controller Interrupt Events (continued)

| Event name | Supported configuration mode | Status bit | Mask bit | This event happens when: |
|------------|--|------------------------|------------------------|---|
| RDR event | I ² C receive mode only | I2Ci.I2C_STAT [13] RDR | I2Ci.I2C_IE[13] RDR_IE | The module is configured as a receiver, a stop (P) condition was received on the I ² C bus, and the RX FIFO level is below the threshold (I2Ci.I2C_BUF[13:8] RTRSH field value + 1). |
| XDR event | I ² C master transmit mode only | I2Ci.I2C_STAT [14] XDR | I2Ci.I2C_IE[14] XDR_IE | The module is configured as a master transmitter, the TX FIFO level is below the threshold (I2Ci.I2C_BUF[5:0] XTRSH field value + 1), and the amount of data still to be transferred is less than this threshold. |

When an interrupt request is generated, the software must read the I2Ci.I2C_STAT register to check which event caused the interrupt request generation, process accordingly, and acknowledge each processed event by writing 1 to the corresponding bit in the I2Ci.I2C_STAT register.

NOTE: The I2Ci.I2C_STAT[9] AAS status bit, corresponding to the AAS event, can be cleared in two ways:

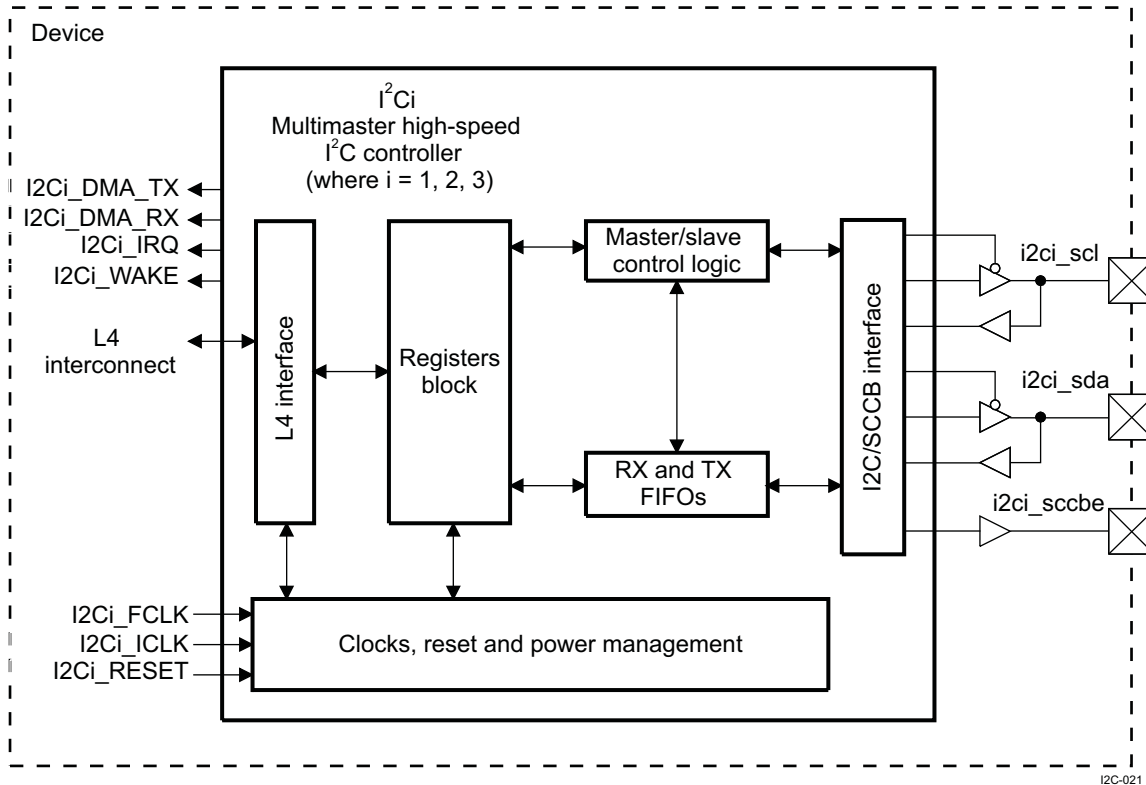

- If the I2Ci.I2C_IE[9] AAS_IE bit is set to 1 (interrupt generation enabled), the status bit is cleared by writing 1 to the I2Ci.I2C_STAT[9] AAS status bit
- If the I2Ci.I2C_IE[9] AAS_IE bit is cleared to 0 (interrupt generation disabled), the status bit is cleared when a new start or stop (P) condition is detected on the I²C bus.

15.4 High-Speed I²C Controller Functional Description

15.4.1 Block Diagram

Figure 15-21 is a functional block diagram of the multimaster I²C HS controller.

Figure 15-21. Multimaster HS I²C Controller Block Diagram

NOTE: The i2c1_sccb signal is not available.

The three multimaster HS I²C controllers can be configured in F/S I²C mode, in HS I²C mode, or in SCCB mode. The operation mode is selected by configuring the I2Ci.I2C_CON[13:12] OPMODE field.

Table 15-10 lists the available operation modes.

Table 15-10. Operation Mode Selection

| Operation Mode | I2Ci.I2C_CON[13:12] OPMODE field value |
|--------------------------------------|--|
| Fast/standard (F/S) I ² C | 0x0 |
| High-speed (HS) I ² C | 0x1 |
| SCCB | 0x2 |
| Reserved (not used) | 0x3 |

15.4.2 Transmit Mode in I²C Mode

This mode is available for master or slave. The master and slave modes are configurable with the I2Ci.I2C_CON[10] MST bit (0: slave mode, 1: master mode).

In master mode, the transmit mode is configured by setting the I2Ci.I2C_CON[9] TRX bit to 1. The MPU subsystem puts the data to transmit in the TX FIFO by writing to the I2Ci.I2C_DATA[7:0] DATA bit field.

The transmitter can write new data to this register when the I2Ci.I2C_STAT[4] XRDY bit is set to 1, or when the I2Ci.I2C_STAT[14] XDR bit is set to 1 according to the draining mechanism description.

A master transmitter requests new data if the I2Ci.I2C_CNT[15:0] DCOUNT bit field value is not 0. A slave transmitter requests new data if a read is performed by the external master.

NOTE: The HS I2C controller I2C4 is configured in master transmitter mode, and its configuration cannot be changed.

15.4.3 Receive Mode in I²C Mode

This mode is available for master or slave. In master mode, it is configured by clearing the I2Ci.I2C_CON[9] TRX bit to 0.

The MPU subsystem can read new data from the I2Ci.I2C_DATA[15:0] DCOUNT bit field when the I2Ci.I2C_STAT[3] RRDY bit is set to 1, or when the I2Ci.I2C_STAT[13] RDR bit is set according to the draining mechanism description.

Each time the I2Ci.I2C_STAT[3] RRDY bit is set to 1, if the interrupt is enabled (the I2Ci.I2C_IE[3] RRDY_IE bit must be set to 1), the I²C controller generates an interrupt to the MPU subsystem.

NOTE: In interrupt mode, the MPU subsystem must read this bit after each read in the I2Ci.I2C_DATA register to ensure that no other data is waiting for the FIFO to be read. For a new interrupt to be received, the I2Ci.I2C_STAT[3] RRDY bit must be cleared in the interrupt routine.

If the DMA receive mode is enabled (the I2Ci.I2C_BUF[15] RDMA_EN bit is set), this bit is forced to 0 and no interrupt is generated; instead, a DMA RX request to the sDMA controller is generated.

15.4.4 FIFO Management

Each multimaster HS I²C controller implements two internal 8-bit FIFOs, the RX and TX FIFOs.

Table 15-11 lists the depth of these FIFOs, depending on the instance of the I²C controller.

Table 15-11. RX and TX FIFO Depths

| I ² C Controller Instance | RX and TX FIFO Depth (in bytes) |
|--------------------------------------|---------------------------------|
| I2C1 | 8 |
| I2C2 | 8 |
| I2C3 | 64 |

The depth of the RX and TX FIFOs can be checked by reading the I2Ci.I2C_BUFSTAT[15:14] FIFODEPTH bit field (0x0: 8 bytes, 0x1: 16 bytes, 0x2: 32 bytes, and 0x3: 64 bytes).

15.4.4.1 FIFO Interrupt Mode Operation

In FIFO interrupt mode (relevant interrupts enabled by the I2Ci.I2C_IE register), the processor is informed of the receiver and transmitter status by an interrupt signal. These interrupts are raised when the RX/TX FIFO thresholds (defined by the I2Ci.I2C_BUF[13:8] RTRSH field value + 1 for the RX FIFO or the I2Ci.I2C_BUF[5:0] XTRSH field value + 1 for the TX FIFO) are reached; the interrupt signals instruct the LH to transfer data to the destination (from the I²C controller module in receive mode and/or from any source to the I²C controller FIFO in transmit mode).

Figure 15-22 and Figure 15-23 show receive and transmit operations, respectively, from a FIFO management point of view.

Figure 15-22. Receive FIFO Interrupt Request Generation

I2C-022

In [Figure 15-22](#), the RRDY interrupt condition shows that the condition for generating an RRDY interrupt is achieved. The interrupt request is generated when this signal is active, and it can be cleared only by the LH by writing 1 in the I2Ci.I2C_STAT[3] RRDY bit. If the condition is still present after clearing the previous interrupt, another interrupt request is generated.

In receive mode, an RRDY interrupt is generated as soon as the FIFO reaches its receive threshold (I2Ci.I2C_BUF[13:8] RTRSH field value + 1). The interrupt can be deasserted only when the LH has handled enough bytes to make the number of bytes in the RX FIFO lower than the programmed threshold. For each interrupt, the LH can be configured to read a number of bytes equal to the value of the RX FIFO threshold.

NOTE: In SCCB mode, the RX and TX threshold values must be set to 1 by setting the I2Ci.I2C_BUF[13:8]RTRSH and I2Ci.I2C_BUF[5:0]XTRSH fields to 0x0.

Figure 15-23. Transmit FIFO Interrupt Request Generation

I2C-023

In [Figure 15-23](#), the XRDY interrupt condition shows that the condition for generating an XRDY interrupt is achieved. The interrupt request is generated when TX FIFO is empty or when the TX FIFO threshold is not reached, and the LH can clear the XRDY status bit by writing 1 in the I2Ci.I2C_STAT[4] XRDY bit after transmitting the configured number of bytes. If the condition is still present after clearing the previous interrupt, another interrupt request is generated.

In interrupt mode, the module offers two options for the LH application to handle the interrupts:

- When detecting an interrupt request (XRDY/RRDY type), the LH can write/read 1 data byte to/from the TX/RX FIFO and then clear the interrupt. The module reasserts the interrupt until the interrupt condition is no longer met.
- When detecting an interrupt request (XRDY/RRDY type), the LH can be programmed to write/read the number of data bytes specified by the corresponding FIFO threshold (I2Ci.I2C_BUF[5:0] XTRSH field value + 1 for the TX threshold or I2Ci.I2C_BUF[13:8] RTRSH field value + 1 for the RX threshold). In this case, the interrupt condition is cleared and the next interrupt is asserted again when the XRDY/RRDY condition is met again.

If the second-interrupt-serving approach is used, an additional mechanism (draining feature) is implemented for cases where the transfer length is not a multiple of the FIFO threshold value (see Section 15.4.4.4).

NOTE: In slave transmit mode (the I2Ci.I2C_CON[10] MST bit is cleared and the I2Ci.I2C_CON[9] TRX bit is set to 1), the draining feature must not be used, because the transfer length is not known at configuration time, and the external master can end the transfer at any point by not acknowledging 1 data byte. If the draining feature is used in slave transmit mode, data can remain in the TX FIFO without being transmitted over the I²C bus. In this case, the TX FIFO must be cleared by setting the I2Ci.I2C_BUF[6] TXFIFO_CLR bit.

15.4.4.2 FIFO Polling Mode Operation

In FIFO polled mode (the I2Ci.I2C_IE[4] XRDY_IE and I2Ci.I2C_IE[3] RRDY_IE bits are disabled, and the I2Ci.I2C_BUF[15] RDMA_EN and I2Ci.I2C_BUF[7] XDMA_EN bits are disabled), the status of the module (receiver or transmitter) can be checked by polling the I2Ci.I2C_STAT[4] XRDY and the I2Ci.I2C_STAT[3] RRDY bits (the I2Ci.I2C_STAT[13] RDR and I2Ci.I2C_STAT[14] XDR bits can also be polled if the draining feature is enabled). The I2Ci.I2C_STAT[4] XRDY and I2Ci.I2C_STAT[3] RRDY bits accurately reflect the interrupt conditions described in the discussion of the FIFO interrupt mode operation.

15.4.4.3 FIFO DMA Mode Operation (I²C Mode Only)

In receive mode, a DMA request is generated by the I2Ci_DMA_RX signal as soon as the RX FIFO exceeds its threshold level (I2Ci.I2C_BUF[13:8] RTRSH field value + 1). This request is deasserted when the number of bytes defined by the threshold level is read by the sDMA controller.

Figure 15-24 shows the DMA request generation in receive mode.

Figure 15-24. Receive FIFO DMA Request Generation

I2C-024

In transmit mode, a DMA request is automatically asserted by the I2Ci_DMA_TX signal when the TX FIFO is empty. This request is deasserted when the number of bytes (I2Ci.I2C_BUF[5:0] XTRSH field value + 1) is written in the FIFO by the sDMA controller. If an insufficient number of bytes is written, the DMA request remains active. Figure 15-25 and Figure 15-26 show the DMA TX transfers with different values for the I2Ci.I2C_BUF[5:0] XTRSH field.

Figure 15-25. Transmit FIFO Request Generation (High Threshold)

Figure 15-26. Transmit FIFO Request Generation (Low Threshold)

NOTE: In SCCB mode, the RX and TX threshold values must be set to 1 by setting the I2Ci.I2C_BUF[13:8]RTRSH and I2Ci.I2C_BUF[5:0]XTRSH fields to 0x0.

15.4.4.4 Draining Feature (I²C Mode Only)

The draining feature is implemented to handle the end of a transfer whose length is not a multiple of the FIFO threshold values (I2Ci.I2C_BUF[13:8] RTRSH field value + 1 for the RX threshold and I2Ci.I2C_BUF[5:0] XTRSH field value + 1 for the TX threshold). It also offers the possibility of transferring the remaining number of bytes (because the threshold is not reached).

This feature prevents the LH or the sDMA controller from trying more FIFO accesses than necessary (for example, to generate at the end of a transfer a DMA RX request having fewer bytes in the FIFO than the configured DMA transfer length). Otherwise, an AERR interrupt is generated by the I2Ci.I2C_STAT[7] AERR status bit.

The draining mechanism generates an interrupt using the I2Ci.I2C_STAT[13] RDR or the I2Ci.I2C_STAT[14] XDR status bit at the end of the transfer, informing the LH that it must check the amount of data left to be transferred (the I2Ci.I2C_BUFSTAT[13:8] RXSTAT or I2Ci.I2C_BUFSTAT[5:0] TXSTAT fields) and enable the draining feature of the DMA controller by reconfiguring the DMA transfer length according to this value (when the DMA mode is enabled) or perform only the required number of data accesses (when the DMA mode is disabled).

In receive mode (master or slave), if the RX FIFO threshold (I2Ci.I2C_BUF[13:8] RTRSH field value + 1) is not reached, but the transfer ends on the I²C bus and there is still data in the RX FIFO (less than the threshold), the receive draining interrupt (the I2Ci.I2C_STAT[13] RDR status bit) is asserted to inform the LH that it can read the amount of data in the FIFO (the I2Ci.I2C_BUFSTAT[13:8] RXSTAT field). The LH performs a number of data read accesses equal to the I2Ci.I2C_BUFSTAT[13:8] RXSTAT field value (interrupt or polling mode), or reconfigures the sDMA controller with the required value to drain the FIFO.

In master transmit mode, if the TX FIFO threshold (I2Ci.I2C_BUF[5:0] XTRSH field value + 1) is not reached, but the amount of data remaining to be written in the TX FIFO is less than the threshold, the transmit draining interrupt (the I2Ci.I2C_STAT[14] XDR status bit) is asserted to inform the LH that it can read the amount of data remaining to be written in the TX FIFO (the I2Ci.I2C_BUFSTAT[5:0] TXSTAT field). The LH must write the required number of data bytes specified by the I2Ci.I2C_BUFSTAT[5:0] TXSTAT field value or reconfigure the sDMA controller with the value required to transfer the last bytes to the FIFO.

In master mode, the LH can alternately skip the checking of the I2Ci.I2C_BUFSTAT[5:0] TXSTAT and I2Ci.I2C_BUFSTAT[13:8] RXSTAT field values, because it can obtain this information internally (by computing the the I2Ci.I2C_CNT[15:0] DATACOUNT field value modulo I2Ci.I2C_BUF[13:8] RTRSH or I2Ci.I2C_BUF[5:0] XTRSH).

By default, the draining feature is disabled; it can be enabled using the I2Ci.I2C_IE[14] XDR_IE or I2Ci.I2C_IE[13] RDR_IE bits (default disabled) only for transfers with lengths not equal to the threshold values (I2Ci.I2C_BUF[5:0] XTRSH field value + 1 for the TX threshold or I2Ci.I2C_BUF[13:8] RTRSH field value + 1 for the RX threshold).

15.4.5 Programmable Multislave Channel Feature (I²C Mode Only)

This feature allows each multimaster HS I²C controller to be addressed using four separate Own Addresses configured in the I2Ci.I2C_OAx registers (with x = 0, 1, 2, 3). An additional register (I2Ci.I2C_ACTOA) is used to indicate to the LH which address is used by the external master to communicate with the I²C controller.

Each Own Address can be independently configured in 7-bit or 10-bit mode by setting the corresponding bit (I2Ci.I2C_CON[7] XOA0, I2Ci.I2C_CON[6] XOA1, I2Ci.I2C_CON[5] XOA2, or I2Ci.I2C_CON[4] XOA3).

15.4.6 Automatic Blocking of the I²C Clock Feature (I²C Mode Only)

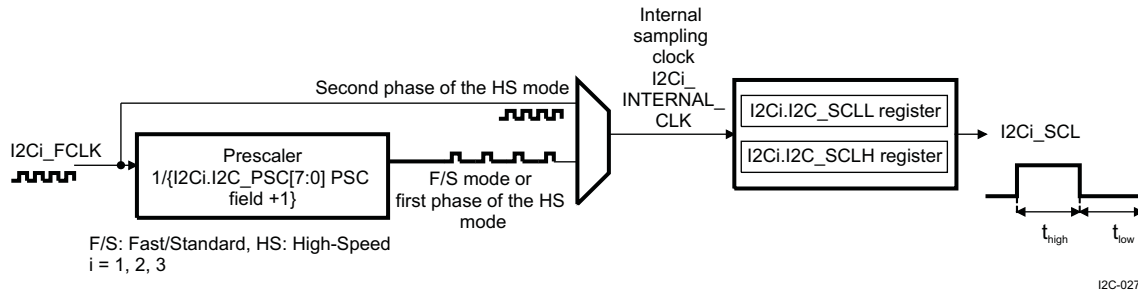

This feature offers the possibility for the LH to command the blocking of the I²C clock after the slave addressing phase, when the I²C controller is addressed by an external master device using a certain Own Address.

The release of the I²C clock (i2ci_scl signal, with i = 1, 2, 3) can be performed independently for each Own Address (I2Ci.I2C_OAi registers, with i = 0, 1, 2, 3) by deasserting the corresponding bit in the I2Ci.I2C_SBLOCK register.

15.4.7 Clocking

Figure 15-27 shows the I²C clock generation of the HS I²C controllers.

Figure 15-27. I²C Clock Generation

Each multimaster HS I²C controller uses the I2Ci_FCLK functional clock in the PRCM module. The internal sampling clock I2Ci_INTERNAL_CLK is generated by dividing the functional clock by (I2Ci.I2C_PSC[7:0] PSC field value + 1) in F/S mode, in SCCB mode, or in the first phase of HS mode; or by directly using the functional clock in the second phase of HS mode (prescaler is bypassed).

The low time of the I2Ci_SCL signal is determined by the I2Ci.I2C_SCLL[7:0] SCLL field in F/S mode, in SCCB mode, or in the first phase of HS mode; or by the I2Ci.I2C_SCLL[15:8] HSSCLL field in the second phase of HS mode.

The high time of the I2Ci_SCL signal is determined by the I2Ci.I2C_SCLH[7:0] SCLH field in F/S mode, in SCCB mode, or in the first phase of HS mode; or by the I2Ci.I2C_SCLH[15:8] HSSCLH field in the second phase of HS mode.

Table 15-12 lists the t_{LOW} and t_{high} values in master mode only (in slave mode, the I²C controller does not generate the I²C clock).

Table 15-12. t_{LOW} and t_{high} Values of the I²C Clock

| Mode | I2Ci_INTERNAL_CLK | t_{LOW} | t_{high} |
|------------------------------|--|--|--|
| F/S, SCCB, or HS first phase | $I2Ci_FCLK / (I2Ci.I2C_PSC[7:0] PSC\ field + 1)$ | $(I2Ci.I2C_SCLL[7:0] SCLL\ field\ value + 7) \times I2Ci_INTERNAL_CLK\ period$ | $(I2Ci.I2C_SCLH[7:0] SCLH\ field\ value + 5) \times I2Ci_INTERNAL_CLK\ period$ |
| HS second phase | I2Ci_FCLK | $(I2Ci.I2C_SCLL[15:8] HSSCLL\ field\ value + 7) \times I2Ci_INTERNAL_CLK\ period$ | $(I2Ci.I2C_SCLH[15:8] HSSCLH\ field\ value + 5) \times I2Ci_INTERNAL_CLK\ period$ |

NOTE: The equations in Table 15-12 give the SCL timing values for SCLL/SCLH/HSSCLL/HSSCLH at HS I²C controller outputs. Actual tlow and thigh periods may vary, depending on the board (the load capacitance on the SCL signal). If necessary, any adjustments to the SCLL/SCLH/HSSCLL/HSSCLH values must be determined by measurements of actual SCL signal on the board

NOTE: For HS mode, both the I2Ci.I2C_SCLL[15:8] HSSCLL and I2Ci.I2C_SCLL[7:0] SCLL fields must be programmed (the first phase of an HS transaction is performed at F/S speed).

For HS mode, both the I2Ci.I2C_SCLH[15:8] HSSCLH and I2Ci.I2C_SCLH[7:0] SCLH fields must be programmed (the first phase of an HS transaction is performed at F/S speed).

CAUTION

During active mode (I2Ci.I2C_CON[15] I2C_EN bit is set to 1), make no changes to the I2Ci.I2C_SCLL and I2Ci.I2C_SCLH registers. Changes may result in unpredictable behavior.

NOTE: Each multimaster HS I²C controller can be used with an internal secondary pullup. This pullup is mandatory when the I²C controller is configured in HS mode for a bit rate of 3.4M bps, and the bus line capacitance exceeds 45 pF. Pullups can be programmed through the CONTROL.CONTROL_DEVCONF1[12] I2C1HSMASMASTER bit for I2C1, the CONTROL.CONTROL_DEVCONF1[13] I2C2HSMASMASTER bit for I2C2, and the CONTROL.CONTROL_DEVCONF1[14] I2C3HSMASMASTER bit for I2C3.

The maximum bit rate specified by the SCCB specifications is 100K b/s.

15.4.8 Noise Filter

The noise filter is used to suppress any noise that is 50 ns or less in case of F/S and SCCB operation modes, and any noise that is 10 ns or less in case of HS mode operation. The noise filter is always one period of the I2Ci_INTERNAL_CLK clock. This way, for HS mode operation (prescaler bypassed), the filter suppresses spikes of less than 10.4 ns.

For SCCB modes (for example, I2Ci.I2C_PSC[7:0] PSCbit field = 4), the maximum width of suppressed spikes is 52 ns.

To ensure correct filtering, the prescaler must be programmed accordingly by the I2Ci.I2C_PSC[7:0] PSC bit field.

15.4.9 System Test Mode

A system test mode is available for multimaster HS I²C controller module testing. This mode is enabled by setting the I2Ci.I2C_SYSTEST[15] ST_EN to 1. When this bit is cleared to 0, the I²C controller is configured in normal operation mode.

In system test mode, the I2Ci_SYSTEST[13:12] TMODE bit field selects the type of test. Table 15-13 lists the tests available for the multimaster HS I²C controllers.

Table 15-13. List of tests for the Multimaster HS I²C Controllers

| I2Ci.I2C_SYSTEST[13:12] TMODE field value | Test | Description |
|---|---|--|
| b00 | Functional mode | Normal operation mode |
| b01 | Reserved (not used) | |
| b10 | Test of i2ci_scl serial clock line | The i2ci_scl line is driven with a permanent clock as if mastered with the parameters set in the I2Ci.I2C_PSC, I2Ci.I2C_SCLL, and I2Ci.I2C_SCLH registers. |
| b11 | Loop-back mode + i2ci_scl/ i2ci_sda/ i2ci_sccbce input/output | In the master transmit mode only, data transmitted out of the I2Ci.I2C_DATA register (write action) is received in the same I2Ci.I2C_DATA register through an internal path through the FIFO buffers. The DMA and interrupt requests are normally generated if they are enabled. Moreover, the i2ci_scl, i2ci_sda, and i2ci_sccbce lines are controlled with the I2Ci.I2C_SYSTEST[4:0] bits. |

NOTE: When the I2Ci.I2C_SYSTEST[13:12] TMODE field = b11, the I²C controller must be configured in I²C F/S (I2Ci.I2C_CON[13:12] OPMODE = b00) or I²C HS mode (I2Ci.I2C_CON[13:12] OPMODE = b01). The loop-back mode is not available in SCCB mode (I2Ci.I2C_CON[13:12] OPMODE = b10).

NOTE: In normal operation mode (I2Ci.I2C_SYSTEST[15] ST_EN clear to 0), the I2Ci.I2C_SYSTEST[4:0] bits that control the i2ci_scl, i2ci_sda, and i2ci_sccbce lines in system test mode are read-only bits.

In system test mode (I2Ci.I2C_SYSTEST[15] ST_EN set to 1), the I2Ci.I2C_STAT[5:0] status bits can be set to 1 when the I2Ci.I2C_SYSTEST[11] SSB bit is set to 1. Clearing the I2Ci.I2C_SYSTEST[11] SSB bit to 0 does not clear the I2Ci.I2C_STAT[5:0] status bits to 0. The I2Ci.I2C_STAT[5:0] status bits can be cleared to 0 only by writing 1 in the corresponding bits.

15.4.10 Write and Read Operations in SCCB Mode

In SCCB mode, the multimaster HS I²C controller can write or read a single byte to or from the external SCCB device.

To write a single byte to the external SCCB device, the multimaster HS I²C controller must be configured in multimaster transmitter mode by setting the I2Ci.I2C_CON[10] MST and I2Ci.I2C_CON[9] TRX bits to 1. The external device slave address (7-bit address of the ID value) is set in the I2Ci.I2C_SA register; the register address (8-bit subaddress in the external SCCB device) is set in the I2Ci.I2C_OA0 register. The 8-bit data to be transmitted is written by the LH in the I2Ci.I2C_DATA register.

To read a single byte from the external SCCB device, the multimaster HS I²C controller must be configured in multimaster receiver mode by setting the I2Ci.I2C_CON[10] MST to 1 and by clearing the I2Ci.I2C_CON[9] TRX bit to 0. The external device slave address (7-bit address of the ID value) is set in the I2Ci.I2C_SA register; the register address (8-bit subaddress in the external SCCB device) is set in the I2Ci.I2C_OA0 register. The 8-bit data received from the external SCCB device is read by the LH from the I2Ci.I2C_DATA register.

NOTE: In SCCB mode, the RX and TX thresholds must be set to 1 by configuring the I2Ci.I2C_BUF[13:8] RTRSH and I2Ci.I2C_BUF[5:0]XTRSH fields to 0x0.

15.4.11 Power Chip Communication Operations

The master transmitter HS I²C controller I2C4 inside the voltage controller of the PRM module is used to send configuration commands from the LH to external power chip(s).

For voltage control operations, the LH must set the slave address of the first power chip in the PRCM.PRM_VC_SMPS_SA[6:0] SA0 field, and the slave address of the second power chip (if necessary) in the PRCM.PRM_VC_SMPS_SA[22:16] SA1 field.

The LH must also configure the specific registers in the voltage controller of the PRCM module, for the voltage control and power-sequencing functions.

A high-priority bypass mode is available to allow the LH to configure the external power chip(s) through the I²C bus. To write an 8-bit data to the configuration registers of an external power chip, the LH must set the 7-bit external power chip slave address in the PRCM.PRM_VC_BYPASS_VAL[6:0] SLAVEADDR field, the configuration register address in the PRCM.PRM_VC_BYPASS_VAL[15:8] REGADDR field, and the 8-bit data in the PRCM.PRM_BYPASS_VAL[23:16] register.

For details about voltage control, see , *Power, Reset, and Clock Management*.

15.5 High-Speed I²C Controller Basic Programming Model

15.5.1 Multimaster HS I²C Controller Basic Programming Model in I²C Mode

This section describes the programming model of the multimaster HS I²C controllers configured in I²C mode.

15.5.1.1 Main Program

15.5.1.1.1 Configure the Module Before Enabling the I²C Controller

Before enabling the I²C controller, perform the following steps:

1. Enable the functional and interface clocks (see [Section 15.3.1.1.1](#)).
2. Program the prescaler to obtain an approximately 12-MHz internal sampling clock (I2Ci_INTERNAL_CLK) by programming the corresponding value in the I2Ci.I2C_PSC[3:0] PSC field. This value depends on the frequency of the functional clock (I2Ci_FCLK). Because this frequency is 96MHz, the I2Ci.I2C_PSC[7:0] PSC field value is 0x7.
3. Program the I2Ci.I2C_SCLL[7:0] SCLL and I2Ci.I2C_SCLH[7:0] SCLH fields to obtain a bit rate of 100K bps or 400K bps. These values depend on the internal sampling clock frequency (see [Table 15-12](#)).
4. (Optional) Program the I2Ci.I2C_SCLL[15:8] HSSCLL and I2Ci.I2C_SCLH[15:8] HSSCLH fields to obtain a bit rate of 400K bps or 3.4M bps (for the second phase of HS mode). These values depend on the internal sampling clock frequency (see [Table 15-12](#)).
5. (Optional) If a bit rate of 3.4M bps is used and the bus line capacitance exceeds 45 pF, program the CONTROL.CONTROL_DEVCONF1[12] I2C1HSMASMASTER bit for I2C1, the CONTROL.CONTROL_DEVCONF1[13] I2C2HSMASMASTER bit for I2C2, or the CONTROL.CONTROL_DEVCONF1[14] I2C3HSMASMASTER bit for I2C3.
6. Configure the Own Address of the I²C controller by storing it in the I2Ci.I2C_OA0 register. Up to four Own Addresses can be programmed in the I2Ci.I2C_OAi registers (with i = 0, 1, 2, 3) for each I²C controller.

NOTE: For a 10-bit address, set the corresponding expand Own Address bit in the I2Ci.I2C_CON register.

7. Set the TX threshold (in transmitter mode) and the RX threshold (in receiver mode) by setting the I2Ci.I2C_BUF[5:0]XTRSH field to (TX threshold - 1) and the I2Ci.I2C_BUF[13:8]RTRSH field to (RX threshold - 1), where the TX and RX thresholds are greater than or equal to 1.
8. Take the I²C controller out of reset by setting the I2Ci.I2C_CON[15] I2C_EN bit to 1.

15.5.1.1.2 Initialize the I²C Controller

To initialize the I²C controller, perform the following steps:

1. Configure the I2Ci.I2C_CON register:
 - For master or slave mode, set the I2Ci.I2C_CON[10] MST bit (0: slave, 1: master).
 - For transmitter or receiver mode, set the I2Ci.I2C_CON[9] TRX bit (0: receiver, 1: transmitter).
2. If using an interrupt to transmit/receive data, set to 1 the corresponding bit in the I2Ci.I2C_IE register (the I2Ci.I2C_IE[4] XRDY_IE bit for the transmit interrupt, the I2Ci.I2C_IE[3] RRDY bit for the receive interrupt).
3. If using DMA to receive/transmit data, set to 1 the corresponding bit in the I2Ci.I2C_BUF register (the I2Ci.I2C_BUF[15] RDMA_EN bit for the receive DMA channel, the I2Ci.I2C_BUF[7] XDMA_EN bit for the transmit DMA channel).

15.5.1.1.3 Configure Slave Address and the Data Control Register

In master mode, configure the slave address register by programming the I2Ci.I2C_SA[9:0] SA field and the number of data bytes (I²C data payload) associated with the transfer by programming the I2Ci.I2C_CNT[15:0] DCOUNT field.

NOTE: For a 10-bit address, set the I2Ci.I2C_CON[8] XSA bit to 1.

15.5.1.1.4 Initiate a Transfer

Poll the I2Ci.I2C_STAT[12] BB bit. If it is cleared to 0 (bus not busy), configure the I2Ci.I2C_CON[0] STT and I2Ci.I2C_CON[1] STP bits. To initiate a transfer, the I2Ci.I2C_CON[0] STT bit must be set to 1, and it is not mandatory to set the I2Ci.I2C_CON[1] STP bit to 1.

15.5.1.1.5 Receive Data

Poll the I2Ci.I2C_STAT[3] RRDY bit, or use the RRDY interrupt (the I2Ci.I2C_IE[3] RRDY_IE bit must be set to 1) or the DMA RX channel (the I2Ci.I2C_BUF[15] RDMA_EN bit must be set to 1) to read the receive data in the I2Ci.I2C_DATA register.

If the transfer length does not equal the RX FIFO threshold (I2Ci.I2C_BUF[13:8]RTRSH field + 1), use the draining feature (enable the RDR interrupt by setting the I2Ci.I2C_IE[13] RDR_IE bit to 1).

NOTE: In receive mode only, the I2Ci.I2C_STAT[11] ROVR (receive overrun) bit indicates whether the receiver has experienced overrun. An overrun condition occurs when the shift register and the RX FIFO are full. An overrun condition does not result in data loss; the I²C controller simply holds the serial clock line i2ci_scl to low to prevent other bytes from being received.

The I2Ci.I2C_STAT[7] AERR bit is set to 1 when a read access is performed in the I2Ci.I2C_DATA register while the RX FIFO is empty. The corresponding interrupt can be enabled by setting the I2Ci.I2C_IE[7] AERR_IE bit to 1.

15.5.1.1.6 Transmit Data

Poll the I2Ci.I2C_STAT[4] XRDY bit, or use the XRDY interrupt (the I2Ci.I2C_IE[4] XRDY_IE bit must be set to 1) or the DMA TX channel (the I2Ci.I2C_BUF[7] XDMA_EN bit must be set to 1) to write data to the I2Ci.I2C_DATA register.

If the transfer length does not equal the TX FIFO threshold (I2Ci.I2C_BUF[5:0] XTRSH field + 1), use the draining feature (enable the XDR interrupt by setting the I2Ci.I2C_IE[14] XDR_IE bit to 1).

NOTE: In transmit mode only, the I2Ci.I2C_STAT[10] XUDF bit indicates whether the transmitter has experienced underflow.

In master transmit mode, underflow occurs when the shift register and the TX FIFO are empty and there are still some bytes to transmit (the I2Ci.I2C_CNT[15:0] DCOUNT field value is not 0).

In slave transmit mode, underflow occurs when the shift register and the TX FIFO are empty and the external I²C master device still requests data bytes to be read.

The I2Ci.I2C_STAT[7] AERR bit is set to 1 when a write access is performed in the I2Ci.I2C_DATA register while the TX FIFO is full. The corresponding interrupt can be enabled by setting the I2Ci.I2C_IE[7] AERR_IE bit to 1.

15.5.1.2 Interrupt Subroutine Sequence

1. Test for arbitration lost (I2Ci.I2C_STAT[0] AL status bit) and resolve accordingly.
2. Test for no acknowledgment (I2Ci.I2C_STAT[1] NACK status bit) and resolve accordingly.
3. Test for register access ready (I2Ci.I2C_STAT[2] ARDY status bit) and resolve accordingly.

4. Test for receive data ready (I2Ci.I2C_STAT[3] RRDY status bit) and resolve accordingly.
5. Test for transmit data ready (I2Ci.I2C_STAT[4] XRDY status bit) and resolve accordingly.
6. Test for general call (I2Ci.I2C_STAT[5] GC status bit) and resolve accordingly.
7. Test for start (S) condition (I2Ci.I2C_STAT[6] STC status bit) and resolve accordingly. For this test, the functional clock must be inactive.
8. Test for access error (I2Ci.I2C_STAT[7] AERR status bit) and resolve accordingly.
9. Test for bus free (I2Ci.I2C_STAT[8] BF status bit) and resolve accordingly.

15.5.1.3 Programming Flow Diagrams

Figure 15-28 through Figure 15-36 are procedure flowcharts for programming the F/S and HS I²C modes.

15.5.2 High-Speed I²C Controller Basic Programming Model in SCCB Mode

This section describes the programming model of the multimaster HS I²C controllers configured in SCCB mode.

15.5.2.1 Main Program

15.5.2.1.1 Configure the Module Before Enabling the I²C Controller

Before enabling the I²C controller, perform the following steps:

1. Enable the functional and interface clocks (see [Section 15.3.1.1.1](#)).
2. Program the prescaler to obtain an approximately 12-MHz internal sampling clock (I2Ci_INTERNAL_CLK) by programming the corresponding value in the I2Ci.I2C_PSC[7:0] PSC field. This value depends on the frequency of the functional clock (I2Ci_FCLK). Because this frequency is 96MHz, the I2Ci.I2C_PSC[7:0] PSC field value is 0x7.
3. Program the I2Ci.I2C_SCLL[7:0] SCLL and I2Ci.I2C_SCLH[7:0] SCLH fields to obtain a bit rate of 100K bps (maximum authorized bit rate in SCCB mode). This value depends on the internal sampling clock frequency (see [Table 15-12](#)).
4. Configure the 7-bit slave address (ID value) by storing it in the I2Ci.I2C_SA register.
5. Configure the 8-bit register address (subaddress) by storing it in the I2Ci.I2C_OA0 register.

6. Configure the I2Ci.I2C_BUF[13:8]RTRSH field to 0x0 (RX threshold to 1) and the I2Ci.I2C_BUF[5:0]XTRSH field to 0x0 (TX threshold to 1).
7. Take the I²C controller out of reset by setting the I2Ci.I2C_CON[15] I2C_EN bit to 1.

15.5.2.1.2 Initialize the I²C Controller

To initialize the I²C controller, perform the following steps:

1. Configure the I2Ci.I2C_CON register:
 - In SCCB mode, only the master mode is supported; set the I2Ci.I2C_CON[10] MST bit to 1.
 - For transmitter mode (write to the external SCCB device register) or receiver mode (read from the external SCCB device register), set the I2Ci.I2C_CON[9] TRX bit (0: receiver, 1: transmitter).
2. If using an interrupt to transmit/receive data, set to 1 the corresponding bit in the I2Ci.I2C_IE register (the I2Ci.I2C_IE[4] XRDY_IE bit for the transmit interrupt, the I2Ci.I2C_IE[3] RRDY bit for the receive interrupt).

15.5.2.1.3 Initiate a Transfer

Poll the I2Ci.I2C_STAT[12] BB bit. If it is cleared to 0 (bus not busy), set the I2Ci.I2C_CON[0] STT bit to 1. Because a transfer allows the LH to write or read only a single byte to or from the external SCCB device, the transmission automatically stops at the end of the transfer. When the transfer is complete, the I2Ci.I2C_STAT[2] ARDY bit is set to 1. In SCCB mode, the I2Ci.I2C_CON[1] STP bit is not used.

15.5.2.1.4 Receive Data

Poll the I2Ci.I2C_STAT[3] RRDY bit, or use the RRDY interrupt (the I2Ci.I2C_IE[3] RRDY_IE bit must be set to 1) to read the receive data in the I2Ci.I2C_DATA register.

NOTE: In SCCB mode, the I2Ci.I2C_BUF[13:8] RTRSH field (RX threshold) must be set to a value of 0x0 (RX threshold = 1).

15.5.2.1.5 Transmit Data

Poll the I2Ci.I2C_STAT[4] XRDY bit, or use the XRDY interrupt (the I2Ci.I2C_IE[4] XRDY_IE bit must be set to 1) to write the data to the I2Ci.I2C_DATA register.

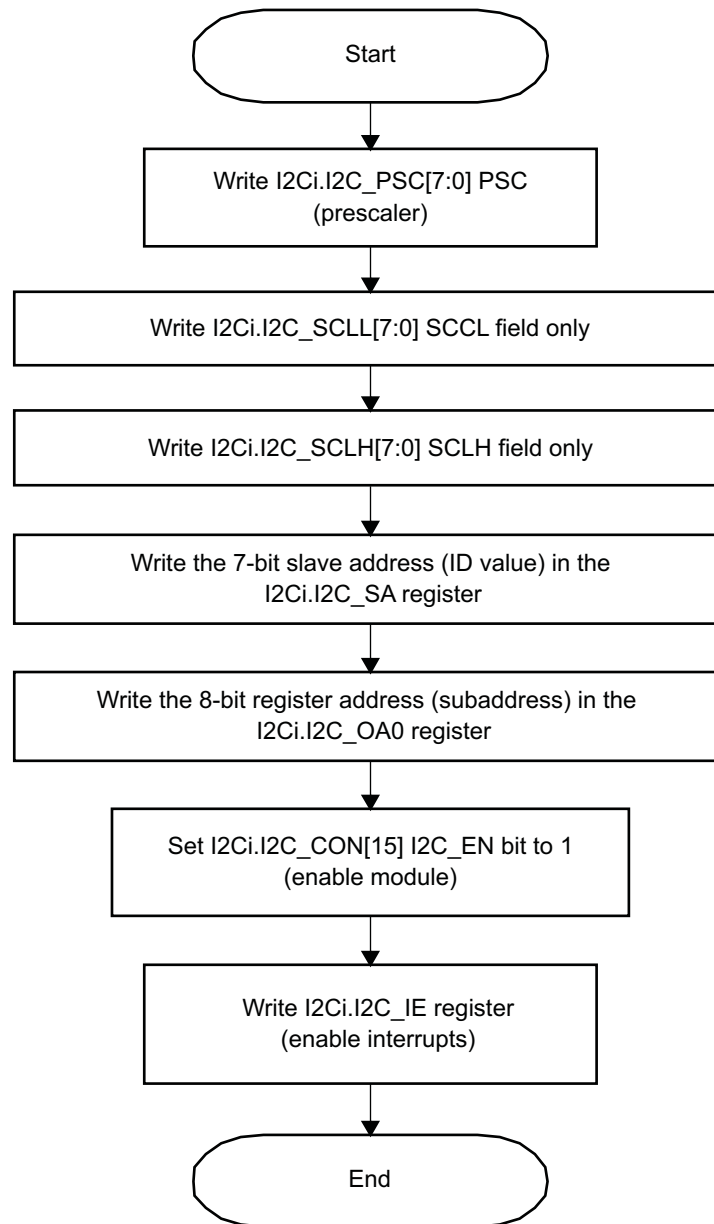

NOTE: In SCCB mode, the I2Ci.I2C_BUF[5:0] XTRSH field (TX threshold) must be set to a value of 0x0 (TX threshold = 1).

15.5.2.2 Interrupt Subroutine Sequence

1. Test for register access ready (I2Ci.I2C_STAT[2] ARDY status bit) and resolve accordingly.
2. Test for receive data ready (I2Ci.I2C_STAT[3] RRDY status bit) and resolve accordingly.
3. Test for transmit data ready (I2Ci.I2C_STAT[4] XRDY status bit) and resolve accordingly.

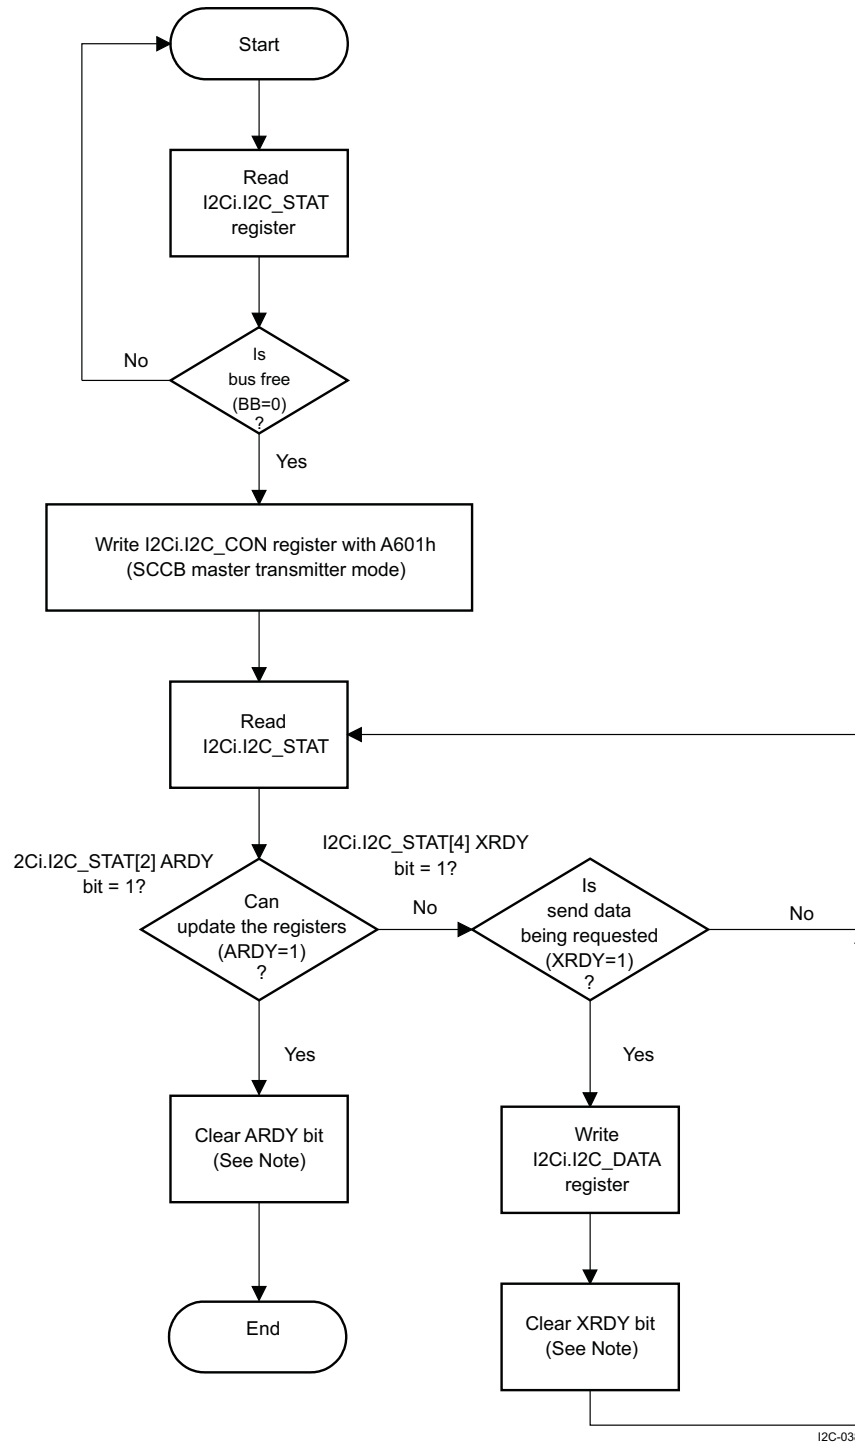

15.5.2.3 Programming Flow Diagrams

Figure 15-37 through Figure 15-41 are procedure flowcharts for programming the SCCB mode.

Figure 15-37. SCCB Setup Procedure

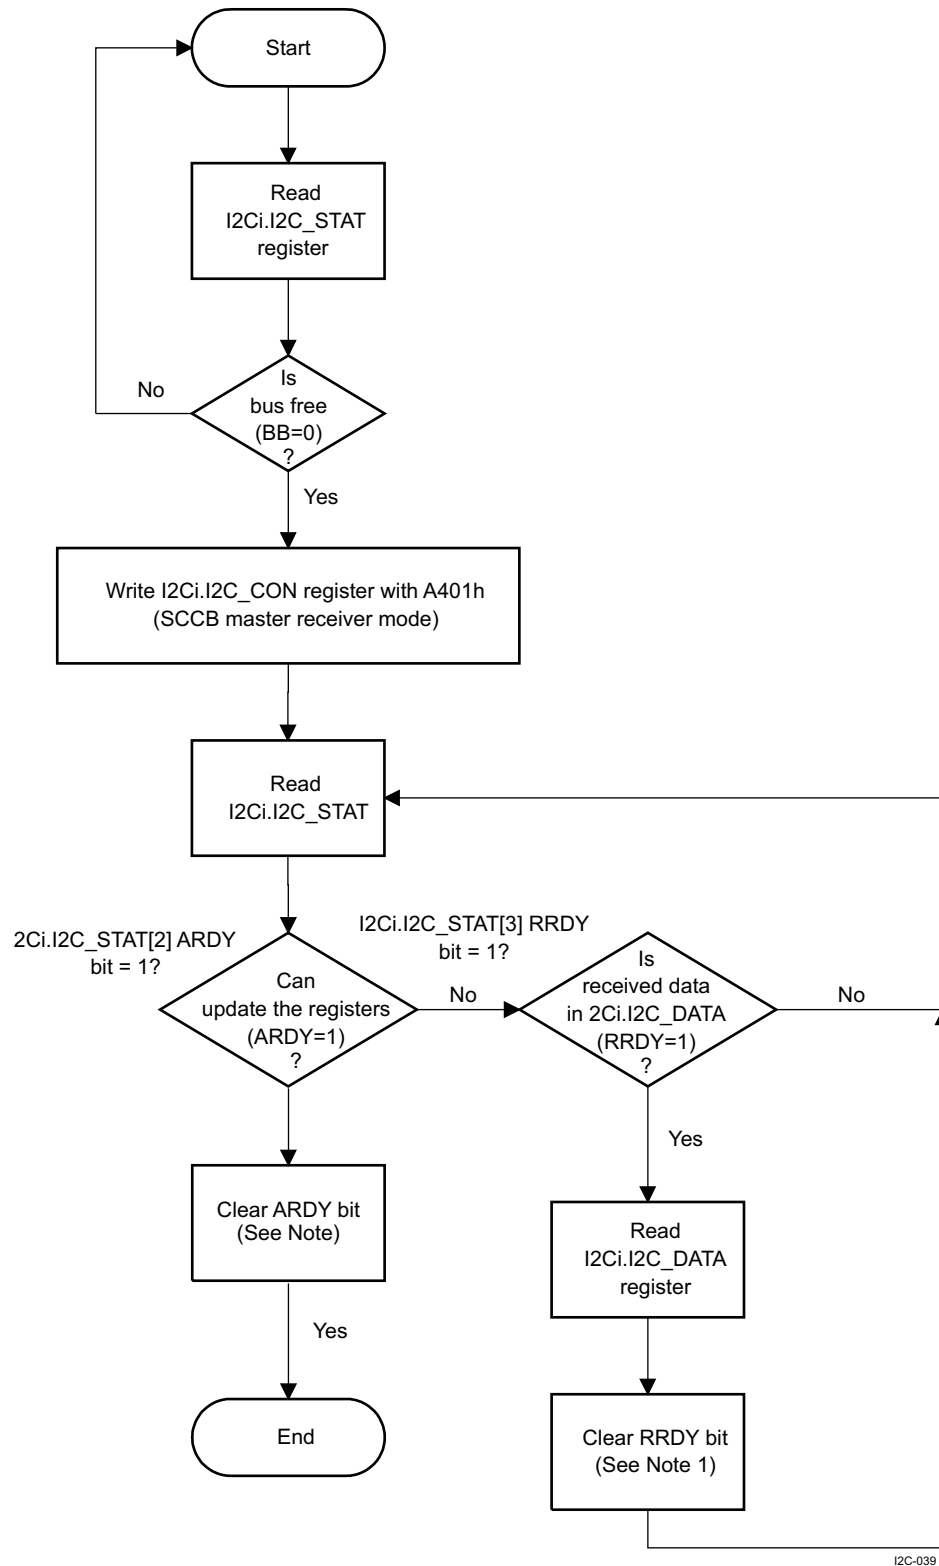

I2C-037

NOTE: The RRDY and ARDY bits are cleared by writing 1 in the corresponding bit in the I2Ci.I2C_STAT register.

15.5.3 Master Transmitter HS I²C Controller I2C4 Basic Programming Model for Communication With Power Chips

This section describes the programming model of the master transmitter HS I²C controller I2C4 for communication with one or more power chips. The HS I²C controller I2C4 allows the two voltage Finite State Machines (FSMs) in the PRCM module of the device to be interfaced to external power chips through the I²C bus for dynamic voltage control of two power supplies and power sequencing. The primary programming tasks are to set up the configuration registers according to the external power supply chip(s) being used.

15.5.3.1 Configure the Voltage Controller Registers

To use the voltage control function, the LH must configure the following registers in the voltage controller of the PRCM module:

- The voltage configuration register address for each VDD channel in the PRCM.PRM_VC_SMPS_RA register
- The ON/ON-low-power-Retention/OFF command configuration register address for each VDD channel in the PRCM.PRM_VC_SMPS_CMD_RA register
- The set of ON/ON-low-power/Retention/OFF voltage/mode values in the PRCM.PRM_VC_CMD_VAL_0 register for the first VDD channel and the PRCM.PRM_VC_CMD_VAL_1 register for the second VDD channel
- The VDD channels configuration selection in the PRCM.PRM_VC_CH_CONF register

For details about voltage controller register configuration, see *Power, Reset, and Clock Management*.

15.5.3.2 Configure the Master Transmitter HS I²C Controller I2C4

At power-on reset, the I2C4 is in HS mode (PRCM.PRM_VC_I2C_CFG[3] HSEN bit). In HS mode, the LH must configure the master code value for the preamble I²C high-speed transmission by configuring the PRCM.PRM_VC_I2C_CFG[2:0] MCODE field. If the external power chips do not support the I²C HS mode, the HS mode can be disabled and F/S mode enabled by clearing the PRCM.PRM_VC_I2C_CFG[3] HSEN bit to 0.

By default, the repeated start operation is enabled (PRCM.PRM_VC_I2C_CFG[4] SREN bit set to 1 at power-on reset). In F/S mode, the repeated start operation can be disabled by clearing the PRCM.PRM_VC_I2C_CFG[4] SREN bit to 0.

15.5.3.3 Configure the External Power Chip(s)

The LH can send configuration commands from one bypass input to the external power chip(s), using the same I²C interface. To send a configuration command, the LH must process as follows:

- Check whether the transmission of a configuration command is ongoing by polling the PRCM.PRM_VC_BYPASS_VAL[24]VALID bit (1: a transmission is ongoing, 0: a new transmission can start).
- Set the external power chip 7-bit slave address in the PRCM.PRM_VC_BYPASS_VAL[6:0] SLAVEADDR field, set the configuration register address of the external power chip in the PRCM.PRM_VC_BYPASS_VAL[15:8] REGADDR field, and set the data to be written to the external power chip configuration register in the PRCM.PRM_VC_BYPASS_VAL[23:16] DATA field.
- Set the PRCM.PRM_VC_BYPASS_VAL[24]VALID bit to 1 to send the configuration command to the external power chip.

15.6 High-Speed I²C Controllers Register Manual

CAUTION

The I2Ci registers are limited to 16 bit and 8 bit data accesses, 32 bit data access is not allowed and can corrupt register content.

NOTE: For details about the master transmitter HS I²C controller I2C4, see , *Power, Reset, and Clock Management*.

Table 15-14 provides the instance summary.

Table 15-14. Instance Summary

| Module Name | Base Address | Size |
|-------------|--------------|-----------|
| I2C1 | 0x4807 0000 | 128 bytes |
| I2C2 | 0x4807 2000 | 128 bytes |
| I2C3 | 0x4806 0000 | 128 bytes |

15.6.1 Multimaster HS I²C Controller Register Mapping Summary

Table 15-15 lists the I2Ci registers (where i = 1, 2 and 3).

| 11 | ROVR | Receive overrun status. Read-only bit. Writing this bit does not affect the read value. Read 0x0: Normal operation Read 0x1: Receiver overrun | R | 0 |
| 10 | XUDF | Transmit underflow status. Read-only bit. Writing this bit does not affect the read value. Read 0x0: Normal operation Read 0x1: Transmit underflow | R | 0 |
| 9 | AAS | Address recognized as slave IRQ status Read 0x0: No action Read 0x1: Address recognized Write 0x0: No effect Write 0x1: Clear this bit to 0. | RW | 0 |
| 8 | BF | Bus Free IRQ status | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|---|------|-------|
| | | Read 0x0: No action Read 0x1: Bus free Write 0x0: No effect Write 0x1: Clear this bit to 0. | | |
| 7 | AERR | Access Error IRQ status Read 0x0: No action Read 0x1: Access error Write 0x0: No effect Write 0x1: Clear this bit to 0. | RW | 0 |
| 6 | STC | Start Condition IRQ status Read 0x0: No action Read 0x1: Start condition detected Write 0x0: No effect Write 0x1: Clear this bit to 0. | RW | 0 |
| 5 | GC | General Call IRQ status. Set to 1 when general call address detected. Interrupt signaled to MPU subsystem Read 0x0: No general call detected Read 0x1: General call address detected Write 0x0: No effect Write 0x1: Clear this bit to 0. | RW | 0 |
| 4 | XRDY | Transmit Data Ready IRQ status. Set to 1 in transmit mode when new data is requested for transmission. When this bit is set to 1, an interrupt is signaled to MPU subsystem Read 0x0: No transmit data is requested for transmission Read 0x1: Transmit data is requested for transmission Write 0x0: No effect Write 0x1: Clear this bit to 0. | RW | 0 |
| 3 | RRDY | Receive Data Ready IRQ status. Set to 1 when in receive mode, causing new data to be able to be read. When this bit is set to 1, an interrupt is signaled to MPU subsystem. Read 0x0: No data available Read 0x1: Receive data available Write 0x0: No effect Write 0x1: Clear this bit to 0. | RW | 0 |
| 2 | ARDY | Register Access Ready IRQ status. Setting this bit to 1 indicates that previous access has been performed and registers are ready to be accessed again. An interrupt is signaled to MPU subsystem. Read 0x0: Module busy Read 0x1: Access ready Write 0x0: No effect Write 0x1: Clear this bit to 0. | RW | 0 |
| 1 | NACK | No Acknowledgment IRQ status. This bit is set when No Acknowledgment has been received. An interrupt is signaled to MPU subsystem. In master mode, the transfer is automatically ended by generating a stop condition on the bus. The I2Ci.I2C_CON[1] STP, I2Ci.I2C_CON[10] MST and I2Ci.I2C_CON[9] TRX bits are automatically cleared to 0 (slave receiver mode). TX and RX FIFOs must be cleared (I2Ci.I2C_BUF[6] TXFIFO_CLR and I2Ci.I2C_BUF[14] RXFIFO_CLR bits set to 1). Read 0x0: Normal operation Read 0x1: No Acknowledge detected Write 0x0: No effect Write 0x1: Clear this bit to 0. | RW | 0 |
| 0 | AL | Arbitration Lost IRQ status. This bit is set automatically by the hardware when the I2C controller inside the device loses arbitration in master transmit mode. An interrupt is signaled to MPU subsystem. Read 0x0: Normal operation | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|-------------------------------------|------|-------|
| | | Read 0x1: Arbitration loss detected | | |
| | | Write 0x0: No effect | | |
| | | Write 0x1: Clear this bit to 0. | | |

Multichannel SPI

This chapter describes the four multichannel serial port interface (McSPI) modules.

NOTE: Some features may not be available or supported in your particular device. For more information, see Chapter 1, the Device Family section, and your device-specific data manual.

| Topic | Page |
|---|-------------|
| 16.1 McSPI Overview | 1868 |
| 16.2 McSPI Environment | 1871 |
| 16.3 McSPI Functional Interface | 1874 |
| 16.4 McSPI Integration | 1879 |
| 16.5 McSPI Functional Description | 1883 |
| 16.6 McSPI Basic Programming Model | 1904 |
| 16.7 McSPI Use Cases and Tips | 1925 |
| 16.8 McSPI Register Manual | 1931 |

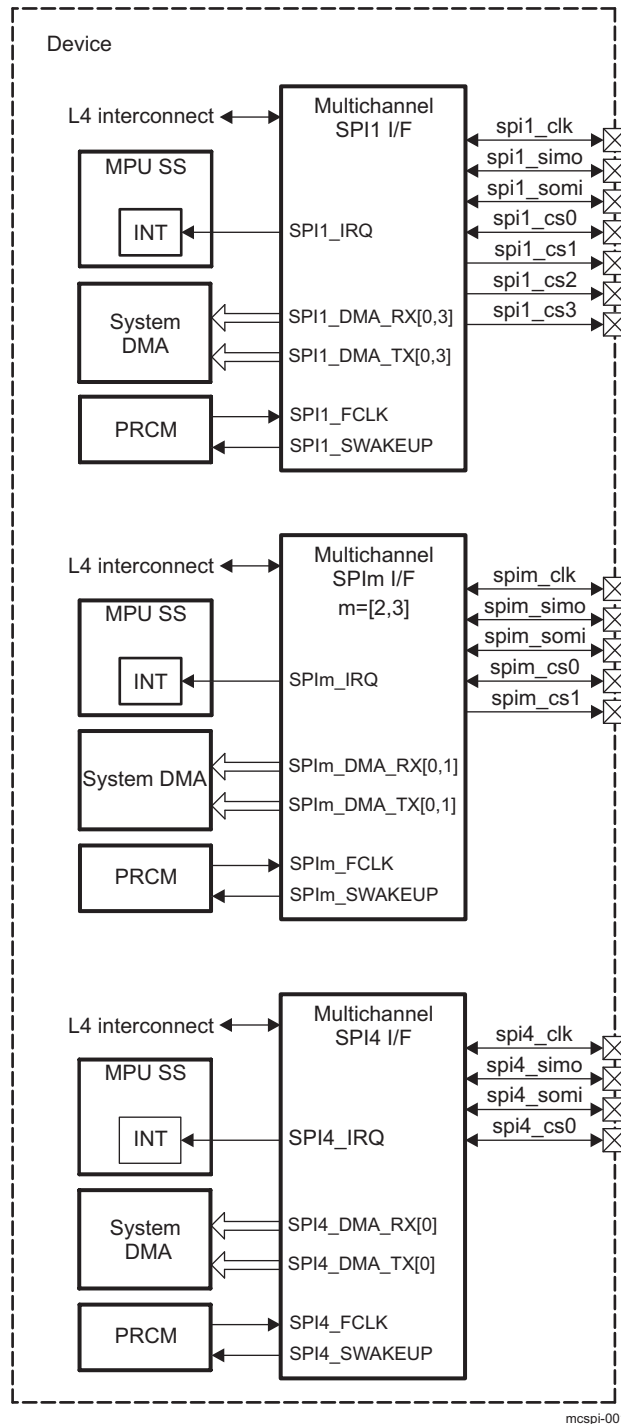

16.1 McSPI Overview

The multichannel serial port interface (McSPI) is a master/slave synchronous serial bus. There are four separate McSPI modules (SPI1, SPI2, SPI3, and SPI4) in the device (see [Figure 16-1](#)). The McSPI modules differ as follows: SPI1 supports up to four peripherals, SPI2 and SPI3 support up to two peripherals, and SPI4 supports only one peripheral.

NOTE: In this chapter, $m=[1,4]$ represents the module instance and x represents the channel in signal and register naming. There are four McSPI instances. Each module instance has different channel numbers:

- SPI1: 4 channels (if $m=1$, $x=4$)
 - SPI2: 2 channels (if $m=2$, $x=2$)
 - SPI3: 2 channels (if $m=3$, $x=2$)
 - SPI4: 1 channel (if $m=4$, $x=1$)
-

Figure 16-1. Multichannel Modules SPI1, SPI2, SPI3, and SPI4

The McSPI instances include the following main features:

- Serial clock with programmable frequency, polarity, and phase for each channel
- Wide selection of SPI word lengths ranging from 4 bits to 32 bits
- Up to four master channels or single channel in slave mode
- Master multichannel mode:
 - Full duplex/half duplex
 - Transmit-only/receive-only/transmit-and-receive modes

- Flexible I/O port controls per channel
- Two direct memory access (DMA) requests (read/write) per channel
- Single interrupt line for multiple interrupt source events
- Power management through wake-up capabilities
- Enable the addition of a programmable start-bit for SPI transfer per channel (start-bit mode)
- Support start-bit write command
- Support start-bit pause and break sequence
- 64 bytes built-in FIFO available for a single channel
- Force CS mode for continuous transfers

16.2 McSPI Environment

Figure 16-2 shows a simplified overview of a typical application system using the McSPI. This example is based on a TFS chipset (TFS6040-0098), including a 2.2-inch color-active matrix thin-film transistor (TFT) liquid crystal display (LCD) with a light-emitting diode (LED) front light, a four-wire resistive touch-screen panel, and LCD controllers. This chipset is associated with the TSC2005 or TSC2006 touch-screen controller, powered by a power-management unit, and driven by the device. The McSPI device interface is set to master mode; the touch-screen McSPI controller interface operates in slave mode.

Figure 16-2. Typical Application Using the McSPI

mcspi-034

Figure 16-3 through Figure 16-8 show master mode and slave mode configurations. Each mode can be wired on a single-duplex or full-duplex configuration.

16.2.1 SPI Interface in Master Mode

Figure 16-3 shows a case in master mode (full-duplex) where the McSPI module is connected with two slave devices.

Figure 16-3. McSPI Master Mode (Full-Duplex)

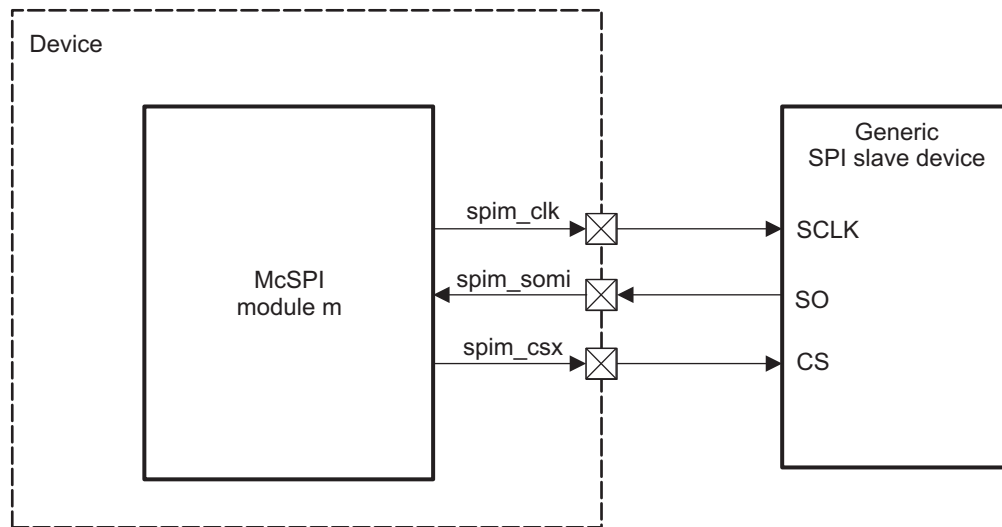

mcspi-002

NOTE: In this case m=[1,3].

Figure 16-4 shows the master single mode, which can also be configured in receive-only mode.

Figure 16-4. McSPI Master Single Mode (Receive-Only)

108-003

16.2.2 SPI Interface in Slave Mode

Figure 16-5 shows a case in slave mode (full-duplex).

NOTE: Only channel 0 can be configured as slave, and only spin_cs0 can be used as a chip-enable in slave mode.

Figure 16-5. McSPI Slave Mode (Full Duplex)

108-004

Figure 16-6 shows the slave single mode, which can also be configured in transmit-only mode.

16.3 McSPI Functional Interface

16.3.1 Basic McSPI Pins for Master Mode

Figure 16-7 shows all of the McSPI interface signals in master mode.

Figure 16-7. McSPI Interface Signals in Master Mode

108-006

Table 16-1 describes the McSPI I/O in master mode.

Table 16-1. McSPI I/O Description (Master Mode)

| Signal Name | I/O | Description | Reset ⁽¹⁾ |
|-------------|-----|--|----------------------|
| spim_clk | O | SPI module serial clock ⁽²⁾ | Unknown |
| spim_simo | O | SPI module serial data master out (slave input, master output) | Unknown |
| spim_somi | I | SPI module serial data master input (slave output, master input) | – |
| spim_csx | O | SPI module chip-select x output | Low |

⁽¹⁾ After reset, the SPI modules are in slave mode by default. This paragraph implies that the McSPI module is configured in slave mode. (See the MCSPI_MODULCTRL[2] MS bit in the module control register [MCSPI_MODULCTRL]).

⁽²⁾ This output signal is also used as re-timing input.

16.3.2 Basic McSPI Pins for Slave Mode

Figure 16-8 shows all of the McSPI interface signals in slave mode.

Figure 16-8. McSPI Interface Signals in Slave Mode

108-007

Table 16-2 describes the McSPI I/O in slave mode.

Table 16-2. McSPI I/O Description (Slave Mode)

| Signal Name | I/O | Description | Reset ⁽¹⁾ |
|--------------|-----|---|----------------------|
| spim_clk | I | SPIm module serial clock | Unknown |
| spim_simo | I | SPIm module serial data master out (slave input, master output) | Unknown |
| spim_somi | O | SPIm module serial data master input (slave output, master input) | – |
| spim_cs0 | I/O | SPIm module chip-select 0 input | HiZ |
| spim_cs1/2/3 | O | SPIm module chip-select 1/2/3 output | Low |

⁽¹⁾ After reset, the SPI modules are in slave mode by default. This paragraph implies that the McSPI module is configured in slave mode. (See the MCSPI_MODULCTRL[2] MS bit in Module Control Register (MCSPI_MODULCTRL).)

16.3.3 Multichannel SPI Protocol and Data Format

The synchronous SPI protocol allows a master device to initiate serial data transfers to a slave device. A slave select line (spim_csx) allows selection of an individual slave SPI device. Slave devices that are not selected do not interfere with SPI bus activities.

McSPI offers the flexibility to modify the following parameters to adapt to the device features:

- Word length
McSPI supports any SPI word ranging from 4 bits to 32 bits long (SPIm.MCSPI_CHxCONF[11:7] WL field).
SPI word length can be changed between transmissions to allow the master device to communicate with peripheral slaves that have different requirements.
- SPI enable (spim_csx, for channel x of instance m)
The polarity of the SPI enable signals is programmable (SPIm.MCSPI_CHxCONF[6] EPOL bit). spim_csx signals can be active high or low.
The assertion of the spim_csx signals is programmable and can be manually or automatically asserted. The manual assertion mode is available in single master mode only. spim_csx can be kept active between words with the SPIm.MCSPI_CHxCONF[20] FORCE bit.
Two consecutive words for two different slave devices can go along with active spim_csx signals with different polarity (see the example in [Section 16.6, McSPI Basic Programming Model](#)).
- Programmable start-bit
In start-bit mode a start-bit is added before the SPI word length to indicate how the next SPI word must be handled. The start-bit is enabled by setting SPIm.MCSPI_CHxCONF[23] SBE bit to 1. The SPIm.MCSPI_CHxCONF[24] SBPOL bit defines the polarity of the start-bit.
- Programmable SPI clock
 - Bit rate
In master mode, the baud rate of the SPI serial clock is programmable using the 48-MHz reference clock (from the power, reset, and clock management [PRCM] module). [Table 16-3](#) gives the spim_clk bit rates obtained for data transfer when programming the clock divider (SPIm.MCSPI_CHxCONF[5:2] CLKD bit field).

Table 16-3. SPI Master Clock Rates

| Divider | Clock Rate |
|---------|------------|
| 1 | 48 MHz |
| 2 | 24 MHz |
| 4 | 12 MHz |
| 8 | 6 MHz |
| 16 | 3 MHz |
| 32 | 1.5 MHz |
| 64 | 750 kHz |
| 128 | 375 kHz |

Table 16-3. SPI Master Clock Rates (continued)

| Divider | Clock Rate |
|---------|------------|
| 256 | ~187 kHz |
| 512 | ~93.7 kHz |
| 1024 | ~46.8 kHz |
| 2048 | ~23.4 kHz |
| 4096 | ~11.7 kHz |
| 8192 | ~5.8 kHz |
| 16384 | ~2.9 kHz |
| 32768 | ~1.5 kHz |

– Polarity and phase

The polarity (the SPI_{Im}.MCSPI_CHxCONF[1] POL bit) and the phase (the SPI_{Im}.MCSPI_CHxCONF[0] PHA bit) of the SPI serial clock (spim_clk) are configurable to offer four combinations. Software selects the right combination, depending on the device. See [Table 16-4](#) and [Figure 16-9](#).

Table 16-4. Phase and Polarity Combinations

| Polarity (POL) | Phase (PHA) | SPI Mode | Comments |
|----------------|-------------|----------|--|
| 0 | 0 | Mode 0 | spim_clk is active high and sampling occurs on the rising edge. |
| 0 | 1 | Mode 1 | spim_clk is active high and sampling occurs on the falling edge. |
| 1 | 0 | Mode 2 | spim_clk is active low and sampling occurs on the falling edge. |
| 1 | 1 | Mode 3 | spim_clk is active low and sampling occurs on the rising edge. |

Figure 16-9. Phase and Polarity Combinations

108-009

16.3.3.1 Transfer Format

In both master and slave modes, McSPI drives the data lines when spim_csx is asserted.

Each word is transmitted starting with the most-significant bit (MSB).

This section explains the two cases of data transmission determined by the clock phase (PHA) and the type of data transmission using a start-bit (SBE) called the start-bit mode:

- Transmission in mode 0 and mode 2 (PHA = 0)

When PHA = 0, the first bit of the SPI word to transmit (on the master or the slave data output pin) is valid one half cycle of spim_clk after the spim_csx assertion.

Therefore, the first edge of the `spim_clk` line is used by the master to sample the first data bit sent by the slave. On the same edge, the first data bit sent by the master is sampled by the slave.

On the next `spim_clk` edge, the received data bit is shifted into the receive shift register and a new data bit is transmitted on the serial data line.

This process continues for a number of pulses on the `spim_clk` line defined by the SPI word length programmed in the master device, with data being latched on odd-numbered edges and shifted on even-numbered edges. See [Figure 16-10](#).

Figure 16-10. Full-Duplex Transfer Format With PHA = 0

- Transmission in mode 1 and mode 3 (PHA = 1)

When PHA = 1, the first bit of the SPI word to transmit (on the master or the slave data output pin) is valid on the following `spim_clk` edge (one half cycle later). This is the sampling edge for the master and slave. A synchronization delay is added between the `spim_csx` activation and the first `spim_clk` edge.

The received data bit is shifted into the shift register on the third `spim_clk` edge.

This process continues for a number of pulses on the `spim_clk` line defined by the SPI word length programmed in the master device, with data being latched on even-numbered edges and shifted on odd-numbered edges.

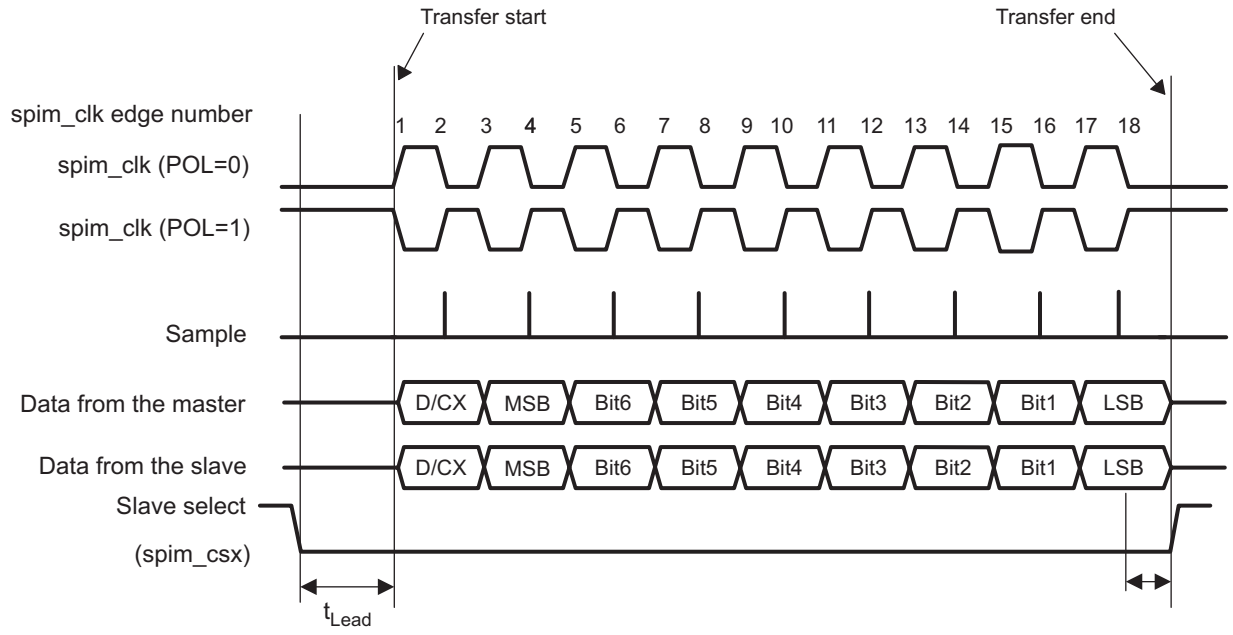

NOTE: The minimum synchronization delay is one cycle of `spim_clk`, if the `spim_clk` frequency equals the `SPI_M_FCLK` (McSPI_M functional clock) frequency in master mode. The minimum synchronization delay is one-half cycle of `spim_clk`, if the `spim_clk` frequency is lower than the `SPI_M_FCLK` frequency in both master and slave modes.

- Transmission with a start-bit (SBE = 1)

When the `SPI_M.MCSPICHXCONF[23]` SBE bit = 1, a start-bit is added before the MSB to indicate whether the next SPI word must be handled as a command or as data.

[Figure 16-11](#) shows an example of a data transfer with an extra start-bit.

Figure 16-11. Extended SPI Transfer With a Start-Bit (SBE = 1)

16.4 McSPI Integration

16.4.1 McSPI Description

Figure 16-12 highlights the McSPI module integration in the device.

16.4.2 Clocking, Reset, and Power-Management Scheme

16.4.2.1 Clocking

Each McSPI module is clocked with an independent functional clock of 48 MHz from the PRCM module (SPIIm_FCLK with $m = [1,4]$) and with an interface clock, CORE_L4_ICLK (L4 interconnect):

- SPIIm_FCLK is the McSPI module m functional clock and is used to clock the McSPI internal logic. The source of SPIIm_FCLK is the PRCM CORE_48M_FCLK output clock.
- SPIIm_ICLK is the McSPI module m interface clock and is used to synchronize the McSPI L4 port to the L4 interconnect. All accesses from the interconnect are synchronous with SPIIm_ICLK. The source of SPIIm_ICLK is the PRCM CORE_L4_ICLK output clock.

From a global system power management perspective, when one or both of the McSPI clocks is not required, the McSPI module can be deactivated at the PRCM level in the corresponding registers.

Table 16-5 describes the McSPI module PRCM clock control bits.

Table 16-5. McSPI Clocks

| McSPI Clock | Associated PRCM Clock Output | Enable Bit | Autoidle Bit |
|-------------|------------------------------|---|---|
| SPIIm_FCLK | CORE_48M_FCLK | PRCM.CM_FCLKEN1_CORE.EN_M CSPIIm (with $m=[1,4]$) | N/A |
| SPIIm_ICLK | CORE_L4_ICLK | PRCM.CM_ICLKEN1_CORE.EN_M CSPIIm (with $m=[1,4]$) | PRCM.CM_AUTOIDLE1_CORE.AUTO _MCSPIIm (with $m=[1,4]$) |

NOTE:

- The PRCM CORE_48M_FCLK output is gated at the PRCM level, assuming that all modules sharing it are disabled in the corresponding register. Disabling the McSPI module is a necessary but insufficient condition.
- The PRCM CORE_L4_ICLK output is gated at the PRCM level, assuming that all modules sharing it are disabled in the corresponding register. Disabling the McSPI module is a necessary but insufficient condition.
- The PRCM.CM_AUTOIDLE1_CORE bit is used to link/unlink the McSPI module from CORE_L4_ICLK-related clock domain transitions.

For more information about source clocks gating and domain transitions, see , *Power, Reset, and Clock Management*. For more information on power saving management, see [Section 16.5.7](#).

16.4.2.2 Power Domain

The McSPI modules belong to the CORE power domain (see [Table 16-6](#)).

Table 16-6. Power Domain

| Peripherals | Power Domain |
|---------------|-------------------|
| McSPI modules | CORE power domain |

16.4.2.3 Hardware Reset

As part of the CORE power domain, CORE_RST is issued by the PRCM module (for more information about the CORE power domain implementation and CORE_RST signal, see , *Power, Reset, and Clock Management*). The module is reset by hardware when an active-low reset signal is asserted. The hardware reset signal has a global reset effect on the module. All configuration registers and all state-machines are reset in all clock domains (see [Table 16-7](#)).

Table 16-7. McSPI Hardware Reset

| Peripherals | Name | Comments |
|--------------|----------|----------------------|
| McSPI module | CORE_RST | Same as global reset |

16.4.2.4 Software Reset

The SPIm.MCSPI_SYSCONFIG[1] SOFTRESET bit controls the software reset of the SPI interface. Writing 1 to this bit enables active software reset functionality, which is equivalent to a hardware reset. The bit is automatically reset by hardware.

NOTE: The SPIm.MCSPI_SYSCONFIG register is not sensitive to software reset.

16.4.3 Hardware Requests

16.4.3.1 DMA Requests

Each channel includes two DMA requests, one for reception and one for transmission (see [Table 16-8](#)).

Table 16-8. DMA Requests

| Attributes | DMA Request | Name | Mapping | Comments |
|-------------|-------------|--------------|----------|-----------------------------------|
| SPI1 | | | | |
| | 8 | SPI1_DMA_TX0 | S_DMA_34 | Destination is system DMA (sDMA). |
| | | SPI1_DMA_RX0 | S_DMA_35 | |
| | | SPI1_DMA_TX1 | S_DMA_36 | |
| | | SPI1_DMA_RX1 | S_DMA_37 | |
| | | SPI1_DMA_TX2 | S_DMA_38 | |
| | | SPI1_DMA_RX2 | S_DMA_39 | |
| | | SPI1_DMA_TX3 | S_DMA_40 | |
| | | SPI1_DMA_RX3 | S_DMA_41 | |
| SPI2 | | | | |
| | 4 | SPI2_DMA_TX0 | S_DMA_42 | Destination is sDMA. |
| | | SPI2_DMA_RX0 | S_DMA_43 | |
| | | SPI2_DMA_TX1 | S_DMA_44 | |
| | | SPI2_DMA_RX1 | S_DMA_45 | |
| SPI3 | | | | |
| | 4 | SPI3_DMA_TX0 | S_DMA_14 | Destination is sDMA. |
| | | SPI3_DMA_RX0 | S_DMA_15 | |
| | | SPI3_DMA_TX1 | S_DMA_22 | |
| | | SPI3_DMA_RX1 | S_DMA_23 | |
| SPI4 | | | | |
| | 2 | SPI4_DMA_TX0 | S_DMA_69 | Destination is sDMA. |
| | | SPI4_DMA_RX0 | S_DMA_70 | |

16.4.3.2 Interrupt Requests

Each McSPI module handles one interrupt line (see [Table 16-9](#)).

Table 16-9. Interrupt Requests

| Attributes | Interrupt Request | Name | Mapping | Comments |
|-------------|-------------------|----------|----------|--|
| SPI1 | 1 | SPI1_IRQ | M_IRQ_65 | Destination is the microprocessor unit (MPU) interrupt controller. |
| SPI2 | 1 | SPI2_IRQ | M_IRQ_66 | Destination is the MPU interrupt controller. |
| SPI3 | 1 | SPI3_IRQ | M_IRQ_91 | Destination the MPU interrupt controller. |
| SPI4 | 1 | SPI4_IRQ | M_IRQ_48 | Destination is the MPU interrupt controller. |

16.4.3.3 Wake-Up Requests

[Table 16-10](#) lists the wake-up requests.

Table 16-10. Wake-Up Requests

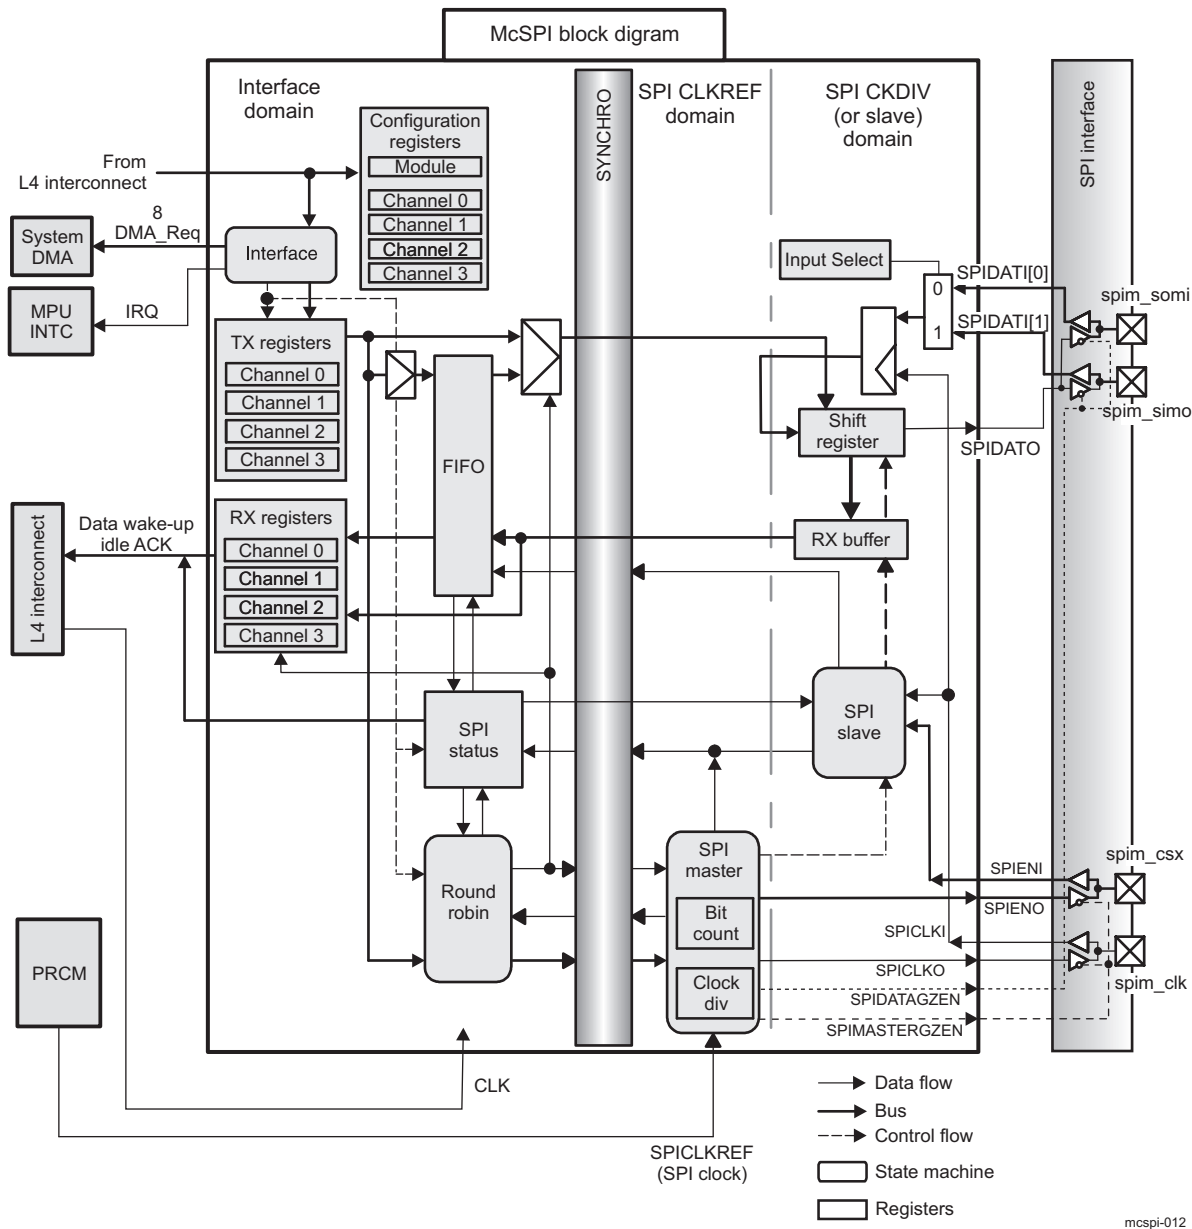

| Attributes | Wake Request | Name | Mapping | Comments |
|-------------|--------------|----------|--------------|---------------------------------|
| SPI1 | 1 | spi1_cs0 | SPI1_SWAKEUP | Destination is the PRCM module. |
| SPI2 | 1 | spi2_cs0 | SPI2_SWAKEUP | Destination is the PRCM module. |
| SPI3 | 1 | spi3_cs0 | SPI3_SWAKEUP | Destination is the PRCM module. |
| SPI4 | 1 | spi4_cs0 | SPI4_SWAKEUP | Destination is the PRCM module. |

16.5 McSPI Functional Description

16.5.1 McSPI Block Diagram

Figure 16-13 shows the McSPI module.

Figure 16-13. McSPI Block Diagram

mcspi-012

16.5.2 Master Mode

16.5.2.1 Master Mode Features

The McSPI master mode supports multichannel communication with up to four independent SPI communication channel contexts. The McSPI initiates a data transfer on the data lines (spim_simo and spim_somi) and generates clock (spim_clk) and control signals (spim_csx).

Connected to multiple external devices, the McSPI exchanges data with one SPI device at a time through two main modes (available in slave mode):

- Two-data-pins interface mode (transmit-and-receive mode for full-duplex transmission)
- Single-data-pin interface mode (recommended for half-duplex transmission)

Two DMA request events (read and write) allow synchronized accesses of the DMA controller with the activity of McSPI.

Three interrupt events can be used for data transmission and reception in master mode (for more information on interrupts, see [Section 16.5.5.1, Interrupt Events in Master Mode](#)).

16.5.2.2 Master Transmit-and-Receive Mode (Full Duplex)

In full-duplex transmission, data is transmitted (shifted out serially on `spim_simo`) and received (shifted in serially on `spim_somi`) simultaneously on separate data lines.

The master transmit-and-receive mode is programmable per channel (the `SPI.MCSPI_CHxCONF[13:12]` TRM field).

Channel access to the shift registers for transmission/reception is based on the `MCSPI_TXx` transmitter register state, the `MCSPI_RXx` receiver register state, and round robin arbitration.

Channels that meet the following rules are included in the round robin list of active channels scheduled for transmission and/or reception. The arbiter skips channels that do not meet the rules and searches in the rotation for the next enabled channel.

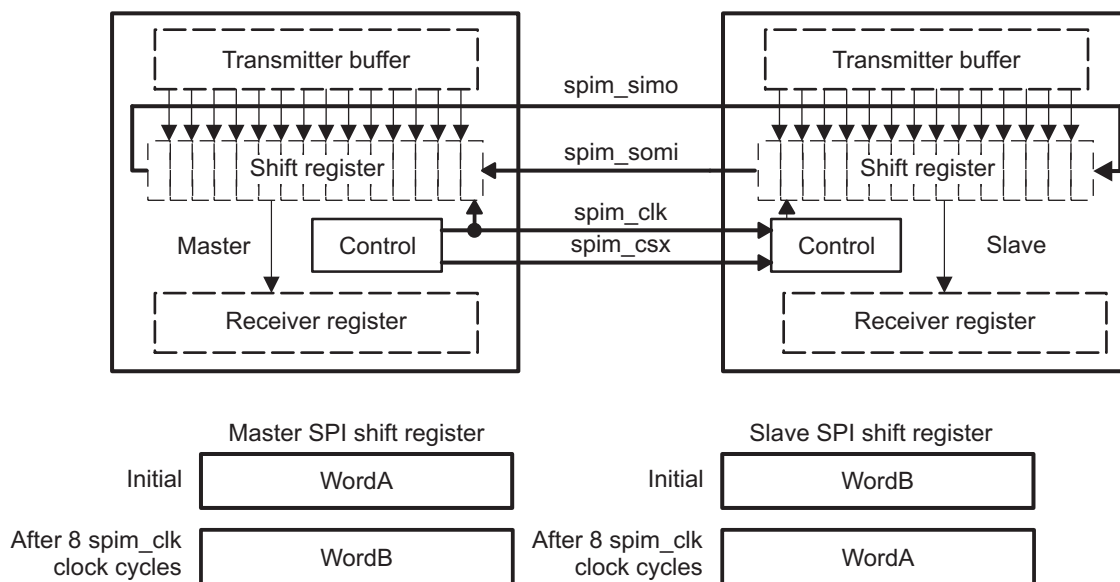

- Rule 1: Only enabled channels (the `SPI.MCSPI_CHxCTRL[0]` EN bit) can be scheduled for transmission and/or reception.
- Rule 2: If its `MCSPI_TXx` transmitter register is not empty (the `SPI.MCSPI_CHxSTAT[1]` TXS bit), an enabled channel can be scheduled when the shift register is assigned. If the `MCSPI_TXx` register is empty when the shift register is assigned, the `TXx_UNDERFLOW` event is activated, and the next enabled channel with new data to transmit is scheduled (see also the transmit-only mode).
- Rule 3: An enabled channel can be scheduled if its receive register is not full (the `SPI.MCSPI_CHxSTAT[0]` RXS bit) when the shift register is assigned (see also the receive-only mode). Therefore, the `MCSPI_RXx` register cannot be overwritten. Note that the `SPI1.MCSPI_IRQSTATUS[3]` `RX0_OVERFLOW` bit is never set to this mode.

When SPI word transfer completes (the `SPI.MCSPI_CHxSTAT[2]` EOT bit is set), the updated `MCSPI_TXx` register of the next scheduled channel is loaded into the shift register. The serialization (transmit-and-receive) starts depending on the channel communication configuration. When serialization completes, the received data transfers to the channel receive register.

The serial clock (`spim_clk`) synchronizes shifting and sampling of the information on the two serial data lines (`spim_simo` and `spim_somi`). Each time a bit transfers out from the master, 1 bit transfers in from the slave.

[Figure 16-14](#) shows an example of a full-duplex system with a master device (McSPI module *m*) on the left and a slave device on the right. After eight cycles of the serial clock `spim_clk`, WordA transfers from the master to the slave. At the same time, WordB transfers from the slave to the master.

Figure 16-14. SPI Full-Duplex Transmission (Example)

108-013

16.5.2.3 Master Transmit-Only Mode (Half Duplex)

The master transmit-only mode prevents the MPU from reading the `MCSPi_RXx` register (minimizing data movement) when only transmission is meaningful.

The master transmit-only mode is programmable per channel (the `SPIm.MCSPi_CHxCONF[13:12]` TRM field). Transmission starts only after data is loaded into the `MCSPi_TXx` register.

Rule 1 and Rule 2, defined in Section 16.5.2.2, are applicable in this mode.

Rule 3, defined in Section 16.5.2.2, is not applicable.

In master transmit-only mode, the `MCSPi_RXx` register state FULL does not prevent transmission and the `MCSPi_RXx` register is always overwritten with the new SPI word. This event is not significant when only transmission is meaningful. Thus, the `RX0_OVERFLOW` bit in the `SPIm.MCSPi_IRQSTATUS` register is never set in this mode.

The hardware automatically disables the `RX_FULL` interrupt and the DMA read requests.

The transfer status is given by the `SPIm.MCSPi_CHxSTAT[2]` EOT bit.

16.5.2.4 Master Receive-Only Mode (Half Duplex)

The master receive mode prevents the MPU from refilling the `MCSPi_TXx` register (minimizing data movement) when only reception is meaningful.

The master receive mode is programmable per channel (the `SPIm.MCSPi_CHxCONF[13:12]` TRM field).

The master receive-only mode enables channel scheduling only on the empty state of the `MCSPi_RXx` register.

Rule 1 and Rule 3, defined in Section 16.5.2.2, are applicable in this mode.

Rule 2, defined in Section 16.5.2.2, is not applicable.

In the master receive-only mode, software must write dummy data to the `MCSPi_TXx` register and only after the TX buffer is empty (check the `MCSPi_CH0STAT[2]` bit in the software). Only one dummy write is enough to receive any number of words from the slave. Software should ensure that the `MCSPi_TXx` register is always full (the `TXx_EMPTY` bits of `SPIm.MCSPi_IRQSTATUS`) when receiving. The content of the `MCSPi_TXx` register is always loaded into the shift register when the shift register is assigned. After writing the dummy data to the `MCSPi_TXx` register, the `TXx_EMPTY` and `TXx_UNDERFLOW` bits in the `SPIm.MCSPi_IRQSTATUS` register are never set in receive-only mode.

The `SPIm.MCSPi_CHxSTAT[2]` EOT bit gives the status of serialization. The `RXx_FULL` bits of the `SPIm.MCSPi_IRQSTATUS` register are set when received data is loaded from the shift register to the corresponding `MCSPi_RXx` register. The `SPIm.MCSPi_IRQSTATUS[3]` `RX0_OVERFLOW` bit is never set in this mode.

16.5.2.5 Single-Channel Master Mode

When the McSPI is configured as a master device with a single enabled channel, the assertion of the `spim_csx` signal can be controlled in two different ways:

- If the `MCSPi_MODULCTRL[0]` `SINGLE` bit is set to 0, `spim_csx` assertion/deassertion after each SPI word is automatically controlled by the McSPI module (see subsections of [Section 16.5.2.1, Master Mode Features](#)).
- If the `MCSPi_MODULCTRL[0]` `SINGLE` bit and the `MCSPi_CHxCONF[20]` `FORCE` bit are set to 1: `spim_csx` assertion/deassertion is controlled by software (see [Section 16.5.2.5.1, Programming Tips When Switching to Another Channel](#)).

16.5.2.5.1 Programming Tips When Switching to Another Channel

When a single channel is enabled and data transfer is ongoing:

- Wait for completion of the SPI word transfer (wait until the `SPIm.MCSPi_CHxSTAT[2]` EOT bit is set to 1) before disabling the current channel and enabling a different channel.
- Disable the current channel first, and then enable the other channel.

16.5.2.5.2 Force `spim_csx` Mode

Continuous transfers are manually allowed by keeping the `spim_csx` signal active for successive SPI words transfer. Several sequences (configuration/enable/disable of the channel) can be run without deactivating the `spim_csx` line. This mode is supported by all channels and any master sequence can be used (transmit-receive, transmit-only, receive-only).

Keeping the `spim_csx` active mode is supported when:

- A single channel is used (with the `SPIm.MCSPi_MODULCTRL[0]` `SINGLE` bit set to 1).
- Transfer parameters are loaded in the configuration register of the appropriate channel (`SPIm.MCSPi_CHxCONF`).

The state of the `spim_csx` signal is programmable.

- Writing 1 to the `SPIm.MCSPi_CHxCONF[20]` `FORCE` bit drives the `spim_csx` line high when the `SPIm.MCSPi_CHxCONF[6]` `EPOL` bit is set to 0. `spim_csx` is driven low when the `SPIm.MCSPi_CHxCONF[6]` `EPOL` bit is set to 1.
- Writing 0 to the `SPIm.MCSPi_CHxCONF[20]` `FORCE` bit drives the `spim_csx` line low when the `SPIm.MCSPi_CHxCONF[6]` `EPOL` bit is set to 0. `spim_csx` is driven high when the `SPIm.MCSPi_CHxCONF[6]` `EPOL` bit is set to 1.
- A single channel is enabled (the `SPIm.MCSPi_CHxCTRL[0]` `EN` bit is set to 1). The first enabled channel activates the `spim_csx` line.

When the channel is enabled, the `spim_csx` signal activates with the programmed polarity. As in the multichannel master mode, the transfer start depends on the status of the `MCSPi_TXx` register (the `SPIm.MCSPi_CHxSTAT[1]` `TXS` bit), the status of the `MCSPi_RXx` register (the `SPIm.MCSPi_CHxSTAT[1]` `RXS` bit), and the defined mode (the `SPIm.MCSPi_CHxCONF[13:12]` `TRM` field) of the channel enabled.

The SPIm.MCSPI_CHxSTAT[2] EOT bit gives the transfer status of each SPI word. The RXx_FULLL bit in the SPIm.MCSPI_IRQSTATUS register is set when received data is loaded from the shift register to the MCSPI_RXx register.

A change in the configuration parameters is propagated directly on the SPI interface. If the spim_csx signal is activated, ensure that the configuration is changed only between SPI words to avoid corrupting the current transfer.

NOTE: To avoid data corruption, spim_csx polarity and spim_clk phase and spim_clk polarity must not be modified when the spim_csx signal is activated.

A delay between SPI words that requires the connected SPI slave device to switch from one configuration (transmit-only for instance) to another (receive-only for instance) must be handled by software.

At the end of the last SPI word, the channel must be deactivated (the SPIm.MCSPI_CHxCTRL[0] EN bit set to 0) and spim_csx can be forced to its inactive state using the SPIm.MCSPI_CHxCONF[20] FORCE bit.

Figure 16-15 and Figure 16-16 show successive transfers with spim_csx maintained active low with a different configuration for each SPI word in single-data-pin and dual-data-pin interface modes, respectively.

Figure 16-15. Continuous Transfers With spim_csx Maintained Active (Single-Data-Pin Interface Mode)

Figure 16-16. Continuous Transfers With spim_csx Maintained Active (Dual-Data-Pin Interface Mode)

NOTE: The turbo mode described in Section 16.5.2.5.3, Turbo Mode, maintains spim_csx in active mode when the following conditions are met:

- A single channel is explicitly used (the SPIm.MCSPI_MODULCTRL[0] SINGLE bit is set to 1).
- Turbo mode is enabled in the configuration of the channel. (The SPIm.MCSPI_CHxCONF[19] TURBO bit is set to 1.)

16.5.2.5.3 Turbo Mode

The turbo mode improves the throughput of the SPI interface when a single channel is enabled by allowing transfers until the shift register and the `MCSPi_RXx` register are full. The turbo mode is useful (time savings) when a transfer exceeds two words. This mode is programmable per channel (via the `SPI1.MCSPi_CHxCONF[9]` TURBO bit).

When several channels are enabled, the TURBO bit has no effect and the channel access to the shift registers remains as previously described.

In turbo mode, Rule 1 and Rule 2 applies, but Rule 3 does not (see Section 16.5.2.2). An enabled channel can be scheduled if its receive register is full (the `SPI.MCSPi_CHxSTAT[0]` RXS bit) at the time of the shift-register assignment until the shift register is full.

The `MCSPi_RXx` register cannot be overwritten in turbo mode. Consequently, the `SPI.MCSPi_IRQSTATUS[3]` RX0_OVERFLOW bit is never set in this mode.

16.5.2.6 Start Bit Mode

In start bit mode, an extended bit is added before the SPI word in order to indicate whether the next SPI word must be handled as a command or as data. This feature is only available in master mode. The start bit mode cannot be used at the same time as turbo mode and/or force `spim_csx` mode. In this case, only one channel can be used; round-robin arbitration is not possible.

This mode is programmable per channel by setting the `SPI.MCSPi_CHxCONF[23]` SBE bit to 1. The polarity of the extended bit is programmable per channel. When the `SPI.MCSPi_CHxCONF[24]` SBPOL bit is set to 0, the SPI word must be handled as a command. When the `SPI.MCSPi_CHxCONF[24]` SBPOL bit is set to 1, the SPI word must be handled as data. Moreover, start-bit polarity can be changed dynamically during start bit transfer without disabling the channel for reconfiguration; in this case, users must configure the `SPI.MCSPi_CHxCONF[24]` SBPOL bit before writing the SPI word to be transmitted to the TX register.

16.5.2.7 Chip-Select Timing Control

The chip select timing control is only available in master mode with automatic chip select generation (`MCSPi_MODULCTRL[0]` SINGLE bit field set to 0), to add a programmable delay between chip select assertion and first clock edge, or chip select removal and last clock edge.

This mode is programmable per channel (the TCS bit of the `SPI.MCSPi_CHxCONF` register).

Figure 16-17 shows the chip-select SPIEN timing control.

Figure 16-17. Chip-Select SPIEN Timing Controls

108-016

NOTE: Because of the design implementation for transfers using a clock divider ratio set to 1 (clock bypassed), a half cycle must be added to the value between chip-select assertion and the first clock edge with PHA = 1 or between chip-select removal and the last clock edge with PHA = 0.

16.5.2.8 Programmable SPI Clock (spim_clk)

In master mode, the baud rate of the SPI serial clock is programmable.

An internal reference clock, SPIm_FCLK, is used as input of a programmable divider (the SPIm.MCSPI_CHxCONF[5:2] CLKD field) to generate the bit rate of the serial output clock spim_clk.

Table 16-11 summarizes the supported divisor values.

Table 16-11. SPI Master Clock Rates

| Divider | Clock Rate |
|---------|------------|
| 1 | 48 MHz |
| 2 | 24 MHz |
| 4 | 12 MHz |
| 8 | 6 MHz |
| 16 | 3 MHz |
| 32 | 1.5 MHz |
| 64 | 750 kHz |
| 128 | 375 kHz |
| 256 | ~187 kHz |
| 512 | ~93.7 kHz |
| 1024 | ~46.8 kHz |
| 2048 | ~23.4 kHz |
| 4096 | ~11.7 kHz |
| 8192 | ~5.8 kHz |
| 16384 | ~2.9 kHz |
| 32768 | ~1.5 kHz |

16.5.2.8.1 Clock Ratio Granularity

By default the clock division ratio is defined by the SPIm.MCSPI_CHxCONF[5:2] CLKD bit field with power of two granularity leading to a clock division in range 1 to 4096, in this case the duty cycle is always 50%. With the SPIm.MCSPI_CHxCONF[29] CLKG bit, clock division granularity can be changed to one clock cycle, in that case the SPIm.MCSPI_CHxCTRL[15:8] EXTCLK bit field is concatenated with SPIm.MCSPI_CHxCONF[5:2] CLKD bit field to give a 12-bit width division ratio in range 1 to 4096.

When granularity is one clock cycle (CLKG set to 1), for odd value of clock ratio the clock high level lasts one clock cycle more than low level depending on SPIm.MCSPI_CHxCONF[1] POL bit and SPIm.MCSPI_CHxCONF[0] PHA bit refer to Table 16-12.

Table 16-12. CLKSPIO High/Low Time Computation

| Clock ratio Fratio | CLKSPIO High Time | CLKSPIO Low Time |
|--------------------|----------------------------------|----------------------------------|
| 1 | T _{high_ref} | T _{low_ref} |
| Even ≥ 2 | T _{ref} * (Fratio/2) | T _{ref} * (Fratio/2) |
| Odd ≥ 3 (POL=PHA) | T _{ref} * (Fratio-1) /2 | T _{ref} * (Fratio+1) /2 |
| Odd ≥ 3 (POL≠PHA) | T _{ref} * (Fratio+1) /2 | T _{ref} * (Fratio-1) /2 |

NOTE: Fratio = spi1_clk frequency (Fout) division ratio.
 Thigh = spi1_clk High Time period.
 Tlow = spi1_clk Low Time period.
 T_ref = SPI1_FCLK period.
 Thigh_ref = SPI1_FCLK high Time period.
 Tlow_ref = SPI1_FCLK low Time period.

If CLKG = 1: Fratio = EXTCLK concatenated with CLKD + 1 as shown below:

| Fratio - 1 | | | | | | | | | | | |
|---|----|----|----|----|----|---|---|--|---|---|---|
| 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| SPI1.MCSPI_CHxCTRL[15:8] EXTCLK bit field | | | | | | | | SPI1.MCSPI_CHxCONF[5:2] CLKD bit field | | | |
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 5 | 4 | 3 | 2 |

For odd ratio values, the duty cycle is calculated as below:

$$\text{Duty_cycle} = (1-1/\text{Fratio})/2$$

Table 16-13 shows clock granularity examples with a clock source frequency of 48 MHz.

Table 16-13. Clock Granularity Examples

| EXTCLK | CLKD | CLKG | Fratio | PHA | POL | Thigh (ns) | Tlow (ns) | Tperiod (ns) | Duty Cycle | Fout (MHz) |
|--------|------|------|--------|-----|-----|------------|-----------|--------------|------------|------------|
| X | 0 | 0 | 1 | X | X | 10.4 | 10.4 | 20.8 | 50-50 | 48 |
| X | 1 | 0 | 2 | X | X | 20.8 | 20.8 | 41.6 | 50-50 | 24 |
| X | 2 | 0 | 4 | X | X | 41.6 | 41.6 | 83.2 | 50-50 | 12 |
| X | 3 | 0 | 8 | X | X | 83.2 | 83.2 | 166.4 | 50-50 | 6 |
| 0 | 0 | 1 | 1 | X | X | 10.4 | 10.4 | 20.8 | 50-50 | 48 |
| 0 | 1 | 1 | 2 | X | X | 20.8 | 20.8 | 41.6 | 50-50 | 24 |
| 0 | 2 | 1 | 3 | 1 | 0 | 41.6 | 20.8 | 62.4 | 66-33 | 16 |
| 0 | 2 | 1 | 3 | 1 | 1 | 20.8 | 41.6 | 62.4 | 33-66 | 16 |
| 0 | 3 | 1 | 4 | X | X | 41.6 | 41.6 | 83.2 | 50-50 | 12 |
| 5 | 0 | 1 | 81 | 1 | 0 | 852.8 | 832 | 1684.8 | 50.6-49.4 | 0.592 |
| 5 | 7 | 1 | 88 | X | X | 915.2 | 915.2 | 1830.4 | 50-50 | 0.545 |

16.5.3 Slave Mode

To select the McSPI slave mode, set the SPI1.MCSPI_MODULCTRL[2] MS bit.

A McSPI slave device can be connected to up to four external SPI master devices but handles transactions with one SPI master device at a time.

In slave mode, the McSPI initiates data transfer on the data lines (spim_simo and spim_somi) when it is selected by an active control signal (spim_csx) and receives an SPI clock (spim_clk) from the external SPI master device. Only channel 0 can be configured as a slave. In slave mode, the McSPI uses the edge of spim_csx to detect word length. For this reason, spim_csx must become inactive between each word.

The McSPI does not support spim_csx active between SPI words. It uses the edge to detect word length.

16.5.3.1 Dedicated Resources

Only channel 0 can be enabled in slave mode. In this section registers name such as SPI1.MCSPI_CHxCTRL stand for SPI1.MCSPI_CH0CTRL where x=0 (channel 0 control register).

Figure 16-18 shows an example of four slaves wired on a single master device.

Figure 16-18. Example of McSPI Slave With One Master and Multiple Slave Devices on Channel 0

108-017

The channel 0 in slave mode has the following resources:

- Its own channel enable, programmable with the SPIm.MCSPI_CHxCTRL[0] EN bit (with x=0). This channel must be enabled before transmission and reception.
- For this mode, the slave-select signal can be detected only on spin_cs0.
- Its own transmitter register, SPIm.MCSPI_TXx (with x=0), on top of the common transmit shift register. If the MCSPI_TXx register is empty, the SPIm.MCSPI_CHxSTAT[1] TXS bit (with x=0) is set. If McSPI is selected by an external master (the active signal on the spim_csx port assigned to channel 0), the MCSPI_TXx register content of channel 0 is always loaded into the shift register, whether its content is updated or not. The MCSPI_TXx register must be loaded before McSPI is selected by a master.
- Its own receiver register, SPIm.MCSPI_RXx (with x=0), on top of the common receive shift register. If the MCSPI_RXx register is full, the SPIm.MCSPI_CHxSTAT[0] RXS bit (with x=0) is set.

NOTE: The MCSPI_TXx register and MCSPI_RXx registers of the other channels are not used. Reading from or writing to a channel register other than channel 0 has no effect.

- Its own communication configuration with the following parameters through the SPIm.MCSPI_CHxCONF register (with x=0):
 - Transmit and receive modes, programmable with the TRM field
 - Interface mode (two data pins or single data pin) and data pins assignment, both programmable with the IS and DPE bits. (The SPIm modules are in slave mode after reset and must be properly configured for the modules to act in master mode.)
 - SPI word length, programmable with the WL bit
 - spim_csx polarity, programmable with the EPOL bit
 - spim_clk polarity, programmable with the POL bit

- spim_clk phase, programmable with the PHA bit

The spim_clk frequency of a transfer is controlled by the external SPI master connected to the McSPI slave device. The SPIm.MCSPI_CHxCONF[5:2] CLKD field (with x=0) is not used in slave mode.

NOTE: The configuration of the channel can be loaded in the SPIm.MCSPI_CHxCONF register (with x=0) only when the channel is disabled.

- Two DMA request events, read and write, synchronize read/write accesses of the DMA controller with the activity of McSPI. DMA requests are asserted using the SPIm.MCSPI_CHxCONF[15] DMAR bit (with x=0) for reading and the SPIm.MCSPI_CHxCONF[14] DMAW bit (with x=0) for writing.
- Four interrupt events (see [Section 16.5.5.2, Interrupt Events in Slave Mode](#))

16.5.3.2 Slave Transmit-and-Receive Mode

The slave receive mode is programmable (set the SPIm.MCSPI_CHxCONF[13:12] TRM field (with x=0) to 0x0).

In slave transmit-and-receive mode, the MCSPI_TXx register must be loaded before McSPI is selected by an external SPI master device.

After a channel is enabled, transmission and reception proceed with interrupt and DMA request events.

The MCSPI_TXx register content is always loaded in the shift register whether it is updated or not. The event TXx_UNDERFLOW is activated accordingly and does not prevent transmission.

When an SPI word transfer completes (the SPIm.MCSPI_CHxSTAT0[2] EOT bit (with x=0) set to 1), the received data is transferred to the channel receive register.

To use McSPI as a slave transmit-only device, the RXx_FULL and RX0_OVERFLOW interrupts and DMA read requests must be disabled due to the MCSPI_RXx register state (see [Section 16.5.5.2, Interrupt Events in Slave Mode](#)).

16.5.3.3 Slave Transmit-Only Mode

The slave transmit-only mode is programmable (set the SPIm.MCSPI_CHxCONF[13:12] TRM field (with x=0) to 0x2) and avoids the requirement for the MPU to read the MCSPI_RXx register (minimizing data movement) only when transmission is meaningful.

To use the McSPI as a slave transmit-only device, the RXx_FULL and RX0_OVERFLOW interrupts and DMA read requests must be disabled because of the MCSPI_RXx register state.

When the SPI word transfer completes, the SPIm.MCSPI_CHxSTAT[2] EOT bit is set (with x=0).

[Figure 16-19](#) shows a half-duplex system with a master device on the left and a transmit-only slave device on the right. Each time a bit transfers out from the slave device, 1 bit transfers in the master. After eight cycles of the serial clock spim_clk, WordB transfers from the slave to the master.

Figure 16-19. SPI Half-Duplex Transmission (Transmit-Only Slave)

108-031

16.5.3.4 Slave Receive-Only Mode

The slave receive mode is programmable (set the `SPIm.MCSPI_CHxCONF[13:12]` TRM field (with `x=0`) to `0x1`).

In receive-only mode, the `MCSPI_TXx` register must be loaded before the McSPI is selected by an external SPI master device. The `MCSPI_TXx` register content is always loaded into the shift register whether it is updated or not. The `TXx_UNDERFLOW` event is activated accordingly and does not prevent transmission.

When an SPI word transfer completes (the `SPIm.MCSPI_CHxSTAT0[2]` EOT bit (with `x=0`) is set to 1), the received data is transferred to the channel receive register.

To use the McSPI as a slave receive-only device, the `TXx_EMPTY` and `TXx_UNDERFLOW` interrupts and the DMA write requests must be disabled due to the `MCSPI_TXx` register state.

For a full-duplex transmission, the serial clock (`spim_clk`) synchronizes shifting and sampling of the information on the single serial data line. For full duplex, two data lines are required. If `spim_clk` synchronizes on a single serial data line, the data line should be half-duplex.

Figure 16-20 shows an example of a half-duplex system with a master device on the left and a receive-only slave device on the right. Each time a bit transfers out from the master, 1 bit transfers in from the slave. After eight cycles of the serial clock `spim_clk`, Word A transfers from the master to the slave.

Figure 16-20. SPI Half-Duplex Transmission (Receive-Only Slave)

108-032

16.5.4 FIFO Buffer Management

The McSPI controller has a built-in 64 bytes buffer to unload DMA or interrupt handler and improve data throughput.

This buffer can be used by only one channel at once and is selected by setting `SPIm.MCSPI_CHxCONF[28] FFER` bit or `SPIm.MCSPI_CHxCONF[27] FFEW` bit to 1. If several channel are selected and several FIFO enable bit fields set to 1, the controller forces buffer not to be used, it is the responsibility of the driver to set only one FIFO enable bit field.

The buffer can be used in the modes defined below:

- Master or Slave mode.
- Transmit only, Receive only or Transmit/Receive mode.
- Single channel or turbo mode, or in normal round robin mode. In round robin mode the buffer is used by only one channel.
- Every word length `SPIm.MCSPI_CHxCONF[11:7] WL` are supported.

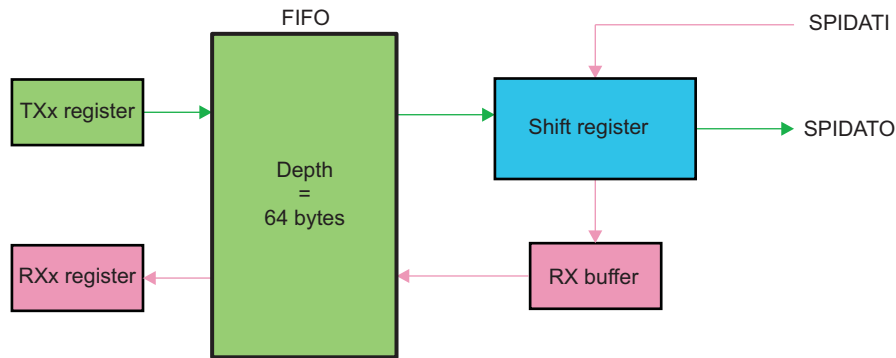

In transmit/receive mode, the buffer can be used in transmit (see Figure 16-21) or receive (see Figure 16-22) directions, or in both directions. If only one direction is chosen in transmit/receive mode, the full buffer is used for this direction. In both directions, the buffer is split into two 32-byte buffers, one for each direction. See Figure 16-23.

Figure 16-21. Buffer Use in Transmit Direction Only

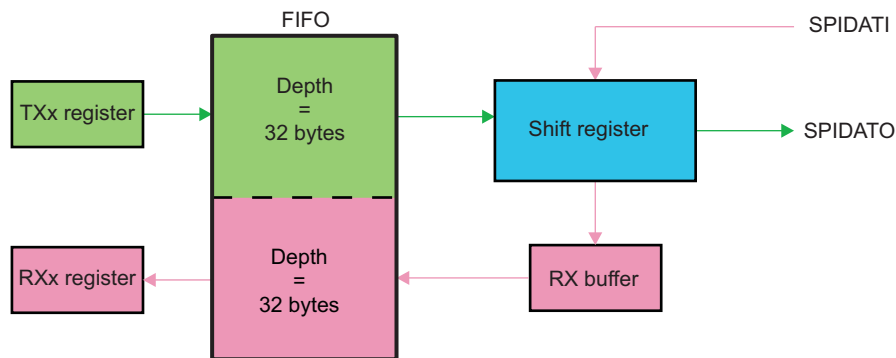

mcspl-102

Figure 16-22. Buffer Use in Receive Direction Only

mcspi-103

Figure 16-23. Buffer Used For Both Transmit/Receive Directions

mcspi-101

Two levels SPIm.MCSPI_XFERLEVEL[5:0] AEL and SPIm.MCSPI_XFERLEVEL[13:8] AFL rule the buffer management. The granularity of these levels is one byte, then it is not aligned with SPI word length. It is the responsibility of the driver to set these values as a multiple of SPI word length defined in WL. Table 16-14 shows the number of byte written in the FIFO depending on the word length.

Table 16-14. FIFO Writes, Word Length Relationship

| SPI Word Length WL | $3 \leq WL \leq 7$ | $8 \leq WL \leq 15$ | $16 \leq WL \leq 31$ |
|------------------------------------|--------------------|---------------------|----------------------|
| Number of byte written in the FIFO | 1 byte | 2 bytes | 4 bytes |

The FIFO buffer pointers are reset when the corresponding channel is enabled or FIFO configuration changes.

16.5.4.1 Buffer Almost Full

The MCSPI_XFERLEVEL[13:8] AFL bit field is needed when the buffer is used to receive SPI word from a slave (MCSPI_CHxCONF[28] FFER bit must be set to 1). It defines the Almost Full buffer status. See Figure 16-24.

When FIFO pointer reaches this level an interrupt or a DMA request is sent to the MPU to enable system to read AFL+1 bytes from Receive register. Be careful AFL+1 must correspond to a multiple value of MCSPI_CHxCONF[11:7] WL bit field.

When DMA is used, the request is de-asserted after the first Receive register read.

No new request will be asserted again as long as system has not performed the right number of read accesses.

Figure 16-24. Buffer Almost Full Level (AFL)

NOTE: [MCSPI_IRQSTATUS](#) register bits are not available in DMA mode. In DMA mode, the [SPIm_DMA_RXx](#) request is asserted on the same conditions than the [MCSPI_IRQSTATUS](#) [Rx_FULL](#) flag.

16.5.4.2 Buffer Almost Empty

The [MCSPI_XFERLEVEL\[5:0\]](#) AEL bit field is needed when the buffer is used to transmit SPI word to a slave ([MCSPI_CHxCONF\[27\]](#) FFEW bit must be set to 1). It defines the Almost Empty buffer status. See [Figure 16-25](#).

When FIFO pointer has not reached this level an interrupt or a DMA request is sent to the MPU to enable system to write AEL+1 bytes to Transmit register. Be careful AEL+1 must correspond to a multiple value of [MCSPI_CHxCONF\[11:7\]](#) WL bit field.

When DMA is used, the request is de-asserted after the first Transmit register write.

No new request will be asserted again as long as system has not performed the right number of write accesses.

Figure 16-25. Buffer Almost Empty Level (AEL)

NOTE: [MCSPI_IRQSTATUS](#) register bits are not available in DMA mode. In DMA mode, the [SPIm_DMA_TXx](#) request is asserted on the same conditions than the [MCSPI_IRQSTATUS](#) [Tx_EMPTY](#) flag.

16.5.4.3 End of Transfer Management

When the FIFO buffer is enabled for a channel, the user shall previously configure in the MCSPI_XFERLEVEL register the AEL and AFL levels and especially the MCSPI_XFERLEVEL[31:16] WCNT bit field to define the number of SPI words to be transferred using the FIFO before enabling the channel.

This counter allows the controller to stop the transfer correctly after a defined number of SPI word transfers. If WCNT is set to 0x0000, the counter is not used and the user must stop the transfer manually by disabling the channel, in this case the user does not know how many SPI transfers have been done. For received words, software shall poll the CHxSTAT[5] RXFFE bit and read the MCSPI_RXx Receive register to empty the FIFO buffer.

When the End Of Word count interrupt is generated (MCSPI_IRQSTATUS[17] EOW bit set), the user can disable the channel and poll the MCSPI_CHxSTAT[5] RXFFE bit to know it lasts SPI words in the FIFO buffer and read them.

No new request will be asserted again as long as system has not performed the right number of write accesses.

NOTE: The RXFFE status bit shows only the FIFO status. The data received are stored not only in the FIFO, but also in the shift register and the MCSPI_RX register. Therefore, the FIFO can be empty even after receiving two words.

16.5.5 Interrupts

Each channel can issue interrupt events.

Each interrupt event has status bits in the SPIm.MCSPI_IRQSTATUS register (RXx_FULL, TXx_UNDERFLOW, TXx_EMPTY, ...) with x = [0,3] that indicate if service is required. Each status bit has an interrupt enable bit (a mask) in the SPIm.MCSPI_IRQENABLE register (RXx_FULL_ENABLE, TXx_UNDERFLOW_ENABLE, TXx_EMPTY_ENABLE, ...).

When an interrupt occurs and a mask is later applied on it, the interrupt line is not asserted again, even if the interrupt source is not serviced.

The McSPI supports interrupt-driven and polling operations.

16.5.5.1 Interrupt Events in Master Mode

In master mode, the interrupt events related to the MCSPI_TXx register state are TXx_EMPTY and TXx_UNDERFLOW. The interrupt event related to the MCSPI_RXx register state is RXx_FULL.

16.5.5.1.1 TXx_EMPTY

The TXx_EMPTY event is activated when a channel is enabled and its MCSPI_TXx register is empty (transient event). Enabling a channel automatically triggers this event, except in master receive-only mode (see Section 16.5.2.4, *Master Receive-Only Mode*). When the FIFO buffer is enabled (MCSPI_CHxCONF[27] FFEW bit set to 1), the MCSPI_IRQSTATUS TXx_EMPTY bit is set as soon as there is enough space in buffer to write a number of bytes defined by the MCSPI_XFERLEVEL[5:0] AEL bit field.

The MCSPI_TXx register must be loaded with data to remove the source of the interrupt; the SPIm.MCSPI_IRQSTATUS TXx_EMPTY interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new TXx_EMPTY event will be asserted as soon as the MPU has not performed the number of write into the MCSPI_TXx register defined by MCSPI_XFERLEVEL[5:0] AEL bit field. It is the responsibility of the MPU to perform the right number of writes.

16.5.5.1.2 TXx_UNDERFLOW

The event TXx_UNDERFLOW is activated when the channel is enabled and if the [MCSPI_TXx](#) register or if the FIFO is empty (not updated with new data) when an external master device starts a data transfer with the McSPI (transmit and receive).

The TXx_UNDERFLOW is a harmless warning in master mode.

To avoid having TXx_UNDERFLOW event at the beginning of a transmission, the event TXx_UNDERFLOW is not activated when no data has been loaded into the [MCSPI_TXx](#) register since channel has been enabled. To avoid having TXx_UNDERFLOW event, the [MCSPI_TXx](#) register must be loaded seldom.

The SPIm.[MCSPI_IRQSTATUS](#) TXx_UNDERFLOW interrupt status bit must be cleared for interrupt line de-assertion (if event enable as interrupt source).

16.5.5.1.3 RXx_FULL

The RXx_FULL event is activated when channel is enabled and [MCSPI_RXx](#) register becomes filled (transient event). When FIFO buffer is enabled ([MCSPI_CHxCONF](#)[28] FFER bit set to 1), the RXx_FULL is asserted as soon as the number of bytes holds in the FIFO to be read reaches the [MCSPI_XFERLEVEL](#)[13:8] AFL threshold.

The [MCSPI_RXx](#) register must be read to remove the source of the interrupt; the [MCSPI_IRQSTATUS](#) RXx_FULL interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new RXx_FULL event will be asserted as soon as the MPU has not performed AFL+1 reads into [MCSPI_RXx](#). It is the responsibility of MPU to perform the right number of reads.

16.5.5.1.4 End Of Word Count

The [MCSPI_IRQSTATUS](#)[17] EOW event (End Of Word count) is activated when channel is enabled and configured to use the built-in FIFO. This interrupt is raised when the controller had performed the number of transfer defined in the [MCSPI_XFERLEVEL](#)[31:16] WCNT bit field. If WCNT is set to 0x0000, the counter is not enable and this interrupt is not generated.

The End of Word count interrupt also indicates that the SPI transfer is halt on channel using the FIFO buffer as soon as [MCSPI_XFERLEVEL](#)[31:16] WCNT is not reloaded and the channel is not re-enabled.

The [MCSPI_IRQSTATUS](#)[17] EOW interrupt status bit must be cleared for interrupt line de-assertion (if event enable as interrupt source).

16.5.5.2 Interrupt Events in Slave Mode

In slave mode, the interrupt events related to the [MCSPI_TXx](#) register state are TXx_EMPTY and TXx_UNDERFLOW. The interrupt events related to the [MCSPI_RXx](#) register state are RXx_FULL and RX0_OVERFLOW (channels 1, 2, and 3 do not have a receiver overflow status bit). See the [MCSPI_IRQSTATUS](#) register.

16.5.5.2.1 TXx_EMPTY

The TXx_EMPTY event is activated when a channel is enabled and its [MCSPI_TXx](#) register is empty. Enabling the channel automatically raises this event. If the FIFO buffer is enabled ([MCSPI_CHxCONF](#)[27] FFEW bit set to 1), the TXx_EMPTY event is asserted as soon as there is enough space in buffer to write a number of byte defined by the [MCSPI_XFERLEVEL](#)[5:0] AEL bit field.

The [MCSPI_TXx](#) register must be loaded with data to remove the source of the interrupt; the SPIm.[MCSPI_IRQSTATUS](#) TXx_EMPTY interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new TXx_EMPTY event will be asserted as soon as the MPU has not performed the number of write into the [MCSPI_TXx](#) register defined by [MCSPI_XFERLEVEL](#)[5:0] AEL bit field. It is the responsibility of the MPU to perform the right number of writes.

16.5.5.2.2 TXx_UNDERFLOW

The TXx_UNDERFLOW event is activated when a channel is enabled and if the [MCSPI_TXx](#) register is empty (not updated with new data) when an external master device starts a data transfer with the McSPI (transmit and receive).

When FIFO is enabled, the data emitted while underflow event is raised is not the last data written in the FIFO but the next data in the FIFO (an old transmitted value or a dummy data is the FIFO has been reset).

TXx_UNDERFLOW indicates an error (data loss) in slave mode.

To avoid having a TXx_UNDERFLOW event at the beginning of a transmission, the TXx_UNDERFLOW event is not activated when data is not loaded into the [MCSPI_TXx](#) register because the channel is enabled.

The SPIm.[MCSPI_IRQSTATUS](#) TXx_UNDERFLOW interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

16.5.5.2.3 RXx_FULL

The RXx_FULL event is activated when a channel is enabled and the [MCSPI_RXx](#) register is being filled (transient event). When FIFO buffer is enabled ([MCSPI_CHxCONF](#)[28] FFER bit set to 1), RXx_FULL is asserted as soon as there is a number of bytes holds in buffer to read defined by the [MCSPI_XFERLEVEL](#)[13:8] AFL bit field.

The [MCSPI_RXx](#) register must be read to remove the source of the interrupt; the SPIm.[MCSPI_IRQSTATUS](#) RXx_FULL interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

When FIFO is enabled, no new RXx_FULL event will be asserted as soon as the MPU has not performed AFL+1 reads into [MCSPI_RXx](#). It is the responsibility of MPU to perform the right number of reads.

16.5.5.2.4 RX0_OVERFLOW

The RX0_OVERFLOW event is activated in slave mode in either transmit-and-receive or receive-only mode, when a channel is enabled and the [MCSPI_RXx](#) register or FIFO is full when a new SPI word is received. The [MCSPI_RXx](#) register is always overwritten with the new SPI word. If the FIFO is enabled data within the FIFO are overwritten, it must be considered as corrupted. The RX0_OVERFLOW event should not appear in slave mode using the FIFO.

The RX0_OVERFLOW indicates an error (data loss) in slave mode.

The [MCSPI_IRQSTATUS](#)[3] RX0_OVERFLOW interrupt status bit must be cleared for interrupt line deassertion (if the event is enabled as the interrupt source).

16.5.5.2.5 End Of Word Count

The [MCSPI_IRQSTATUS](#)[17] EOW event (End Of Word count) is activated when channel is enabled and configured to use the built-in FIFO. This interrupt is raised when the controller had performed the number of transfer defined in the [MCSPI_XFERLEVEL](#)[31:16] WCNT bit field. If WCNT is set to 0x0000, the counter is not enabled and this interrupt is not generated.

The End of Word count interrupt also indicates that the SPI transfer is halt on channel using the FIFO buffer as soon as WCNT is not reloaded and channel re-enabled.

The [MCSPI_IRQSTATUS](#)[17] EOW interrupt status bit must be cleared for interrupt line de-assertion (if event enable as interrupt source).

16.5.5.3 Interrupt-Driven Operation

An interrupt enable bit, in SPIm.[MCSPI_IRQENABLE](#) register, can be set to enable each event to generate interrupt requests when the corresponding event occurs. Status bits are automatically set by hardware logic conditions.

When an event occurs (the single interrupt line is asserted), the MPU must:

- Read the SPIm.**MCSPI_IRQSTATUS** register to identify which event occurred.
- Read the **MCSPI_RXx** register that corresponds to the event to remove the source of an **RXx_FULL** event or write into the **MCSPI_TXx** register that corresponds to the event to remove the source of a **TXx_EMPTY** event. No action is required to remove the source of the **WKS** (wake-up), **TXx_UNDERFLOW**, and **RX0_OVERFLOW** events.
- Write 1 into the corresponding bit of the SPIm.**MCSPI_IRQSTATUS** register to clear an interrupt status and then release the interrupt line.

The interrupt status bit must always be reset after channel enabling and before events are enabled as interrupt sources.

16.5.5.4 Polling

When the interrupt capability of an event is disabled in the SPIm.**MCSPI_IRQENABLE** register, the interrupt line is not asserted, but the status bits in the SPIm.**MCSPI_IRQSTATUS** register can be polled by software to detect when the corresponding event occurs.

Once the expected event occurs:

- **RXx_FULL**: To remove the source of the event, the MPU must read the corresponding **MCSPI_RXx** register.
- **TXx_EMPTY**: To remove the source of the event, the MPU must write into the corresponding **MCSPI_TXx** register.
- **WKS** (wake-up), **TXx_UNDERFLOW**, and **RX0_OVERFLOW**: No action is required to remove the source of the event.

To clear an interrupt, set the corresponding status bit of the SPIm.**MCSPI_IRQSTATUS** register to 1. This does not affect the interrupt line state.

16.5.6 DMA Requests

The sDMA controller module manages DMA accesses. The sDMA controller advantage is to lower the MPU charge for data transfers.

Each McSPI channel can issue DMA requests if they are enabled. There are two DMA request lines per McSPI channel (one for read and one for write).

The DMA read request line is asserted when the McSPI channel is enabled and new data is available in the receive register of the McSPI channel. A DMA read request can be individually masked with the SPI1.**MCSPI_CHxCONF**[15] **DMAR** bit. The DMA read request line is deasserted on read completion of the **MCSPI_RXx** register of the McSPI channel.

The DMA write request line is asserted when the McSPI channel is enabled and the **MCSPI_TXx** register of the McSPI channel is empty. A DMA write request can be individually masked with the SPI1.**MCSPI_CHxCONF**[14] **DMAW** bit. The DMA write request line is deasserted on load completion of the **MCSPI_TXx** register of the channel.

16.5.7 Power Saving Management

Power consumption can be optimized by switching off internal clocks (interface and functional clock) when there is no activity. The McSPI is compliant with the idle and wake-up system handshake protocol.

16.5.7.1 Normal Mode

In normal mode, internal SPI module clocks are automatically switched off (autogating) when there is no activity in slave or master mode.

Autogating of the module interface clock and functional clock occurs when the following conditions are met:

- The SPIm.**MCSPI_SYSCONFIG**[0] **AUTOIDLE** bit is set.
- In master mode, there is no data to transmit or receive in all channels.
- In slave mode, the McSPI is not selected by the external master and there are no register accesses.

Autogating of the module interface clock and functional clock stops when the following conditions are met:

- In master mode, an internal access occurs.
- In slave mode, an internal access occurs or the McSPI is selected by the external master.

16.5.7.2 Idle Mode

At the PRCM module level, when all conditions are met to shut off the CORE_48M_FCLK or CORE_L4_ICLK output clocks (see , *Power, Reset, and Clock Management*, for details), the PRCM module automatically launches a hardware handshake protocol to ensure that the McSPI is ready to have its clocks switched off. Namely, the PRCM module asserts an idle request to the McSPI.

Although this handshake is completely hardware-oriented and out of software control, the method in which the McSPI module acknowledges the PRCM idle request is configurable through the McSPI.SYSCONFIG[4:3] SIDLEMODE bit.

The following list details the settings of the SIDLEMODE bit and the related acknowledgment modes:

- Force-idle mode (the SPIm.MCSPI_SYSCONFIG[4:3] SIDLEMODE bit set to 0x0): the McSPI module acknowledges unconditionally the idle request from the PRCM module, regardless of its internal operations. This mode must be used carefully in this case because it does not prevent the loss of data when the clock is switched off.
- No-idle mode (the SIDLEMODE bit set to 0x1): The McSPI module never acknowledges an idle request from the PRCM module and is safe from a module point of view because it ensures that the clocks remain active. However, it is not efficient to save power because it does not allow the PRCM output clock to be shut off and thus the power domain to be set to a lower power state.
- Smart-idle mode (the SIDLEMODE bit set to 0x2): The McSPI module acknowledges the idle request, basing its decision on its internal activity. Namely, the acknowledge signal is asserted only when all pending transactions, IRQs, or DMA requests are treated. This is the best approach for an efficient system power management.

When configured in smart-idle mode, the McSPI module also offers an additional granularity on the CORE_48M_FCLK and CORE_L4_ICLK gating. The SPIm.SYSCONFIG[9:8] CLOCKACTIVITY bit field determines which clock shuts down (the CORE_48M_FCLK, the CORE_L4_ICLK, neither clock, or both clocks).

The CLOCKACTIVITY setting is used internally to McSPI to determine on which part of the module the conditions to acknowledge the PRCM idle request are tested. For example, if CORE_48M_FCLK is not shut down on a PRCM idle request, McSPI considers only CORE_L4_ICLK and the associated pending activities before acknowledging the request.

Some McSPI features are associated with CORE_L4_ICLK and others with CORE_48M_FCLK. Using the CLOCKACTIVITY bit field along with the smart-idle mode ensures that the features associated with the clock that remains active are always enabled, even if McSPI acknowledges an idle request.

The following list details CLOCKACTIVITY settings and the associated features:

- CLOCKACTIVITY set to 00: ICLK OFF and FCLK OFF, both ICLK and FCLK are taken into account for generating the acknowledge. This setting also means that both FCLK and ICLK are likely to be shut down on a PRCM idle request.
- CLOCKACTIVITY set to 01: ICLK ON and FCLK OFF, ICLK is not shut down on a PRCM idle request; only FCLK is concerned.
- CLOCKACTIVITY set to 10: ICLK OFF and FCLK ON, FCLK is not shut down on a PRCM idle request; only ICLK is concerned.
- CLOCKACTIVITY set to 11: ICLK ON and FCLK ON, none of the clocks are shut down. This means McSPI can potentially acknowledge the idle request without checking the internal functionalities linked to its clocks.

CAUTION

The PRCM module does not have a hardware means of reading the CLOCKACTIVITY settings. Therefore, the software must ensure consistent programming between the CLOCKACTIVITY and the PRCM CORE_48M_FCLK and CORE_L4_ICLK control bits. If the McSPI is disabled in both the CM_FCLKEN and CM_ICLKEN PRCM registers while CLOCKACTIVITY is set to 11, nothing prevents the PRCM module from asserting its idle request, which is acknowledged regardless of the features associated with the McSPI clocks. This can lead to unpredictable behavior.

16.5.7.2.1 Wake-Up Event in Smart-Idle Mode

The module wake-up feature is enabled when both the SPIm.MCSPI_SYSCONFIG[2] ENAWAKEUP and SPIm.MCSPI_WAKEUPENABLE[0] WKEN bits are set. Wake-up capability is relevant only when the module is configured in slave mode.

The module generates an asynchronous wake-up request to the system power manager to switch the interface clock and the functional clock back. A wake-up is requested when channel 0 is enabled and an asynchronous selection occurs on the spim.csx port associated with channel 0 (see the definition for the SPIm.MCSPI_CHxCONF SPIENSLV field (with x=0) in the register description table).

After the McSPI wake-up request, the system power manager must reactivate the interface clock:

- *Before the beginning* of the second SPI word serialization when McSPI is in slave transmit-only mode or in slave transmit-and-receive mode
- *Before the end* of the second received SPI word in slave receive-only mode. To avoid data loss, the first received SPI word must be read from the SPIm.MCSPI_RXx register (with x=0) before the completion of the second SPI word serialization.

Table 16-15 lists the supported cases in wake-up mode.

Table 16-15. Smart-Idle Mode and Wake-Up Capabilities

| Mode | Interface Clock | SPI Clock Ref | Functionality | Wake-Up Event |
|--------|---------------------|---------------------|--|---|
| Master | Must be maintained | Must be maintained | Full functionality, but the module does not generate a new interrupt or DMA request until the system exits wake-up mode. | No wake-up event |
| Slave | Can be switched off | Can be switched off | An SPI word can be transmitted and/or received, but the module does not generate any new interrupts or DMA requests until the system exits wake-up mode. | The module asynchronously sends a wake-up request if an event on the spim.csx port associated to channel 0 is detected. |

In wake-up mode, the interrupt and DMA request lines are no longer asserted.

Any access to the module in wake-up mode generates an error as long as the interface clock is alive.

16.5.7.2.2 Transitions From Smart-Idle Mode to Normal Mode

The McSPI detects the end of the wake period through the idle and wake-up hardware handshake protocol.

The interrupt status register (the SPIm.MCSPI_IRQSTATUS[16] WKS bit) is updated with the event causing the wake-up; the wake-up event at the origin of the transition to the normal mode is converted to its corresponding interrupt when enabled by the SPIm.MCSPI_IRQENABLE[16] WKE bit or the DMA request.

Interrupts and wake-up events have independent enable/disable controls, accessible through the SPIm.MCSPI_IRQENABLE and SPIm.MCSPI_WAKEUPENABLE registers. Software must ensure the overall consistency.

The interrupt status register SPIm.MCSP_I_RQSTATUS is updated with the event causing the wake-up; the wake-up event at the origin of the transition to normal mode is converted to its corresponding interrupt request or DMA request. The module is fully operational.

16.5.7.2.3 Force-Idle Mode

Force-idle mode is enabled and exited as follows:

- Force-idle mode is enabled when the SPIm.MCSP_I_SYSCONFIG[4:3] SIDLEMODE field is set to 0x0. In force-idle mode, McSPI responds unconditionally to the idle request by deasserting unconditionally the interrupt and DMA request lines, if asserted. In addition, the wake-up capability is totally inhibited even if both the SPIm.MCSP_I_SYSCONFIG[2] ENAWAKEUP and SPIm.MCSP_I_WAKEUPENABLE[0] WKEN bits are set.

The transition from normal mode to idle mode does not affect the interrupt event bits of the SPIm.MCSP_I_RQSTATUS register.

In force-idle mode, the module must be disabled so the interrupt and DMA request lines are likely deasserted. The interface clock and SPI clock provided to the McSPI can be switched off.

An idle request during an SPI data transfer can lead to an unexpected and unpredictable result. The software must avoid such a request.

- The module exits force-idle mode through the idle and wake-up hardware handshake protocol. The module is fully operational. The interrupt and DMA request lines are optionally asserted one clock cycle later.

16.6 McSPI Basic Programming Model

16.6.1 Initialization of Modules

Figure 16-26 shows the overview of the module initialization flow process. Section 16.6.2 and Section 16.6.3 show the steps required to configure McSPI modes.

Figure 16-26. Module Initialization Flow

NOTE: Before the `SPIm.MCSPI_SYSSTATUS[0]` RESETDONE bit is set, the CLK and CLKSPIREF clocks must be provided to the module.

To avoid unpredictable behavior, reset the module before changing from master mode to slave mode, or vice versa.

16.6.2 Transfer Procedures without FIFO

In the subsections below, the transfer procedures are described without FIFO using (`MCSPI_CHxCONF[27:28]` FFER and FFEW = 0).

The McSPI allows the transfer of one or more words based on the different modes:

- Master normal, master turbo, slave
- Transmit-and-receive, transmit-only, receive-only
- Write and read requests: Interrupts, DMA

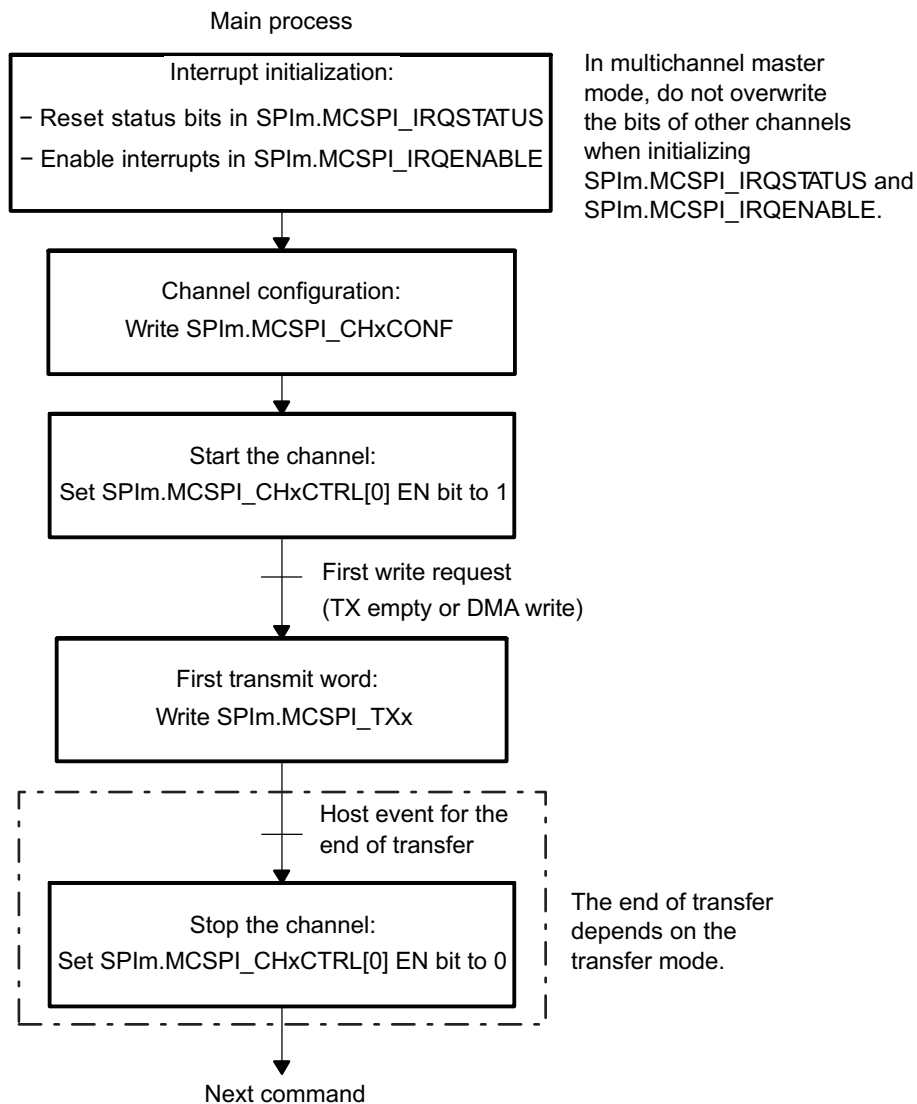

- spi1_csx line assertion/deassertion: Automatic, manual

For these flows, the host process contains the main process and the interrupt routines. The interrupt routines are called on the interrupt signals or by an internal call if the module is used in polling mode.

16.6.2.1 Common Transfer Procedure

Figure 16-27 shows the main sequence common to all transfers. In multichannel master mode, the flows of different channels can be run simultaneously.

Figure 16-27. Common Transfer Sequence: Main Process

108-030

16.6.2.2 End-of-Transfer Procedure

For transfers carried out with DMA or interrupt mode, the end of transfer must be achieved by following the steps shown in the flowcharts corresponding to Table 16-16, which summarizes the end-of-transfer types per transfer mode and provides cross-references for further information.

Table 16-16. End-of-Transfer Sequences

| | | Transmit Receive | | Transmit Only | | Receive Only | |
|---------------|----------------------------------|--------------------------------------|-----|--------------------------------------|--------------------------------------|--|--|
| | | Interrupt | DMA | Interrupt | DMA | Interrupt | DMA |
| Master normal | End of transfer sequence | See Section 16.6.2.3 | | See Section 16.6.2.4 | See Section 16.6.2.4 | See Section 16.6.2.5.1 | See Section 16.6.2.5.1 |
| | Minimum number of words | 1 | 1 | 1 | 1 | 1 | 1 |
| | DMA transfer size ⁽¹⁾ | | w | | w | | w – 1 |
| Master turbo | End of transfer sequence | See Section 16.6.2.3 | | See Section 16.6.2.4 | See Section 16.6.2.4 | See Section 16.6.2.5.2 | See Section 16.6.2.5.2 |
| | Minimum number of words | 1 | 1 | 1 | 1 | 2 | 3 |
| | DMA transfer size ⁽¹⁾ | | w | | w | | w – 2 |
| Slave | End of transfer sequence | See Section 16.6.2.3 | | See Section 16.6.2.4 | See Section 16.6.2.4 | See Section 16.6.2.5.3 | |
| | Minimum number of words | 1 | 1 | 1 | 1 | 1 | 1 |
| | DMA transfer size ⁽²⁾ | | w | | w | w | w |

⁽¹⁾ w = number of words to transfer

⁽²⁾ w = number of words to transfer

The different sequences can be merged in one process to manage transfers of several types. The end-of-transfer sequences are described from the start of the channel.

In these sequences and in later sections of this chapter, some software variables are used:

- WRITE_COUNT (= 0 at initialization): Contains the number of words to transfer
- READ_COUNT (= 0 at initialization): Contains the number of words to receive
- CHANNEL_ENABLE (= false at initialization)
- LAST_TRANSFER (= false at initialization): Indicates that the last word is in transmission
- LAST_REQUEST (= false at initialization): Indicates that the last request is in progress

All variables are initialized before starting the channel.

16.6.2.3 Transmit and Receive Procedure

Figure 16-28 shows the handling procedure for words received and transmitted by interrupt in master and slave modes. The main process flow shows how the end of the transfer must be done after all words are received for this mode.

If the requests are configured in DMA, WRITE_COUNT and READ_COUNT are assigned with the value w when the DMA handler completes w interface accesses.

Figure 16-28. Transmit and Receive (Master and Slave)

108-033

16.6.2.4 Transmit-Only Procedure

16.6.2.4.1 Based on Interrupt Requests

Figure 16-29 shows the handling procedure for words transmitted by interrupt in transmit-only mode. The main process flow shows how the end-of-transfer must be done after all words are received for this mode.

Figure 16-29. Transmit-Only With Interrupts (Master and Slave)

108-023

16.6.2.4.2 Transmit-Only Based on DMA Write Requests

In Figure 16-30, the main process shows completion of the transfer of words in transmit-only mode with DMA write requests.

When the DMA handler completes w interface accesses, WRITE_COUNT is assigned the value w .

Figure 16-30. Transmit-Only With DMA (Master and Slave)

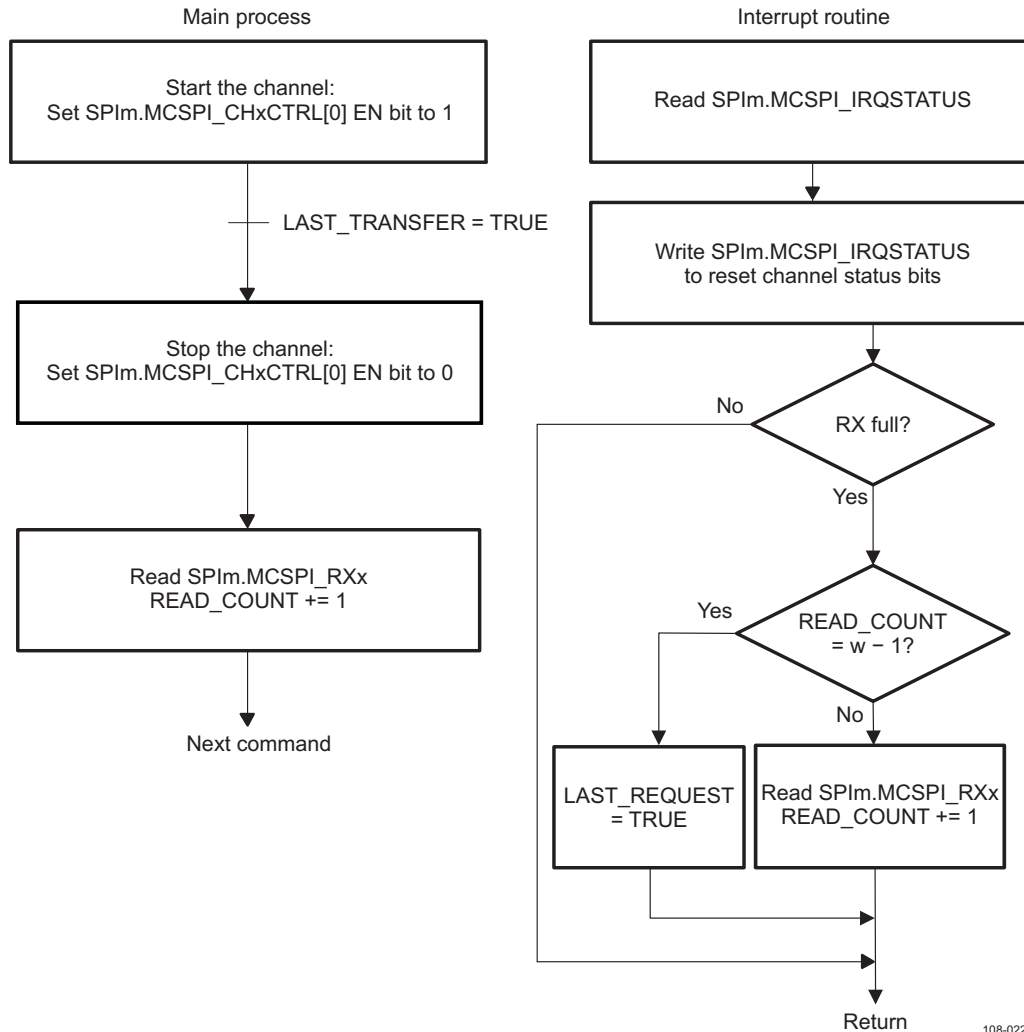

108-024

16.6.2.5 Receive-Only Procedure

16.6.2.5.1 Master Normal Receive-Only Procedure

16.6.2.5.1.1 Based on Interrupt Requests

Figure 16-31 shows the handling procedure for words received by interrupt in master normal receive-only mode. The main process flow shows how the end-of-transfer must be done after all words are received for this mode.

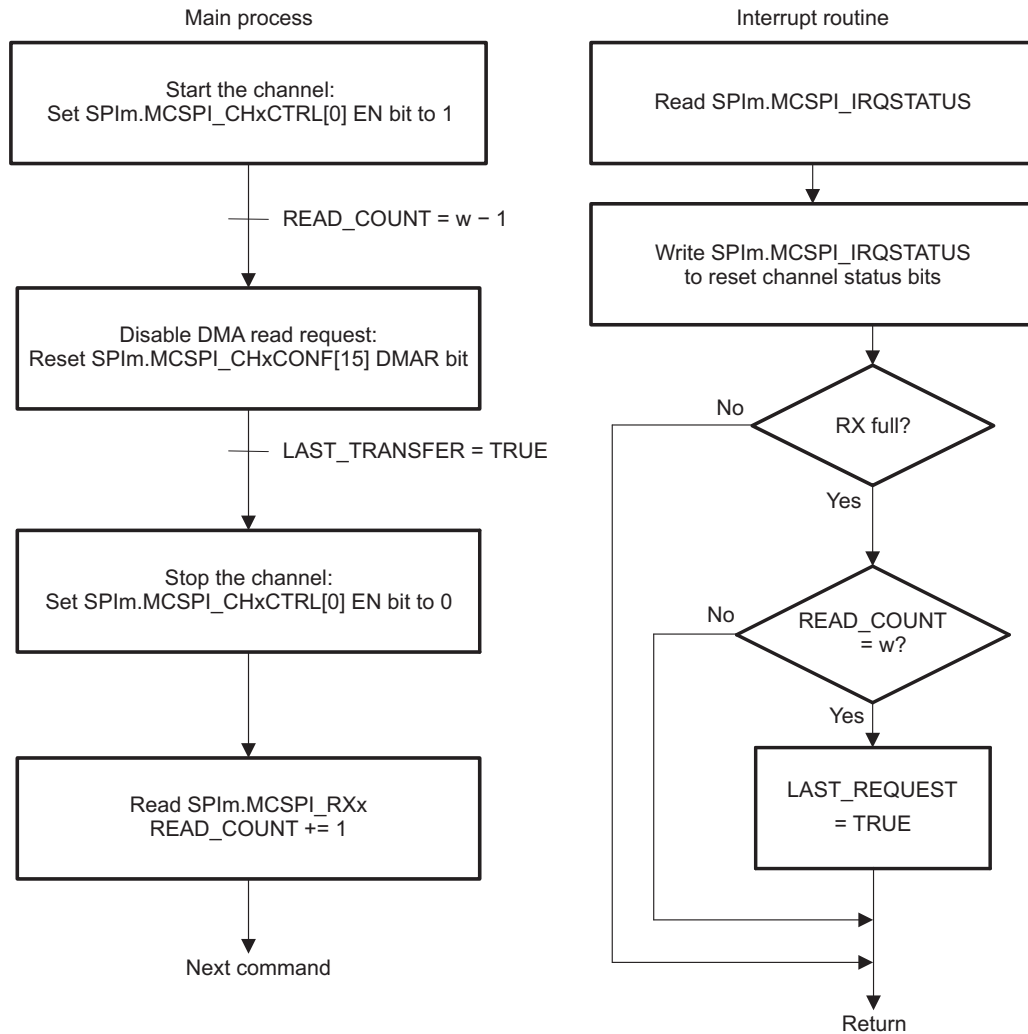

Figure 16-31. Receive Only With Interrupt (Master Normal)

16.6.2.5.1.2 Receive-Only Based on DMA Read Requests

In [Figure 16-32](#), the main process shows the completion of a word transfer in receive-only mode with DMA read requests.

When the DMA handler completes $w - 1$ interface accesses, READ_COUNT is assigned the value $w - 1$.

Figure 16-32. Receive-Only With DMA (Master Normal)

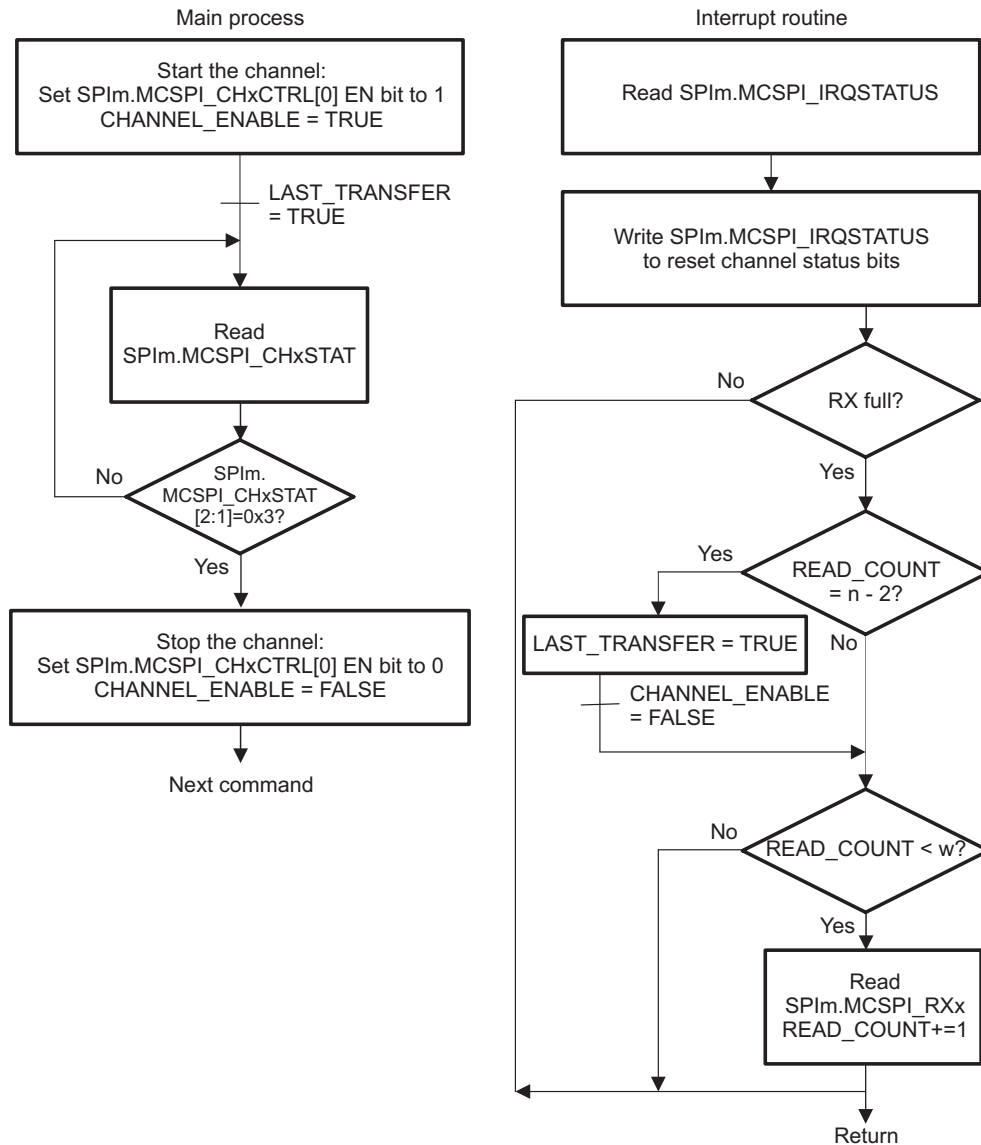

mspi-025

16.6.2.5.2 Master Turbo Receive-Only Procedure

16.6.2.5.2.1 Based on Interrupt Requests

Figure 16-33 shows the handling procedure for words received by interrupt in master turbo receive-only mode. The main process shows how the end-of-transfer must be done after all words are received for this mode.

Figure 16-33. Receive-Only With Interrupt (Master Turbo)

108-027

16.6.2.5.2.2 Based on DMA Read Requests

In [Figure 16-34](#), the main process shows the completion of a word reception in master turbo receive-only mode with DMA write requests.

When the DMA handler completes $w - 2$ interface accesses, `READ_COUNT` is assigned the value $w - 2$.

Figure 16-34. Receive-Only With DMA (Master Turbo)

mspi-028

16.6.2.5.3 Slave Receive-Only Procedure

Figure 16-35 shows the handling procedure for words received by interrupt in slave receive-only mode. The main process shows how the end-of-transfer must be done after all words are received for this mode.

If the requests are configured in DMA, READ_COUNT is assigned the value w when the DMA handler completes w interface processes.

Figure 16-35. Receive Only (Slave)

108-035

16.6.2.6 McSPI Configuration and Operations Example

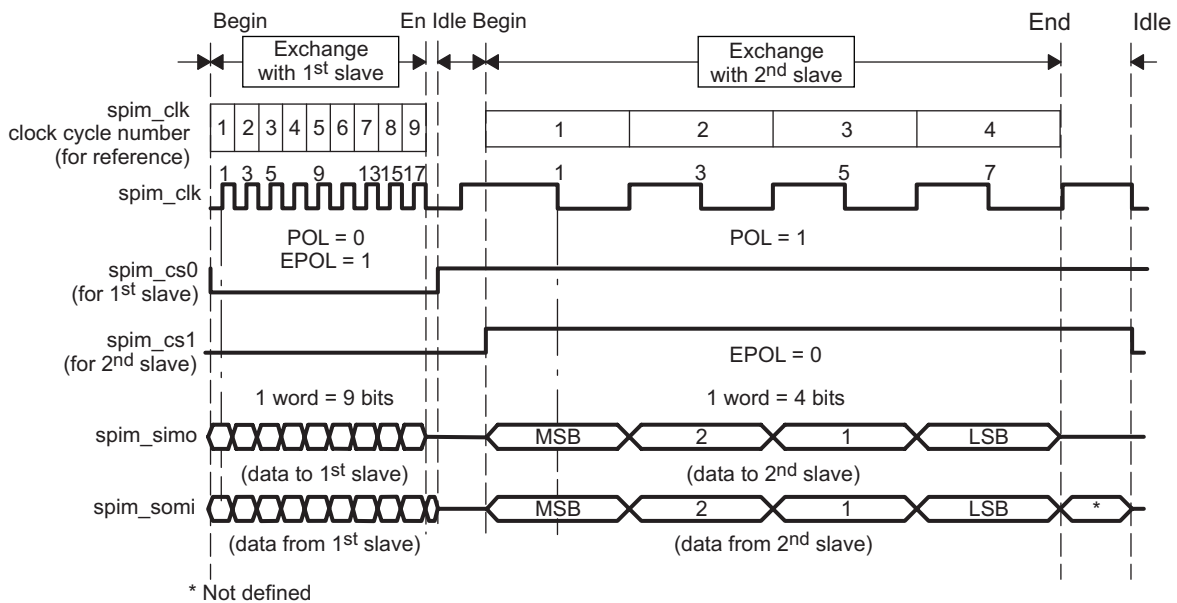

This section details an example of a typical configuration.

Figure 16-36 shows an implementation of successive transfers between two devices (slave) and the McSPI1 (master) in transmit-and-receive mode.

McSPI1 is the master, and spi1_simo shifts out the data to the external slaves. spi1_somi is connected to the data output port of two slave devices. The McSPI1 controls the first device with the spi1_cs0 signal (active low) for the exchange of 9-bit words synchronized with an active-high SPI clock.

The second device is controlled by the spi1_cs1 control signal (active high) for the exchange of 4-bit words synchronized with a SPI clock (active low) with a slower frequency than used with the first slave device.

Figure 16-36. Two SPI Transfers With PHA = 0 (Flexibility of McSPI)

mcspi-036

This section details the steps required for this type of transmission.

16.6.2.6.1 McSPI Initialization Sequence

As shown in Figure 16-26, the McSPI module must first reset all registers and all state-machines.

For a software reset:

1. Set the SPI1.MCSPI_SYSCONFIG[1] SOFTRESET bit to 1.
2. Read the SPI1.MCSPI_SYSSTATUS[0] RESETDONE bit and check that it is set to 1.

16.6.2.6.2 Operations for the First Slave (On Channel 0)

16.6.2.6.2.1 Programming in Polling Mode

16.6.2.6.2.1.1 Mode Selection

The SPI1.MCSPI_CHxCONF register (with x = 0) allows configuration of the operating mode:

1. Set the SPI1.MCSPI_CHxCONF[18] IS bit to 0 for the spi1_somi pin in receive mode.
2. Set the SPI1.MCSPI_CHxCONF[17] DPE1 bit to 0 and the SPI1.MCSPI_CHxCONF[16] DPE0 bit to 1 for the spi1.simo pin in transmit mode.
3. Set the SPI1.MCSPI_CHxCONF[13:12] TRM field to 0x0 for transmit and receive mode.
4. Write 0x8 in the SPI1.MCSPI_CHxCONF[11:7] WL field for 9-bit word length.

5. Set the SPI1.MCSPI_CHxCONF[6] EPOL bit to 1 for spi1_cs0 activated low during active state.
6. Set the SPI1.MCSPI_CHxCONF[1] POL bit to 0 for spi1_clk held high during active state.
7. Set the SPI1.MCSPI_CHxCONF[0] PHA bit to 0 for data latched on odd-numbered edges of the SPI clock.

Clock Initialization and spi1_cs0 Enable

In master mode, the SPI must provide the clock and enable the channel:

8. Set the SPI1.MCSPI_MODULCTRL[2] MS bit to 0 to provide the clock.
9. Set the SPI1.MCSPI_CHxCTRL[0] EN bit to 1 (where x = 0) to enable channel 0.

16.6.2.6.2.1.2 Write Operation

1. Write 1 to the SPI1.MCSPI_IRQSTATUS[0] TX0_EMPTY bit to reset the status.
2. Write the command/address or data value in the SPI1.MCSPI_TX0 register to transmit the value.
3. If the SPI1.MCSPI_IRQSTATUS[0] TX0_EMPTY bit is set to 1, write 1 to it and return to Step 2 (polling method).

16.6.2.6.2.1.3 Read Operation

1. Read the SPI1.MCSPI_IRQSTATUS[2] RX0_FULL bit and if it is set to 1, go to Step 2.
2. If the SPI1.MCSPI_IRQSTATUS[2] RX0_FULL bit is set to 1, write 1 to it and return to Step 1 (polling method).

NOTE: Write and read operations can be performed simultaneously.

16.6.2.6.3 Programming in Interrupt Mode

This section follows the flow of [Figure 16-26](#).

1. Initialize software variables: WRITE_COUNT = 0 and READ_COUNT = 0.
2. Initialize interrupts: Write 0x7 in the SPI1.MCSPI_IRQSTATUS[3:0] field and set the SPI1.MCSPI_IRQENABLE[3:0] field to 0x7.
3. Follow the steps described in [Section 16.6.2.6.2.1.1, Mode Selection](#).
4. If WRITE_COUNT = w and READ_COUNT = w, write SPI1.MCSPI_CHxCTRL[0] = 0x0 (x = 0) to stop the channel.

This interrupt routine follows the flow of [Table 16-16](#) and [Figure 16-28](#).

1. Read the SPI1.MCSPI_IRQSTATUS[3:0] field.
2. If the SPI1.MCSPI_IRQSTATUS[0] TX0_EMPTY bit is set to 1:
 - (a) Write the command/address or data value in SPI1.MCSPI_TXx (where x = 0).
 - (b) WRITE_COUNT += 1
 - (c) Write SPI1.MCSPI_IRQSTATUS[0] = 0x1.
3. If the SPI1.MCSPI_IRQSTATUS[2] RX0_FULL bit is set to 1:
 - (a) Read SPI1.MCSPI_RXx (where x = 0)
 - (b) READ_COUNT += 1
 - (c) Write SPI1.MCSPI_IRQSTATUS[2] = 0x1

16.6.2.6.4 Operations for the Second Slave (on Channel 1) in Polling Mode

16.6.2.6.4.1 Mode Selection

The SPI1.MCSPI_CHxCONF register (with x = 1) allows configuration of the operating mode:

1. Set the SPI1.MCSPI_CH1CONF[18] IS bit to 0 for the spi1_somi pin in receive mode.
2. Set the SPI1.MCSPI_CH1CONF[17] DPE1 bit to 0 and the SPI1.MCSPI_CH1CONF[16] DPE0 bit to 1 for the spi1_somi pin in transmit mode.
3. Set the SPI1.MCSPI_CH1CONF[13:12] TRM field to 0x0 for transmit-and-receive mode.

4. Write 0x3 in the SPI1.MCSPI_CH1CONF[11:7] WL field.
5. Set the SPI1.MCSPI_CH1CONF[6] EPOL bit to 0 for spi1_cs1 activated high during the active state.
6. Set the SPI1.MCSPI_CH1CONF[1] POL bit to 1 for spi1_clk held low during the active state.
7. Set the SPI1.MCSPI_CH1CONF[0] PHA bit to 1 for data latched on even numbered edges of spi1_clk.

Clock Initialization and spi1_cs1 Enable

The SPI1.MCSPI_MODULCTRL[2] MS bit was set to 0 (providing the clock).

In master mode, the SPI must provide the clock and enable the channel:

8. Set the SPI1.MCSPI_CH0CTRL[0] EN bit to 0 to disable channel 0, and set the SPI1.MCSPI_CH1CTRL[0] EN bit to 1 to enable channel 1.

NOTE: Read and write operations for the second slave are identical to those for the first slave.

16.6.2.6.4.2 Write Operation

1. Write 1 to the SPI1.MCSPI_IRQSTATUS[4] TX1_EMPTY bit to reset the status.
2. Write the command/address or data value in the SPI1.MCSPI_TX1 register to transmit the value.
3. If the SPI1.MCSPI_IRQSTATUS[4] TX1_EMPTY bit is set to 1, write 1 to it and return to Step 2 (polling method).

16.6.2.6.4.3 Read Operation

1. Read the SPI1.MCSPI_IRQSTATUS[6] RX1_FULL bit and if it is set to 1, go to Step 2.
2. If the SPI1.MCSPI_IRQSTATUS[6] RX1_FULL bit is set to 1, write 1 to it and return to Step 1 (polling method).

NOTE: Write and read operations can be performed simultaneously.

16.6.3 Transfer Procedures with FIFO

In the subsections below, the transfer procedures are described with FIFO using (MCSPI_CHxCONF[27:28] FFER or/and FFEW = 1).

The MCSPI module allows the transfer of one or more words, according to different modes:

- Master normal, master turbo, slave
- Transmit-and-receive, transmit-only, receive-only
- Write and read requests: Interrupts, DMA

For these flows, the host process contains the main process and the interrupt routine, which is called on the IRQ signals or by an internal call if the module is used in polling mode.

16.6.3.1 Common Transfer Procedure

The common transfer sequence is the host sequence for a transfer of any type defined above.

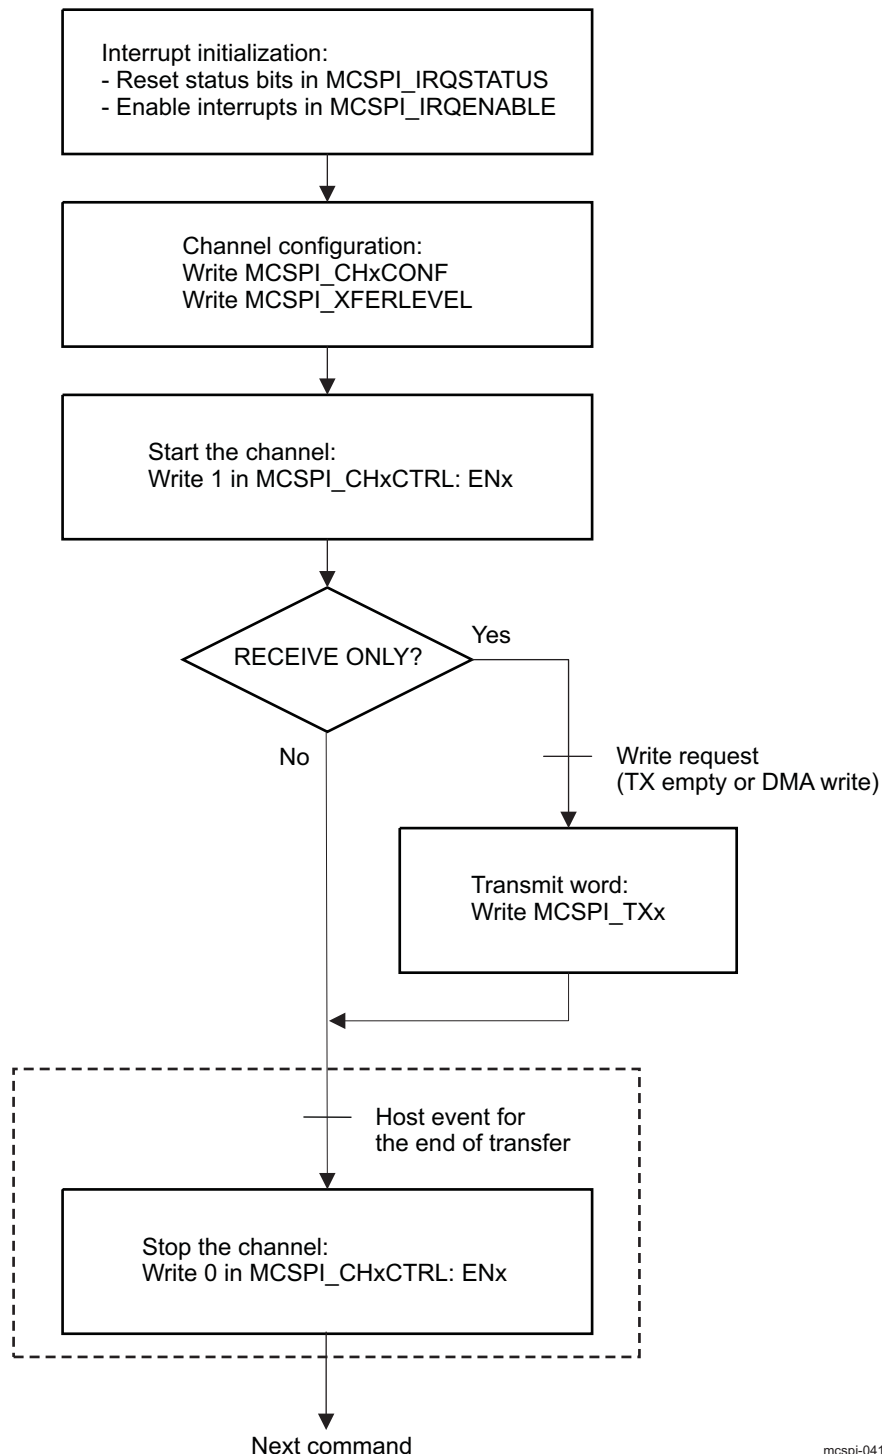

In multichannel, only one channel can use the FIFO. Before enabling the FIFO for a channel (FFExW and FFExR bits in the MCSPI_CHx_CONF register), the host must ensure that the FIFO is not enabled for another channel, even if these channels are not used.

In transmit/receive mode, the FIFO can be enabled for write or read request only, without FIFO for the other request.

In slave mode, only channel 0 only can be activated. The correct spim_csx line is chosen in the MCSPI_CH0CONF register with the SPIENSLV bits.

The MCSPI module can start the transfer only when the first write request is released by writing the MCSPI_TXx register, even in receive-only mode (only one write request occurs in this case). Figure 16-37 shows the main process of the common transfer sequence.

Figure 16-37. Common Transfer Sequence/Main Process

mcspi-041

The MCSPI module can start the transfer only after the first write request is released by writing the [MCSPI_TXx](#) register, even in receive-only mode (only one write request occurs in this case).

This first write request can be managed by the IRQ routine or DMA handler, as are as other requests. It appears in [Figure 16-37](#) to show this point.

The end of the transfer (dotted line in [Figure 16-37](#)) is more complex and depends on the transfer type. [Table 16-17](#) describes the different types of end-of-transfer and the transfer types to which they are applicable.

Table 16-17. End-of-Transfer Types

| Word Count | Transmit/Receive | Transmit Only | Receive Only |
|------------|---|---|---|
| Yes | See Section 16.6.3.2 , <i>Transmit-Receive With Word Count.</i> | See Section 16.6.3.4 , <i>Transmit-Only.</i> | See Section 16.6.3.5 , <i>Receive-Only With Word Count.</i> |
| No | See Section 16.6.3.3 , <i>Transmit-Receive Without Word Count.</i> | See Section 16.6.3.4 , <i>Transmit-Only.</i> | See Section 16.6.3.6 , <i>Receive-Only Without Word Count.</i> |

The sequence differs depending on whether word count is used (MCSPI_XFERLEVEL: WCNT is set or not). The AEL and/or AFL values can be different, but they must be multiples of the word size in the FIFO: 1, 2, or 4 bytes, according to word length.

In these sequences, the transfer to execute has a size of N words.

When accessing the FIFO, only one word is written or read for each OCP access.

In these sequences, the number of words written or read for each write or read FIFO request is:

- write_request_size
- read_request_size

If they are not submultiples of N, the last request sizes are:

- last_write_request_size (< write_request_size)
- last_read_request_size. (< read_request_size)

The different sequences can be merged in one process to manage transfers of several types.

The end-of-transfer sequences are described from the start of the channel.

In these sequences, some soft variables are used:

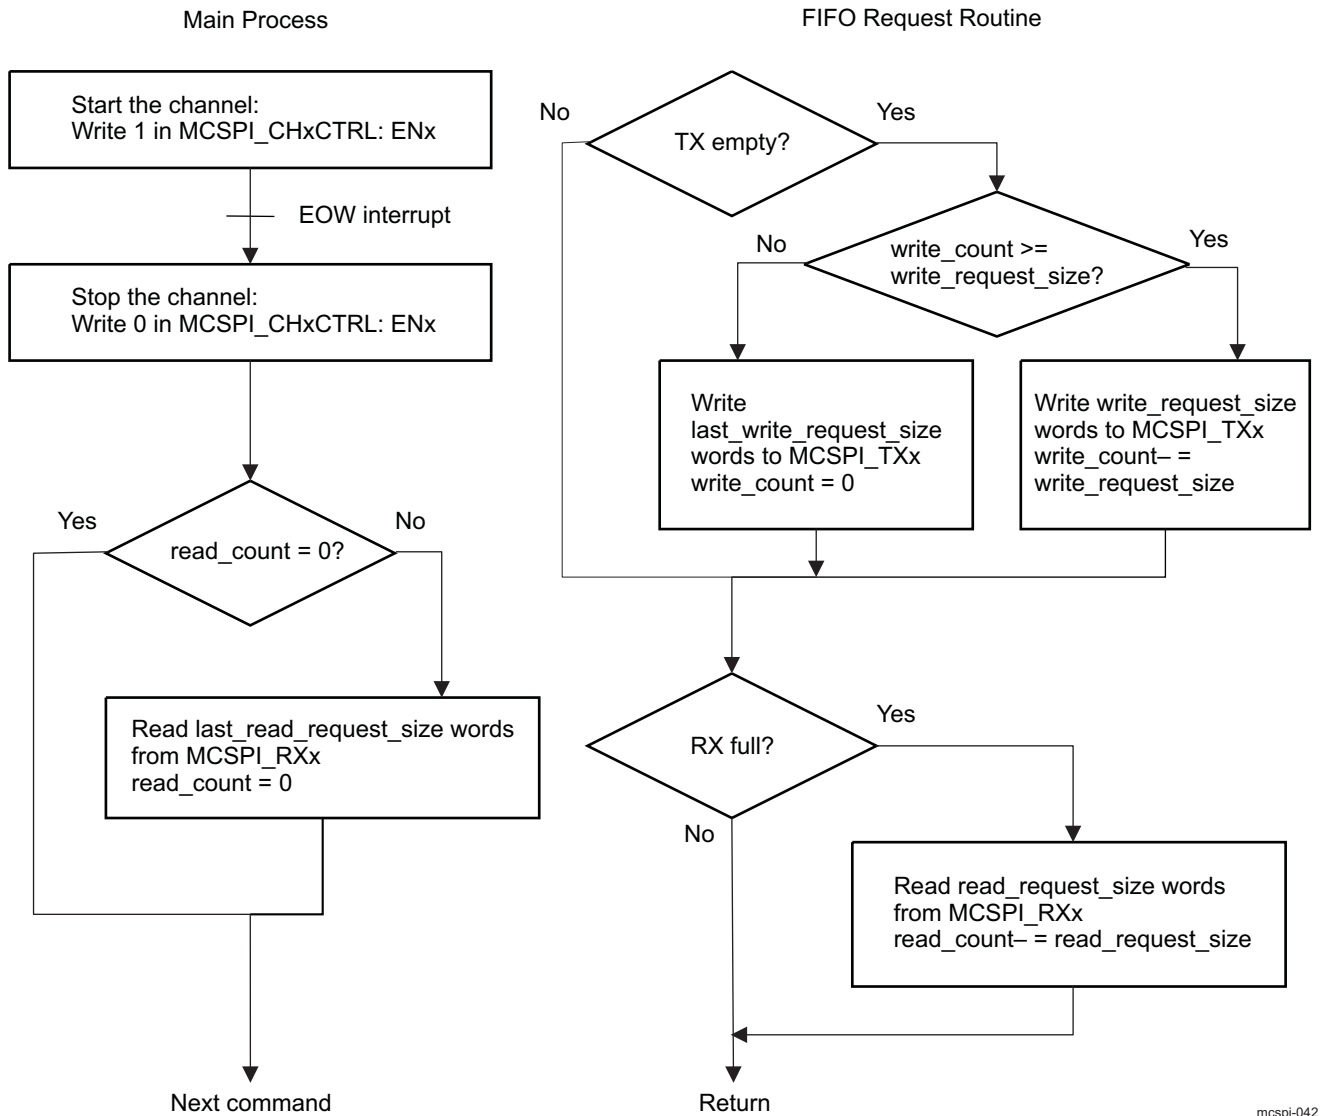

- write_count = N
- read_count = N
- last_request = FALSE

They are initialized before starting the channel.

16.6.3.2 Transmit-Receive Procedure With Word Count (WCNT≠0)

[Figure 16-38](#) shows the flow of a transfer in transmit-receive mode, with word count.

Figure 16-38. Transmit-Receive With Word Count

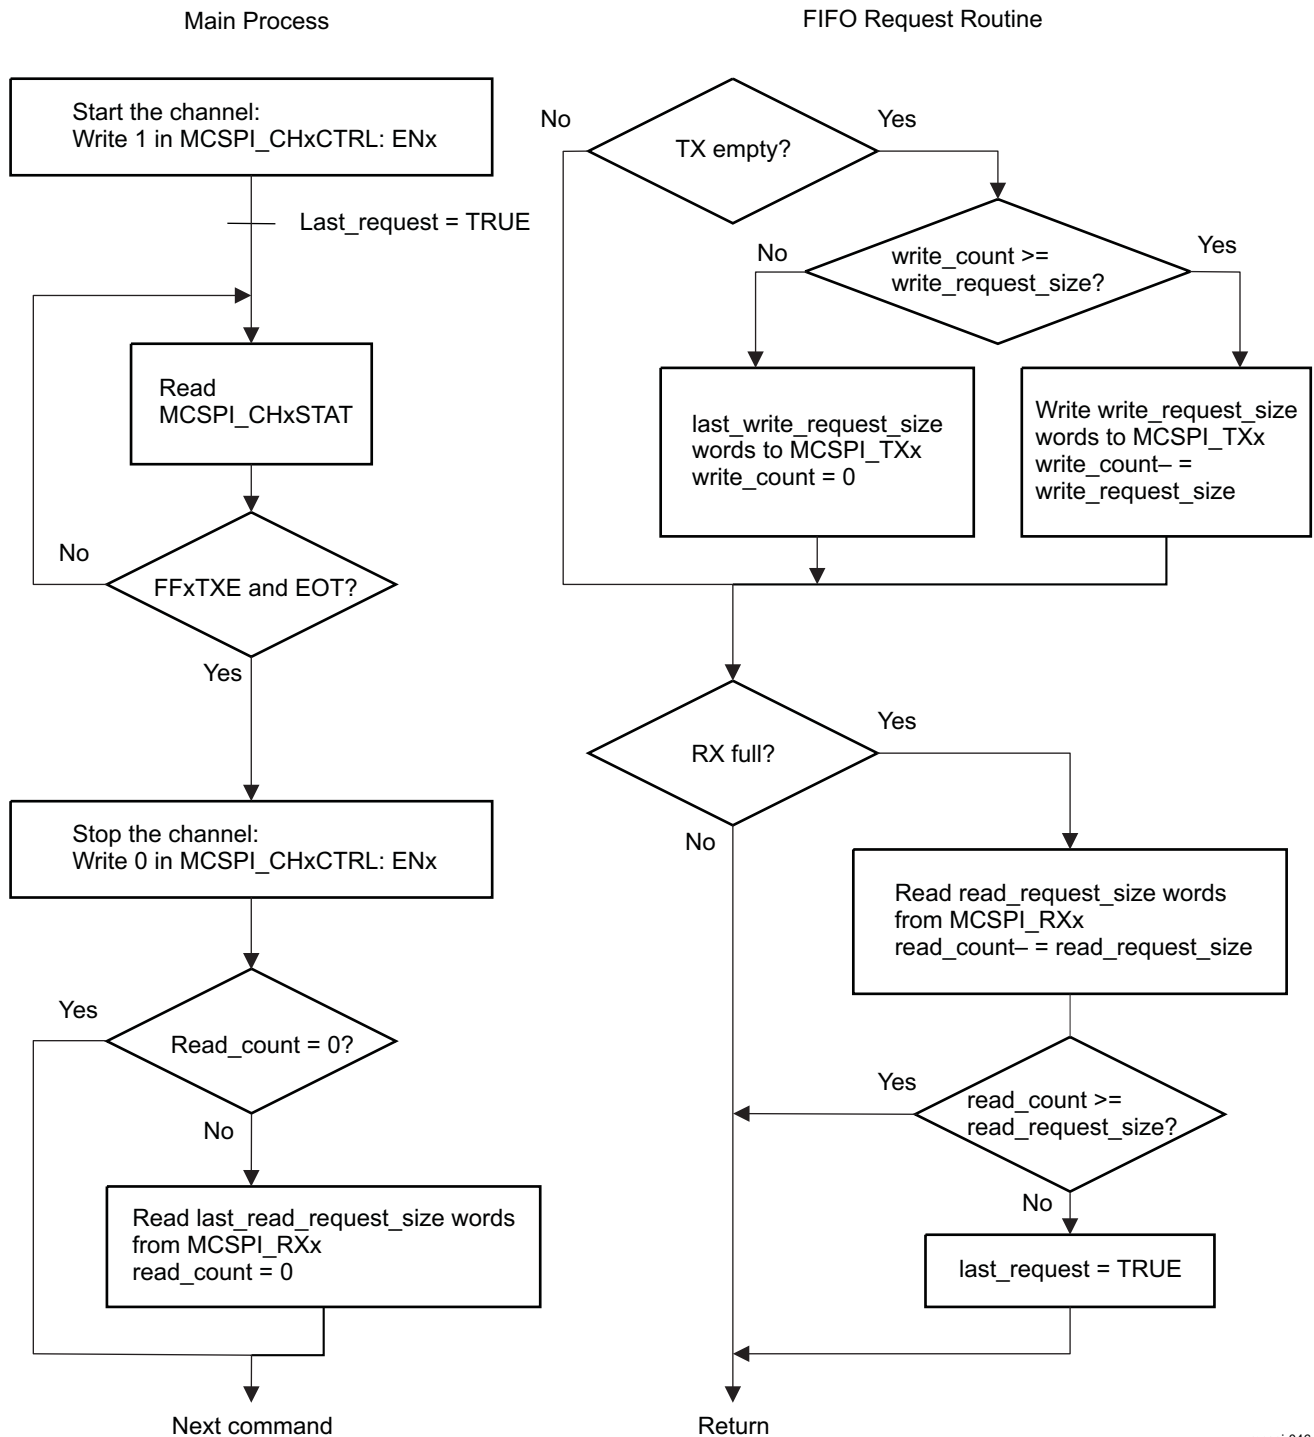

mcspi-042

16.6.3.3 Transmit-Receive Procedure Without Word Count (WCNT=0)

Figure 16-39 shows the flow of a transfer in transmit-receive mode, without word count.

Figure 16-39. Transmit-Receive Without Word Count

mcspi-046

16.6.3.4 Transmit-Only Procedure

Figure 16-40 shows the flow of a transfer in transmit only mode, with our without word count.

Figure 16-40. Transmit-Only

mcspi-047

The difference between word count enabled or not is the condition after starting the channel:

- Word count enable: Wait for EOW interrupt.
- Word count disable: Wait for write_count = 0.

16.6.3.5 Receive-Only Procedure With Word Count (WCNT≠0)

Figure 16-41 shows the flow of a transfer in receive-only mode, with word count.

Figure 16-41. Receive-Only With Word Count

mcspi-045

16.6.3.6 Receive-Only Procedure Without Word Count (WCNT=0)

Figure 16-42 shows the flow of a transfer in receive-only mode, without word count.

16.7 McSPI Use Cases and Tips

16.7.1 How to Configure the McSPI Interface When Connected with an EPSON VGA FlatLink™ 3G Device

16.7.1.1 Overview

This section deals with configuring an EPSON VGA FlatLink™3G device through the McSPI interface. Before transferring data from the external SDRAM memory to the external EPSON VGA display (Figure 16-43), the display subsystem must be set up via the McSPI interface. Several commands must be sent to the EPSON VGA for its configuration.

Figure 16-43. Overview

108-037

In this use case the configuration is the following:

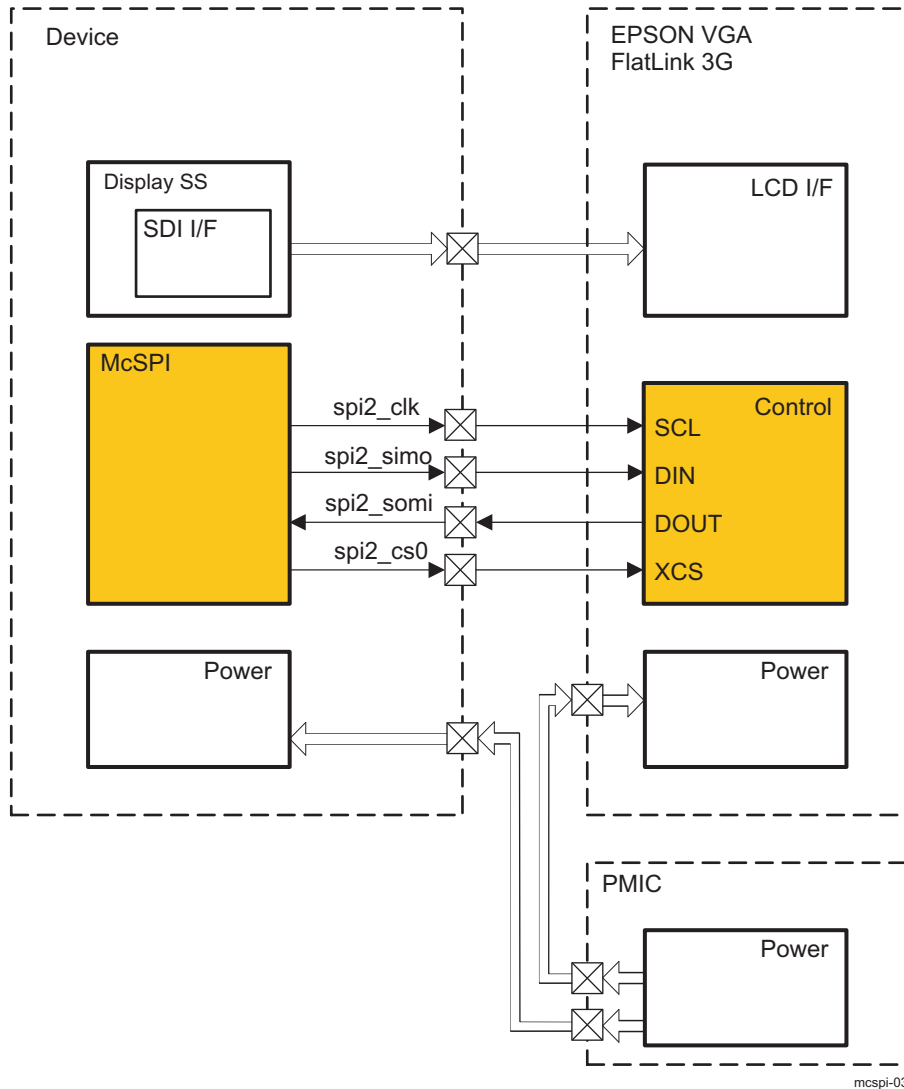

- McSPI2 channel 0 in master mode, EPSON VGA display in slave mode
- Transmit-only and receive-only modes
- No DMA requests and no interrupts used: transmit and receive flag polling

16.7.1.2 Environment

In this use case, the EPSON VGA is connected to the device through channel 0 of the McSPI instance 2 as shown in Figure 16-44 (through `mcspi2_somi`, `mcspi2_simo`, `mcspi2_cs0`).

The display clocks are provided to the EPSON VGA by the device display subsystem. The display configuration clock comes from the McSPI interface (`mcspi2_clk`).

Figure 16-44. Environment

16.7.1.3 Data Path

In this use case, the McSPI2 manages the control path between the MPU subsystem and the EPSON VGA FlatLink™ 3G.

- Display configuration commands are transmitted via the channel 0 transmit register (TX Registers) and the shift register.
- A display status is read via the shift register, the receive buffer, and the channel 0 receive register (RX Registers).

Figure 16-45. McSPI Data Flow

16.7.1.4 Programming Flow

The initialization of the EPSON VGA is done in five steps:

1. McSPI module configuration
2. Send a 'SOFT RESET' command to the EPSON VGA
3. Send a 'SLEEP OUT' command
4. Send a 'DISPLAY ON' command
5. Send a 'READ DISPLAY STATUS' command and receive status data.

The four EPSON VGA commands needed in the EPSON VGA configuration are described in [Table 16-18](#).

Table 16-18. EPSON VGA Configuration Commands

| | D/CX | D7 | D6 | D5 | D4 | D3 | D2 | D1 | D0 | Dummy bit |
|--|------|----|----|----|----|----|----|----|----|-----------|
| SOFT RESET (001h) | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | n/a |
| SLEEP OUT (011h) | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 1 | n/a |
| DISPLAY ON (029h) | 0 | 0 | 0 | 1 | 0 | 1 | 0 | 0 | 1 | n/a |
| READ DISPLAY STATUS (009h and dummy bit '0') | 0 | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 1 | 0 |

The following subsections describe each of these initialization steps.

16.7.1.4.1 McSPI Module Configuration

Before configuring the external display VGA, the multi-channel serial port interface must be initialized as detailed in the following steps:

1. Enable the McSPI2 functional and interface clocks through the PRCM.CM_FCLKEN1_CORE[18] EN_MCSPi2 and PRCM.CM_ICLKEN1_CORE[18] EN_MCSPi2 fields.
2. Proceed to a McSPI software reset through the [MCSPI_SYSCONFIG\[1\]](#) SOFTRESET field. The SOFTRESET bit is automatically reset by hardware.
3. Poll the [MCSPI_SYSSTATUS\[0\]](#) RESETDONE field to check the software reset status.
4. Disable channel 0 through the [MCSPI_CHxCTRL\[0\]](#) EN field (with x=0).
5. Disable all interrupts ([MCSPI_IRQENABLE](#) register) then clear interrupt status register ([MCSPI_IRQSTATUS](#)). Interrupts are disabled once at this stage. Even if some interrupts of the [MCSPI_IRQSTATUS](#) register are set, no interrupt can go out to the MPU subsystem.
6. Set the module in Master mode and multichannel mode through the [MCSPI_MODULCTRL](#) register.
7. Configure channel 0 in transmit-only mode, with a word length of 9-bit through the [MCSPI_CHxCONF](#) register (with x=0). A word length of 9 bits is required to transmit the required command (SOFT RESET, SLEEP OUT, or DISPLAY ON) to the EPSON display, as detailed in [Table 16-18](#). Those 9 bits are serially transmitted on spi2_simo in the sequence D/CX, D7 to D0.

[Table 16-19](#) shows all registers to be configured with the required value for the McSPI module configuration and the use case values.

Table 16-19. McSPI Configuration Registers Print

| Register Name (with x=0) | Physical Address | Value | Value Description |
|------------------------------------|------------------|-------------|--|
| PRCM.CM_FCLKEN1_CORE[18] | 0x4800 4A00 | 0x1 | Enable McSPI2 functional clock |
| PRCM.CM_ICLKEN1_CORE[18] | 0x4800 4A10 | 0x1 | Enable McSPI2 interface clock |
| MCSPI_SYSCONFIG[1] | 0x4809 A010 | 0x1 | Initiate a software reset |
| MCSPI_SYSSTATUS | 0x4809 A014 | 0x0000 0001 | The RESETDONE field is set at 1 when the reset is complete |
| MCSPI_CHxCTRL | 0x4809 A034 | 0x0000 0000 | Disable channel 0 |
| MCSPI_IRQENABLE | 0x4809 A01C | 0x0000 0000 | Disable all interrupts |
| MCSPI_IRQSTATUS | 0x4809 A018 | 0x0001 777F | Clear all interrupts |
| MCSPI_MODULCTRL | 0x4809 A028 | 0x0000 0000 | Master mode, multichannel |

Table 16-19. McSPI Configuration Registers Print (continued)

| | | | |
|-------------------------------|-------------|-------------|---|
| MCSPI_CHxCONF | 0x4809 A02C | 0x0001 2453 | CLKD = 4 (CLKSPIREF divided internally by 16) WL = 9-bit Transmit-only Receive on spi2_somi Transmit on spi2_simo |
|-------------------------------|-------------|-------------|---|

16.7.1.4.2 'SOFT RESET', 'SLEEP OUT' and 'DISPLAY ON' Commands

Once the McSPI interface is configured, three commands must be send to the external display VGA: a software reset to reinitiate the external display, a 'SLEEP OUT' command to wake it up, and a 'DISPLAY ON' to turn on the display. Those three commands follow the same procedure, described here below, only the command opcode changes.

1. Enable channel 0 through the [MCSPI_CHxCTRL\[0\]](#) EN field (with x=0).
2. Write the command opcode to the [MCSPI_TXx](#) (with x=0) register so that it could be transmitted to the external display VGA. To transmit the SOFT RESET command, write 001h in the [MCSPI_TXx](#) (with x=0) register. To transmit a SLEEP OUT command write 011h and to transmit a DISPLAY ON command write 029h.
3. Poll the [MCSPI_CHxSTAT\[1\]](#) TXS field (with x=0) to check for transmit status. When the word has been transmitted, TXS is automatically set to 1.
4. Disable channel 0 through the [MCSPI_CHxCTRL\[0\]](#) EN field (with x=0).

[Table 16-20](#) shows all registers to be configured with the required value for the those commands and the use case values.

Table 16-20. Display Configuration Registers Print

| Register Name (with x=0) | Physical Address | Value | Value Description |
|----------------------------------|------------------|-------------------------|--|
| MCSPI_CHxCTRL | 0x4809 A034 | 0x0000 0001 | Enable channel 0 |
| MCSPI_TXx | 0x4809 A038 | 0x001 0x011 0x029 | Transmit a 'SOFT RESET' command to the EPSON VGA display Transmit a 'SLEEP OUT' command Transmit a 'DISPLAY ON' command |
| MCSPI_CHxSTAT[1] | 0x4809 A030 | 0x1 | The word in MCSPI_TXx has been transmitted when the TXS flag is set to 1 |
| MCSPI_CHxCTRL | 0x4809 A034 | 0x0000 0000 | Disable channel 0 |

16.7.1.4.3 'READ DISPLAY STATUS' Command

Once the EPSON VGA display is initialized, a 'READ DISPLAY STATUS' command is sent to the external display VGA to read and check the status of the component, such as Partial mode, Sleep In mode, Display status, Horizontal and Vertical Synchronization On or Off states.

The 'READ DISPLAY STATUS' command is not 9- but 10-bit long because the EPSON VGA display requires a dummy cycle between the transmission of the last command bit (D0 in [Table 16-18](#)) and the reception of the first data bit (the display status data is 32-bit long). In other words, a dummy bit is added as less significant bit of the command. Hence, those 10 bits are serially transmitted on spi2_simo in the sequence D/CX, D7 to D0, dummy bit.

1. Set the module in Master mode and single channel mode through the [MCSPI_MODULCTRL](#) register.
2. Configure channel 0 in transmit-only mode, with a word length of 10-bit through the [MCSPI_CHxCONF](#) register (with x=0).
3. Enable channel 0 through the [MCSPI_CHxCTRL\[0\]](#) EN field.
4. Shift left of one bit the command opcode 009h so that the required dummy bit ('0') can be sent after the D/CX and D7 to D0 bits to the EPSON VGA display. Refer to [Table 16-18](#) for more information. Then, write this command (012h) to the [MCSPI_TXx](#) (with x=0) register so that it could be transmitted to the EPSON VGA display.

5. Poll the [MCSPI_CHxSTAT\[1\]](#) TXS bit (with x=0) to check transmit status. When the word has been transmitted, TXS is automatically set to 1.
6. Read the [MCSPI_CHxSTAT\[1\]](#) RXS bit to check receive status. If data has already been received (RXS is set to 1) read the [MCSPI_RXx](#) (with x=0) receive register; this will automatically deactivate the RXS flag (RXS is automatically cleared).
7. Configure channel 0 in receive-only mode, with a word length of 32-bit through the [MCSPI_CHxCONF](#) register.
8. Poll the [MCSPI_CHxSTAT\[1\]](#) RXS bit to check receive status. When data has been received, RXS is automatically set to 1. The 32-bit display status information is available in the McSPI2 channel 0 receive register: [MCSPI_RXx](#) (with x=0).
9. Set channel 0 in transmit-only mode through the [MCSPI_CHxCONF](#) register.

[Table 16-21](#) shows all registers to be configured with the required value for the McSPI module configuration and the use case values.

Table 16-21. Display Status Check Registers Print

| Register Name (with x=0) | Physical Address | Value | Value Description |
|--------------------------------------|------------------|-------------|--|
| MCSPI_MODULCTRL | 0x4809 A028 | 0x0000 0001 | Master mode, single channel |
| MCSPI_CHxCONF | 0x4809 A02C | 0x0011 24D3 | CLKD = 4 (CLKSPIREF divided internally by 16) WL = 10-bit Transmit-only Receive on spi2_somi Transmit on spi2_simo |
| MCSPI_CHxCTRL | 0x4809 A034 | 0x0000 0001 | Enable channel 0 |
| MCSPI_TTx | 0x4809 A038 | 0x0000 0012 | Send a 'READ DISPLAY STATUS' command. See Table 16-18 . |
| MCSPI_CHxSTAT[1] TXS | 0x4809 A030 | 0x1 | The word in MCSPI_TTx has been transmitted if the TXS flag is set to 1 |
| MCSPI_CHxSTAT[0] RXS | 0x4809 A030 | - | Read RXS flag. Data has been received in MCSPI_RXx if the RXS flag is set to 1 |
| MCSPI_RXx | 0x4809 A03C | - | Read MCSPI_RXx only if the RXS bit is equal to 1 (this is a dummy read that will automatically clear the RXS flag) |
| MCSPI_CHxCONF | 0x4809 A02C | 0x0011 1FD0 | CLKD = 4 (CLKSPIREF divided internally by 16) WL = 32-bit Receive-only Receive on spi2_somi Transmit on spi2_simo |
| MCSPI_CHxSTAT[0] RXS | 0x4809 A030 | 0x0 | Data has been received in MCSPI_RXx when the RXS flag is set to 1. |
| MCSPI_CHxCONF | 0x4809 A02C | 0x0011 2453 | Back in transmit-only mode Receive on spi2_somi Transmit on spi2_simo |

16.8 McSPI Register Manual

16.8.1 McSPI Instance Summary

Table 16-22 lists the McSPI instances.

Table 16-22. McSPI Instance Summary

| Bits | Field Name | Description | Type | Reset |
|-------|---------------|---|------|--------|
| 31:18 | Reserved | Reads returns 0 | RW | 0x0000 |
| 17 | EOW | End of word count event when a channel is enabled using the FIFO buffer and the channel had sent the number of SPI word defined by MCSPI_XFERLEVEL[31:16] WCNT bit field. Write 0x0: Event status bit unchanged. Read 0x0: Event false. Write 0x1: Event status bit is reset. Read 0x1: Event is pending. | RW | 0x0 |
| 16 | WKS | Wake-up event in slave mode when an active control signal is detected on the spim_csx line programmed in the MCSPI_CHxCONF[SPIENSLV] field (where x=0 only) Write 0x0: Event status bit unchanged Read 0x0: Event false Write 0x1: Event status bit is reset. Read 0x1: Event is pending. | RW | 0x0 |
| 15 | Reserved | Reads returns 0. | RW | 0x0 |
| 14 | RX3_FULL | MCSPi_RX3 register is full (only when channel 3 is enabled) Write 0x0: Event status bit unchanged Read 0x0: Event false Write 0x1: Event status bit is reset. Read 0x1: Event is pending. | RW | 0x0 |
| 13 | TX3_UNDERFLOW | MCSPi_TX3 register underflow (only when channel 3 is enabled) ⁽¹⁾ Write 0x0: Event status bit unchanged Read 0x0: Event false Write 0x1: Event status bit is reset. Read 0x1: Event is pending. | RW | 0x0 |
| 12 | TX3_EMPTY | MCSPi_TX3 register is empty (only when channel 3 is enabled) ⁽²⁾ Write 0x0: Event status bit unchanged Read 0x0: Event false Write 0x1: Event status bit is reset. Read 0x1: Event is pending. | RW | 0x0 |
| 11 | Reserved | Read returns 0. | RW | 0x0 |
| 10 | RX2_FULL | MCSPi_RX2 register full (only when channel 2 is enabled) Write 0x0: Event status bit unchanged Read 0x0: Event false Write 0x1: Event status bit is reset. Read 0x1: Event is pending. | RW | 0x0 |
| 9 | TX2_UNDERFLOW | MCSPi_TX2 register underflow (only when channel 2 is enabled) ⁽¹⁾ Write 0x0: Event status bit unchanged Read 0x0: Event false Write 0x1: Event status bit is reset. Read 0x1: Event is pending. | RW | 0x0 |
| 8 | TX2_EMPTY | MCSPi_TX2 register empty (only when channel 2 is enabled) ⁽²⁾ Write 0x0: Event status bit unchanged Read 0x0: Event false | RW | 0x0 |

⁽¹⁾ The MCSPi_TXx register is empty (not updated by host or DMA with new data) before its time slot assignment. Exception: No TX_UNDERFLOW event when no data has been loaded into the MCSPi_TXx register since channel has been enabled.

⁽²⁾ Enabling the channel automatically rises this event.

| Bits | Field Name | Description | Type | Reset |
|------|---------------|--|------|-------|
| | | Write 0x1: Event status bit is reset. Read 0x1: Event is pending. | | |
| 7 | Reserved | Read returns 0. | RW | 0x0 |
| 6 | RX1_FULL | MCSPi_RX1 register full (only when channel 1 is enabled) Write 0x0: Event status bit unchanged Read 0x0: Event false Write 0x1: Event status bit is reset. Read 0x1: Event is pending. | RW | 0x0 |
| 5 | TX1_UNDERFLOW | MCSPi_TX1 register underflow (only when channel 1 is enabled) ⁽¹⁾ Write 0x0: Event status bit unchanged Read 0x0: Event false Write 0x1: Event status bit is reset. Read 0x1: Event is pending. | RW | 0x0 |
| 4 | TX1_EMPTY | MCSPi_TX1 register empty (only when channel 1 is enabled) ⁽³⁾ Write 0x0: Event status bit unchanged Read 0x0: Event false Write 0x1: Event status bit is reset. Read 0x1: Event is pending. | RW | 0x0 |
| 3 | RX0_OVERFLOW | MCSPi_RX0 register overflow (only in slave mode) Write 0x0: Event status bit unchanged Read 0x0: Event false Write 0x1: Event status bit is reset. Read 0x1: Event is pending. | RW | 0x0 |
| 2 | RX0_FULL | MCSPi_RX0 register full (only when channel 0 is enabled) Write 0x0: Event status bit unchanged Read 0x0: Event false Write 0x1: Event status bit is reset. Read 0x1: Event is pending. | RW | 0x0 |
| 1 | TX0_UNDERFLOW | MCSPi_TX0 register underflow (only when channel 0 is enabled) ⁽⁴⁾ Write 0x0: Event status bit unchanged Read 0x0: Event false Write 0x1: Event status bit is reset. Read 0x1: Event is pending. | RW | 0x0 |
| 0 | TX0_EMPTY | MCSPi_TX0 register empty (only when channel 0 is enabled) ⁽³⁾ Write 0x0: Event status bit unchanged Read 0x0: Event false Write 0x1: Event status bit is reset. Read 0x1: Event is pending. | RW | 0x0 |

⁽³⁾ Enabling the channel automatically rises this event.

⁽⁴⁾ The MCSPi_Txx register is empty (not updated by host or DMA with new data) before its time slot assignment.
Exception: No TX_UNDERFLOW event when no data has been loaded into the MCSPi_Txx register since channel has been enabled.

| Bits | Field Name | Description | Type | Reset |
|-------|------------|--|------|---------|
| 31:12 | Reserved | Reads returns 0 | RW | 0x00000 |
| 11 | SSB | Set status bit 0x0: No action. Writing 0 does not clear already set status bits; This bit must be cleared prior attempting to clear a status bit of the MCSPI_IRQSTATUS register. 0x1: Force to 1 all status bits of MCSPI_IRQSTATUS register. Writing 1 into this bit sets to 1 all status bits contained in the MCSPI_IRQSTATUS register. | RW | 0 |
| 10 | SPIENDIR | Set the direction of the spim_cs lines and spim_clk line 0x0: Output (as in master mode) 0x1: Input (as in slave mode) | RW | 0 |
| 9 | SPIDATDIR1 | Set the direction of the SPIDAT[1] (spim_simo) 0x0: Output 0x1: Input | RW | 0 |
| 8 | SPIDATDIR0 | Set the direction of the SPIDAT[0] (spim_somi) 0x0: Output 0x1: Input | RW | 0 |
| 7 | WAKD | SWAKEUP output (signal data value of internal signal to system). The signal is driven high or low according to the value written into this register bit. 0x0: The pin is driven low. 0x1: The pin is driven high. | RW | 0 |
| 6 | SPICLK | spim_clk line (signal data value) If MCSPI_SYST[SPIENDIR] = 1 (input mode direction), this bit returns the value on the spim_clk line (high or low) and a write into this bit has no effect. If MCSPI_SYST[SPIENDIR] = 0 (output mode direction), the spim_clk line is driven high or low according to the value written into this register. | RW | 0 |
| 5 | SPIDAT_1 | spim_somi line (signal data value) If MCSPI_SYST[SPIDATDIR1] = 0 (output mode direction), the spim_somi line is driven high or low according to the value written into this register. | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|---|------|-------|
| | | If MCSPI_SYST[SPIDATDIR1] = 1 (input mode direction), this bit returns the value on the spim_somi line (high or low) and a write into this bit has no effect. | | |
| 4 | SPIDAT_0 | spim_simo line (signal data value) If MCSPI_SYST[SPIDATDIR0] = 0 (output mode direction), the spim_simo line is driven high or low according to the value written into this register. If MCSPI_SYST[SPIDATDIR0] = 1 (input mode direction), this bit returns the value on the spim_simo line (high or low) and a write into this bit has no effect. | RW | 0 |
| 3 | SPIEN_3 | spim_cs3 line (signal data value) If MCSPI_SYST[SPIENDIR] = 0 (output mode direction), the spim_cs3 line is driven high or low according to the value written into this register. If MCSPI_SYST[SPIENDIR] = 1 (input mode direction), this bit returns the value on the spim_cs3 line (high or low) and a write into this bit has no effect. | RW | 0 |
| 2 | PIEN_2 | spim_cs2 line (signal data value) If MCSPI_SYST[SPIENDIR] = 0 (output mode direction), the spim_cs2 line is driven high or low according to the value written into this register. If MCSPI_SYST[SPIENDIR] = 1 (input mode direction), this bit returns the value on the spim_cs2 line (high or low) and a write into this bit has no effect. | RW | 0 |
| 1 | SPIEN_1 | spim_cs1 line (signal data value) If MCSPI_SYST[SPIENDIR] = 0 (output mode direction), the spim_cs1 line is driven high or low according to the value written into this register. If MCSPI_SYST[SPIENDIR] = 1 (input mode direction), this bit returns the value on the spim_cs1 line (high or low) and a write into this bit has no effect. | RW | 0 |
| 0 | SPIEN_0 | spim_cs0 line (signal data value) If MCSPI_SYST[SPIENDIR] = 0 (output mode direction), the spim_cs0 line is driven high or low according to the value written into this register. If MCSPI_SYST[SPIENDIR] = 1 (input mode direction), this bit returns the value on the spim_cs0 line (high or low) and a write into this bit has no effect. | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|-------|------------|--|------|-------|
| 31:30 | Reserved | Read returns 0s. | RW | 0x00 |
| 29 | CLKG | Clock divider granularity. This register defines the granularity of channel clock divider: power of two or one clock cycle granularity. When this bit is set, the MCSPI_CHxCTRL[15:8] EXTCLK bit field must be configured to reach a maximum of 4096 clock divider ratio. Then the clock divider ratio is a concatenation of MCSPI_CHxCONF[5:2] CLKD and EXTCLK values. 0x0: Clock granularity of power of two 0x1: One clock cycle ganularity | RW | 0x0 |
| 28 | FFER | FIFO enabled for Receive. Only one channel can have this bit field set. 0x0: The buffer is not used to Receive data 0x1: The buffer is used to Receive data | RW | 0x0 |
| 27 | FFEW | FIFO enabled for Transmit. Only one channel can have this bit field set. 0x0: The buffer is not used to Transmit data 0x1: The buffer is used to Transmit data | RW | 0x0 |
| 26:25 | TCS | Chip select time control Defines the number of interface clock cycles between CS toggling and first (or last) edge of SPI clock. 0x0: 0.5 clock cycle 0x1: 1.5 clock cycles 0x2: 2.5 clock cycles 0x3: 3.5 clock cycles | RW | 0x0 |
| 24 | SBPOL | Start bit polarity 0x0: Start bit polarity is held to 0 during SPI transfer. 0x1: Start bit polarity is held to 1 during SPI transfer. | RW | 0x0 |
| 23 | SBE | Start bit enable for SPI transfer 0x0: Default SPI transfer length as specified by WL bit field 0x1: Start bit D/CX added before SPI transfer. Polarity is defined by MCSPI_CHxCONF[SBPOL] . | RW | 0x0 |
| 22:21 | Reserved | Write the reset value. Read returns the reset value. | RW | 0x0 |
| 20 | FORCE | Manual spim_csx assertion to keep spim_csx for channel x active between SPI words (single channel master mode only). The MCSPI_MODULCTRL[0] SINGLE bit must bit set to 1. | RW | 0x0 |

| Bits | Field Name | Description | Type | Reset |
|-------|------------|---|------|-------|
| | | 0x0: Writing 0 into this bit drives the spin_csx line low for channel x when MCSPI_CHxCONF [6] EPOL = 0, and drives it high when MCSPI_CHxCONF [6] EPOL = 1. 0x1: Writing 1 into this bit drives the spin_csx line high for channel x when MCSPI_CHxCONF [E6] EPOL = 0, and drives it low when MCSPI_CHxCONF [6] EPOL = 1. | | |
| 19 | TURBO | Turbo mode 0x0: Turbo is deactivated (recommended for single SPI word transfer) 0x1: Turbo is activated to maximize the throughput for multi-SPI word transfers. | RW | 0x0 |
| 18 | IS | Input select 0x0: Data Line 0 (spim_somi) selected for reception 0x1: Data Line 1 (spim_simo) selected for reception | RW | 0x1 |
| 17 | DPE1 | Transmission enable for data line 1 (spim_simo) 0x0: Data Line 1 (spim_simo) selected for transmission 0x1: No transmission on data Line 1 (spim_simo) | RW | 0x1 |
| 16 | DPE0 | Transmission enable for data line 0 (spim_somi) 0x0: Data Line 0 (spim_somi) selected for transmission 0x1: No transmission on data Line 0 (spim_somi) | RW | 0x0 |
| 15 | DMAR | DMA Read request The DMA Read request line is asserted when the channel is enabled and a new data is available in the receive register of the channel. The DMA Read request line is deasserted on read completion of the receive register of the channel. 0x0: DMA read request disabled 0x1: DMA read request enabled | RW | 0x0 |
| 14 | DMAW | DMA Write request. The DMA write request line is asserted when the channel is enabled and the MCSPI_TXx register of the channel is empty. The DMA write request line is deasserted on load completion of the MCSPI_TXx register of the channel. 0x0: DMA write request disabled 0x1: DMA write request enabled | RW | 0x0 |
| 13:12 | TRM | Transmit/receive modes 0x0: Transmit and receive mode 0x1: Receive-only mode 0x2: Transmit-only mode 0x3: Reserved | RW | 0x0 |
| 11:7 | WL | SPI word length 0x0: Reserved 0x1: Reserved 0x2: Reserved 0x3: The SPI word is 4-bit long 0x4: The SPI word is 5-bit long 0x5: The SPI word is 6-bit long 0x6: The SPI word is 7-bit long 0x7: The SPI word is 8-bit long 0x8: The SPI word is 9-bit long 0x9: The SPI word is 10-bit long 0xA: The SPI word is 11-bit long | RW | 0x00 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|---|------|-------|
| | | 0xB: The SPI word is 12-bit long | | |
| | | 0xC: The SPI word is 13-bit long | | |

HDQ/1-Wire

This chapter describes the features and functions of the HDQ/1-Wire module.

NOTE: Some features may not be available or supported in your particular device. For more information, see Chapter 1, the Device Family section, and your device-specific data manual.

17.1 HDQ/1-Wire Overview

The HDQ/1-Wire module implements the hardware protocol of the master functions of the Benchmark HDQ and the Dallas Semiconductor 1-Wire® protocols. These protocols use a single wire for communication between the master (HDQ/1-Wire controller) and the slave (HDQ/1-Wire external compliant device).

Figure 17-1 shows the HDQ/1-Wire controller module.

Figure 17-1. HDQ/1-Wire Highlight

The HDQ and 1-Wire module has a generic L4 interface and is intended to be used in an interrupt-driven fashion. The one-pin interface is implemented as an open-drain output at the device level.

The HDQ operates from a fixed 12-MHz functional clock provided by the PRCM module.

Only the MPU subsystem uses the HDQ/1-Wire module.

The main features of the HDQ/1-Wire module support the following:

- Benchmark HDQ protocol
- Dallas Semiconductor 1-Wire protocol
- Power-down mode

The HDQ/1-Wire module provides a communication rate of 5K bits/s over an address space of 128 bytes.

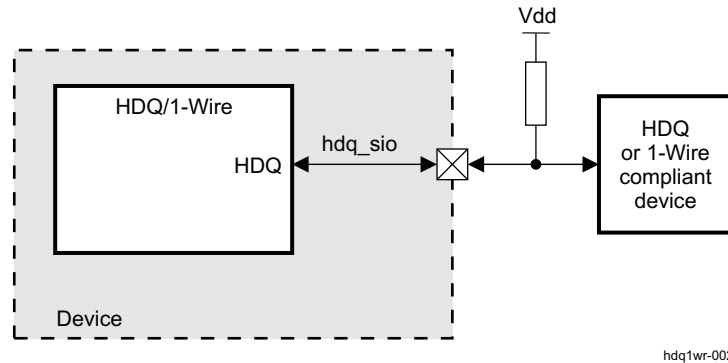

A typical application of the HDQ/1-Wire module is the communication with battery monitor (gas gauge) integrated circuits.

17.2 HDQ/1-Wire Environment

17.2.1 HDQ/1-Wire Functional Interface

Figure 17-2 shows a typical application using the HDQ/1-Wire connection.

Figure 17-2. HDQ/1-Wire Typical Application System Overview

An external pullup is required, because the two protocols use a return-to-1 mechanism (that is, after any command, the line is pulled to a logical high level).

The HDQ/1-Wire module operates according to a command structure that is programmed into transmit command registers (as described in Section 17.5).

The 1-Wire mode runs at slower speeds than the capabilities of the mode.

Table 17-1 describes the external pullup signal from an HDQ or 1-Wire compliant device.

Table 17-1. I/O Description

| Signal Name | I/O | Description | Value at Reset |
|-------------|-------|--------------------------|----------------|
| hdq_sio | Bidir | Serial data input/output | 1 |

17.2.2 HDQ and 1-Wire (SDQ) Protocols

17.2.2.1 HDQ Protocol Initialization (Default)

In HDQ mode, the firmware does not require the host to create an initialization pulse to the slave. However, the slave can be reset by using an initialization pulse (also referred to as a break pulse). The initialization pulse is generated by setting the INITIALIZATION bit (HDQ.HDQ_CTRL_STATUS[2]). The slave does not respond with a presence pulse as it does in the 1-Wire protocol.

The HDQ is a command-based protocol in which the host sends a command byte to the slave. The command directs the slave either to store the next eight bits of data received to a register specified by the command byte (write operation) or to output the eight bits of data from a register specified by the command byte (read operation). The master implementation is a simple byte engine. The sending of the ID, command/address, and data is controlled by firmware. The master engine provides only a single HDQ.HDQ_TX_DATA register.

The command and data bytes consist of a stream of eight bits with a maximum transmission rate of 5K bits/s. The least significant bit (LSB) of a command or data byte is transmitted first. If a communication time-out occurs between the host and the slave (for example, if the host waits longer than the specified time for the slave to respond, or if this is the first access command), then the host must send an initialization pulse (BREAK pulse) before sending the command again.

The slave detects a break when the HDQ pin is driven to a logic-low state for a specified break time $t(B)$ or greater. The HDQ pin then returns to its normal ready-high logic state for a specified break-recovery time $t(BR)$. The slave is then ready for a command from the host processor. Figure 17-3 shows this behavior.

An interrupt condition indicates either a TX-complete, an RX-complete, or a time-out condition. Reading the interrupt status register clears all interrupt conditions. Only one interrupt signal is sent to the microcontroller, and only one overall mask bit can enable or disable the interrupt. The interrupt conditions cannot be individually masked.

Figure 17-3. HDQ Break-Pulse Timing Diagram

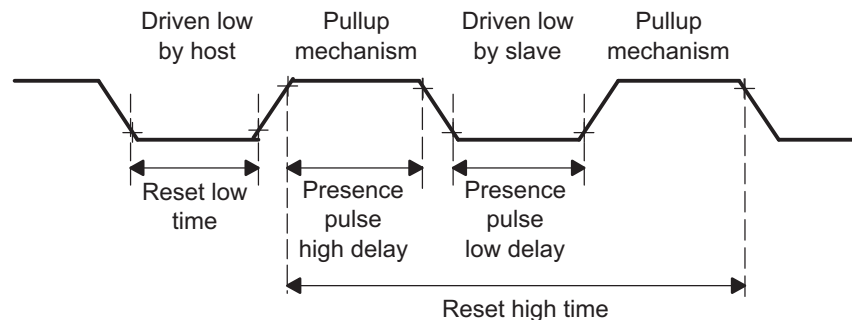

17.2.2.2 1-Wire (SDQ) Protocol Initialization

In 1-Wire (SDQ) protocol, the host first sends an initialization pulse (by pulling the line to a logic-low state) and then waits for the slave to respond with a presence pulse before enabling any communication sequence.

As for the initialization pulse, the presence pulse is a low-going edge on the line initiated by the slave. The timing diagram in [Figure 17-4](#) shows the 1-Wire (SDQ) reset sequence.

Figure 17-4. 1-Wire (SDQ) Reset Timing Diagram

The host drives the line to a logic-low state for a minimum of reset low time. Once the slave detects this pulse, it must drive the line to a logic-low state within the presence pulse high delay for a minimum period of presence pulse low time.

If the slave does not respond within this interval of time, a time-out event occurs and no transaction can be initiated. The host must initiate the reset sequence again before sending any command to the slave.

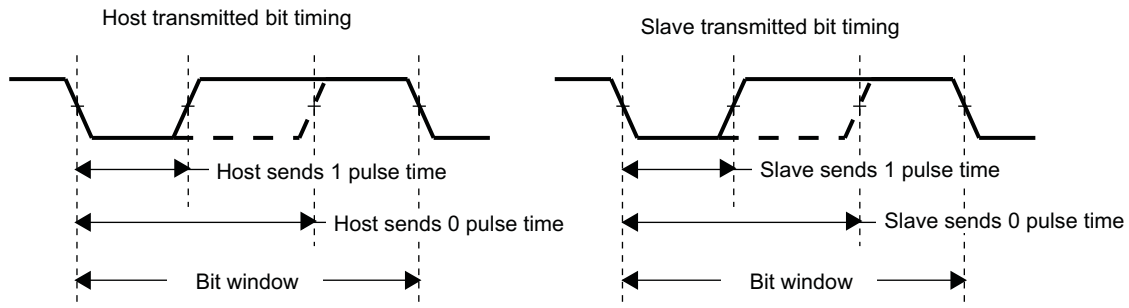

On the other hand, if the slave sends back its presence pulse within the specified interval of time, the communication can be enabled after the reset high time.

17.2.2.3 Communication Sequence (HDQ and 1-Wire Protocols)

This section describes the part common to both protocols.

After a successful break pulse (HDQ mode) or initialization sequence (1-Wire protocol), the host and slave are ready for bit transmission. Each bit to transmit (either from the host to the slave or from the slave to the host) is preceded by a low-going edge on the line, as shown in [Figure 17-5](#).

Figure 17-5. HDQ/1-Wire Transmitted Bit Timing

hdq1wr-005

The return-to-1 data-bit frame consists of three distinct sections. The first section starts the transmission when either the slave or the host takes the line to a logic-low state. The next section is the actual data transmission in which the data must be valid during a specified period of time after the negative edge that starts the communication. The final section stops the transmission by returning the HDQ/1-Wire line to a logic-high state. Communication with an HDQ/1-Wire slave always occurs with the LSB being transmitted first.

The command byte of the HDQ/1-Wire protocols consists of eight contiguous valid command bits. The command byte contains two fields: R/W command and address. The R/W bit of the command byte determines whether the command is a read or a write, and the address field containing bits AD6-AD0 indicates the address to be read or written. [Table 17-2](#) lists the command byte values.

Table 17-2. HDQ/1-Wire Command Byte

| 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
|-----|-----|-----|-----|-----|-----|-----|-----|
| R/W | AD6 | AD5 | AD4 | AD3 | AD2 | AD1 | AD0 |

- R/W** Indicates whether the command byte is a read or a write. A 1 indicates a write command; the following eight bits must be written to the register specified by the address field of the command byte. A 0 indicates that the command is a read. On a read command, the slave outputs the requested register contents.
- AD6-AD0** Represent the seven bits labeled AD6-AD0 containing the address portion of the register to be accessed. The communication sequence example in [Figure 17-6](#) shows a read command at address 0x55; the received data is 0x65.

Figure 17-6. HDQ/1-Wire Communication Sequence

hdq1wr-006

17.3 HDQ/1-Wire Integration

Figure 17-7 shows the HDQ/1-Wire module integration in the device.

Figure 17-7. HDQ/1-Wire Integration

17.3.1 Clocking, Reset, and Power Management Scheme

17.3.1.1 HDQ/1-Wire Clocks

There are two clock domains in the HDQ/1-Wire module: the functional clock domain and the interface clock domain.

- **HDQ_FCLK** belongs to the functional clock domain. It is a fixed 12-MHz clock provided by the PRCM. It is used to clock the internal module logic.

The **HDQ_FCLK** source is the **CORE_12M_FCLK** PRCM output, which is derived from the **CORE_48M_FCLK** clock signal (a 1/4 ratio is applied). The **CORE_12M_FCLK** clock is issued from the peripherals DPLL4. For more information about the clock, see , *Power, Reset, and Clock Management*.

When the HDQ/1-Wire module no longer requires the **HDQ_FCLK**, the software can disable it at the PRCM level by setting the **EN_HDQ** bit (**PRCM.CM_FCLKEN1_CORE[22]**) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it either.

For details about the PRCM register settings and DPLL4 configuration, see , *Power, Reset, and Clock Management*.

- **HDQ_ICLK** is the interface clock. It runs at L4 interconnect clock speed and is used to trigger access to the HDQ/1-Wire L4 interface. Its source is the PRCM **CORE_L4_ICLK** signal. It typically runs at L3/2 frequency.

When the HDQ/1-Wire module no longer requires the **HDQ_ICLK**, the software can disable it at the PRCM level by setting the **EN_HDQ** bit (**PRCM.CM_ICLKEN1_CORE[22]**) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it either.

It is also possible to activate an autoidle mode for this clock (**AUTO_HDQ** bit **PRCM.CM_AUTOIDLE1_CORE[22]** set to 1). In this case, **HDQ_ICLK** follows the CORE clock domain behavior. For more information, see , *Power, Reset, and Clock Management*.

17.3.1.2 HDQ/1-Wire Reset Scheme

Global reset of the module is done either by activating the **CORE_RST** signal in the **CORE_RST** domain (for more information, see , *Power, Reset, and Clock Management*) or by setting to 1 the **SOFTRESET** bit **HDQ.HDQ_SYSCONFIG[1]**. Setting this bit enables an active software reset functionality equivalent to a hardware reset.

17.3.1.3 HDQ/1-Wire Power Domain

The HDQ/1-Wire belongs to the CORE power domain. For more information about the CORE power domain, see , *Power, Reset, and Clock Management*.

17.3.2 Hardware Requests

The HDQ/1-Wire can generate one interrupt:

- HDQ_IRQ: This is an interrupt to the MPU subsystem interrupt controller. It is mapped on M_IRQ_58.

17.4 HDQ/1-Wire Functional Description

The HDQ/1-Wire module works with both the HDQ and 1-Wire protocols. The protocols use a single wire to establish communication between the master and the slave. Both protocols use a return-to-1 mechanism; that is, after any command is driven, the line is pulled to a high level. This mechanism requires an external pullup.

17.4.1 HDQ/1-Wire Block Diagram

Figure 17-8 shows the HDQ/1-Wire block diagram.

Figure 17-8. HDQ/1-Wire Block Diagram

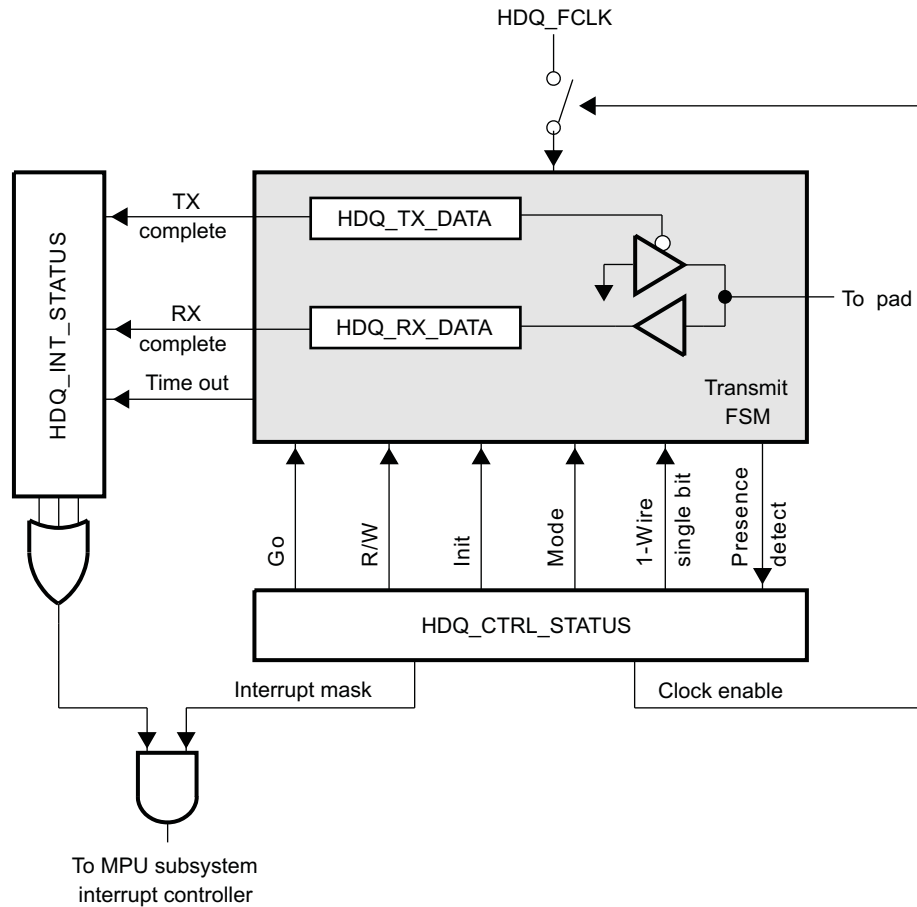

hdq1wr-008

The MODE bit HDQ.HDQ_CTRL_STATUS[0] allows selection between the HDQ and 1-Wire protocols. This bit is assumed static for design purposes. The configuration is in HDQ mode by default.

Figure 17-9 shows the protocol-dedicated register scheme.

Figure 17-9. Protocol Registers Description

hdq1wr-009

The receive and transmit operations are performed with respect to the HDQ protocol timing. The module is implemented once in the OMAP device and is clocked with a single clock whether it runs HDQ or 1-Wire protocol. Although the data exchange is slower than the capabilities of the 1-Wire mode, this mode still meets the timing requirements and practical considerations. That is, the 1-Wire protocol runs at the HDQ protocol speed, which is slower (5K bits/s). The timing parameters and protocol are different in the two modes.

17.4.2 HDQ Mode (Default)

17.4.2.1 HDQ Mode Features

The HDQ mode supports the following:

- Benchmark HDQ protocol
- Power-down mode

17.4.2.2 Description

In the HDQ mode, there is no need for the host to create an initialization pulse to the slave. However, the host can reset the slave by using an initialization pulse (also known as a break pulse). Setting the **INITIALIZATION** bit **HDQ.HDQ_CTRL_STATUS[2]** creates this pulse by pulling the line down. When the slave receives the pulse, it is ready for communication but does not respond with a presence pulse.

In a typical write operation, two bytes are sent to the slave. The first byte corresponds to the command/address byte, and the second byte corresponds to the data to be written.

In a typical read operation, the host sends a command/address byte and the slave returns a byte of data.

The master is implemented to send and receive bytes. Sending the command/address and data is controlled by the firmware. The master provides only a single data TX register.

The HDQ protocol is a return-to-1 protocol. Consequently, after a byte is sent to the slave (either command/address + data for a write, or just command/address for a read), the host pulls the line up. The line is set to the high-impedance state in the device and an external pullup brings it to a logical high level.

In the case of a read operation, the slave also drives the line to a logic-low state before sending the requested data.

If the host initiates a read and does not receive data within a specified interval of time (that is, the slave does not drive the line low within this interval), the TIMEOUT bit HDQ.HDQ_INT_STATUS[0] is set, thereby indicating a read failure. The TIMEOUT bit remains set until the host reads the interrupt status register (HDQ.HDQ_INT_STATUS).

An interrupt condition indicates either a TX-complete, an RX-complete, or a time-out on a transaction. The corresponding bit is set in the interrupt status register (HDQ.HDQ_INT_STATUS). This register is cleared as soon as it is read.

Only one interrupt signal is sent to the MPU, and only an overall mask can enable or disable the interrupts. These interrupts cannot be individually masked.

17.4.2.3 Single-Bit Mode

In HDQ mode, the single-bit mode (1_WIRE_SINGLE_BIT bit HDQ.HDQ_CTRL_STATUS[7] set to 1) has no effect because the HDQ protocol supports only byte transfers.

17.4.2.4 Interrupt Conditions

The HDQ/1-Wire module provides the following interrupt status:

1. Transmission complete:

A write operation of one byte was completed. Successful or failed completion is not indicated, because there is no acknowledgment from the slave in HDQ protocol. This interrupt condition is cleared by reading the interrupt status register (HDQ.HDQ_INT_STATUS).

2. Read complete:

In HDQ mode, the interrupt status indicates that a byte has been successfully read. This interrupt condition is cleared by reading the interrupt status register (HDQ.HDQ_INT_STATUS).

3. Presence detect/time-out:

In HDQ mode, the interrupt status indicates that after a read command initiated by the host, the slave did not pull the line low within the specified time. This interrupt condition is cleared by reading the interrupt status register (HDQ.HDQ_INT_STATUS).

In HDQ mode, a time-out condition is also used to indicate the successful completion of a break pulse. That is, if the master has sent the break pulse, it is indicated with a time-out instead of a TX-complete.

Only one interrupt is generated to the MPU based on any of these interrupt conditions. A read operation on the interrupt status register clears all the interrupt status bits that were previously set.

17.4.3 1-Wire Mode

17.4.3.1 1-Wire Mode Features

The 1-Wire mode supports the following:

- Dallas Semiconductor 1-Wire protocol
- Power-down mode
- Single-bit mode

17.4.3.2 Description

The 1-Wire mode requires an initialization pulse to be sent to the slave(s) connected on the interface. If a slave is present, it responds with a presence pulse.

The initialization pulse is sent after INITIALIZATION bit HDQ.HDQ_CTRL_STATUS[2] is set. The firmware sends the initialization pulse depending on the value of this bit.

The slave presence on the line is detected by a presence bit in the control and status register. When the slave receives the initialization pulse, it sends back its presence pulse by pulling down the line. The module detects this low-going edge and sets the PRESENCEDETECT bit HDQ.HDQ_CTRL_STATUS[3].

In a similar way, if a presence pulse is not received from the slave after an initialization pulse is sent, the PRESENCEDETECT bit remains cleared.

Whether or not a presence pulse is detected after an initialization pulse is sent, the TIMEOUT bit HDQ.HDQ_INT_STATUS[0] is set and an interrupt condition is generated.

In 1-Wire mode, the generated interrupt condition means the maximum time allowed for receiving the response has elapsed and the software must check the PRESENCEDETECT bit to determine whether or not there was a presence pulse.

The INITIALIZATION bit is cleared at the end of the initialization pulse at the same time as the TIMEOUT bit is set. The TIMEOUT bit is cleared when the interrupt status register (HDQ.HDQ_INT_STATUS) is read.

For read operations, 1-Wire is a bit-by-bit protocol, which means the slave must be clocked by the host for each bit of the byte to read.

The line is pulled up at the end of the command/address byte. On the first read, the host creates a low-going edge to initiate a bit read. The line is then pulled up (pulled to the high-impedance state by the host and set to a high logical level by the external pullup) and the slave either drives the line low to transmit a 0 or does not drive the line to transmit a 1. This sequence is repeated for each bit to read.

The first bit the host receives is the LSB, and the last bit is the most significant bit (MSB) in the receive data register (HDQ.HDQ_RX_DATA).

An interrupt condition indicates either a TX-complete, an RX-complete, or a time-out condition (that is, the time allowed for the slave to indicate its presence has elapsed). A read operation on the interrupt status register clears the interrupt conditions previously set. As in the HDQ mode, only one interrupt signal is sent to the MPU. Only an overall mask bit can enable or disable the interrupt (the interrupt conditions cannot be masked individually).

17.4.3.3 1-Wire Single-Bit Mode Operation

A single-bit mode can be entered by setting the appropriate bit in the control and status register (1_WIRE_SINGLE_BIT bit HDQ.HDQ_CTRL_STATUS[7]). In this mode, only one bit of data at a time is transferred between the master and the slave. After the bit is transferred, an interrupt is generated (that is, there is an RX-complete for a read operation and a TX-complete for a write operation). Bit 0 of the RX register (HDQ.HDQ_RX_DATA) is updated each time a bit is received from the slave; bit 0 of the TX register (HDQ.HDQ_TX_DATA) contains the bit to be sent.

17.4.3.4 Interrupt Conditions

The HDQ/1-Wire module provides the following interrupt status:

1. Transmission complete:
A write operation of one byte was completed. Successful or failed completion is not indicated, because there is no acknowledgment from the slave in 1-Wire protocol. This interrupt condition is cleared by reading the interrupt status register (HDQ.HDQ_INT_STATUS).
2. Read complete:
In 1-Wire mode, the interrupt status indicates that a byte has been successfully read. This interrupt condition is cleared by reading the interrupt status register (HDQ.HDQ_INT_STATUS).
3. Presence detect/time-out:
In 1-Wire mode, the interrupt status indicates that it is now valid to check the PRESENCEDETECT bit. This interrupt condition is cleared by reading the interrupt status register (HDQ.HDQ_INT_STATUS).

Only one interrupt is generated to the MPU based on any of these interrupt conditions. A read operation on the interrupt status register clears all interrupt status bits that were previously set.

17.4.3.5 Status Flags

The presence-condition-detected status flag is contained in the PRESENCEDETECT bit HDQ.HDQ_CTRL_STATUS[3]. This is valid only in 1-Wire mode. The flag is updated when TIMEOUT bit HDQ.HDQ_INT_STATUS[0] is set. Therefore, its correct value shows only after the interrupt is generated. The firmware must wait for the time-out condition; otherwise, the flag keeps its previous value and is undefined.

17.4.4 Module Power Saving

17.4.4.1 Autoidle Mode

The HDQ/1-Wire module provides an autoidle function in its interconnect clock domain.

The interconnect clock autoidle power-saving mode is enabled or disabled through the AUTOIDLE bit HDQ.HDQ_SYSCONFIG[0]. When this mode is enabled and there is no activity on the interconnect interface, the interconnect clock (HDQ_ICLK) is disabled inside the module, thereby reducing power consumption. When there is new activity on the interconnect interface, the interconnect clock is restarted with no latency penalty. This mode is disabled by default after a reset.
