This mode is recommended to reduce power consumption.

17.4.4.2 Power-Down Mode

The HDQ/1-Wire module also provides a power-saving function in its functional clock domain.

Setting the CLOCKENABLE bit in the control and status register (CLOCKENABLE bit HDQ.HDQ_CTRL_STATUS[5]) to 0 shuts off the functional clock (HDQ_FCLK) to the state-machine. The state-machine is reset when the functional clock is disabled; if any transaction is ongoing, it is aborted into the reset state.

The register values are not affected by disabling the functional clock.

Do not access the module registers after the software has put the module in power-down mode except to write to the CLOCKENABLE bit to take the module out of power-down mode.

17.4.5 System Power Management and Wakeup

As part of the system-wide power-management scheme, the HDQ/1-Wire module can go into idle state at the request of the PRCM module (for more information, see , *Power, Reset, and Clock Management*). However, the HDQ/1-Wire module does not support handshake protocol with the PRCM. The HDQ/1-Wire module can go into idle mode only as part of the L4 interconnect clock domain (both CORE_L4_ICLK and FUNC_12M_CLK belong to the L4 interconnect clock domain).

When the AUTO_HDQ bit PRCM.CM_AUTOIDLE1_CORE[22] is set, the HDQ/1-Wire module behavior follows the L4 interconnect clock domain behavior. If the whole domain is put into idle, the HDQ/1-Wire is also put into idle.

Software must ensure correct clock management.

CAUTION

There is no hardware mechanism to prevent cutting off the HDQ/1-Wire clocks while the module is performing a transfer. The result would be a loss of data being transferred.

17.5 HDQ/1-Wire Basic Programming Model

The HDQ/1-Wire module can be considered a simple byte engine because it only implements the hardware interface layer for both HDQ and 1-Wire protocols. The correct sequencing is controlled by the firmware, which is described in this section.

17.5.1 Module Initialization Sequence

17.5.1.1 Mode Selection

MODE bit HDQ.HDQ_CTRL_STATUS[0] allows selection between the HDQ and 1-Wire protocols. When set to 0, the protocol is HDQ; when set to 1, the protocol is 1-Wire. The bit is assumed static for design purposes. The configuration is in HDQ mode by default.

Although this bit can be modified at any point, it is strongly recommended that it be modified only as part of the boot-up configuration.

17.5.1.2 Reset/Initialization

No slave presence test is required in HDQ mode; however, the slave can be reset by setting the INITIALIZATION bit HDQ.HDQ_CTRL_STATUS[2] and the GO bit HDQ.HDQ_CTRL_STATUS[4]. The line is then pulled down (break pulse) and the bit returns to 0 after the pulse is sent. Upon completion, a time-out interrupt is also generated. The slave does not respond to this pulse.

In 1-Wire mode, the slave returns a presence pulse when it receives the initialization pulse. The protocol for initialization is as follows:

1. Set the INITIALIZATION bit HDQ.HDQ_CTRL_STATUS[2] to 1 and the GO bit HDQ.HDQ_CTRL_STATUS[4] to 1 to send the pulse. When the pulse is sent, the bit is cleared in the register.
2. Wait for the presence detect flag (TIMEOUT bit HDQ.HDQ_INT_STATUS[0]) to generate an interrupt. This flag is set when the response time allowed to the slave has elapsed, whether it has sent a pulse or not.
3. Read the HDQ.HDQ_CTRL_STATUS register to check whether the presence pulse has been received before starting any transfer.

17.5.2 HDQ Protocol Basic Programming Model

17.5.2.1 Write Operation

The write operation sequence is as follows:

1. Write the command/address or data value to the TX write register (HDQ.HDQ_TX_DATA).

NOTE: Steps 2 and 3 can be performed simultaneously.

2. Set DIR bit HDQ.HDQ_CTRL_STATUS[1] to indicate a write.
3. Set GO bit HDQ.HDQ_CTRL_STATUS[4] to start the transmission.
 - (a) The hardware sends the byte from the TX write register.
 - (b) In a write operation, the TIMEOUT bit is always cleared, because there is no acknowledge mechanism from the slave.
 - (c) When the write operation is completed, the TX-complete flag is set in the interrupt status register (TXCOMPLETE bit HDQ.HDQ_INT_STATUS[2]). If interrupts are masked (that is, the corresponding bit has been previously set in the control and status register), no interrupt signal is generated.
 - (d) The GO bit HDQ.HDQ_CTRL_STATUS[4] is cleared at the end of a write operation.
4. The software must read the interrupt status register to clear the interrupt.
5. Repeat step 1 through step 4 for each successive byte to write.

17.5.2.2 Read Operation

The read operation sequence is as follows:

1. Write the command value to the TX write register (HDQ.HDQ_TX_DATA).
2. Set DIR bit HDQ.HDQ_CTRL_STATUS[1] to 0 and GO bit HDQ.HDQ_CTRL_STATUS[4] to 1 and wait for the TX-complete interrupt.

NOTE: Steps 3 and 4 can be performed simultaneously.

3. Set DIR bit HDQ.HDQ_CTRL_STATUS[1] to 1 to indicate a read.
4. Write 1 to GO bit HDQ.HDQ_CTRL_STATUS[4] to initiate the read.
 - (a) The hardware detects a low-going edge on the line (generated by the slave) and receives 8 bits of data in the RX receive buffer register (HDQ.HDQ_RX_DATA). The first bit received is the LSB and the last bit is the MSB. The master performs this step as soon as the slave sends the data, irrespective of the state of GO bit HDQ.HDQ_CTRL_STATUS[4]. However, an RX-complete interrupt is generated only when the software writes the GO bit.
 - (b) If a time-out occurs, the TIMEOUT bit HDQ.HDQ_CTRL_STATUS[0] is set.
 - (c) Completion of the operation is indicated by setting the RX-complete flag in the interrupt status register (RXCOMPLETE bit HDQ.HDQ_INT_STATUS[1]. If interrupts are masked (that is, the corresponding bit was previously set in the control and status register), no interrupt signal is generated.
 - (d) At the end of the read operation, the GO bit HDQ.HDQ_CTRL_STATUS[4] is cleared. It is also cleared if a time-out is detected
5. The software must read the interrupt status register (HDQ.HDQ_INT_STATUS) to determine whether an RX was successfully completed or a time-out occurred.
6. The software reads the RX receive buffer register (HDQ.HDQ_RX_DATA) to retrieve the read data from the slave.
7. Repeat step 1 through step 6 for each successive byte.

NOTE: In HDQ mode, the address/command is written only once to the slave. However, after the first byte is received, an RX-complete interrupt is set. Therefore, the software must initiate the read of the second byte by setting the GO bit in the control and status register. The first byte received is shadowed and provided to the software while the hardware is fetching the second byte of data.

17.5.3 1-Wire Mode (SDQ) Basic Programming Model

17.5.3.1 Write Operation

The write operation sequence is as follows:

1. Write the ID, command, or data value to the TX write register (HDQ.HDQ_TX_DATA).

NOTE: Steps 2 and 3 can be performed simultaneously.

2. Set DIR bit HDQ.HDQ_CTRL_STATUS[1] to 0 to indicate a write operation.
3. Set GO bit HDQ.HDQ_CTRL_STATUS[4] to 1 to start the transmission.
 - (a) The hardware sends the byte stored in the TX write register.
 - (b) In a write operation, the TIMEOUT bit is always cleared.
 - (c) When the operation is completed, the TX-complete flag is set in the interrupt status register (TXCOMPLETE bit HDQ.HDQ_INT_STATUS [2]). No interrupt signal is generated if interrupts are masked (that is, the corresponding bit was previously set in the control and status register).
 - (d) The GO bit of the control and status register is cleared at the end of a write operation.
4. The software must read the interrupt status register (HDQ.HDQ_INT_STATUS) to clear the interrupt.
5. Repeat step 1 through step 4 for each successive byte to write.

17.5.3.2 Read Operation

The read operation sequence is as follows:

1. Write the address to the TX write register (HDQ.HDQ_TX_DATA).
2. Set DIR bit HDQ.HDQ_CTRL_STATUS[1] to 0 and the GO bit HDQ.HDQ_CTRL_STATUS[4] to 1 and wait for the TX-complete interrupt flag.
3. Write the command value to the TX write register (HDQ.HDQ_TX_DATA).
4. Set DIR bit HDQ.HDQ_CTRL_STATUS[1] to 0 and GO bit HDQ.HDQ_CTRL_STATUS[4] to 1 and wait for the TX-complete interrupt flag.

NOTE: Steps 5 and 6 can be performed simultaneously.

5. Set DIR bit HDQ.HDQ_CTRL_STATUS[1] to 1 to indicate a read.
6. Set GO bit HDQ.HDQ_CTRL_STATUS[4] to 1 to start the transmission.
 - (a) The hardware (master) generates a low-going edge and clocks 8 bits of data into the RX receive register (HDQ.HDQ_RX_DATA). The first bit received is the LSB and the last bit is the MSB.
 - (b) TIMEOUT bit HDQ.HDQ_INT_STATUS[0] is always cleared in a read operation.
 - (c) When the operation is complete, the RX-complete flag is set in the interrupt status register (RXCOMPLETE bit HDQ.HDQ_INT_STATUS[1]). No interrupt signal is generated if the interrupts are masked (that is, the corresponding bit was previously set in the control and status register).
 - (d) GO bit HDQ.HDQ_CTRL_STATUS[4] is cleared at the end of the read. It is also cleared if a time-out occurs.
7. The software must read the interrupt status register to determine whether an RX was successfully completed or a time-out occurred.
8. The software reads the RX receive buffer register (HDQ.HDQ_RX_DATA) to retrieve the read data from the slave.
9. Repeat step 1 through step 8 for each successive byte.

17.5.3.3 1-Wire Bit Mode Operation

Select the single-bit mode by setting the 1_WIRE_SINGLE_BIT bit HDQ.HDQ_CTRL_STATUS[7] to 1. In this mode, only one bit of data at a time is transferred between the master and the slave. After the bit is transferred, the corresponding interrupt flag is set (that is, there is an RX-complete (RXCOMPLETE bit HDQ.HDQ_INT_STATUS[1]) for a read operation and a TX-complete (TXCOMPLETE bit HDQ.HDQ_INT_STATUS[2]) for a write operation). Bit 0 of the RX register (HDQ.HDQ_RX_DATA) is updated each time a bit is received; bit 0 of the TX register (HDQ.HDQ_TX_DATA) contains the bit of data to be sent.

17.5.4 Power Management

The software has independent control of the two clock domains (interconnect clock: HDQ_ICLK and functional clock: HDQ_FCLK). Because there is no acknowledge mechanism from the HDQ/1-Wire module to an idle request, the software must ensure that a clock is not shut off while a transfer is being processed (the data would be lost).

If the autoidle function (AUTOIDLE bit HDQ.HDQ_SYSCONFIG[0] set to 1) provides a safe transfer (the module wakes up the HDQ_ICLK as soon as a transfer is initiated), the power-down mode and the PRCM idle requests (through the whole L4 clock domain idle request) must be handled carefully.

The following sections describe the steps to follow to use the power-down and idle modes.

17.5.4.1 Module Power-Down Mode

1. Before shutting off the HDQ_FCLK, wait for an RX-complete or a TX-complete interrupt.
 - In a read operation, the transfer is completed when the RX-complete flag (RXCOMPLETE bit HDQ.HDQ_INT_STATUS [1]) generates an interrupt.
 - In a write operation, the transfer is completed when the TX-complete flag (TXCOMPLETE bit HDQ.HDQ_INT_STATUS [2]) generates an interrupt. The software must check whether the interrupt was generated after the address/command byte was sent or after the data byte was sent.

The clock must not be shut off after the command/ address byte is sent; otherwise, the data is not written to the slave.

HDQ.HDQ_INT_STATUS must be read to clear the interrupt condition.

2. Set the CLOCKENABLE bit HDQ.HDQ_CTRL_STATUS[5] to 0 to disable the clock.

Do not access the module registers after the software has put the module into power-down mode except to write to the clock-enable bit to take the module out of power-down mode.

17.5.4.2 System Idle Mode

This section describes the steps to follow at the module level before enabling the idle mode at the system level (for more information about the system power management scheme, see , *Power, Reset, and Clock Management*).

As part of the L4 interconnect clock domain, the HDQ/1-Wire clocks can be cut at the PRCM level. HDQ_FCLK can be cut if the EN_HDQ bit PRCM.CM_FCLKEN1_CORE [22] is set to 0 and no other modules require CORE_12M_FCLK. The software must verify that no transfer is in progress.

In a read operation:

1. Wait for an RX-complete interrupt.

In a read operation, the transfer is completed when the RX-complete flag (RXCOMPLETE bit HDQ.HDQ_INT_STATUS [1]) generates an interrupt.

2. Read the HDQ.HDQ_INT_STATUS to clear the read-complete interrupt flag.
3. Read the HDQ.HDQ_RX_DATA to retrieve the read data.
4. The HDQ_ICLK can be shut off by entering the system idle mode.

In a write operation:

1. Wait for a TX-complete interrupt.

In a write operation, the transfer is completed when the TX-complete flag (TXCOMPLETE bit HDQ.HDQ_INT_STATUS[2]) generates an interrupt. The software must check whether the interrupt was generated after the address/command byte was sent or after the data byte was sent. The clock must not be shut off after the command/address byte is sent; otherwise, the data is not written to the slave.

2. Read the HDQ.HDQ_INT_STATUS to clear the TX-complete interrupt flag.
3. The HDQ_ICLK can be shut off by entering the system idle mode.

Concerning HDQ_ICLK, two situations can occur:

- The clock is no longer required and EN_HDQ bit PRCM.CM_ICLKEN1_CORE[22] is set by software. In this case, the clock is cut off, provided no other modules require it. Before setting the EN_HDQ bit, the software must follow the steps described in this section.
- AUTO_HDQ bit PRCM.CM_AUTOIDLE1_CORE[22] is set. In this case, the software must verify that all HDQ/1-Wire transfers are complete before enabling the L4 interconnect clock domain idle mode. Otherwise, the HDQ/1-Wire has no way to prevent the clock from being cut, because no hardware mechanism exists. The steps listed in this section must be verified before putting the L4 clock domain into idle state.

17.6 HDQ/1-Wire Use Cases and Tips

17.6.1 How to Configure the HDQ/1-Wire when Connected with a BQ27000 Gauge

17.6.1.1 Environment

Figure 17-10 details the OMAP device connections with the BQ27000 gauge.

Figure 17-10. Environment

17.6.1.2 Programming Flow

This section details the programming flow of the HDQ/1-Wire. [Figure 17-11](#) shows the main steps of this configuration. The BQ27000 gauge uses the HDQ mode.

Figure 17-11. HDQ/1-Wire Configuration in HDQ Mode

17.6.1.3 Pad Configuration and HDQ/1-Wire Clock and Power Management

[Table 17-3](#) shows the pad multiplexing and the clock and power management configuration to select for the HDQ/1-Wire module.

Table 17-3. Registers Print for HDQ/1-Wire Configuration

| Register Name | Address | Value | Value description |
|--------------------------------------|--------------|-------------|--|
| SCM.CONTROL_PA DCONF_I2C3_SDA | 0x 4800 21C4 | 0x0118 0100 | Configure hdq_sio pad in mode 0 |
| PRCM.CM_FCLKEN 1_CORE | 0x4800 4A00 | 0x0020 0000 | Enable HDQ/1-Wire Functional clock |
| PRCM.CM_ICLKEN 1_CORE | 0x4800 4A10 | 0x0020 0000 | Enable HDQ/1-Wire Interface clock |
| HDQ_CTRL_STATU S | 0x480B 200C | 0x0000 0020 | Enable clocks and select the HDQ mode |
| HDQ_SYSCONFIG | 0x480B 2014 | 0x0000 0000 | Module clock is free-running (Disable autoidle mode) |

17.6.1.4 HDQ/1-Wire Software Reset

Perform a software reset as described in [Figure 17-12](#).

Figure 17-12. Software Reset Flowchart

hdq1wr-013

[Table 17-4](#) describes the registers to be configured for the HDQ/1-Wire software reset step.

Table 17-4. Registers Print for HDQ/1-Wire Software Reset

| Register Name | Address | Value | Value description |
|-------------------------------|-------------|-------------|---|
| HDQ_SYSCONFIG | 0x480B 2014 | 0x0000 0002 | Initiate a software reset. The HDQ_SYSCONFIG[1] SOFTRESET is automatically reset by hardware. |
| HDQ_SYSSTATUS | 0x480B 2018 | 0x0000 0001 | The HDQ_SYSSTATUS[0] RESETDONE is set to 1 when the reset sequence is done. |

17.6.1.5 Interrupts Enable

[Table 17-5](#) describes the registers to be configured for the interrupts enable step and the use case values.

Table 17-5. Registers Print for HDQ/1-Wire Interrupts Enable

| Register Name | Address | Value | Value description |
|--------------------------------------|-------------|-------------|-------------------|
| HDQ_CTRL_STATU S | 0x480B 200C | 0x0000 0060 | Enable Interrupts |

17.6.1.6 Read and Write Operations

The Read and Write operations in HDQ mode are described in [Section 17.5.2](#). Please, refer to this section to see how HDQ/1-Wire registers are configured for these operations.

Some write operations are needed to configure the BQ27000 gauge: for example, it is necessary to write a COMMAND KEY (0xA9 or 0x56) in the Device Control Register of the gauge. For more information, see the TI BQ27000 gauge specification.

17.7 HDQ/1-Wire Register Manual

17.7.1 HDQ/1-Wire Instance Summary

Table 17-6 lists the HDQ/1-Wire instances.

Table 17-6. Instance Summary

| Module Name | Base Address | Size |
|-------------|--------------|----------|
| HDQ/1-Wire | 0x480B 2000 | 4K bytes |

CAUTION

All reserved bits must be written with 0. There is no synchronization between the register clock domain and the state-machine domain. Therefore, the following rules must be observed when accessing the module registers:

- A read from the interrupt status register or the receive buffer register is not allowed unless the processor has been interrupted by the module.
- After the release of the GO bit in the control and status register, no access to the TX data register or the control and status register is allowed until the processor has been interrupted by the module.
- Polling of the interrupt status register by software to determine whether an interrupt was generated is not allowed.
- No access to the module registers should be done after the software puts the module in power-down mode (by setting bit 5 of the control and status register to 0) except to re-enable the clock.

CAUTION

The HDQ/1-Wire registers are limited to 32-bit data accesses. 16-bit and 8-bit are not allowed and can corrupt register content.

17.7.2 HDQ/1-Wire Register Mapping Summary

Table 17-7 lists the HDQ/1-Wire registers.

Table 17-7. HDQ/1-Wire Register Summary

| Register Name | Type | Register Width (Bits) | Address Offset | HDQ/1-Wire Physical Address |
|-----------------|------|-----------------------|----------------|-----------------------------|
| HDQ_REVISION | R | 32 | 0x000 | 0x480B2000 |
| HDQ_TX_DATA | RW | 32 | 0x004 | 0x480B2004 |
| HDQ_RX_DATA | R | 32 | 0x008 | 0x480B2008 |

Multi-Channel Buffered Serial Port

This chapter introduces the Multi-Channel Buffered Serial Port (McBSP).

NOTE: Some features may not be available or supported in your particular device. For more information, see Chapter 1, the Device Family section, and your device-specific data manual.

| Topic | Page |
|--|------|
| 18.1 McBSP Overview | 1980 |
| 18.2 McBSP Environment | 1983 |
| 18.3 McBSP Integration | 1992 |
| 18.4 McBSP Functional Description | 2013 |
| 18.5 McBSP Basic Programming Model | 2048 |
| 18.6 McBSP Register Manual | 2076 |

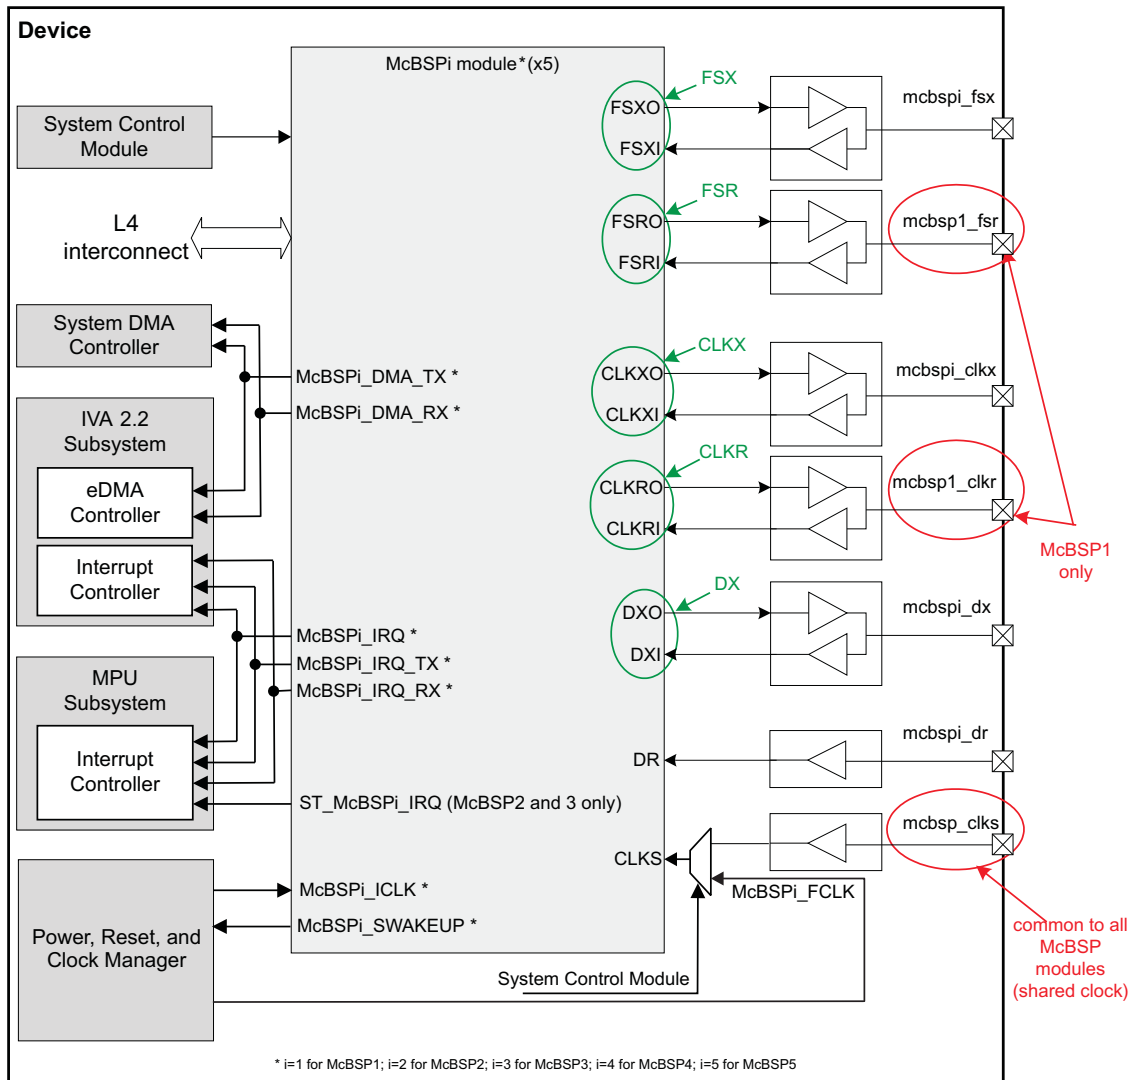

18.1 McBSP Overview

The multichannel buffered serial port provides a full-duplex direct serial interface between the device and other devices in a system such as other application chips (digital base band), audio and voice codec (power management device), etc. Because of its high level of versatility, it can accommodate to a wide range of peripherals and clocked frame oriented protocols (for details, see [Section 18.1.1](#)).

The device provides five instances of the McBSP module.

Figure 18-1 shows the McBSP overview in the device.

Figure 18-1. McBSP Highlight

001

18.1.1 McBSP Features

The main features of the McBSP modules are:

- L4 interconnect slave interface supports:
 - 32-bit data bus width
 - 32-bit access supported
 - 16- /8-bit access supported only by data registers
 - 10-bit address bus width
 - Burst mode not supported

- Write nonposted transaction mode supported
- 128 × 32-bit words (512 bytes) for each buffer for transmit/receive operations (McBSP1, 3, 4, 5)
- 5K bytes (1024 × 32 bits for audio buffer + 256 × 32 bits for buffer) for each buffer for transmit/receive audio operations (McBSP2 only)
- Interrupts configurable in legacy mode (2 requests) or PRCM compliant (1 request)
- Transmit and receive DMA requests triggered with programmable FIFO thresholds
- SIDETONE core support: Audio loopback capability (McBSP2 and 3 only)
- Multidrop support
- Serial interface description
 - 6 pin configuration (McBSP 1 only)
 - 4 pin configuration (McBSP2, 3, 4, 5)
 - Full-duplex communication
 - Multichannel selection modes
 - Support to enable or block transfers in each of the channels
 - 128 channels for transmission and for reception
 - Direct interface to industry-standard codecs, analog interface chips (AICs), and other serially connected A/D and D/A devices:
 - Inter-IC sound (I2S) compliant devices
 - Pulse code modulation (PCM) devices
 - Time division multiplexed (TDM) bus devices

CAUTION

McBSP modules do not offer support for μ -law and A-law companding, two partitions mode dynamic reassignment, AC'97, and SPI protocol.

- A wide selection of data sizes: 8, 12, 16, 20, 24, and 32 bits
- Bit reordering (send/receive least significant bit [LSB])
- Clock and frame-synchronization generation support:
 - Independent clocking and framing for reception and for transmission up to 48 MHz
 - Support for external generation of clock signals and frame-synchronization (frame-sync) signals
 - A programmable sample rate generator for internal generation and control of clock signals and frame-sync signals
 - Programmable polarity for frame-sync pulses and for clock signals

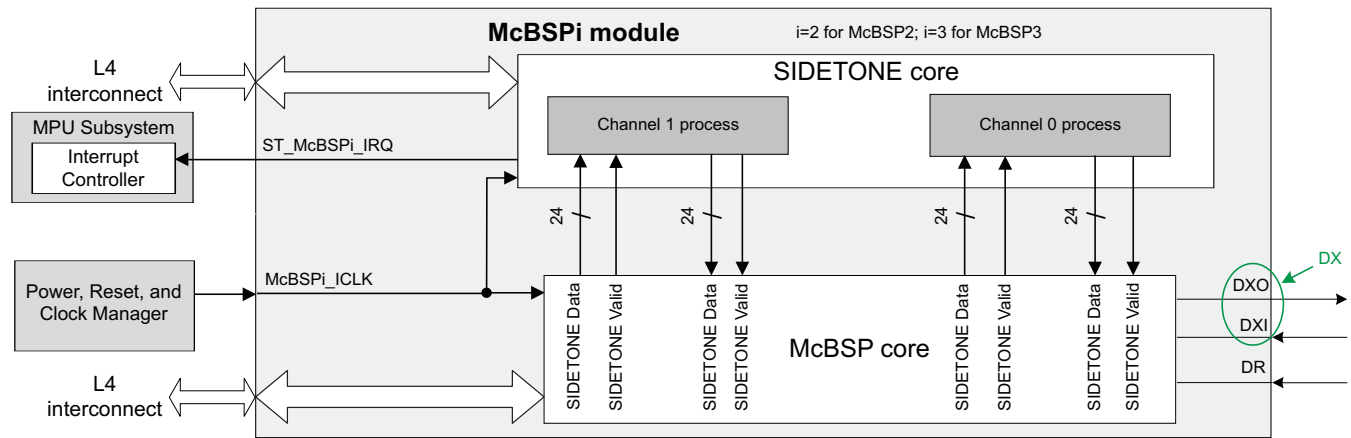

NOTE:

- McBSP modules do not support features such as re-transmit or re-receive of an erroneous frame or word.
- McBSP modules support dual phase frames to provide I2S fully compliant capabilities. But, this dual phase mode is limited at one channel (or word) for each phase instead of 128 channels max for single phase mode.

18.1.2 SIDETONE Core

The purpose of this section is to present the SIDETONE core implemented in McBSP2 and 3 modules. It is required that two of the audio input channels to be looped back, filtered, and mixed to the two corresponding audio output channels.

Data to be processed comes on two separate paths (one for each channel) through a simple interface. After filtering the data, gain is applied and outputted through a similar interface. For more details, see [Figure 18-2](#).

Figure 18-2. SIDETONE Core Architecture

002

The SIDETONE core offers the following features:

- Filter coefficients are shared between the two channels (the filter coefficient is assumed to represent values in the range $-1...+1$)
- Gains are independent for the two channels (the gain coefficients are in the range $-2...+2$)
- The filter output is multiplied with the gain, and the result is rounded to output channel word width.
- The FIR filter length is 128 samples.
- Filtered loop back signals are added to the corresponding output signals, and saturation is applied if the result exceeds arithmetic range.
- Filter coefficients and gains are programmable:
 - Coefficients are changed while audio is stopped.
 - Gains are changed at any time (also during audio operation with SIDETONE enabled).

18.2 McBSP Environment

This section describes the intended functions for McBSP module from an environment point of view (that is, external connections). It presents the McBSP connectivity options, lists the possible interfaces, and details the protocol and data format used in each case.

18.2.1 McBSP Functions

The device provides five instances of the McBSP module, called McBSP1, McBSP2, McBSP3, McBSP4, and McBSP5.

List of recommended usage (non exhaustive) per McBSP modules in the device:

- McBSP1: Digital baseband (DBB) Data
- McBSP2: Audio data with audio buffer and SIDETONE feature
- McBSP3: Bluetooth voice data with SIDETONE feature
- McBSP4: DBB voice data
- McBSP5: Midi data

Table 18-1 describes the functions and the corresponding application fields.

Table 18-1. Functions Description

| Function | Application field | Recommended McBSP module | Description |
|------------------|---|--------------------------|---|
| Control and Data | Digital Base Band (DBB) Data | McBSP1 | Serial interface to transfer data |
| Audio Data | Audio Data with Audio Buffer | McBSP2 | Audio interface to transfer audio data with Inter-IC Sound codec (I2S) |
| | Audio Data with Audio Buffer and SIDETONE feature | | |
| | Midi Data | McBSP5 | |
| Voice Data | Bluetooth Voice Data | McBSP3 | Voice interface to transfer voice data with Pulse Code Modulation codec (PCM) |
| | Bluetooth Voice Data with SIDETONE feature | | |
| | DBB Voice Data | McBSP4 | |

18.2.2 McBSP Signals Descriptions

The five McBSP modules consist of a data-flow path and a control path connected to external devices by a serial interface with 6 pins configuration (McBSP 1 only) or 4 pins configuration (McBSP2, 3, 4, 5).

For a McBSP module with 6 pins configuration, an internal loop back capability between Transmitter and Receiver clock signals, and both frame synchronization signals enables using the McBSP module with 4 pins configuration. The related internal multiplexers are controlled through the System Control Module on the device (see [Section 18.3](#)).

Table 18-2. Input/Output Description

| Pin Name ⁽¹⁾ | I/O ⁽²⁾ | Description | Internal Signal Name | Reset Value | Control and Data | Audio Data | Voice Data |
|-------------------------|--------------------|---|----------------------|-------------|------------------|------------|------------|
| mcbasp_clks | I | External clock (shared by all McBSP modules) | CLKS | - | ✓ | ✓ | ✓ |
| mcbspi_dr | I | Receive serial data | DR | - | ✓ | ✓ | ✓ |
| mcbspi_dx | I/O ⁽³⁾ | Transmit serial data | DX | 0 | ✓ | ✓ | ✓ |
| mcbspi_clkx | I/O ⁽³⁾ | Transmit clock ⁽⁴⁾ | CLKX | 0 | ✓ | ✓ | ✓ |
| mcbspi_fsx | I/O ⁽³⁾ | Transmit frame synchronization ⁽⁵⁾ | FSX | 0 | ✓ | ✓ | ✓ |
| mcbasp1_clkr | I/O ⁽³⁾ | Receive clock ⁽⁶⁾ | CLKR | 1 | ✓ | | |
| mcbasp1_fsr | I/O ⁽³⁾ | Receive frame synchronization ⁽⁷⁾ | FSR | 0 | ✓ | | |

⁽¹⁾ I = 1 to 5

⁽²⁾ I = Input; O = Output

⁽³⁾ For details of the input/output selection, see [Section 18.2.3.1](#).

⁽⁴⁾ This signal is also used as CLKR when it is configured as output.

⁽⁵⁾ This signal is also used as FSR when it is configured as output.

⁽⁶⁾ This signal is also used as CLKX when it is configured as input.

⁽⁷⁾ This signal is also used as FSX when it is configured as input.

- The mcbasp_clks pin can be used to inject an external clock. This clock is used to generate control signals depending on the module internal configuration (see [Section 18.4.3](#)). The CLKS signal of the McBSP modules is linked to an external signal through the mcbasp_clks pin, but the CLKS signal can also be linked to an internal clock provided by PRCM of the device. For more information, see [Section 18.3](#).
- Data are transmitted to external devices interfacing with McBSP modules via the mcbspi_dx pin. Data from those devices are received on the mcbspi_dr pin.

NOTE: The mcbspi_dx pin is an input/output signal to use the McBSP module in half-duplex mode.

- Control information is communicated via the following pins: mcbspi_clkx (transmit clock), mcbasp1_clkr (receive clock), mcbspi_fsx (transmit frame-sync), and mcbasp1_fsr (receive frame-sync).

CAUTION

External pins mcbasp1_clkr and mcbasp1_fsr are connected to pads only for McBSP1 module; other McBSP modules don't have these connections. For these modules, CLKR and FSR signals sources are mcbspi_clkx and mcbspi_fsx pins, respectively. Consequently, there is a light restriction on other McBSP modules when used in full-duplex mode. Both reception and transmission use the same clock signal and the same frame synchronization signal.

18.2.3 McBSP Functions Description

18.2.3.1 McBSP Modes

For all McBSP functions, McBSP modules can operate in master or slave mode. The difference between these modes is the definition of the source of McBSP clocks and McBSP frames synchronization:

- Master mode: McBSP module provides them to the external device

- Slave mode: McBSP module receives them from the external device

The choice between the two modes depends of technical data of the external device and the type of interface (protocols and data formats). For one McBSP module, there are four possible functions:

1. Transmit and receive master mode
2. Transmit and receive slave mode
3. Transmit master mode and receive slave mode
4. Transmit slave mode and receive master mode

NOTE: If the McBSP module has a serial interface with 4 pins configuration (McBSP2, 3, 4, 5), only modes 1 or 2 are possible.

Figure 18-3 shows the connection between the McBSP1 module (6 pins configuration) and an external device in transmit master mode and receive slave mode.

Figure 18-3. Mode Overview of McBSP1 Module

Figure 18-4 shows the connection between the McBSPi module, with I = 2, 3, 4 or 5 (4 pins configuration) and an external device in transmit and receive master mode.

Figure 18-4. Mode Overview of McBSPi Module

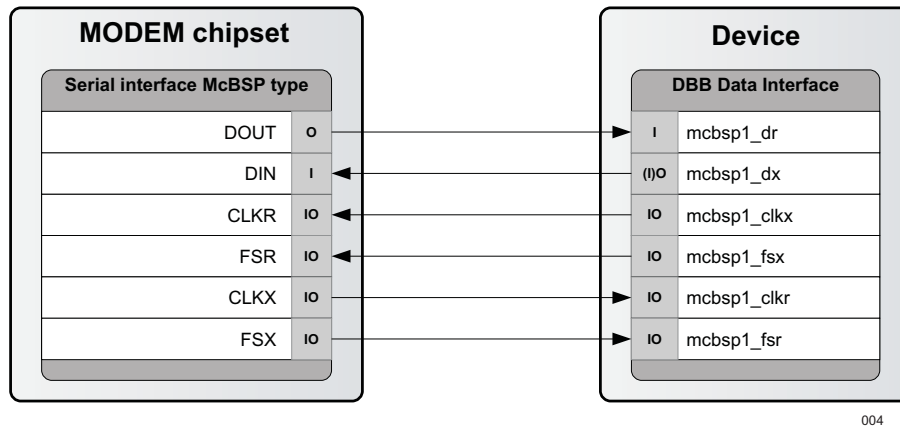

18.2.3.2 McBSP Functions

18.2.3.2.1 McBSP Function 1: Control and Data

In full-duplex mode (reception and transmission use independent clock signals and frame synchronization signals), the McBSP module can be used to exchange control and data with an external chipset, allowing the device to be interfaced with a modem device. Figure 18-5 shows typical connections between device and modem chipset to illustrate DBB data application.

Figure 18-5. DBB Data Application

In Figure 18-5, the McBSP1 module is configured in transmit master mode and in receive slave mode.

18.2.3.2.2 McBSP Function 2: Audio Data

The McBSP module is connected to audio devices through the I2S interface. The I2S link serial interface is a TDM slot based serial interface that is used to transfer audio data. Those audio devices can be either AICs or other serially connected A/D and D/A devices.

Figure 18-6 shows typical connections between device and a typical device of analog audio interface (power management device) to illustrate Audio Data application. The typical device contains several audio analog inputs and outputs, as well as digital microphone inputs.

Figure 18-6. Audio Data Application

In Figure 18-6, the McBSP2 module is configured in transmit and receive master mode.

18.2.3.2.3 McBSP Function 3: Voice Data

The McBSP module is connected to a voice device through the PCM interface. The PCM link serial interface is a TDM slot based serial interface that is used to transfer voice data. The voice devices can be either modem chipsets, Bluetooth chipsets or others devices with voice data interface.

Figure 18-7 shows typical connections between device and Bluetooth chipset (TI BRF6300 or TI BRF6350) to illustrate voice data application.

Figure 18-7. Voice Data Application

In Figure 18-7, the McBSP3 module is configured in transmit and receive master mode.

18.2.4 McBSP Protocols and Data Formats

The McBSP module can use one of the three protocols with associated data formats:

- Serial protocol to exchange serial data
- Audio protocol to exchange the audio samples
- Voice protocol to exchange the voice samples

The McBSP modules offer the flexibility to modify the following parameters to adapt to the device features as described in the following subsections.

18.2.4.1 Words, Frames, and Phases Definitions

18.2.4.1.1 Words or Channels

The data bits are transferred (transmission or reception) in a group called a serial word or channel. The number of bits in a word (length) is programmable via bits field (McBSPi.MCBSPLP_RCR1_REG[7:5] RWDLEN1 field and McBSPi.MCBSPLP_RCR2_REG[7:5] RWDLEN2 field, McBSPi.MCBSPLP_XCR1_REG[7:5] XWDLEN1 field and McBSPi.MCBSPLP_XCR2_REG[7:5] XWDLEN2 field) and can be 8, 12, 16, 20, 24 or 32 bits (see Section 18.4.2.3). The McBSP module uses clock signals to control the time for each bit transfer. Data are sampled/driven on rising or falling edge of clock signals. This clock polarity is programmable via bits field of pin-control register (McBSPi.MCBSPLP_PCR_REG).

For more information, see Section 18.4.2.4.

18.2.4.1.2 Frames

One or more words (max 128) are transferred in a group called a frame. The McBSP module can transmit / receive a maximum of 128 words per frame, programmable via bits field of transmit and receive control registers (McBSPi.MCBSPLP_XCR1_REG/McBSPi.MCBSPLP_XCR2_REG and McBSPi.MCBSPLP_RCR1_REG/McBSPi.MCBSPLP_RCR2_REG). For more details, see Section 18.4.2.3.

All the words in a frame are sent in a continuous stream. However, there can be pauses between frame transfers. The McBSP module uses frame-synchronization signals to determine when each frame is received/transmitted. When a pulse occurs on a frame-synchronization signal, the McBSP module begins receiving/transmitting a frame of data. When the next pulse occurs, the McBSP module receives/transmits the next frame, and so on. Frame-synchronization pulse is active high or low. This pulse polarity is programmable via bits field of pin-control register (McBSPi.MCBSPLP_PCR_REG).

Each frame transfer can be delayed by 0, 1, or 2 clock cycles, depending on the value of bits for transmit and receive control registers (McBSPi.MCBSPLP_XCR2_REG and McBSPi.MCBSPLP_RCR2_REG). For more information, see Section 18.4.4.6.3 and Section 18.4.4.3.3.

18.2.4.1.3 Phases

The McBSP module allows configuring each frame to contain one or two phases. The McBSP module supports dual phase frames to provide I2S fully compliant capabilities. These two phases represent left and right channels of audio stereo signals.

The limitation on dual phase frame is that the number of words per phase must be set to one for both first and second phase. But, the number of bits per word can be specified differently for each of the two phases of a frame, allowing greater flexibility in structuring data transfers.

For example, software may define a frame composed of a first phase with one 12-bit word and a second phase with one 16-bit word. This configuration allows the software to compose frames for custom applications. For more details, see [Section 18.4.2.4](#).

[Figure 18-8](#) shows signal activity for two possible reception/transmission scenarios.

Figure 18-8. McBSP Reception/Transmission Signal Activity

18.2.4.2 Serial Protocol and Data Formats

18.2.4.2.1 Protocol

The serial protocol is used to send and receive control data without specific formats. This allows McBSP module to accommodate all serial devices and their protocols.

18.2.4.2.2 Data Format

[Figure 18-9](#) shows typical operation of the McBSP clock and frame sync signals. Serial clocks CLKR and CLKX define the boundaries between bits for receive and transmit, respectively. Similarly, frame-sync signals FSR and FSX define the beginning of an element and/or frame transfer. The McBSP module allows the configuration of the following parameters for data and frame synchronization:

- Polarity of FSR, FSX, CLKX, and CLKR
- The number of words per frame
- The number of bits per word
- Whether subsequent frame synchronization restarts the serial data stream or is ignored
- The data delay from frame synchronization to first data bit which can be 0-, 1-, or 2-bit delays

The configuration is independent for receive and transmit parts. For more details and configuration examples, see [Section 18.4](#) and [Section 18.5](#).

Figure 18-9. Serial Data Formats

009

18.2.4.3 Audio Protocol and Data Formats

18.2.4.3.1 Protocol

The I2S protocol is used to send and receive audio data from 8 KHz up to 48 KHz sampling rate (frame-sync frequency), with 16 bits or 32 bits per words (Supported frequencies are 8, 11.025, 12, 16, 22.05, 24, 32, 44.1 and 48 KHz).

The frame-synchronization signal defines the frame length in the I2S protocol. Each frame consists of a fixed number of words. In dual-phase frame, the frame-synchronization signal is low for the left phase time slot and is high for the right phase time slot. In addition, the frame-synchronization signal is synchronous to the falling edge of the clock signal.

18.2.4.3.2 Data Formats

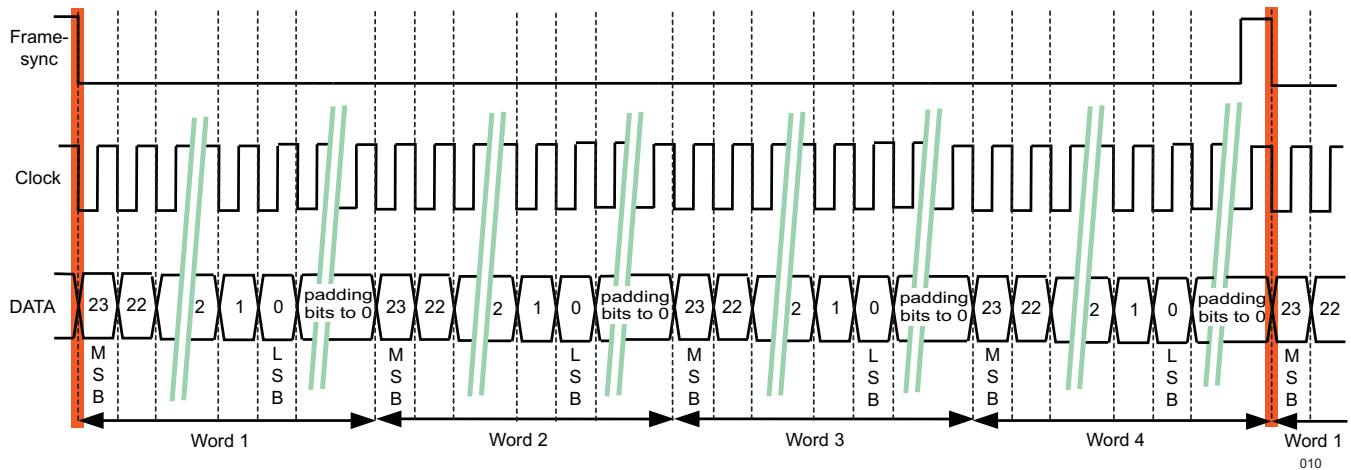

The I2S protocol supports TDM, I2S, left justified, and right justified data formats.

Bits of each word (sample) are clocked using clock signal. For each word, MSB is first. LSBs are padded to 0 when the data length (8, 12, 16, 20, or 24 bits) is less than the sample word width (16 or 32 bits).

18.2.4.3.2.1 TDM Data Format

Figure 18-10 shows that each frame of TDM data format is composed of four words (or channels).

Figure 18-10. TDM Data Format; Word Width: 32 Bits; Data Length: 24 Bits

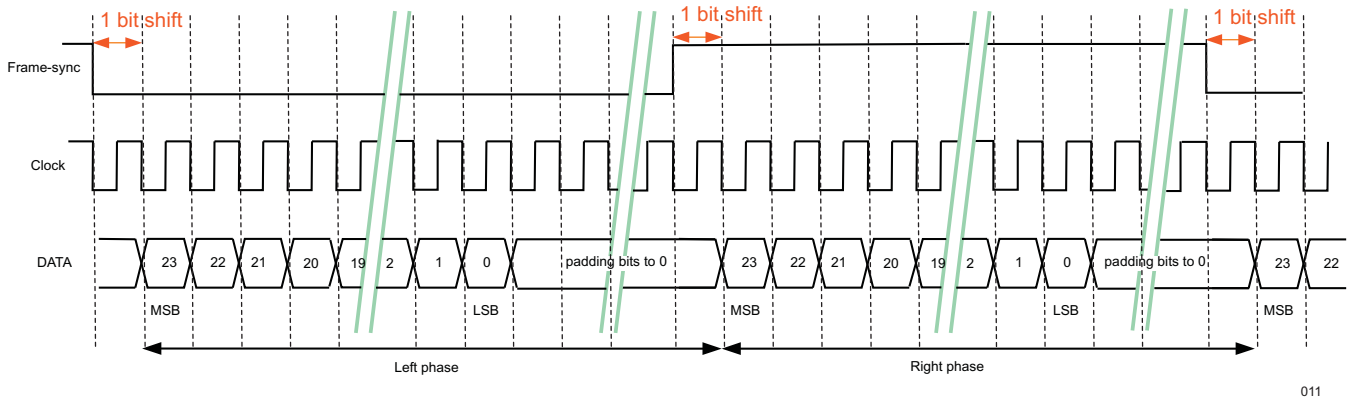

010

18.2.4.3.2.2 I2S Data Format

Figure 18-11 shows an example with 24 bits data (MSB first) and 8 padding bits at '0'.

Figure 18-11. I2S Data Format; Word Width: 32 Bits; Data Length: 24 Bits

18.2.4.3.2.3 Left Justified Data Format

Figure 18-12 shows an example with 24 bits data (MSB first) and 8 padding bits at '0'.

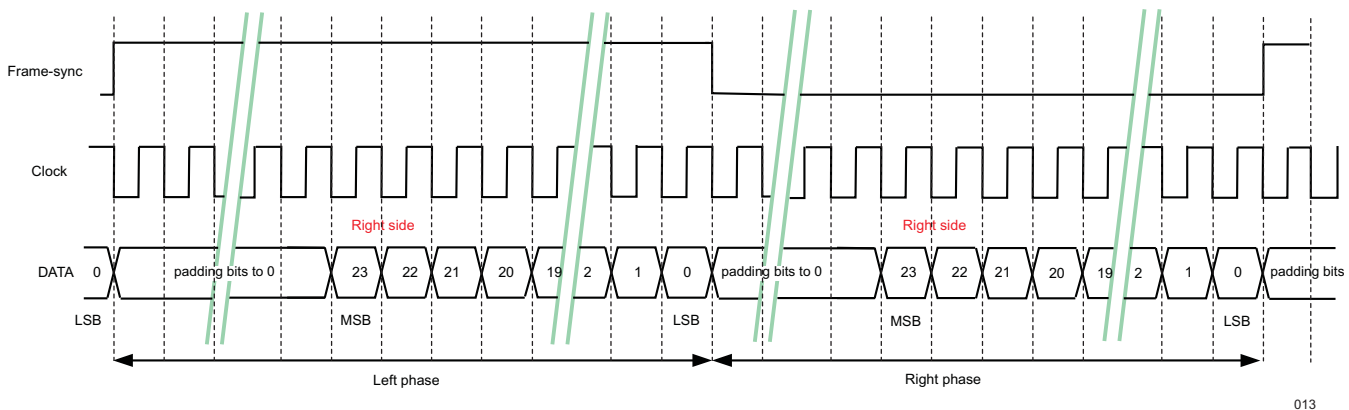

Figure 18-12. Left Justified Data Format; Word Width: 32 Bits; Data Length: 24 Bits

18.2.4.3.2.4 Right Justified Data Format

Figure 18-13 shows an example with 8 padding bits at '0' and 24 bits data (MSB first).

Figure 18-13. Right Justified Data Format; Word Width: 32 Bits; Data Length: 24 Bits

18.2.4.4 Voice Protocol and Data Formats

18.2.4.4.1 Protocol

The PCM protocol is intended to transfer voice data at 8 kHz (default narrowband mode) or 16 kHz (wideband mode) sample rates (frame-sync frequency). PCM protocol can act as a slave or master, and is used by the Bluetooth interface and the modem generic interface. The frame-synchronization defines the frame length in the PCM protocol. Bits are clocked using PCM clock signal, with MSB first.

18.2.4.4.2 Data Formats

Two modes are available for the PCM protocol: mode 1 and mode 2. For these both modes, it has two types of operations: Mono or stereo channels. The difference between PCM mode 1 and PCM mode 2 is in the way they use either the rising or the falling edge of clock signal, and the frame-synchronization polarity.

- PCM Mode 1: Input data is latched on the falling edge of the clock, and the transmitted data starts on the rising edge of the clock. Frame-synchronization pulse is active high.
- PCM Mode 2: Input data is latched on the falling edge of the clock, and the transmitted data starts on the falling edge of the clock. Frame-synchronization pulse is active low.

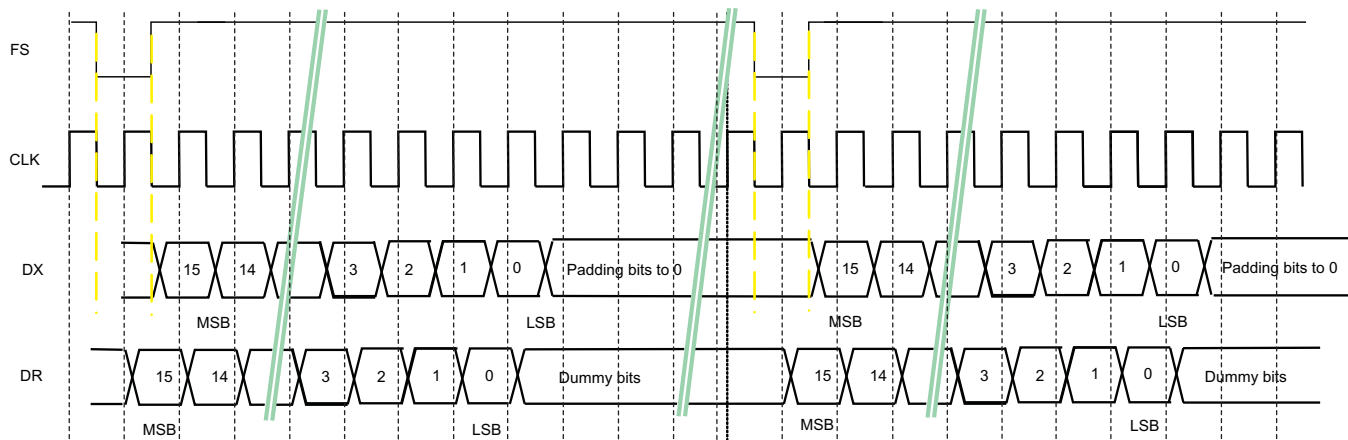

Figure 18-14 and Figure 18-15 shows an example of PCM protocol, mode 1 and mode 2, respectively, for a frame composed one word (width: 32 bits) with 16 bits data.

18.3 McBSP Integration

This section describes the McBSP modules integration inside the device and all the details about signal source controls, clocks, resets, power management, and hardware requests.

McBSP modules are divided into 2 families: McBSP modules that are gated in CORE domain (McBSP1 and 5), and McBSP modules that are gated in PER domain (McBSP2, 3, and 4).

For more details on CORE and PER domain, see , *Power, Reset and Clock Management*.

Figure 18-16 through Figure 18-20 highlight the integration of the McBSP modules in the device including interrupt handlers, DMA requests, clock generators, and interconnections.

18.3.1 Signal Source Control

The FSR, CLKR and CLKS signals sources are defined by the system control module. The control registers of the system control module are used to select these signals sources.

18.3.1.1 McBSP1 Module (6 Pins Configuration)

The MCBSP1_CLKS bit of the CONTROL.CONTROL_DEVCONF0[2] register is used to select the McBSP1 module CLKS signal source:

- When set to '0', the CLKS source is from the CORE_96M_FCLK
- When set to '1', the CLKS source is from the mcbbsp_clks pin

The MCBSP1_CLKR bit of the CONTROL_DEVCONF0[3] register is used to select the McBSP1 module CLKR signal source:

- When set to '0', the CLKR source is from the CLKR input signal
- When set to '1', the CLKR source is from the CLKX input signal

The MCBSP1_FSR bit of the CONTROL_DEVCONF0[4] register is used to select the McBSP1 module FSR signal source:

- When set to '0', the FSR source is from the FSR input signal
- When set to '1', the FSR source is from the FSX input signal

18.3.1.2 McBSP2, 3, 4, and 5 modules (4 pins configuration)

For these McBSPi modules, there are no external mcbspi_clkr and mcbspi_fxr pins (I=2, 3, 4, and 5).

Consequently, the system control module controls only the internal connection of CLKS input signals. The settings are explained in [Section 18.3.2.2.2](#), [Section 18.3.2.2.3](#), [Section 18.3.2.2.4](#), and [Section 18.3.2.2.5](#).

18.3.2 Clocking, Reset, and Power Management Scheme

18.3.2.1 Power Domain

McBSP1 and McBSP5 modules belong to the CORE domain, whereas the McBSP2, McBSP3, and McBSP4 modules belong to the PER (peripheral) domain. This separation of McBSP modules in two power domain allows major part of the device to be switched off while keeping active McBSP2, 3, and 4.

For more information about these power domains, see , *Power Reset and Clock Management*.

18.3.2.2 Clocks

There are two clock domains in the McBSP module:

- Functional clock domain
- Interface clock domain

Table 18-3. Clocking Signals Input to McBSP Module

| Type | Name | Source | Description |
|------------|--------------------|---|--|
| Interface | McBSPi_ICLK | PER_L4_ICLK (McBSP2, 3, 4) ⁽¹⁾ | The L4 interface clock is used for the module internal L4 interconnect slave interface and all depending parts of the Interface clock domain. |
| | | CORE_L4_ICLK (McBSP1, 5) ⁽¹⁾ | |
| Functional | CLKS | PER_96M_FCLK (McBSP2, 3, 4) ⁽¹⁾ | McBSP module is running using either a functional clock generated internally (master mode) or supplied from its serial interface (slave mode) for the internal logic. Internal registers select the source of the functional clock and the divider ratio to apply. |
| | | CORE_96M_FCLK (McBSP1, 5) ⁽¹⁾ | |
| | | mcbbsp_clks (external source common to all McBSP modules) | |
| Functional | CLKX | mcbbsp_clkx (external source) | Functional clock after division in any mode is limited to maximum frequency divided by 2. |
| Functional | CLKR (McBSP1 only) | mcbbsp1_clkr (external source) | |

⁽¹⁾ For more information about these sources, see , *Power Reset and Clock Management*.

18.3.2.2.1 McBSP1 Clocks

The McBSP1 module is clocked by a functional clock (CLKS, CLKX, or CLKR) and an interface clock (McBSP1_ICLK).

- The functional clock is used to generate control signals depending on the module internal configuration (see [Section 18.4](#)). For McBSP1 module, the functional clock comes from the CLKS signal, CLKX signal, or CLKR signal. The choice between these three clocks is defined by the SCLKME bit of the McBSP1.MCBSPLP_PCR_REG[7] register and the CLKSM bit of the McBSP1.MCBSPLP_SRGR2_REG[13] register.

The CLKS signal of the McBSP1 module is linked to an internal clock (CORE_96M_FCLK) provided by PRCM, whereas the CLKS signal can also be linked to an external signal through the mcbbsp_clks pin of the device boundary. The McBSP1_CLKS bit of the CONTROL.CONTROL_DEVCONF0[2] register is used to select the McBSP1 module CLKS signal source:

- 0: The CLKS source is from the CORE_96M_FCLK.
- 1: The CLKS source is from the mcbbsp_clks pin.

For more information on this register , see [Chapter 6, System Control Module](#).

NOTE: When the McBSP1 module does not require the PRCM functional clock anymore, the software can disable it at the PRCM level by setting the EN_MCBSP1 bit (PRCM.CM_FCLKEN1_CORE[9]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it. For more details, see , *Power Reset and Clock Management*.

At PRCM level, when all the conditions to shut-off CORE_96M_FCLK clock are met the PRCM automatically launches a **Hardware** handshake protocol to ensure McBSP1 is ready to have this clock switched off. Namely, the PRCM asserts an idle request to McBSP1. For more details, see , *Power Reset and Clock Management*.

The CLKX and CLKR signals are connected either by mcbbsp1_clkx or mcbbsp1_clkr pads. These signals are used like functional clocks by the intermediary of the sample rate generator (SRG).

- The McBSP1_ICLK runs at the L4 core interconnect clock speed. It is used to trigger access to the McBSP1 L4 interface and McBSP1 configuration interface via the MPU/IVA2.2 shared bus. It can also be an input clock for the McBSP sample-rate generator (clock divider), depending on the module configuration (see [Section 18.4.3](#)). Its source is the CORE_L4_ICLK signal.

NOTE: When the McBSP1 module does not require the interface clock anymore, the software can disable it at the PRCM level by setting the EN_MCBSP1 bit (PRCM.CM_ICLKEN1_CORE[9]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it. For more information, see , *Power Reset and Clock Management*.

At PRCM level, when all the conditions to shut-off CORE_L4_ICLK clock are met the PRCM automatically launches a hardware handshake protocol to ensure McBSP1 is ready to have this clock switched off. Namely, the PRCM asserts an idle request to McBSP1. For more details, see , *Power Reset and Clock Management*.

It is also possible to activate an autoidle mode for this clock (PRCM.CM_AUTOIDLE1_CORE[9] register AUTO_MCBSP1 bit set to 1). In this case, McBSP1_ICLK follows the CORE_L4 clock domain behavior on the device. For more information, see , *Power Reset and Clock Management*.

18.3.2.2.2 McBSP2 Clocks

The McBSP2 module is clocked by a functional clock (CLKS, CLKX or CLKR) and an interface clock (McBSP2_ICLK).

- The functional clock is used to generate control signals depending on the module internal configuration (see [Section 18.4](#)). For McBSP2 module, the functional clock comes from the CLKS signal CLKX signal, or CLKR signal. The choice between these three clocks is defined by the SCLKME bit of the McBSP2.MCBSPLP_PCR_REG[7] register and the CLKSM bit of the McBSP2.MCBSPLP_SRGR2_REG[13] register.

The CLKS signal of the McBSP2 module is linked to an internal clock (PER_96M_FCLK) provided by PRCM, whereas the CLKS signal can also be linked to an external signal through the mcbbsp_clks pin of the device boundary. The McBSP2_CLKS bit of the CONTROL.CONTROL_DEVCONF0[6] register is used to select the McBSP2 module CLKS signal source:

- 0: The CLKS source is from the PER_96M_FCLK.
- 1: The CLKS source is from the mcbbsp_clks pin.

For more information, see [Chapter 6, System Control Module](#).

NOTE: When the McBSP2 module does not require the functional clock anymore, the software can disable it at the PRCM level by setting the EN_MCBSP2 bit (PRCM.CM_FCLKEN_PER[0]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it. For more details, see , *Power Reset and Clock Management*.

At PRCM level, when all the conditions to shut-off PER_96M_FCLK clock are met the PRCM automatically launches a hardware handshake protocol to ensure McBSP2 is ready to have this clock switched off. Namely, the PRCM asserts an idle request to McBSP2. For more details, see , *Power Reset and Clock Management*.

Only, the CLKX signal is connected by mcbbsp2_clkx pads. The CLKR signal is connected to the CLKX signal. These signals are used like functional clocks by the intermediary of the SRG.

- The McBSP2_ICLK runs at the L4 core interconnect clock speed. It is used to trigger access to the McBSP2 L4 interface and McBSP2 configuration interface via the MPU/IVA2.2 shared bus. It can also be an input clock for the McBSP sample-rate generator (clock divider), depending on the module configuration (see [Section 18.4.3](#)). Its source is either the PER_L4_ICLK signal.

NOTE: When the McBSP2 module does not require the interface clock anymore, the software can disable it at the PRCM level by setting the EN_MCBSP2 bit (PRCM.CM_ICLKEN_PER[0]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it. For more information, see , *Power Reset and Clock Management*.

At PRCM level, when all the conditions to shut-off PER_L4_ICLK clock are met the PRCM automatically launches a hardware handshake protocol to ensure McBSP2 is ready to have this clock switched off. Namely, the PRCM asserts an idle request to McBSP2. For more details, see , *Power Reset and Clock Management*.

It is also possible to activate an autoidle mode for this clock (PRCM.CM_AUTOIDLE_PER[0] register AUTO_MCBSP2 bit set to 1). In this case, McBSP2_ICLK follows the CORE_L4 clock domain behavior on the device. For more information, see , *Power Reset and Clock Management*.

18.3.2.2.3 McBSP3 Clocks

The McBSP3 module is clocked by a functional clock (CLKS, CLKX or CLKR) and an interface clock (McBSP3_ICLK).

- The functional clock is used to generate control signals depending on the module internal configuration (see [Section 18.4](#)). For McBSP3 module, the functional clock comes from the CLKS signal CLKX signal, or CLKR signal. The choice between these three clocks is defined by the SCLKME bit of the MCBSP3.MCBSPLP_PCR_REG[7] register and the CLKSM bit of the MCBSP3.MCBSPLP_SRGR2_REG[13] register.

The CLKS signal of the McBSP3 module is linked to an internal clock (PER_96M_FCLK) provided by PRCM, whereas the CLKS signal can also be linked to an external signal through the mcbbsp_clks pin of the device boundary. The MCBSP3_CLKS bit of the CONTROL.CONTROL_DEVCONF1[0] register is used to select the McBSP3 module CLKS signal source:

- 0: The CLKS source is from the PER_96M_FCLK.
- 1: The CLKS source is from the mcbbsp_clks pin.

For more information, see [Chapter 6](#), *System Control Module*.

NOTE: When the McBSP3 module does not require the functional clock anymore, the software can disable it at the PRCM level by setting the EN_MCBSP3 bit (PRCM.CM_FCLKEN_PER[1]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it. For more details, see , *Power Reset and Clock Management*.

At PRCM level, when all the conditions to shut-off PER_96M_FCLK clock are met the PRCM automatically launches a hardware handshake protocol to ensure McBSP3 is ready to have this clock switched off. Namely, the PRCM asserts an idle request to McBSP3. For more details, see , *Power Reset and Clock Management*.

Only, the CLKX signal is connected by mcbbsp3_clkx pads. The CLKR signal is connected to the CLKX signal. These signals are used like functional clocks by the intermediary of SRG.

- The McBSP3_ICLK runs at the L4 core interconnect clock speed. It is used to trigger access to the McBSP3 L4 interface and McBSP3 configuration interface via the MPU/IVA2.2 shared bus. It can also be an input clock for the McBSP sample-rate generator (clock divider), depending on the module configuration (see [Section 18.4.3](#)). Its source is either the PER_L4_ICLK signal.

NOTE: When the McBSP3 module does not require the interface clock anymore, the software can disable it at the PRCM level by setting the EN_MCBSP3 bit (PRCM.CM_ICLKEN_PER[1]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it. For more information, see , *Power Reset and Clock Management*.

At PRCM level, when all the conditions to shut-off PER_L4_ICLK clock are met the PRCM automatically launches a hardware handshake protocol to ensure McBSP3 is ready to have this clock switched off. Namely, the PRCM asserts an idle request to McBSP3. For more details, see , *Power Reset and Clock Management*.

It is also possible to activate an autoidle mode for this clock (PRCM.CM_AUTOIDLE_PER[1] register AUTO_MCBSP3 bit set to 1). In this case, McBSP3_ICLK follows the PER_L4 clock domain behavior on the device. For more information, see , *Power Reset and Clock Management*.

18.3.2.2.4 McBSP4 Clocks

The McBSP4 module is clocked by a functional clock (CLKS or CLKX) and an interface clock (McBSP4_ICLK).

- The functional clock is used to generate control signals depending on the module internal configuration (see [Section 18.4](#)). For McBSP4 module, the functional clock comes from the CLKS signal, the CLKX signal, or the CLKR signal. The choice between these three clocks is defined by the SCLKME bit of the MCBSP4.MCBSPLP_PCR_REG[7] register and the CLKSM bit of the MCBSP4.MCBSPLP_SRGR2_REG[13] register.

The CLKS signal of the McBSP4 module is linked to an internal clock (PER_96M_FCLK) provided by PRCM, whereas the CLKS signal can also be linked to an external signal through the mcbbsp_clks pin of the device boundary. The MCBSP4_CLKS bit of the CONTROL.CONTROL_DEVCONF1[2] register is used to select the McBSP4 module CLKS signal source:

- 0: The CLKS source is from the PER_96M_FCLK.
- 1: The CLKS source is from the mcbbsp_clks pin.

For more information, see [Chapter 6, System Control Module](#).

NOTE: When the McBSP4 module does not require the functional clock anymore, the software can disable it at the PRCM level by setting the EN_MCBSP4 bit (PRCM.CM_FCLKEN_PER[2]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it. For more details, see , *Power Reset and Clock Management*.

At PRCM level, when all the conditions to shut-off PER_96M_FCLK clock are met the PRCM automatically launches a hardware handshake protocol to ensure McBSP4 is ready to have this clock switched off. Namely, the PRCM asserts an idle request to McBSP4. For more details, see , *Power Reset and Clock Management*.

Only the CLKX signal is connected by mcbbsp4_clkx pads. The CLKR signal is connected to the CLKX signal. These signals are used like functional clocks by the intermediary of SRG.

- The McBSP4_ICLK runs at the L4 core interconnect clock speed. It is used to trigger access to the McBSP4 L4 interface and McBSP4 configuration interface via the MPU/IVA2.2 shared bus. It can also be an input clock for the McBSP sample-rate generator (clock divider), depending on the module configuration (see [Section 18.4.3](#)). Its source is either the PER_L4_ICLK signal.

NOTE: When the McBSP4 module does not require the interface clock anymore, the software can disable it at the PRCM level by setting the EN_MCBSP4 bit (PRCM.CM_ICLKEN_PER[2]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it. For more information, see , *Power Reset and Clock Management*.

At PRCM level, when all the conditions to shut-off PER_L4_ICLK clock are met the PRCM automatically launches a hardware handshake protocol to ensure McBSP4 is ready to have this clock switched off. Namely, the PRCM asserts an idle request to McBSP4. For more details, see , *Power Reset and Clock Management*.

It is also possible to activate an autoidle mode for this clock (PRCM.CM_AUTOIDLE_PER[2] register AUTO_MCBSP4 bit set to 1). In this case, McBSP4_ICLK follows the PER_L4 clock domain behavior on the device. For more information, see , *Power Reset and Clock Management*.

18.3.2.2.5 McBSP5 Clocks

The McBSP5 module is clocked by a functional clock (CLKS or CLKX) and an interface clock (McBSP5_ICLK).

- The functional clock is used to generate control signals depending on the module internal configuration (see [Section 18.4](#)). For McBSP5 module, the functional clock comes from the CLKS signal, the CLKX signal, or the CLKR signal. The choice between these three clocks is defined by the SCLKME bit of the MCBSP5.MCBSPLP_PCR_REG[7] register and the CLKSM bit of the MCBSP5.MCBSPLP_SRGR2_REG[13] register.

The CLKS signal of the McBSP5 module is linked to an internal clock (CORE_96M_FCLK) provided by PRCM. The CLKS signal can also be linked to an external signal through the mcbbsp_clks pin of the device boundary. The MCBSP5_CLKS bit of the CONTROL.CONTROL_DEVCONF1[4] register is used to select the McBSP5 module CLKS signal source:

- 0: The CLKS source is from the CORE_96M_FCLK.
- 1: The CLKS source is from the mcbbsp_clks pin.

For more information, see [Chapter 6, System Control Module](#).

NOTE: When the McBSP5 module does not require the functional clock anymore, the software can disable it at the PRCM level by setting the EN_MCBSP5 bit (PRCM.CM_FCLKEN1_CORE[10]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it. For more details, see , *Power Reset and Clock Management*.

At PRCM level, when all the conditions to shut-off CORE_96M_FCLK clock are met the PRCM automatically launches a hardware handshake protocol to ensure McBSP5 is ready to have this clock switched off. Namely, the PRCM asserts an idle request to McBSP5. For more details, see , *Power Reset and Clock Management*.

Only, the CLKX signal is connected by mcbbsp5_clkx pads. The CLKR signal is connected to the CLKX signal. These signals are used like functional clocks by the intermediary of SRG.

- The McBSP5_ICLK runs at the L4 core interconnect clock speed. It is used to trigger access to the McBSP5 L4 interface and McBSP5 configuration interface via the MPU/IVA2.2 shared bus. It can also be an input clock for the McBSP sample-rate generator (clock divider), depending on the module configuration (see [Section 18.4.3](#)). Its source is either the CORE_L4_ICLK signal.

NOTE: When the McBSP5 module does not require the interface clock anymore, the software can disable it at the PRCM level by setting the EN_MCBSP5 bit (PRCM.CM_ICLKEN1_CORE[10]) in the PRCM registers. The clock is effectively cut, provided the other modules that receive it do not require it. For more information, see , *Power Reset and Clock Management*.

At PRCM level, when all the conditions to shut-off CORE_L4_ICLK clock are met the PRCM automatically launches a hardware handshake protocol to ensure McBSP5 is ready to have this clock switched off. Namely, the PRCM asserts an idle request to McBSP5. For more details, see , *Power Reset and Clock Management*.

It is also possible to activate an autoidle mode for this clock (PRCM.CM_AUTOIDLE1_CORE[10] register AUTO_MCBSP5 bit set to 1). In this case, McBSP5_ICLK follows the CORE_L4 clock domain behavior on the device. For more information, see , *Power Reset and Clock Management*.

18.3.2.2.6 SIDETONE Clock

The SIDETONE feature, in the McBSP2 and McBSP3 modules, is clocked only by an interface clock (McBSP2_ICLK or McBSP3_ICLK).

CAUTION

See [Section 18.3.2.2.2](#) and [Section 18.3.2.2.3](#) for information on McBSP2_ICLK and McBSP3_ICLK clocks.

When the SIDETONE feature does not require the clock anymore, the software can disable it at the SIDETONE level by setting the McBSPi.ST_SYSCONFIG_REG[0] AUTOIDLE bit in SIDETONE registers. To conserve power, when SIDETONE feature is not active or there is no activity on SIDETONE feature, the McBSPi_ICLK clock supports an automatic gating that is enabled or disabled by setting the McBSPi.ST_SYSCONFIG_REG[0] AUTOIDLE bit.

- When this bit is asserted (set to 1), the McBSPi_ICLK clock auto-gating is enabled and this clock is disabled internally to the SIDETONE feature, thus reducing power consumption, but not to the McBSP module that contains this feature.
After reset, the automatic clock gating is enabled; thus, this bit must be disabled by software for activated SIDETONE feature.
- When this bit is set to 0, the McBSPi_ICLK clock auto-gating is disabled and this clock is enabled. The SIDETONE feature can be used normally.

18.3.2.3 Hardware and Software Reset

McBSP1 and McBSP5 modules belong to the CORE domain and their reset signal is the CORE_RST signal from the PRCM module, whereas McBSP2, 3 and 4 modules belong to the PER domain and their reset signal is the PER_RST signal from the PRCM module.

For more details about these signals, see , *Power Reset and Clock Management*.

Table 18-4. Software Reset Signals to All McBSP Modules

| Type | Bit Field | Register Source | Activation | Description |
|----------|-----------|---------------------------------|-------------|---|
| Software | SOFTRESET | MCBSPi.MCBSPLP_SYSCONFIG_REG[1] | Active high | McBSP global software reset |
| | RRST | MCBSPi.MCBSPLP_SPCR1_REG[0] | Active low | This resets and disables the receiver, including the RB. |
| | XRST | MCBSPi.MCBSPLP_SPCR2_REG[0] | | This resets and disables the transmitter, including the XB. |
| | GRST | MCBSPi.MCBSPLP_SPCR2_REG[6] | | SRG is reset |

Table 18-4. Software Reset Signals to All McBSP Modules (continued)

| Type | Bit Field | Register Source | Activation | Description |
|------|-----------|-----------------------------|------------|--|
| | FRST | MCBSPi.MCBSPLP_SPCR2_REG[7] | | Frame-sync logic is reset. Frame-sync generated signal is not generated by the SRG |

For more details about these signals, see [Section 18.6](#). See [Section 18.5.1.1](#), for a complete description of the McBSP initialization procedure.

18.3.2.4 Power Management

18.3.2.4.1 McBSP Operating States

Two operating states are defined for all the McBSP modules:

- **ACTIVE** state: The module is running synchronously on the interface and functional clock, interrupts and DMA requests can be generated according to the configuration (register, master or slave mode, etc) and the external signals.
- **IDLE** state: As part of the system power management, the PRCM module can request the McBSP modules to enter IDLE state. Depending on the configured acknowledgment mode: Force Idle, No Idle and Smart Idle modes, a McBSP module will effectively enter IDLE state or not. As soon as a McBSP module enters IDLE state, it doesn't have anymore activities except those unrelated to clock activity (for example wake-up features) and its clocks are likely to be switched off at PRCM level.

NOTE: Idle request and idle acknowledge are only internal signals, with no means to observe or to control. The signals generation and control is purely hardware (managed automatically by the PRCM and the McBSP module depending on the SIDLEMODE settings).

18.3.2.4.2 McBSP Acknowledgment Modes

During initialization or configuration of the McBSP module, the software must configure how the McBSP module will answer an IDLE solicitation from the PRCM module (that is, the way idle acknowledge will be asserted following an idle request assertion).

Each McBSP module can be configured via the MCBSPi.MCBSPLP_SYSCONFIG_REG[4:3] SIDLEMODE field as one of the following acknowledgment modes:

- **Force Idle mode** (SIDLEMODE bit = 0x0): An idle request is acknowledged unconditionally, regardless of the internal state of the module. The McBSP module immediately enters Idle state (no activity), interface and PRCM functional clock can be stopped, no interrupts and DMA requests can be generated. In this mode, the McBSP module freezes all the internal activity when the PRCM clocks are switched off by the PRCM module, leading to a potential loss of data.

CAUTION

In Force Idle mode, the wake-up feature is inhibited.

CAUTION

If the McBSP functional part, transmitter or receiver, is running within this period of time (the functional clock source is not the PRCM functional clock), the internal state of the McBSP module will not be idle (FSM states, processes, etc.), and when the McBSP module exits from the Force Idle state unexpected behavior may happen in both receiver and transmitter. To avoid this, both receive and transmit parts, must be disabled by software prior to idle request assertion (all functional clock external sources must be disabled).

- No Idle mode (SIDLEMODE bit = 0x1): An idle request is never acknowledged, meaning it will prevent the PRCM from switching off its related clocks and from putting in a lower power state than the power domain it belongs to. The McBSP module never enters Idle state (is active).
- Smart Idle mode (SIDLEMODE bit = 0x2): Acknowledgment to an idle request is given based on the internal activity of the McBSP module. The McBSP module is in a waiting state, interface / functional clocks can be stopped, no interrupt can be generated, a wake-up signal can be generated according to the configuration (See [Section 18.3.2.4.4](#)) and external signals.

NOTE: The value `MCBSPi.MCBSPLP_SYSCONFIG_REG[4:3]` SIDLEMODE field = 0x3 must not be used.

When configured in Smart Idle mode, McBSP module also offers an additional granularity on `McBSPi_FCLK` and `McBSPi_ICLK` gating. `McBSPi.MCBSPLP_SYSCONFIG_REG[9:8]` CLOCKACTIVITY bit field is used to determine which clock will be shut down (`McBSPi_FCLK`, `McBSPi_ICLK`, none of them or both of them).

CLOCKACTIVITY setting is used in the McBSP module to determine on which part of the module the conditions to acknowledge the PRCM idle request will be tested. As an example, if `McBSPi_FCLK` is said not to be shut down upon a PRCM idle request, this means McBSP module will only consider `McBSPi_ICLK` and the associated pending activities before acknowledging the request.

NOTE: Some of McBSP features are associated to `McBSPi_ICLK` and others to `McBSPi_FCLK`. Using the CLOCKACTIVITY along with the Smart Idle mode ensures that the features associated with the clock that will remain active are always enabled, even if McBSP has acknowledged an idle request. For more information, see [Section 18.3.2.4.4](#).

[Table 18-5](#) lists the value of the bit field and indicates if the interface (`McBSPi_ICLK`) and PRCM functional (`McBSPi_FCLK`) clocks can be switched-off or not when an idle request is received by McBSP module.

Table 18-5. State of Clocks When the Module is in Idle State

| CLOCKACTIVITY Value | Interface Clock (<code>McBSPi_ICLK</code>) | PRCM Functional Clock (<code>CORE_96M_FCLK</code> or <code>PER_96M_FCLK</code>) |
|---------------------|--|--|
| 0b00 | OFF | OFF |
| 0b01 | OFF | ON |
| 0b10 | ON | OFF |
| 0b11 | ON | ON |

NOTE: OFF means this clock can be switched-off.

ON means this clock must be maintained during wake up period.

CAUTION

The PRCM module does not have any hardware mean to read CLOCKACTIVITY settings. It is thus software responsibility to ensure a consistent programming between `McBSPi.MCBSPLP_SYSCONFIG_REG[9:8]` CLOCKACTIVITY bit field and PRCM `96M_FCLK` and `L4_ICLK` control bits (for more information about clocks, see [Section 18.3.2.2, Clocks](#)). If McBSP module is disabled in both `CM_FCLKEN` and `CM_ICLKEN` PRCM registers while CLOCKACTIVITY is set to 11, nothing prevents the PRCM module from asserting its idle request which will be acknowledged regardless of the features associated with the McBSP clocks. This may lead to unpredictable behaviors.

The software can disable all clocks at the McBSP module level by setting the IDLE_EN bit in McBSPi.MCBSPLP_PCR_REG[14] registers. The IDLE_EN bit allows stopping all the clocks in the McBSP module (legacy):

- When set to '0', the McBSP module is running
- When set to '1', the clocks in the McBSP module are shut off when both IDLE_EN =1 and his power domain is in idle mode.

18.3.2.4.3 Wake-Up Capability

When configured in Smart Idle mode, the sources for wake-up generation are a subset of the interrupt sources. The wake up sources are enabled by setting the McBSPi.MCBSPLP_SYSCONFIG_REG[2] ENAWAKEUP bit (wake up feature control):

- Set to '0', wake up capability is disabled
- Set to '1', wake up capability is enabled

The McBSPi_SWAKEUP signal is the McBSP module asynchronous wake-up signal sent to the PRCM module when a wake-up generation is requested.

The wake up configurations are defined by setting the corresponding bits in the McBSPi.MCBSPLP_WAKEUPEN_REG register.

18.3.2.4.3.1 Receive Wake-up

There are 4 receive possible wake up configurations:

- McBSPi.MCBSPLP_WAKEUPEN_REG[3] RRDYEN bit: The McBSP module asserts the McBSPi_SWAKEUP request when the receive buffer reaches the high threshold value (RTHRESHOLD value + 1) of the McBSPi.MCBSPLP_THRSH1_REG register. If the McBSPi.MCBSPLP_IRQENABLE_REG[3] RRDYEN bit is set to 1, the McBSP module sends an interrupt (McBSPi_IRQ) request to the MPU or IVA 2.2 subsystems when exiting from idle mode (interrupt will be asserted once the McBSPi.MCBSPLP_IRQSTATUS_REG[3] RRDY bit changes from '0' to '1', indicating that received data is ready to be read).
- McBSPi.MCBSPLP_WAKEUPEN_REG[2] REOFEN bit: The McBSP module asserts the McBSPi_SWAKEUP request at the end of the frame. If the McBSPi.MCBSPLP_IRQENABLE_REG[2] REOFEN bit is set to 1, the McBSP module sends an interrupt (McBSPi_IRQ) request to the MPU or IVA 2.2 subsystems when exiting idle mode.
- McBSPi.MCBSPLP_WAKEUPEN_REG[1] RFSREN bit: The McBSP module sends a McBSPi_SWAKEUP request to the PRCM module when a receive frame-sync pulse is detected while the McBSP module is in idle mode. If the McBSPi.MCBSPLP_IRQENABLE_REG[1] RFSREN bit is set to 1, the McBSP module sends an interrupt (McBSPi_IRQ) request to the MPU or IVA 2.2 subsystems when exiting idle mode.
- McBSPi.MCBSPLP_WAKEUPEN_REG[0] RSYNCERREN bit: The McBSP module asserts the McBSPi_SWAKEUP request when an unexpected receive frame-sync pulse is detected. If the McBSPi.MCBSPLP_IRQENABLE_REG[0] RSYNCERREN bit is set to 1, the McBSP module sends an interrupt (McBSPi_IRQ) request o the MPU or IVA 2.2 subsystems when exiting from idle mode (interrupt is asserted once the McBSPi.MCBSPLP_IRQSTATUS_REG[0] RSYNCERR bit changes from '0' to '1', indicating that a receive error occurred).

18.3.2.4.3.2 Transmit Wakeup

For transmit, there are also 5 possible wake-up configuration scenarios:

- McBSPi.MCBSPLP_WAKEUPEN_REG[14] XEMPTYEOFEN bit: The McBSP module asserts the McBSPi_SWAKEUP request when a complete frame was transmitted and the transmit buffer is empty. If the McBSPi.MCBSPLP_IRQENABLE_REG[14] XEMPTYEOFEN bit is set to 1, the McBSP module sends an interrupt (McBSPi_IRQ) request to the MPU or IVA 2.2 subsystems when exiting from idle mode.

- McBSPi.MCBSPLP_WAKEUPEN_REG[10] XRDYEN bit: The McBSP module asserts the McBSPi_SWAKEUP request when the transmit buffer reaches the high threshold value (XTHRESHOLD value + 1) of the McBSPi.MCBSPLP_THRSH2_REG register. If the McBSPi.MCBSPLP_IRQENABLE_REG[10] XRDYEN bit is set to 1, the McBSP module sends an interrupt (McBSPi_IRQ) request to the MPU or IVA 2.2 subsystems when exiting from idle mode (interrupt is asserted once the McBSPi.MCBSPLP_IRQSTATUS_REG[10] XRDY bit changes from '0' to '1', indicating that transmit buffer data is ready to accept new data).
- McBSPi.MCBSPLP_WAKEUPEN_REG[9] XEOFEN bit: The McBSP module asserts the McBSPi_SWAKEUP request at the end of the frame. If the McBSPi.MCBSPLP_IRQENABLE_REG[9] XEOFEN bit is set to 1, the McBSP module sends an interrupt (McBSPi_IRQ) request to the MPU or IVA 2.2 subsystems when exiting from idle mode.
- McBSPi.MCBSPLP_WAKEUPEN_REG[8] XFSXEN bit: The McBSP module sends a McBSPi_SWAKEUP request when a transmit frame-sync pulse is detected while the module is in idle mode. If the McBSPi.MCBSPLP_IRQENABLE_REG[8] XFSXEN bit is set to 1, the McBSP module sends an interrupt (McBSPi_IRQ) request to the MPU or IVA 2.2 subsystems when exiting from idle mode.
- McBSPi.MCBSPLP_WAKEUPEN_REG[7] XSYNCERREN bit: The McBSP module asserts the McBSPi_SWAKEUP request when an unexpected transmits frame-sync pulse is detected. If the McBSPi.MCBSPLP_IRQENABLE_REG[7] XSYNCERREN bit is set to 1, the McBSP module sends an interrupt (McBSPi_IRQ) request to the MPU or IVA 2.2 subsystems when exiting from idle mode (interrupt will be asserted once the McBSPi.MCBSPLP_IRQSTATUS_REG[7] XSYNCERR bit changes from '0' to '1', indicating that a transmit error occurred).

18.3.2.4.3.3 Notes

When mcbbsp1_fsr/mcbbsp1_fsx pins is configured as an output, the FSR/FSX wake-up generation makes no sense (the module cannot be in Smart Idle mode).

Detection of RSYNCERR/XSYNCERR during idle mode can be used only when mcbbsp1_fsr/mcbbsp1_fsx pins is configured as an input and the remote system knows to assert such an error to trigger the wake up of the McBSP module.

The module does not implement interrupt request (IRQ) assertion when configured as (GPIO). Pins that can be used to accept input signals and/or send output signals but are not linked to specific uses); also a wake up capability in this mode is not available.

18.3.2.4.4 Analysis of the Receiver Smart Idle Behavior

The analysis of the power mode behavior is shown in [Table 18-6](#) :

In this table, the CLKRM bit is in the McBSPi.MCBSPLP_PCR_REG register on position 8, CLKXM bit in the McBSPi.MCBSPLP_PCR_REG[9] register, and CLOCKACTIVITY bit in the McBSPi.MCBSPLP_SYSCONFIG_REG[9:8] register.

The value X signifies that the bit value is not significant.

Table 18-6. McBSP Smart Idle Mode Configuration Behavior

| CLKRM Bit | CLKXM Bit | McBSP Mode | Source of Functional Clock | CLOCKACTIVITY Bit | Behavior |
|-----------|-----------|------------|----------------------------|-------------------|--|
| 0 | 0 | Slave | outside | 0bXX | The module acknowledges the idle request as soon as there is no pending DMA, interrupt request or transmit buffer threshold synchronization (only when wake-up event is set on transmit threshold reached), regardless of the CLOCKACTIVITY settings or receive and transmit activity. |

Table 18-6. McBSP Smart Idle Mode Configuration Behavior (continued)

| CLKRM Bit | CLKXM Bit | McBSP Mode | Source of Functional Clock | CLOCKACTIVITY Bit | Behavior |
|-----------|-----------|-----------------|----------------------------|-------------------|--|
| 0 | 1 | Transmit Master | McBSPi_ICLK | 0b0X | <p>The McBSP will not acknowledge the idle request unless:</p> <ul style="list-style-type: none"> The transmit part is disabled (XDISABLE) or under software reset (XRST) and the receive part is not using the transmit loop-back clock (CLKR is not connected to the CLKX input pin). Both transmit and receive parts are disabled (XDISABLE/RDISABLE) or under software reset (XRST/RRST) <p>The idle acknowledge is asserted as soon as there is no pending DMA, interrupt request or transmit/receive buffer threshold synchronization (only when wake-up event is set on transmit/receive threshold reached) and the pending transmit and/or receive frames were completed in case of transmit and/or receive disable.</p> |
| | | | CLKS | 0bX0 | |
| | | | McBSPi_ICLK | 0b1X | |
| | | | CLKS | 0bX1 | |
| | | | CLKR (outside) | 0bXX | |
| | | | CLKR (outside) | 0bXX | |
| 1 | 0 | Receive master | McBSPi_ICLK | 0b0X | <p>The McBSP will not acknowledge the idle request unless: The receive part is disabled (RDISABLE) or under software reset (RRST)</p> <p>The Idle acknowledge is asserted as soon as there is no pending DMA, interrupt request or transmit/receive buffer threshold synchronization (only when wake-up event is set on transmit/receive threshold reached) and the pending transmit and/or receive frames were completed in case of transmit and/or receive disable.</p> |
| | | | CLKS | 0bX0 | |
| | | | McBSPi_ICLK | 0b1X | |
| | | | CLKS | 0bX1 | |
| | | | CLKX | 0bXX | |
| | | | CLKX | 0bXX | |

Table 18-6. McBSP Smart Idle Mode Configuration Behavior (continued)

| CLKRM Bit | CLKXM Bit | McBSP Mode | Source of Functional Clock | CLOCKACTIVITY Bit | Behavior |
|-----------|-----------|-----------------------------|----------------------------|-------------------|--|
| 1 | 1 | Transmit and Receive Master | McBSPi_ICLK | 0b0X | The McBSP will not acknowledge the idle request unless: Both transmit and receive parts are disabled (XDISABLE/RDISABLE) or under software reset (XRST/RRST) The idle acknowledge is asserted as soon as there is no pending DMA, interrupt request or transmit/receive buffer threshold synchronization (only when wake-up event is set on transmit/receive threshold reached) and the pending transmit and/or receive frames were completed in case of transmit and/or receive disable. Note that no wake-up event is available in this mode since the entire McBSP and remote device activity is frozen. |
| | | | CLKS | 0bX0 | |
| | | | McBSPi_ICLK | 0b1X | The module acknowledges the idle request as soon as there is no pending DMA, interrupt request or transmit/receive buffer threshold synchronization (only when wake-up event is set on transmit/receive threshold reached). |
| | | | CLKS | 0bX1 | |

NOTE: The RFSREN/XFSXEN mode is suitable for wake-up generation when both clocks (PRCM functional and interface) are switched off and mcbasp1_fsr/mcbspi_fsx pins is configured as input. The frame-sync pulse is asynchronously detected during idle.

The RSYNCERREN/XSYNCERREN mode can be used to wake-up the McBSP module only by a remote module implementing such a feature, to trigger a wake up. This mode requires functional clock to be active.

18.3.3 Hardware Requests

18.3.3.1 DMA Requests

The DMA requests are shared between the IVA2.2 subsystem DMA controller (eDMA) and system DMA controller (sDMA). Each of the five McBSP modules can generate two DMA events:

- McBSPi_DMA_TX : McBSPi module transmit request
- McBSPi_DMA_RX : McBSPi module receive request

The following table summarizes the DMA events with the mapping on both DMA controllers.

Table 18-7. McBSP DMA Requests

| Request Name | Mapping | Destination | Description |
|---------------|-------------------------|--|-----------------------------|
| McBSP1_DMA_TX | EDMA_REQ[0] S_DMA_30 | IVA2.2 subsystem DMA controller system DMA controller | write (or transmit) request |
| McBSP1_DMA_RX | EDMA_REQ[1] S_DMA_31 | IVA2.2 subsystem DMA controller system DMA controller | read (or receive) request |
| McBSP2_DMA_TX | EDMA_REQ[2] S_DMA_32 | IVA2.2 subsystem DMA controller system DMA controller | write (or transmit) request |
| McBSP2_DMA_RX | EDMA_REQ[3] S_DMA_33 | IVA2.2 subsystem DMA controller system DMA controller | read (or receive) request |
| McBSP3_DMA_TX | EDMA_REQ[4] S_DMA_16 | IVA2.2 subsystem DMA controller system DMA controller | write (or transmit) request |
| McBSP3_DMA_RX | EDMA_REQ[5] S_DMA_17 | IVA2.2 subsystem DMA controller system DMA controller | read (or receive) request |
| McBSP4_DMA_TX | EDMA_REQ[6] S_DMA_18 | IVA2.2 subsystem DMA controller system DMA controller | write (or transmit) request |
| McBSP4_DMA_RX | EDMA_REQ[7] S_DMA_19 | IVA2.2 subsystem DMA controller system DMA controller | read (or receive) request |
| McBSP5_DMA_TX | EDMA_REQ[8] S_DMA_20 | IVA2.2 subsystem DMA controller system DMA controller | write (or transmit) request |
| McBSP5_DMA_RX | EDMA_REQ[9] S_DMA_21 | IVA2.2 subsystem DMA controller system DMA controller | read (or receive) request |

18.3.3.2 Interrupt Requests

18.3.3.2.1 McBSP Interrupt Requests

Each of the five McBSP modules can generate three interrupts, shared between the MPU subsystem and IVA2.2 subsystem interrupt controllers:

- McBSPi_IRQ: McBSPi module common interrupt request
- McBSPi_IRQ_TX: McBSPi module transmit interrupt request
- McBSPi_IRQ_RX: McBSPi module receive interrupt request

The following tables list the interrupt requests with the mapping.

Table 18-8. McBSP Common Interrupt Requests

| Request Name | Mapping | Destination |
|--------------|--------------------------|---|
| McBSP1_IRQ | IVA2_IRQ[33] M_IRQ_16 | IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller |
| McBSP2_IRQ | IVA2_IRQ[34] M_IRQ_17 | IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller |
| McBSP3_IRQ | IVA2_IRQ[35] M_IRQ_22 | IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller |
| McBSP4_IRQ | IVA2_IRQ[36] M_IRQ_23 | IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller |

Table 18-8. McBSP Common Interrupt Requests (continued)

| Request Name | Mapping | Destination |
|--------------|--------------------------|---|
| McBSP5_IRQ | IVA2_IRQ[37] M_IRQ_27 | IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller |

Table 18-9. McBSP Transmit Interrupt Requests

| Request Name | Mapping | Destination |
|---------------|--------------------------|---|
| McBSP1_IRQ_TX | IVA2_IRQ[16] M_IRQ_59 | IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller |
| McBSP2_IRQ_TX | IVA2_IRQ[19] M_IRQ_62 | IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller |
| McBSP3_IRQ_TX | IVA2_IRQ[21] M_IRQ_89 | IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller |
| McBSP4_IRQ_TX | IVA2_IRQ[23] M_IRQ_54 | IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller |
| McBSP5_IRQ_TX | IVA2_IRQ[25] M_IRQ_81 | IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller |

Table 18-10. McBSP Receive Interrupt Requests

| Request Name | Mapping | Destination |
|---------------|--------------------------|---|
| McBSP1_IRQ_RX | IVA2_IRQ[17] M_IRQ_60 | IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller |
| McBSP2_IRQ_RX | IVA2_IRQ[20] M_IRQ_63 | IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller |
| McBSP3_IRQ_RX | IVA2_IRQ[22] M_IRQ_90 | IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller |
| McBSP4_IRQ_RX | IVA2_IRQ[24] M_IRQ_55 | IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller |
| McBSP5_IRQ_RX | IVA2_IRQ[26] M_IRQ_82 | IVA2.2 subsystem interrupt controller MPU subsystem interrupt controller |

An event can generate an interrupt request when the corresponding mask bit in the `McBSPi.MCBSPLP_IRQENABLE_REG` register is set to '1'.

[Table 18-11](#) and [Table 18-12](#) summarize the events causing the generation of an interrupt request.

Table 18-11. McBSP Transmit Interrupt Events

| Event Name | Status Bit | Mask Bit | Description |
|---------------------------------------|--|--|---|
| Transmit buffer empty at end of frame | McBSPi.MCBSPLP_IRQSTATUS_REG[14] XEMPTYEOF | McBSPi.MCBSPLP_IRQENABLE_REG [14] XEMPTYEOFEN | This event happens when a complete frame was transmitted and the transmit buffer is empty . |
| Overflow | McBSPi.MCBSPLP_IRQSTATUS_REG[12] XOVFLSTAT | McBSPi.MCBSPLP_IRQENABLE_REG [12] XOVFLEN | This event happens when transmit data buffer is full and a new data is written in this buffer. The new data written is discarded. |
| Underflow | McBSPi.MCBSPLP_IRQSTATUS_REG[11] XUNDFLSTAT | McBSPi.MCBSPLP_IRQENABLE_REG [11] XUNDFLEN | This event happens when transmit data buffer is empty and a new data is required to be transmitted. |
| Threshold reached | McBSPi.MCBSPLP_IRQSTATUS_REG[10] XRDY | McBSPi.MCBSPLP_IRQENABLE_REG [10] XRDYEN | This event happens when the transmit buffer free locations are equal or above the THRS2_REG value. |
| End of Frame | McBSPi.MCBSPLP_IRQSTATUS_REG[9] XEOF | McBSPi.MCBSPLP_IRQENABLE_REG [9] XEOFLEN | This event happens when a complete frame was transmitted. |

Table 18-11. McBSP Transmit Interrupt Events (continued)

| Event Name | Status Bit | Mask Bit | Description |
|------------------|---|--|---|
| Frame-sync | McBSPi.MCBSPLP_IRQSTATUS_REG[8] XFSX | McBSPi.MCBSPLP_IRQENABLE_REG [8] XFSXEN | This event happens when a new transmit frame synchronization is asserted. |
| Frame-sync error | McBSPi.MCBSPLP_IRQSTATUS_REG[7] XSYNCERR | McBSPi.MCBSPLP_IRQENABLE_REG [7] XSYNCERREN | This event happens when a transmit frame synchronization error is detected. |

Table 18-12. McBSP Receive Interrupt Events

| Event Name | Status bit | Mask bit | Description |
|-------------------|---|---|---|
| Overflow | McBSPi.MCBSPLP_IRQS TATUS_REG[5] ROVFLSTAT | McBSPi.MCBSPLP_IRQENABLE_ REG[5] ROVFLEN | This event happens when receive data buffer is full and a new data is written in this buffer. The new data written is discarded. |
| Underflow | McBSPi.MCBSPLP_IRQS TATUS_REG[4] XUNDFLSTAT | McBSPi.MCBSPLP_IRQENABLE_ REG[4] RUNDLEN | This event happens when read operation is performed to the receive data register while receive buffer is empty; data read while underflow condition is undefined. |
| Threshold reached | McBSPi.MCBSPLP_RQS TATUS_REG[3] RRDY | McBSPi.MCBSPLP_IRQENABLE_ REG[3] RRDYEN | This event happens when the receive buffer occupied locations are equal or above the THRS1_REG value. |
| End of Frame | McBSPi.MCBSPLP_IRQS TATUS_REG[2] REOF | McBSPi.MCBSPLP_IRQENABLE_ REG[2] REOFLEN | This event happens when a complete frame was received. |
| Frame-sync | McBSPi.MCBSPLP_IRQS TATUS_REG[1] RFSR | McBSPi.MCBSPLP_IRQENABLE_ REG[1] RFSREN | This event happens when a new receive frame synchronization is asserted. |
| Frame-sync error | McBSPi.MCBSPLP_IRQS TATUS_REG[0] RSYNCERR | McBSPi.MCBSPLP_IRQENABLE_ REG[0] RSYNCERREN | This event happens when a receive frame synchronization error is detected. |

Once an interrupt request is generated, the software must read the McBSPi.MCBSPLP_IRQSTATUS_REG register to check what event has caused the interrupt request generation, and acknowledge each processed event by writing a 1 to the corresponding bit in the McBSPi.MCBSPLP_IRQSTATUS_REG register.

NOTE: All Status bits can be cleared in two ways:

- If the corresponding mask bit is set to '1' (interrupt generation enabled), the status bit is cleared by writing a '1'.
- If the corresponding mask bit is cleared to '0' (interrupt generation disabled), the status bit is cleared when a new start or stop condition is detected on the receiver/transmitter.

18.3.3.2.2 SIDETONE_McBSP Interrupt Requests

The McBSP2 and McBSP3 can generate another interrupt to the MPU subsystem interrupt controller:

- **ST_McBSPi_IRQ:** SIDETONE interrupt request for McBSPi module (where I = 2, 3).

Table 18-13. SIDETONE_McBSP Interrupt Requests

| Request Name | Mapping | Destination |
|---------------|---------|------------------------------------|
| ST_McBSP2_IRQ | M_IRQ_4 | MPU subsystem interrupt controller |
| ST_McBSP3_IRQ | M_IRQ_5 | MPU subsystem interrupt controller |

Table 18-14. SIDETONE_McBSP Interrupt Events

| Event Name | Status Bit | Mask Bit | Description |
|------------|---|--|---|
| Over-run | McBSPi.ST_IRQSTATUS_REG[0] OVRRError | McBSPi.ST_IRQENABLE_REG[0] OVRRErrorREN | This event happens when a new data to be processed arrives before the previous one has ended. |

Once an interrupt request has been generated, the software must read the McBSPi.ST_IRQSTATUS_REG register to check what event caused the interrupt request generation, and acknowledge each processed event by writing a 1 to the corresponding bit in the McBSPi.ST_IRQSTATUS_REG register.

NOTE: The McBSPi.ST_IRQSTATUS_REG[0] OVRRError status bit can be cleared in two ways:

- If the McBSPi.ST_IRQENABLE_REG[0] OVRRErrorREN mask bit is set to '1' (interrupt generation enabled), the status bit is cleared by writing a '1'.
- If the McBSPi.ST_IRQENABLE_REG[0] OVRRErrorREN mask bit is cleared to '0' (interrupt generation disabled), the status bit is cleared when a new start or stop condition is detected on the SIDETONE channels.

18.4 McBSP Functional Description

This section is a functional description of the McBSP module.

18.4.1 Block Diagram

Figure 18-21, Figure 18-22, and Figure 18-23 show functional block diagrams of the five instances of the McBSP modules.

These figures regroup the McBSP modules by categories:

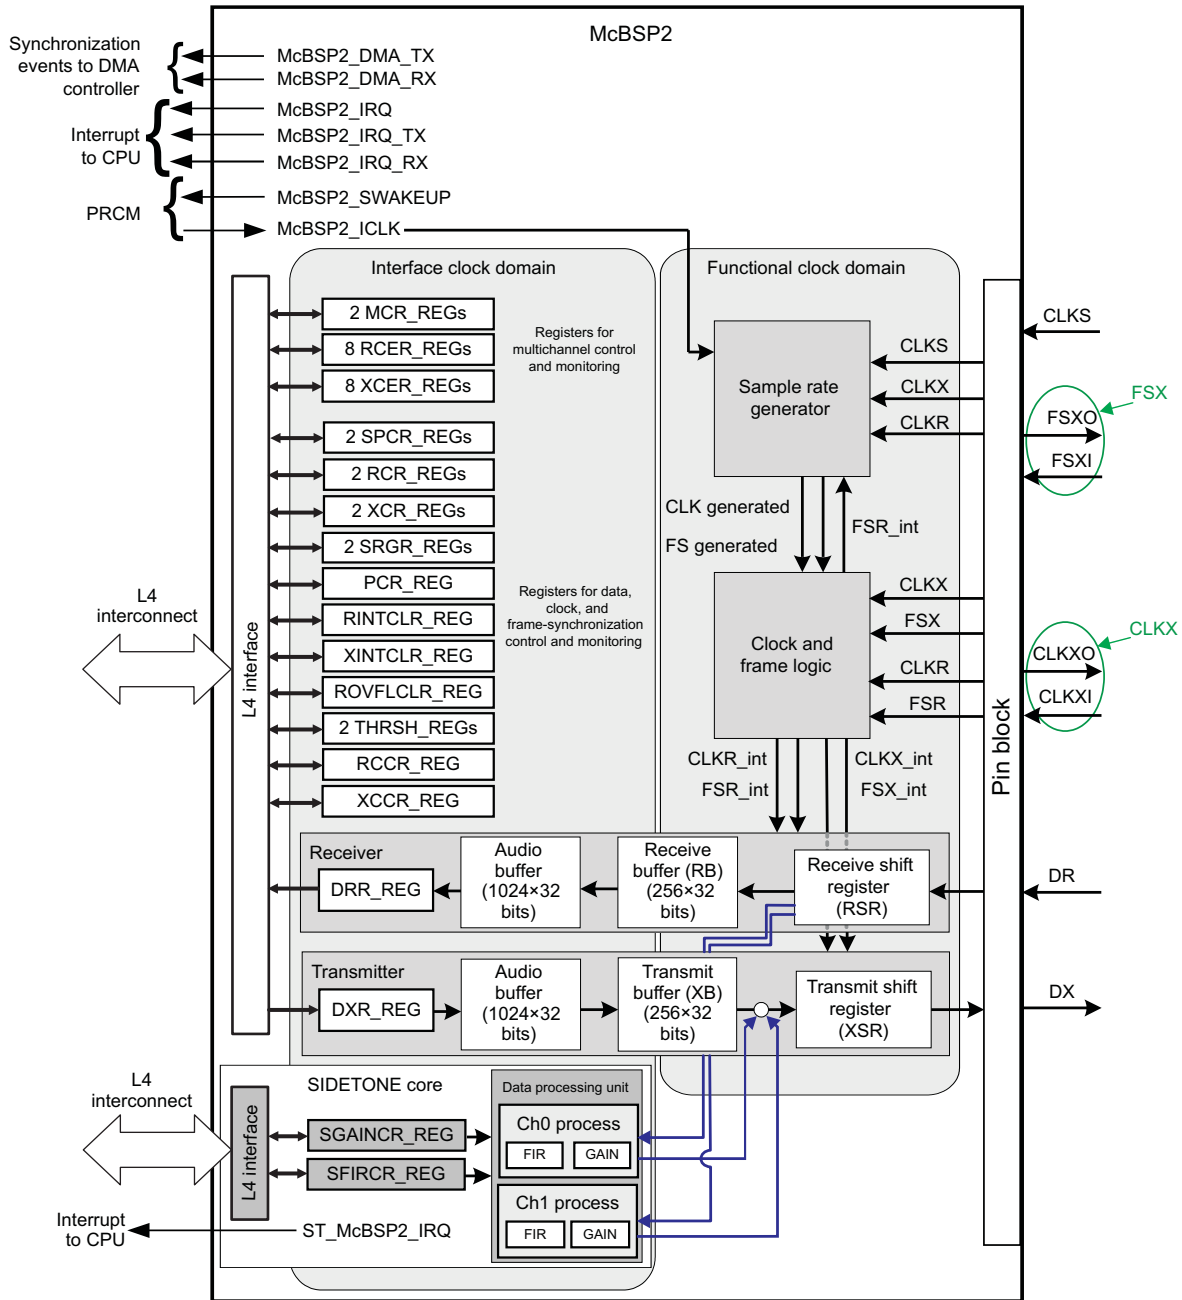

- McBSP module without audio buffer and SIDETONE core: McBSP1, McBSP4 and McBSP5
- McBSP module with audio buffer and SIDETONE core: McBSP2
- McBSP module without audio buffer, but with SIDETONE core: McBSP3

mcbasp_022

Figure 18-23. McBSP3 Block Diagram

mcbasp_023

18.4.2 McBSP Data Transfer Process

For McBSP1, McBSP3, McBSP4, and McBSP5 modules, receive and transmit operations are triple-buffered (512 bytes buffers organized in 32-bit words are used).

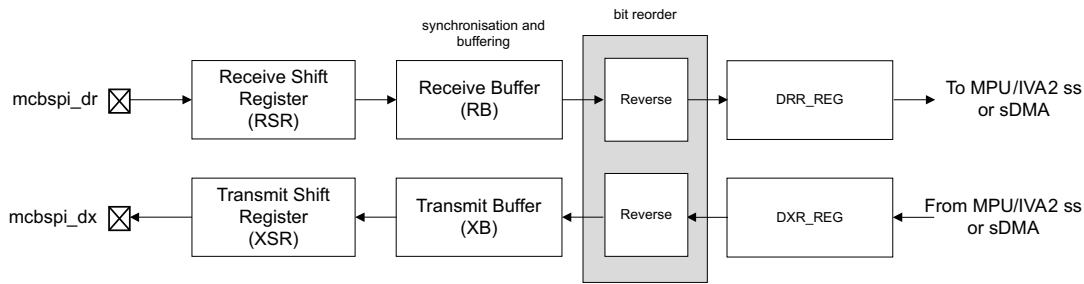

For the McBSP2 module, receive and transmit operations are quadruple-buffered (5K bytes buffers organized in 32-bit words are used). Receive and transmit buffers are separated in two memories: The same buffer as the others McBSP modules (1K bytes) and an audio buffer (4K bytes). The audio buffer is the largest one and is clocked by the interface clock, while the other buffer is used for synchronizing data to/from the audio buffer with the functional transmit/receive clock domains. Figure 18-25 shows this implementation in the McBSP2 data transfer paths.

All registers of McBSP data transfer paths are 32-bits wide. [Figure 18-24](#) and [Figure 18-25](#) illustrate the McBSP data transfer paths.

CAUTION

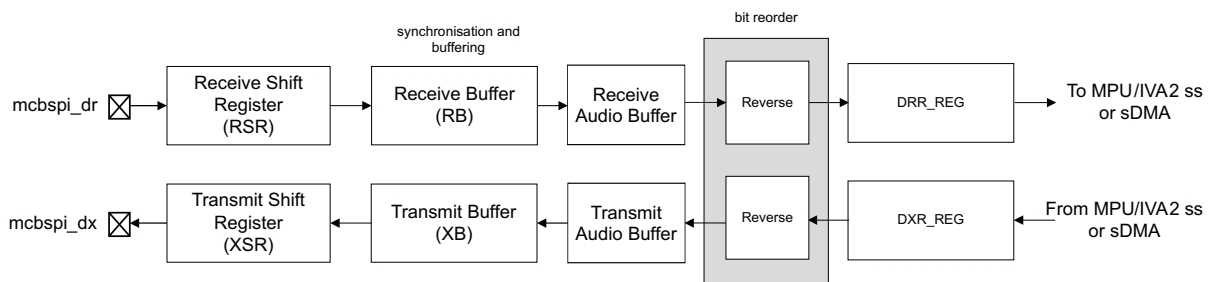

The McBSP registers (DRR_REG and DXR_REG) are limited to 32-bit data accesses (L4 Interconnect). 16-bit and 8-bit is not allowed and can corrupt register content.

Figure 18-24. McBSP Data Transfer Paths

024

Figure 18-25. McBSP2 Data Transfer Paths

068

18.4.2.1 Data Transfer Process for 8- / 12- / 16- / 20- / 24- / 32-bits Long Words

CAUTION

For each data word length, one data occupies one 32-bit buffer word.

Receive data arrives on the mcbspi_dr pin and is shifted into the receive shift register (RSR). When a full word (depending on the data length configuration) is received, the content of the shift register is copied into the receive buffer (RB) if it is not full. When the RB threshold is reached the McBSP module asserts DMA or interrupt request and the RB content is then transferred (the sDMA or the eDMA controller reads the data receive register McBSPi.MCBSPLP_DRR_REG).

Transmit data is written by the MPU subsystem, the IVA2.2 subsystem or the DMA controller to data transmit register (McBSPi.MCBSPLP_DXR_REG) using the McBSPi.MCBSPLP_SPCR2_REG[1] XRDY bit enable input (when a byte is not enabled, the byte value in the memory will contain the previous written value). If there is no previous data in transmit shift register (XSR), the value from the transmit buffer (XB) is copied to XSR; otherwise, the content is copied to the XSR when the last bit of the previous data is shifted out on the mcbspi_dx pin.

18.4.2.2 Bit Reordering (Option to Transfer LSB First)

Generally, the McBSP module transmits or receives all data with the MSB first. However, some data protocols require the LSB to be transferred first.

If you set `McBSPi.MCBSPLP_XCR2_REG[4:3] XREVERSE=0b01`, the bit ordering of the data words is reversed (LSB first) before being sent to the serial port. If you set `McBSPi.MCBSPLP_RCR2_REG[4:3] RREVERSE=0b01`, the bit ordering of the data words is reversed during reception (LSB first).

This feature is available for all the data formats from 8 up to 32-bit data length.

18.4.2.3 Clocking and Framing Data

This section explains basic concepts and terminology important for understanding how McBSP data transfers are timed and delimited.

Figure 18-26. Conceptual Block Diagram for Clock and Frame Generation

MCBSP_025

18.4.2.3.1 Clocking

Data is shifted one bit at a time from the `mcbspi_dr` pin to the RSRs or from the XSRs to the `mcbspi_dx` pin. The time for each bit transfer is controlled by the rising or falling edge of a clock signal.

The receive clock signal (`CLKR_int`) controls bit transfers from the `mcbspi_dr` pin to the RSRs. The transmit clock signal (`CLKX_int`) controls bit transfers from the XSRs to the `mcbspi_dx` pin. `CLKR_int` or `CLKX_int` signals can be derived from a pin at the boundary of the McBSP module (`mcbspi_clkr` and `mcbspi_clkx` respectively) or derived from inside the McBSP module (see Figure 18-26). The clocks source is selected by programming the `McBSPi.MCBSPLP_PCR_REG[9]` `CLKXM` bit and the `McBSPi.MCBSPLP_PCR_REG[8]` `CLKRM` bit respectively.

When the `McBSPi.MCBSPLP_PCR_REG[9]` `CLKXM` bit (transmitter clock mode) is set to:

- '0', `CLKX_int` is driven by an external clock and `mcbspi_clkx` is an input pin.
- '1', `CLKX_int` is driven by the internal sample rate generator and `mcbspi_clkx` is an output pin.

For the `McBSPi.MCBSPLP_PCR_REG[8]` `CLKRM` bit (receiver clock mode), see Table 18-15.

Table 18-15. Receiver Clock Mode

| Value | Digital loop back mode | mcbspi_clkr pin | Description |
|-------|---|-----------------|--|
| 0x0 | <code>McBSPi.MCBSPLP_XCCR_REG[5]</code> <code>DLB</code> bit =0 | input | <code>CLKR_int</code> is driven by an external clock |
| | <code>McBSPi.MCBSPLP_XCCR_REG[5]</code> <code>DLB</code> bit =1 | High-impedance | <code>CLKR_int</code> is driven by <code>CLKX_int</code> . The <code>CLKX_int</code> is derived based on the <code>CLKXM</code> value. |

Table 18-15. Receiver Clock Mode (continued)

| Value | Digital loop back mode | mcbspi_clkr pin | Description |
|-------|---------------------------------------|-----------------|---|
| 0x1 | McBSPi.MCBSPLP_XCCR_REG[5] DLB bit =0 | output | CLKR_int is driven by the internal sample rate generator |
| | McBSPi.MCBSPLP_XCCR_REG[5] DLB bit =1 | output | CLKR_int is driven by CLKX_int. The CLKX_int is derived based on the CLKXM value. |

The polarities of CLKR and CLKX signals are configured in McBSPi.MCBSPLP_PCR_REG register.

The McBSPi.MCBSPLP_PCR_REG[1] CLKXP defines the transmit clock polarity:

- When set to 0, transmit data driven on rising edge of CLKX signal
- When set to 1, transmit data driven on falling edge of CLKX signal

The McBSPi.MCBSPLP_PCR_REG[0] CLKRP defines the receive clock polarity:

- When set to 0, receive data sampled on falling edge of CLKX signal
- When set to 1, transmit data sampled on rising edge of CLKX signal

Figure 18-27 gives an example where the clock signal controls the timing of each bit transfer on the pin.

Figure 18-27. Clock Signal Control of Bit Transfer Timing

026

NOTE: The McBSP module is constrained to operate at an internal functional frequency of up to L4 interface frequency divided by 2. When driving CLKX or CLKR at the pin, choose an appropriate input clock frequency. When using the internal sample rate generator for CLKX/CLKR/CLKS, choose an appropriate input clock frequency (up to L4 interface frequency) and divide down value by programming the McBSPi.MCBSPLP_SRGR1_REG[7:0] CLKGDV bit field.

18.4.2.3.2 Serial Words

Bits traveling between a shift register (RSR or XSR) and a data pin (mcbspi_dr or mcbspi_dx) are transferred in a group called a serial word. The software defines how many bits are in a word by programming:

- For the receiver: the McBSPi.MCBSPLP_RCR1_REG[7:5] RWDLEN1 field and the McBSPi.MCBSPLP_RCR2_REG[7:5] RWDLEN2 field.
- For the transmitter: the McBSPi.MCBSPLP_XCR1_REG[7:5] XWDLEN1 field and the McBSPi.MCBSPLP_XCR2_REG[7:5] XWDLEN2 field.

The difference of use is explained to Section 18.4.2.4.1.

The various possibilities of word length are 8, 12, 16, 20, 24, and 32 bits (for field values, see Section 18.6)

Bits coming from the mcbspi_dr pin are held in the RSR until it holds a full serial word, then the word is passed to the RB and to the McBSPi.MCBSPLP_DRR_REG register.

During transmission, XSR accepts new data from XB after a full serial word has been passed from XSR to the mcbspi_dx pin.

In the example in Figure 18-27, an 8-bit word size was defined (see the transfer of the 8-bit word B).

18.4.2.3.3 Frames and Frame Synchronization

One or more words (up to 128) are transferred in a group called a frame. The software defines how many words are in a frame by programming:

- For the receiver: The McBSPi.MCBSPLP_RCR1_REG[14:8] RFLEN1 field and the McBSPi.MCBSPLP_RCR2_REG[14:8] RFLEN2 field.
- For the transmitter: The McBSPi.MCBSPLP_XCR1_REG[14:8] XFLEN1 field and the McBSPi.MCBSPLP_XCR2_REG[14:8] XFLEN2 field.

The difference between these registers is explained to [Section 18.4.2.4.1](#). For the corresponding between field value and words number, see [Section 18.6](#).

All the words in a frame are sent in a continuous stream. However, there can be pauses between frame transfers. The McBSP module uses frame-synchronization signals (FSG) to determine when each frame is received/transmitted. When a pulse occurs on a frame-synchronization signal, the McBSP module begins receiving/transmitting a frame of data. When the next pulse occurs, the McBSP module receives/transmits the next frame, and so on.

Pulses on the receive frame-synchronization (FSR_int) signal initiate frame transfers on mcbspi_dr. Pulses on the transmit frame-sync (FSX_int) signal initiate frame transfers on mcbspi_dx. FSR_int or FSX_int signals can be derived from a pin at the boundary of the McBSP module (mcbspi_fsr and mcbspi_fsx respectively) or derived from inside the McBSP module (see [Figure 18-25](#)). The frame-sync source is selected by programming the McBSPi.MCBSPLP_PCR_REG[11] FSXM bit and the McBSPi.MCBSPLP_PCR_REG[10] FSRM bit respectively.

When the McBSPi.MCBSPLP_PCR_REG[11] FSXM bit (transmitter frame-sync mode) is set to:

- '0', FSX_int is derived from an external source and mcbspi_fsx is an input pin.
- '1', FSX_int is determined by the McBSPi.MCBSPLP_SRGR2_REG[12] FSGM bit and mcbspi_fsx is an output pin.

For the McBSPi.MCBSPLP_PCR_REG[10] FSRM bit (receiver frame-sync mode), is set to:

- '0', FSR_int is generated by an external source and mcbspi_fsr is an input pin
- '1', FSR_int is generated internally by sample rate generator. The mcbspi_fsx is an output pin except when McBSPi.MCBSPLP_SRGR2_REG[15] GSYNC bit = 0x1

In the example in [Figure 18-26](#), a one-word frame is transferred when a frame-synchronization pulse occurs. The polarities of FSR and FSX signals are programmable by bits on McBSPi.MCBSPLP_PCR_REG register.

The McBSPi.MCBSPLP_PCR_REG[3] FSXP defines the transmit frame-sync polarity:

- When set to '0', frame-sync pulse FSX is active high
- When set to '1', frame-sync pulse FSX is active low

The McBSPi.MCBSPLP_PCR_REG[2] FSRP defines the receive frame-sync polarity:

- When set to '0', frame-sync pulse FSR is active high
- When set to '1', frame-sync pulse FSR is active low

In McBSP operation, the inactive-to-active transition of the frame-synchronization signal indicates the start of the next frame. For this reason, the frame-synchronization signal may be high for an arbitrary number of clock cycles. Only after the signal is recognized to have gone inactive, and then active again, does the next frame synchronization occur.

18.4.2.3.4 Detecting Frame-Synchronization Pulses, Even in Reset State

The McBSP module can generate receive and transmit interrupts to the MPU/IVA2.2 subsystems to indicate specific events in the McBSP module. To facilitate detection of frame synchronization, these interrupts can be sent in response to frame-synchronization pulses (see [Section 18.5](#) for further details).

Unlike other serial port interrupt modes, this mode can operate while the associated portion of the serial port is in reset (such as activating receive interrupt when the receiver is in reset). In this case, McBSPi.MCBSPLP_PCR_REG[0] FSRM bit/McBSPi.MCBSPLP_PCR_REG[1] FSXM bit and McBSPi.MCBSPLP_PCR_REG[2] FSRP bit/McBSPi.MCBSPLP_PCR_REG[3] FSXP bit still select the

appropriate source and polarity of frame synchronization. Thus, even when the serial port is in the reset state, these signals are synchronized to the interface clock (McBSPi_ICLK) and then sent to the MPU/IVA2.2 subsystem in the form of receive interrupt and transmit interrupt at the point where they feed the receiver and transmitter of the serial port. Consequently, a new frame-synchronization pulse can be detected, and then, the MPU/IVA2.2 subsystem can take the serial port out of reset safely.

18.4.2.3.5 Ignoring Frame-Synchronization Pulses

The McBSP module ignores transmit and/or receive frame-synchronization pulses if the frame transfer was started by a previous frame-synchronization pulse (unexpected frame-synchronization pulses). The McBSP module does not support features like retransmit or re-receive of an erroneous frame or word. The receiver or transmitter ignores frame-synchronization pulses until the desired frame length or number of words is reached. For more details on unexpected frame-synchronization pulses, see [Section 18.4.4.3](#), or [Section 18.4.4.6](#)

18.4.2.3.6 Frame Frequency

The frame frequency is determined by the period between frame-synchronization pulses and is defined as shown in the following equation:

Frame frequency = Clock frequency / (Number of clock cycles between two rising edges [or falling edges] of two consecutive frame synchronization pulses)

The frame frequency can be increased by decreasing the time between frame-synchronization pulses (limited only by the number of bits per frame). As the frame transmit frequency increases, the inactivity period between the data packets for adjacent transfers decreases to zero.

18.4.2.3.7 Maximum Frame Frequency

The minimum number of clock cycles between frame synchronization pulses is equal to the number of bits transferred per frame. The maximum frame frequency is defined as shown in the following equation:

Maximum frame frequency = clock frequency / Number of bits per frame

[Figure 18-28](#) below shows the McBSP operating at maximum packet frequency. At maximum packet frequency, the data bits in consecutive packets are transmitted contiguously with no inactivity between bits.

Figure 18-28. McBSP Operating at Maximum Packet Frequency

If there is a 1-bit data delay as shown in [Figure 18-28](#), the frame-synchronization pulse overlaps the last bit transmitted in the previous frame. Effectively, this permits a continuous stream of data, back-to-back transfers.

NOTE: For McBSPi.MCBSPLP_XCR2_REG[1:0] XDATDLY = 0x0 (0-bit data delay), the first bit of data is transmitted asynchronously to the internal transmit clock signal (CLKX_int). For more details, see [Section 18.5.1.6.2.2.5](#).

18.4.2.4 Frame Phases (Dual-Phase Frame I2S Support)

The McBSP module allows you to configure each frame to contain one or two phases. The support for dual-phase frames is required to provide I2S fully compliant capabilities (audio left and right channels—stereo audio stream).

CAUTION

The limitation on dual-phase frame support is that the number of words per phase must be set to 1 for both first and second phase. It is the only possible value for word per frame when using the dual phase frame.

The number of bits per word can be specified differently for each of the two phases of a frame, allowing greater flexibility in structuring data transfers. For example, a user might define a frame as consisting of one phase containing one word of 16 bits, followed by a second phase consisting of one word of 32 bits. This configuration allows the user to compose frames for custom applications such as I2S protocol.

18.4.2.4.1 Number of Phases, Words, and Bits per Frame

Table 18-16 below shows which bit fields in the receive control registers (McBSPi.MCBSPLP_RCR1_REG and McBSPi.MCBSPLP_RCR2_REG) and in the transmit control registers (McBSPi.MCBSPLP_XCR1_REG and McBSPi.MCBSPLP_XCR2_REG) determine the number of phases per frame, the number of words per frame, and the number of bits per word for each phase, for both receiver and transmitter. The maximum number of words per frame is limited to 2 when using dual-phase frames (one word for each phase), and to 128 for a single-phase frame. The number of bits per word can be 8, 12, 16, 20, 24, or 32 bits.

The following legend applies to the table:

- RPHASE => McBSPi.MCBSPLP_RCR2_REG[15] RPHASE bit
- XPHASE => McBSPi.MCBSPLP_XCR2_REG[15] XPHASE bit
- RFLEN1 => McBSPi.MCBSPLP_RCR1_REG[14:8] RFLEN1 field
- RFLEN2 => McBSPi.MCBSPLP_RCR2_REG[14:8] RFLEN2 field
- XFLEN1 => McBSPi.MCBSPLP_XCR1_REG[14:8] XFLEN1 field
- XFLEN2 => McBSPi.MCBSPLP_XCR2_REG[14:8] XFLEN2 field
- RWDLEN1 => McBSPi.MCBSPLP_RCR1_REG[7:5] RWDLEN1 field
- RWDLEN2 => McBSPi.MCBSPLP_RCR2_REG[7:5] RWDLEN2 field
- XWDLEN1 => McBSPi.MCBSPLP_XCR1_REG[7:5] XWDLEN1 field
- XWDLEN2 => McBSPi.MCBSPLP_XCR2_REG[7:5] XWDLEN2 field

Table 18-16. Phases, Words and Bits per Frame Control Bit

| Operation | Number of phases | Words per frame set with | Bits per word set with |
|--------------|------------------|---------------------------|---|
| Reception | 1 (RPHASE=0) | RFLEN1 | RWDLEN1 |
| Reception | 2 (RPHASE=1) | RFLEN1=0x0 and RFLEN2=0x0 | RWDLEN1 for phase 1 RWDLEN2 for phase 2 |
| Transmission | 1 (XPHASE=0) | XFLEN1 | XWDLEN1 |
| Transmission | 2 (XPHASE=1) | XFLEN1=0x0 and XFLEN2=0x0 | XWDLEN1 for phase 1 XWDLEN2 for phase 2 |

18.4.2.4.2 Single-Phase Frame Example

Figure 18-29 below shows an example of a single-phase data frame containing one 8-bit word. Because the transfer is configured for one data bit delay, the data on the mcbspi_dx and mcbspi_dr pins are available one clock cycle after FS(R/X) goes active. The following table shows the assumptions used in the example of this figure.

Table 18-17. Assumptions for the Single-Phase Frame Example

| Assumption | Value | Bit or Field Name |
|--------------------|-------|--|
| Single-phase frame | '0' | McBSPi.MCBSPLP_RCR2_REG[15] RPHASE bit |
| | | McBSPi.MCBSPLP_XCR2_REG[15] XPHASE bit |
| One word per frame | 0x0 | McBSPi.MCBSPLP_RCR1_REG[14:8] RFLEN1 field |
| | | McBSPi.MCBSPLP_XCR1_REG[14:8] XFLEN1 field |

Table 18-17. Assumptions for the Single-Phase Frame Example (continued)

| Assumption | Value | Bit or Field Name |
|--------------------------------------|---------|--|
| 8-bit word length | 0x0 | McBSPi.MCBSPLP_RCR1_REG[7:5] RWDLEN1 field |
| | | McBSPi.MCBSPLP_XCR1_REG[7:5] XWDLEN1 field |
| word length in register2 | ignored | McBSPi.MCBSPLP_RCR2_REG[14:8] RFRLLEN2 field |
| | | McBSPi.MCBSPLP_XCR2_REG[14:8] XWDLEN2 field |
| Receive data clocked on falling edge | '0' | McBSPi.MCBSPLP_PCR_REG[0] CLKRP bit |
| Transmit data clocked on rising edge | | McBSPi.MCBSPLP_PCR_REG[1] CLKXP bit |
| Active-high frame-sync signals | '0' | McBSPi.MCBSPLP_PCR_REG[2] FSRP bit |
| | | McBSPi.MCBSPLP_PCR_REG[3] FSXP bit |
| 1-bit data delay | 01b | McBSPi.MCBSPLP_RCR2_REG[1:0] RDATDLY field |
| | | McBSPi.MCBSPLP_XCR2_REG[1:0] XDARDLY field |

Figure 18-29. Single-Phase Frame for a McBSP Data Transfer

028

18.4.2.4.3 Dual-Phase Frame Example

Figure 18-30 below shows an example of a frame. The first phase consists of one word of 16 bits, followed by a second phase of one word of 8 bits. The entire bit stream in the frame is contiguous. There are no gaps between words/phases. Table 18-18 shows the assumptions used to the example in Figure 18-30.

Table 18-18. Assumptions for the Dual-Phase Frame Example

| Assumption | Value | Bit or Field name |
|--------------------------------------|-------|--|
| Single-phase frame | '1' | McBSPi.MCBSPLP_RCR2_REG[15] RPHASE bit |
| | | McBSPi.MCBSPLP_XCR2_REG[15] XPHASE bit |
| One word per frame | 0x0 | McBSPi.MCBSPLP_RCR1_REG[14:8] RFRLLEN1 field |
| | | McBSPi.MCBSPLP_XCR1_REG[14:8] XFRLLEN1 field |
| 16-bit word length | 0x0 | McBSPi.MCBSPLP_RCR1_REG[7:5] RWDLEN1 field |
| | | McBSPi.MCBSPLP_XCR1_REG[7:5] XWDLEN1 field |
| 8-bit word length | 0x2 | McBSPi.MCBSPLP_RCR2_REG[14:8] RFRLLEN2 field |
| | | McBSPi.MCBSPLP_XCR2_REG[14:8] XWDLEN2 field |
| Receive data clocked on falling edge | '0' | McBSPi.MCBSPLP_PCR_REG[0] CLKRP bit |
| Transmit data clocked on rising edge | | McBSPi.MCBSPLP_PCR_REG[1] CLKXP bit |
| Active-high frame-sync signals | '0' | McBSPi.MCBSPLP_PCR_REG[2] FSRP bit |
| | | McBSPi.MCBSPLP_PCR_REG[3] FSXP bit |
| 0-bit data delay | 00b | McBSPi.MCBSPLP_RCR2_REG[1:0] RDATDLY field |
| | | McBSPi.MCBSPLP_XCR2_REG[1:0] XDARDLY field |

18.4.2.5 McBSP Reception

This section explains the fundamental process of reception in the McBSP module. For details about how to program the McBSP receiver, see [Section 18.5](#), [Section 18.5.1.4](#), and [Section 18.5.1.5](#).

[Figure 18-31](#) and [Figure 18-32](#) below show how reception occurs in the McBSP module. A description of the process follows the figures. [Figure 18-31](#) shows the physical path for the data.

Figure 18-31. McBSP Reception Physical Data Path

030

[Figure 18-32](#) is a timing diagram showing signal activity for one possible reception scenario.

Figure 18-32. McBSP Reception Signal Activity

RRDY: Status of receiver ready bit (high is 1)

The following process describes how data travels from the mcbspi_dr pin to the MPU/IVA2.2 subsystem or to the sDMA controller:

1. The McBSP module waits for a receive frame-synchronization pulse on FSR_int.
2. When the pulse arrives, the McBSP module inserts the appropriate data delay that is selected with the McBSPi.MCBSPLP_RCR2_REG[1:0] RDATDLY bits. In the preceding timing diagram a 1-bit data delay is selected.
3. The McBSP module accepts data bits on the mcbspi_dr pin and shifts them into the RSR. For details on choosing a word length, see [Section 18.5.1.5.2.2.2](#).
4. When a full word is received, the McBSP module copies the contents of the RSR to the RB, provided that RB is not full.
5. When the programmed receive threshold is reached (McBSPi.MCBSPLP_THRSH1_REG[10:0] RTHRESHOLD field), the McBSP module asserts the receiver ready bit (McBSPi.MCBSPLP_SPCR1_REG[1] RRDY bit). This indicates that receive data is ready to be read by the MPU/IVA2.2 subsystem or the sDMA controller by accessing McBSPi.MCBSPLP_DRR_REG register.

The data copied from RB to McBSPi.MCBSPLP_DRR_REG is justified and bit filled according to the

McBSPi.MCBSPLP_SPCR1_REG[14:13] RJUST field.

- The MPU/IVA2.2 subsystem or the sDMA controller reads the data from the data receive register. When the RB is empty, McBSPi.MCBSPLP_SPCR1_REG[1] RRDY bit is cleared.

18.4.2.6 McBSP Transmission

This section explains the fundamental process of transmission in the McBSP module. For details about how to program the McBSP transmitter, see [Section 18.5](#), and [Section 18.5.1.6](#).

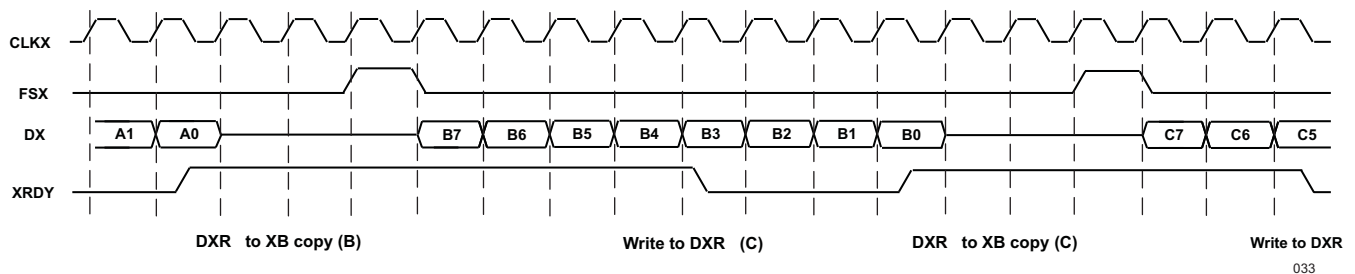

Figures below show how transmission occurs in the McBSP module. A description of the process follows the figures. [Figure 18-33](#) shows the physical path for the data.

Figure 18-33. McBSP Transmission Physical Data Path

[Figure 18-34](#) is a timing diagram showing signal activity for one possible transmission scenario.

Figure 18-34. McBSP Transmission Signal Activity

XRDY: Status of transmitter ready bit (high is 1)

- The MPU/IVA2.2 subsystem or the sDMA controller writes data to the data transmit register (McBSPi.MCBSPLP_DXR_REG). When the XB is reached the transmitter ready bit (McBSPi.MCBSPLP_SPCR2_REG[1] XRDY bit) is cleared to indicate that the transmitter is not ready for new data. For details on choosing a word length, see [Section 18.5.1.6.2.2.2](#).
- When new data arrives in McBSPi.MCBSPLP_DXR_REG register, the McBSP module copies the content of the data transmit register to the XB. In addition, the transmit ready bit (McBSPi.MCBSPLP_SPCR2_REG[1] XRDY bit) is set as long as the buffer contains at least the transmit threshold number of free locations (McBSPi.MCBSPLP_THRSH2_REG[10:0] XTHRESHOLD field). This indicates that the transmitter is ready to accept new data from the MPU/IVA2.2 subsystem or the sDMA controller.
- The McBSP module waits for a transmit frame-synchronization pulse on FSX_int.
- When the pulse arrives, the McBSP module inserts the appropriate data delay that is selected with the McBSPi.MCBSPLP_XCR2_REG[1:0] XDATDLY field.
In the preceding timing diagram, a 1-bit data delay is selected.
- The McBSP module shifts data bits from the XSR to the mcbspi_dx pin.

18.4.2.7 Enable/Disable the Transmit and Receive Processes

The McBSP module has the option to stop-resume the transmit/receive process while the module is in functional mode (out of transmit/receive reset).

When the transmit/receive disable bit (McBSPi.MCBSPLP_XCCR_REG[0] XDISABLE/McBSPi.MCBSPLP_RCCR_REG[0] RDISABLE) is set, the McBSP module stops the transmit/receive operation at the next frame boundary (frame corruption avoided).

During the receive disable state, the frames that are sent (when FSR signal is asserted while receive disable) by the remote device are lost, and receive buffer overflow status bit (McBSPi.MCBSPLP_IRQSTATUS_REG[5] ROVFLSTAT) is not set. Also, the frames received by the remote device while McBSPi.MCBSPLP_XCCR_REG[0] XDISABLE bit is set (when FSX signal is asserted while transmit disable) are meaningless undefined data frames, and transmit buffer underflow status bit (McBSPi.MCBSPLP_IRQSTATUS_REG[11] XUNDFLSTAT) is not set. The presence of the frame synchronization, while transmit/receive process is disabled, can be checked by reading the transmit/receive Frame-sync interrupt status: McBSPi.MCBSPLP_IRQSTATUS_REG[8] XFSX / McBSPi.MCBSPLP_IRQSTATUS_REG[1] RFSR bits.

As soon as the McBSPi.MCBSPLP_XCCR_REG[0] XDISABLE/McBSPi.MCBSPLP_RCCR_REG[0] RDISABLE bit is cleared, the transmit/receive process resumes at the next frame boundary.

NOTE: It is not recommended to use this mechanism together with the possibility to interrogate the transmit/receive buffer status register (McBSPi.MCBSPLP_XBUFFSTAT_REG[7:0] XBUFFSTAT/McBSPi.MCBSPLP_RBUFFSTAT_REG[7:0] RBUFFSTAT field indicating the occupied/available buffer locations), since this register is an interface clock (McBSPi_ICLK) synchronous register and does not reflect the exact number of occupied/free locations available on the functional clock domain.

18.4.2.8 McBSP Data Transfer Mode

NOTE: For all examples in this section, the configured CLKX edge is the rising edge (McBSPi.MCBSPLP_PCR_REG[1] CLKXP bit = 0x0) and the configured CLKR edge is the falling edge (McBSPi.MCBSPLP_PCR_REG[0] CLKRP bit = 0x0). These are the reset values.

In the following timing diagrams, a 1-bit data delay is selected (McBSPi.MCBSPLP_RCR2_REG[1:0] RDATDLY field = 0x01 and McBSPi.MCBSPLP_XCR2_REG[1:0] XDATDLY bit field = 0x01), because data often follows a 1-cycle active frame-synchronization.

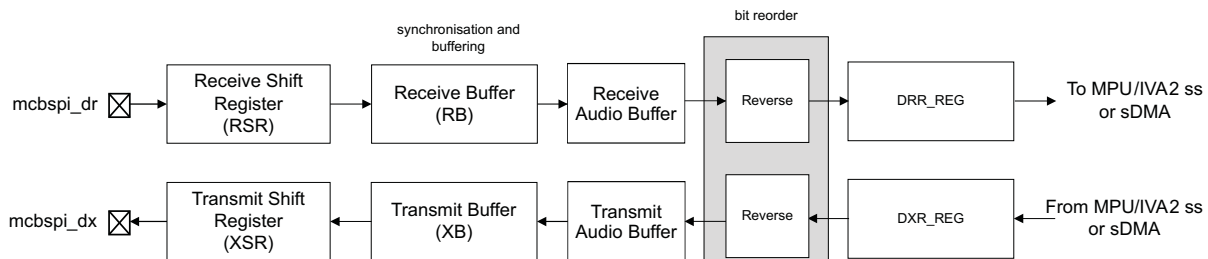

McBSP modules can support two edge selection modes for transmit and receive data transfer at the system level:

- The full cycle mode, for which one clock period is used to transfer the data, generated on one edge and captured on the same edge (one clock period later).
- The half cycle mode, for which one half clock period is used to transfer the data, generated on one edge and captured on the opposite edge (one half clock period later). A new data is generated only every clock period, which permits to ensure the required hold time.

18.4.2.8.1 Transmit Full Cycle Mode

When configured in full cycle mode (McBSPi.MCBSPLP_XCCR_REG[11] XFULL_CYCLE bit = 0x1), the FSX signal is sampled on the configured CLKX edge and the data is driven on the same configured edge. See Figure 18-35.

Figure 18-35. Transmit Full Cycle Timing Diagram

18.4.2.8.2 Transmit Half Cycle Mode

When configured in half cycle mode (McBSPi.MCBSPLP_XCCR_REG[11] XFULL_CYCLE bit = 0x0, reset value), the FSX signal is sampled on the opposite configured CLKX edge and the data is driven on the next configured edge. See Figure 18-36.

Figure 18-36. Transmit Half Cycle Timing Diagram

18.4.2.8.3 Receive Full Cycle Mode

When configured in full cycle mode (McBSPi.MCBSPLP_RCCR_REG[11] RFULL_CYCLE bit = 0x1, reset value), the FSR signal is sampled on the configured CLKR edge and the data is driven on the same configured edge. See Figure 18-37.

Figure 18-37. Receive Full Cycle Timing Diagram

18.4.2.8.4 Receive Half Cycle Mode

When configured in half cycle mode (McBSPi.MCBSPLP_RCCR_REG[11] RFULL_CYCLE bit = 0x0), the FSR signal is sampled on the opposite configured CLKR edge and the data is driven on the next configured edge. See Figure 18-38.

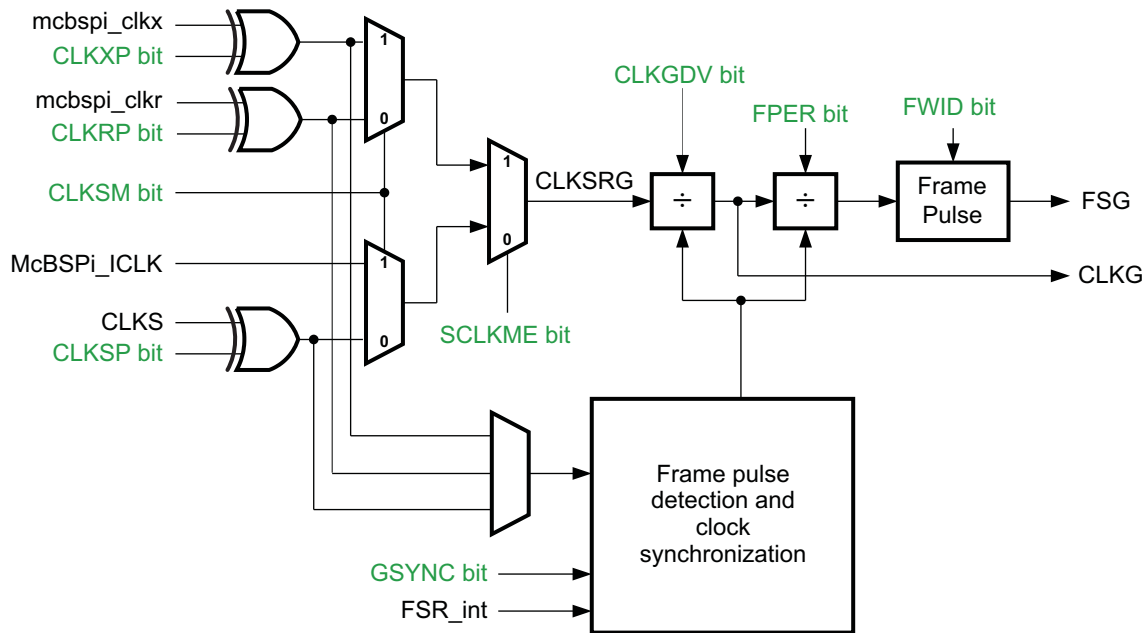

Figure 18-38. Receive Half Cycle Timing Diagram

18.4.3 McBSP SRG

The McBSP module contains an internal SRG that can be used to generate an internal data clock (CLKG) and an internal frame-synchronization signal (FSG). CLKG can be used for bit shifting on the data receive pin (mcbspi_dr) and/or the data transmit pin (mcbspi_dx). FSG can be used to initiate frame transfers on mcbspi_dr pin and/or mcbspi_dx pin. Figure 18-39 is a conceptual block diagram of the SRG.

Figure 18-39. Conceptual Block Diagram of the Sample Rate Generator

mcbasp_034

The source clock for the SRG (labeled CLKS_{RG} in the diagram) can be supplied by either the interface clock (McBSPi_ICLK), or the functional clock (CLKS input), or by an external pin (mcbspi_clkx, or mcbspi_clkr). The source is selected with the McBSPi.MCBSPLP_PCR_REG[7] SCLKME bit and the McBSPi.MCBSPLP_SRGR2_REG[13] CLKSM bit.

If a pin or CLKS signal is used, the polarity of the incoming signal can be inverted with the appropriate polarity bit (McBSPi.MCBSPLP_SRGR2_REG[14] CLKSP bit, McBSPi.MCBSPLP_PCR_REG[1] CLKXP bit, or McBSPi.MCBSPLP_PCR_REG[0] CLKRP bit).

The SRG has a three-stage clock divider that gives CLKG and FSG programmability.

The three stages provide:

- Clock divide-down: The source clock (CLKS_{RG}) is divided according to the McBSPi.MCBSPLP_SRGR1_REG[7:0] CLKGDV field to produce CLKG signal
- Frame period divide-down: CLKG is divided according to the McBSPi.MCBSPLP_SRGR2_REG[11:0] FPER field to control the period from the start of a frame-pulse to the start of the next pulse
- Frame-synchronization pulse-width countdown: CLKG cycles are counted according to the McBSPi.MCBSPLP_SRGR1_REG[15:8] FWID field to control the width of each frame-synchronization pulse

NOTE: The McBSP module cannot operate at an internal functional frequency faster than L4 interface frequency divided by 2. Choose an input clock frequency and a McBSPi.MCBSPLP_SRGR1_REG[7:0] CLKGDV value such that CLKG is less than or equal to L4 interface frequency divided by 2.

In addition to the three-stage clock divider, the sample rate generator has a frame-synchronization pulse detection and clock synchronization module that allows synchronization of the clock divide down with an incoming frame-synchronization pulse on the mcbspi_fsr pin. This feature is enabled or disabled with the McBSPi.MCBSPLP_SRGR2_REG[15] GSYNC bit.

CLKG is used as source to generate the output clocks CLKX/CLKR when the McBSPi.MCBSPLP_PCR_REG[9] CLKXM / McBSPi.MCBSPLP_PCR_REG[8] CLKRM bit indicates that the clock is an output. The output CLKX/CLKR is generated according to the clock polarity setting (see [Figure 18-26](#)).

For details on getting the sample rate generator ready for operation, see [Section 18.5](#).

18.4.3.1 Clock Generation in the SRG

The SRG can produce a clock signal (CLKG) for use by the receiver, the transmitter, or both. Use of the SRG to drive clocking is controlled by the clock mode bits (McBSPi.MCBSPLP_PCR_REG[9] CLKXM and McBSPi.MCBSPLP_PCR_REG[8] CLKRM) and polarity mode bits (McBSPi.MCBSPLP_PCR_REG[1] CLKXP and McBSPi.MCBSPLP_PCR_REG[0] CLKRP).

When a clock mode bit is set to 1 (CLKRM=1 for reception, CLKXM=1 for transmission), the corresponding data clock (CLKR for reception, CLKX for transmission) is driven by the internal SRG output clock (CLKG) according to the polarity setting.

The effects of this setting on the McBSP module are partially affected by the use of the digital loopback (DLB) mode, the analog loop back (ALB) mode and by the synchronous receive/transmit setting, respectively, as described in [Table 18-19](#). The ALB mode is selected with the McBSPi.MCBSPLP_SPCR1_REG[15] ALB bit. The DLB mode is selected with the McBSPi.MCBSPLP_XCCR_REG[5] DLB bit. The synchronous setting is controlled by input signals. These signals are defined by the control registers of the System Control Module (more details, refer [Section 18.3.1](#))

When using the SRG as a clock source, make sure the SRG is enabled (McBSPi.MCBSPLP_SPCR2_REG[6] GRST bit =1).

Table 18-19. Effects of DLB and ALB Bits on Clock Modes

| Mode Bit Settings | | Effect |
|-------------------|---|--|
| CLKRM=1 | DLB=0 and ALB = 0 (Digital and analog loop back mode disabled) | mcbbsp1_clk is an output pin driven by the SRG output clock (CLKG). |
| | DLB=0 and ALB = 1 (Digital loop back mode disabled and Analog loop back mode enabled) | mcbbsp1_clk is an output pin driven by the SRG output clock (CLKG). The receiver functional part internal clock is driven by CLKX input signal provided by mcbbsp1_clkx pin. The source of CLKX depends on the CLKXM bit. The receive frame synchronization is driven by FSX input signal provided by mcbbsp1_fsx pin. The receive data is driven by the DX input loop-back pin (mcbbsp1_dx). |
| | DLB=1 & ALB = 0 (Digital loop back mode enabled and Analog loop back mode disabled) | The SRG and the frame synchronization generator must be enabled. The internal transmit and receive clocks are driven by the SRG (CLKG having the appropriate CLKXP polarity). The transmit and receive frame synchronization signals are driven by FSG (having the appropriate FSXP polarity). The transmit data is connected to the DR input data. Note that in digital loop back mode no serial link activity will be seen by the remote device. |
| | DLB=1 & ALB = 1 (reserved mode) | Undefined functionality. |

Table 18-19. Effects of DLB and ALB Bits on Clock Modes (continued)

| Mode Bit Settings | Effect |
|--|--|
| CLKXM= 1 DLB=0 & ALB = 0 (Digital & analog loop back mode disabled) | mcbspi_clkx is an output pin driven by the SRG output clock (CLKG). |
| DLB=0 & ALB = 1 (Digital loop back mode disabled and Analog loop back mode enabled) | mcbspi_clkx is an output pin driven by the SRG output clock (CLKG). |
| DLB=1 & ALB = 0 (Digital loop back mode enabled and Analog loop back mode disabled) | <p>The SRG and the frame synchronization generator need to be enabled.</p> <p>The internal transmit and receive clocks are driven by the SRG (CLKG having the appropriate CLKXP polarity).</p> <p>The transmit and receive frame synchronization signals are driven by FSG (having the appropriate FSXP polarity).</p> <p>The transmit data is connected to the DR input data.</p> <p>Note that in digital loop back mode no serial link activity will be seen by the remote device.</p> |
| DLB=1 & ALB = 1 (reserved mode) | Undefined functionality. |
| SCM.CONTROL_DEVCONF0[3] MCBSP1_CLKR bit =1 (synchronous setting and DLB = 0 & ALB = 0) | CLKX is an output pin driven by the SRG output clock (CLKG). CLKR is connected to the CLKX. |

18.4.3.2 Frame Sync Generation in the SRG

The SRG can produce a frame-synchronization signal (FSG) for use by the receiver, the transmitter, or both.

If you want the receiver to use FSG for frame synchronization, make sure McBSPi.MCBSPLP_PCR_REG[10] FSRM bit =1. (When FSRM=0, receive frame synchronization is supplied via the mcbspi_fsr pin.)

If you want the transmitter to use FSG for frame synchronization, you must set:

- McBSPi.MCBSPLP_PCR_REG[11] FSXM = 1: This indicates that transmit frame synchronization is supplied by the McBSP module itself rather than from the mcbspi_fsx pin.
- McBSPi.MCBSPLP_SRGR2_REG[12] FSGM=1: This indicates that when FSXM=1, transmit frame synchronization is supplied by the SRG.

NOTE: When FSGM=0 and FSXM=1, the transmit frame-sync signal (FSX) is generated when XB is not empty. When FSGM = 0, McBSPi.MCBSPLP_SRGR2_REG[11:0] FPER and McBSPi.MCBSPLP_SRGR1_REG[15:8] FWID field are used to determine the frame synchronization period and width (external FSX is gated by the buffer empty condition).

In either case, the SRG must be enabled (McBSPi.MCBSPLP_SPCR2_REG[6] GRST bit=1) and the frame-synchronization logic in the SRG must be enabled (McBSPi.MCBSPLP_SPCR2_REG[7] FRST bit=0).

18.4.3.2.1 Choosing the Width of the Frame-sync Pulse

Each pulse on FSG has a programmable width. You program the McBSPi.MCBSPLP_SRGR1_REG[15:8] FWID field, and the resulting pulse width is (FWID+1)CLKG cycles, where CLKG is the output clock of the SRG. The range is from 1 to 256 clock periods.

18.4.3.2.2 Controlling the Period Between the Starting Edges of Frame Sync Pulses

You can control the amount of time from the starting edge of one FSG pulse to the starting edge of the next FSG pulse. This period is controlled in one of two ways, depending on the configuration of the SRG:

- If the SRG is using an external input clock and McBSPi.MCBSPLP_SRGR2_REG[15] GSYNC bit =1, FSG pulses in response to an inactive-to-active transition on the mcbspi_fsr pin. Thus, an external device controls the frame-synchronization period.

- Otherwise, the software program the McBSPi.MCBSPLP_SRGR2_REG[11:0] FPER field, and the resulting frame-synchronization period is (FPER+1)CLKG cycles, where CLKG is the output clock of the SRG. The range is from 1 to 4096 clock periods.

18.4.3.2.3 Keeping FSG Synchronized to an External Clock

When an external signal is selected to drive the SRG, the McBSPi.MCBSPLP_SRGR2_REG[15] GSYNC bit and the mcbspi_fsr pin can be used to configure the timing of FSG pulses.

McBSPi.MCBSPLP_SRGR2_REG[15] GSYNC=1 ensures that the McBSP module and an external device are dividing down the input clock with the same phase relationship.

If McBSPi.MCBSPLP_SRGR2_REG[15] GSYNC=1, an inactive-to-active transition on the mcbspi_fsr pin triggers a resynchronization of CLKG and generation of FSG.

18.4.3.3 Synchronizing SRG Outputs to an External Clock

The SRG can produce a clock signal (CLKG) and a FSG based on an input clock signal that is either the interface clock signal (McBSPi_ICLK), or the CLKS signal (PRCM functional clock or mcbbsp_clks), or a signal at the mcbspi_clkr, or mcbspi_clkx pin. When an external clock (mcbbsp_clks, or mcbspi_clkr, or mcbspi_clkx) is selected to drive the SRG, the McBSPi.MCBSPLP_SRGR2_REG[15] GSYNC bit and the mcbspi_fsr pin can be used to control the timing of CLKG and the pulsing of FSG relative to the chosen input clock. Make GSYNC=1 so that the McBSP module and an external device divide down the input clock with the same phase relationship.

If the McBSPi.MCBSPLP_SRGR2_REG[15] GSYNC bit=1:

- An inactive-to-active transition on the mcbspi_fsr pin triggers a resynchronization of CLKG signal and a pulsing of FSG signal.
- CLKG signal always begins with a high state after synchronization.
- FSR signal is always detected at the same edge of the input clock signal that generates CLKG signal, no matter how long the FSR pulse is.
- The McBSPi.MCBSPLP_SRGR2_REG[11:0] FPER field are ignored because the frame-synchronization period on FSG is determined by the arrival of the next frame-synchronization pulse on the mcbspi_fsr pin.

If the McBSPi.MCBSPLP_SRGR2_REG[15] GSYNC bit=0, CLKG signal runs freely and is not resynchronized, and the frame-synchronization period on FSG signal is determined by McBSPi.MCBSPLP_SRGR2_REG[11:0] FPER field.

18.4.3.3.1 Operating the Transmitter Synchronously with the Receiver

When the McBSPi.MCBSPLP_SRGR2_REG[15] GSYNC bit = 1, the transmitter can operate synchronously with the receiver, provided that the FSX signal is programmed to be driven by FSG signal (McBSPi.MCBSPLP_SRGR2_REG[12] FSGM = 1 and McBSPi.MCBSPLP_PCR_REG[11] FSXM = 1). If the FSR input signal has appropriate timing so that it can be sampled by the falling edge of CLKG signal, it can be used, instead, by setting McBSPi.MCBSPLP_PCR_REG[11] FSXM=0 and connecting FSR signal to FSX externally.

The SRG clock drives the transmit and receive clocking (McBSPi.MCBSPLP_PCR_REG[8] CLKRM bit and McBSPi.MCBSPLP_PCR_REG[9] CLKXM bit are set to 1). Therefore, the CLK(R/X) pin must not be driven by any other driving source.

18.4.3.3.2 Synchronization Examples

Figure 18-40 and Figure 18-41 show the clock and frame-synchronization operation with various polarities of CLKS (the chosen input clock) and FSR signals. These figures assume McBSPi.MCBSPLP_SRGR1_REG[15:8] FWID = 0x0, for an FSG pulse that is one CLKG cycle wide. The McBSPi.MCBSPLP_SRGR2_REG[11:0] FPER field are not programmed; the period from the start of a frame-synchronization pulse to the start of the next pulse is determined by the arrival of the next inactive-to-active transition on the mcbspi_fsr pin.

Each figure shows what happens to CLKG signal when the McBSPi.MCBSPLP_SRGR2_REG[15] GSYNC bit = 1 and if it is initially synchronized or if it is not initially synchronized. Figure 18-41 has a slower CLKG frequency (it has a larger divide-down value in the McBSPi.MCBSPLP_SRGR1_REG[7:0] CLKGDV field).

Figure 18-40. CLKG Synchronization and FSG Generation (GSYNC = 1 and CLKGDV = 0x1)

Figure 18-41. CLKG Synchronization and FSG Generation (GSYNC = 1 and CLKGDV = 0x3)

18.4.4 McBSP Exception/Error Conditions

18.4.4.1 Introduction

There are several serial port events that can constitute a system error. Any error conditions can be a source of an interrupt:

- Receiver overrun (McBSPi.MCBSPLP_IRQSTATUS_REG[5] ROVFLSTAT bit is set to 1, and legacy mode McBSPi.MCBSPLP_SPCR1_REG[2] RFULL bit is set to 1)
This occurs when RB is full and RSR are full with another new word shifted in from mcbspi_dr. Therefore, McBSPi.MCBSPLP_IRQSTATUS_REG[5] ROVFLSTAT (McBSPi.MCBSPLP_SPCR1_REG[2] RFULL) indicates an error condition wherein any new data that can arrive at this time on mcbspi_dr replaces the contents of the RSR, and the previous word is lost. The RSR continues to be overwritten as long as new data arrives on mcbspi_dr and McBSPi.MCBSPLP_DRR_REG register is not read. For more details about overrun in the receiver, see Section 18.4.4.2.
- Unexpected receive frame-synchronization pulse (McBSPi.MCBSPLP_IRQSTATUS_REG[0])

RSYNCERR bit is set to 1, and legacy mode McBSPi.MCBSPLP_SPCR1_REG[3] RSYNCERR bit is set to 1).

This occurs during reception when an unexpected frame-synchronization pulse arrives. An unexpected frame-synchronization pulse is one that is supposed to begin the next frame transfer before all the bits of the current frame have been received. Such a pulse is ignored by the receiver, but sets the McBSPi.MCBSPLP_SPCR1_REG[3] RSYNCERR bit. For more details about receive frame-synchronization errors, see [Section 18.4.4.3, Unexpected Receive Frame-Sync Pulse](#).

- Receiver underflow (McBSPi.MCBSPLP_IRQSTATUS_REG[4] RUNDLSTAT bit is set to '1')
This occurs when sDMA controller or MPU/IVA2.2 subsystem reads data from an empty receive buffer. For more details about underflow in the receiver, see [Section 18.4.4.4](#).
- Transmitter underflow (McBSPi.MCBSPLP_IRQSTATUS_REG[11] XUNDLSTAT bit is set to '1', and legacy mode McBSPi.MCBSPLP_SPCR2_REG[2] XEMPTY bit is set to '0')
If a new frame-synchronization signal arrives when XB is empty, the previous data in the XSR is sent again. This procedure continues for every new frame-synchronization pulse that arrives until McBSPi.MCBSPLP_DXR_REG register is loaded with new data (and the XB is no longer empty). For more details about underflow in the transmitter, see [Section 18.4.4.5](#).
- Unexpected transmit frame-synchronization pulse (McBSPi.MCBSPLP_IRQSTATUS_REG[7] XSYNCERR bit is set to '1', and legacy mode McBSPi.MCBSPLP_SPCR2_REG[3] XSYNCERR bit is set to '1')
This occurs during transmission when an unexpected frame-synchronization pulse arrives. An unexpected pulse is one that is supposed to begin the next frame transfer before all the bits of the current frame have been transferred. Such a pulse is ignored by the transmitter, but sets the McBSPi.MCBSPLP_SPCR2_REG[3] XSYNCERR bit. For more details see [Section 18.4.4.6](#).
- Transmitter overflow (McBSPi.MCBSPLP_IRQSTATUS_REG[12] XOVFLSTAT bit is set to '1')
This occurs when sDMA controller or MPU/IVA2.2 subsystem writes data to a full XB. For more details about underflow in the receiver, see [Section 18.4.4.7](#).

18.4.4.2 Overrun in the Receiver

When McBSPi.MCBSPLP_IRQSTATUS_REG[5] ROVFLSTAT bit set to '1', and McBSPi.MCBSPLP_SPCR1_REG[2] RFULL bit set to '1' (legacy mode) indicates that the receiver has experienced overrun and is in an error condition. Receive overrun is set when all of the following conditions are met:

1. McBSPi.MCBSPLP_DRR_REG is not read even if the McBSPi.MCBSPLP_IRQSTATUS_REG[3] RRDY bit is set (legacy mode) and DMA or interrupt request has been asserted.
2. RB is full
3. RSR is full

As previously described, data arriving on mcbspi_dr is continuously shifted into the Receive Shift Register (RSR). Once a complete word is shifted into the RSR, an RSR-to-RB copy can occur only if the RB is not full.

Either of the following events clears the legacy mode McBSPi.MCBSPLP_SPCR1_REG[2] RFULL bit and allows subsequent transfers to be read properly:

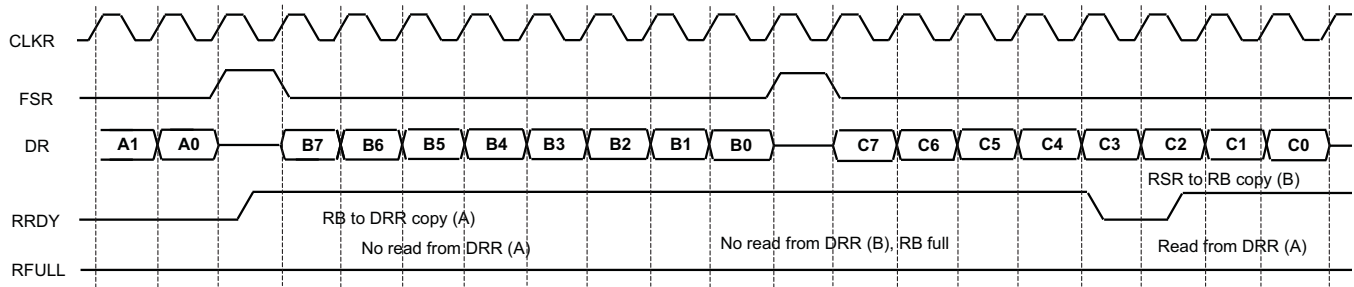

- The MPU/IVA2.2 subsystems or sDMA controller reads McBSPi.MCBSPLP_DRR_REG.
- The receiver is reset individually (McBSPi.MCBSPLP_SPCR1_REG[0] RRST bit =0) or as part of a global reset.

Another frame-synchronization pulse is required to restart the receiver.

According to the McBSPi.MCBSPLP_IRQENABLE_REG register setting, this condition can generate the McBSPi_IRQ line to be asserted low. Writing 1 to the corresponding bit in McBSPi.MCBSPLP_IRQSTATUS_REG register clears the interrupt.

[Figure 18-42](#) shows the receive overrun condition.

Figure 18-42. Overrun in the McBSP Receiver

037

18.4.4.3 Unexpected Receive Frame-sync Pulse

18.4.4.3.1 Possible Responses to Receive Frame-sync Pulses

If a frame-synchronization pulse starts the transfer of a new frame before the current frame is fully received, this pulse is treated as an unexpected frame-synchronization pulse, and the receiver sets the receive frame-synchronization error bit `McBSPi.MCBSPLP_IRQSTATUS_REG[0]` RSYNCERR (and the legacy `McBSPi.MCBSPLP_SPCR1_REG[3]` RSYNCERR bit).

According to the `McBSPi.MCBSPLP_IRQENABLE_REG` register settings this condition can generate the `McBSPi_IRQ` line to be asserted low. Writing 1 to the corresponding bit in `McBSPi.MCBSPLP_IRQSTATUS_REG` register clears the interrupt.

Using the legacy mode, `McBSPi.MCBSPLP_SPCR1_REG[3]` RSYNCERR bit can be cleared only by a receiver reset or by writing 0 to this bit. If you want the McBSP module to notify the MPU/IVA2.2 subsystem of receive frame-synchronization errors, set the legacy mode receive interrupt with the `McBSPi.MCBSPLP_SPCR1_REG[5:4]` RINTM field. When `RINTM = 0b11`, the McBSP module sends a receive interrupt (legacy mode) request to the MPU/IVA2.2 subsystems each time that RSYNCERR is set.

18.4.4.3.2 Example of an Unexpected Receive Frame-sync Pulse

Figure 18-43 shows an unexpected receive frame-synchronization pulse during normal operation of the serial port, with time intervals between data packets.

NOTE: The unexpected receive frame-synchronization pulse does not influence the data receive process, being ignored by the data receive state-machine.

Figure 18-43. Unexpected Frame-sync Pulse During a McBSP Reception

18.4.4.3.3 Preventing Unexpected Receive Frame-sync Pulses

Each frame transfer can be delayed by 0, 1, or 2 CLKR cycles, depending on the value of the `McBSPi.MCBSPLP_RCR2_REG[1:0]` RDATDLY field. For each possible data delay, Figure 18-44 shows when a new frame-synchronization pulse on FSR can safely occur relative to the last bit of the current frame.

Figure 18-44. Proper Positioning of Receive Frame-sync Pulses

039

18.4.4.4 Underflow in the Receiver

The McBSP module indicates a receiver underflow condition by setting the `McBSPi.MCBSPLP_IRQSTATUS_REG[4]` `RUNDFLSTAT` bit. This error occurs when sDMA controller or MPU/IVA2.2 subsystem reads data from an empty RB this happens only if the MPU/IVA2.2 subsystem or sDMA controller does not respect the DMA length, does not wait for DMA request, or does not check the buffer status before reading data. According to the `McBSPi.MCBSPLP_IRQENABLE_REG` register settings this condition can generate the `McBSPi_IRQ` line to be asserted low. Writing 1 to the corresponding bit in `McBSPi.MCBSPLP_IRQSTATUS_REG` register clears the interrupt.

18.4.4.5 Underflow in the Transmitter

The McBSP module indicates a transmitter empty (or underflow) condition by setting the `McBSPi.MCBSPLP_IRQSTATUS_REG[11]` `XUNDFLSTAT` bit. Also the legacy mode `McBSPi.MCBSPLP_SPCR2_REG[2]` `XEMPTY` bit is cleared. Either of the following events activates `XEMPTY` bit (`XEMPTY = 0`):

- `McBSPi.MCBSPLP_DXR_REG` has not been loaded and `XB` is empty, and all bits of the data word in the `XSR` have been shifted out on the `mcbspi_dx` pin.
- The transmitter is reset (by forcing `McBSPi.MCBSPLP_SPCR2_REG[0]` `XRST=0`, or by an global reset) and is then restarted.

`XEMPTY` bit is deactivated (`XEMPTY=1`) when a new word in `McBSPi.MCBSPLP_DXR_REG` is transferred to Transmit Buffer (`XB`). If `McBSPi.MCBSPLP_PCR_REG[11]` `FSXM=1` and `McBSPi.MCBSPLP_SRGR2_REG[12]` `FSGM=0`, the transmit frame-sync signal (`FSX`) is generated when Transmit Buffer (`XB`) is not empty. When `McBSPi.MCBSPLP_SRGR2_REG[12]` `FSGM=0`, `McBSPi.MCBSPLP_SRGR2_REG[11:0]` `FPER` and `McBSPi.MCBSPLP_SRGR1_REG[15:8]` `FWID` are used to determine the frame-synchronization period and width (external `FSX` is gated by the buffer empty condition). Otherwise, the transmitter waits for the next frame-synchronization pulse before sending out the next frame on `mcbspi_dx`.

When the transmitter is taken out of reset (`McBSPi.MCBSPLP_SPCR2_REG[0]` `XRST=1`), it is in a transmitter ready state (`McBSPi.MCBSPLP_SPCR2_REG[1]` `XRDY` bit =1) and transmitter empty (`McBSPi.MCBSPLP_SPCR2_REG[2]` `XEMPTY=0`) state. If `McBSPi.MCBSPLP_DXR_REG` is loaded by the MPU/IVA2.2 subsystem or the sDMA controller before internal `FSX` goes active high, a valid `XB`-to-`XSR` transfer occurs. This allows for the first word of the first frame to be valid even before the transmit frame-synchronization pulse is generated or detected. Alternatively, if a transmit frame-synchronization pulse is detected before `McBSPi.MCBSPLP_DXR_REG` is loaded, zeros are output on `mcbspi_dx`.

The McBSPi.MCBSPLP_IRQSTATUS_REG[11] XUNDFLSTAT bit indicates a real underflow condition, in which the frame is corrupted due to lack of data availability during transmit process. According to the McBSPi.MCBSPLP_IRQENABLE_REG register settings this condition can generate the McBSPi_IRQ line to be asserted low. Writing 1 to the corresponding bit in McBSPi.MCBSPLP_IRQSTATUS_REG register clears the interrupt.

18.4.4.6 Unexpected Transmit Frame-sync Pulse

18.4.4.6.1 Possible Responses to Transmit Frame-sync Pulses

If a frame-synchronization pulse starts the transfer of a new frame before the current frame is fully transmitted, this pulse is treated as an unexpected frame-synchronization pulse, and the transmitter sets the transmit frame-synchronization error bit McBSPi.MCBSPLP_IRQSTATUS_REG[7] XSYNCERR (and the legacy McBSPi.MCBSPLP_SPCR2_REG[3] XSYNCERR bit).

According to the McBSPi.MCBSPLP_IRQENABLE_REG register settings, this condition can generate the McBSPi_IRQ line to be asserted low. Writing 1 to the corresponding bit in status register clears the interrupt.

Using the legacy mode, McBSPi.MCBSPLP_SPCR2_REG[3] XSYNCERR bit can be cleared only by a transmitter reset or by a write of 0 to this bit. If you want the McBSP module to notify the MPU/IVA2.2 subsystem of frame-synchronization errors, you can set a special transmit interrupt mode with the McBSPi.MCBSPLP_SPCR2_REG[5:4] XINTM field. When XINTM=0b11, the McBSP module sends a transmit interrupt request to the MPU/IVA2.2 subsystem each time that XSYNCERR is set.

18.4.4.6.2 Example of Unexpected Transmit Frame-Synchronization Pulse

Figure 18-45 shows an unexpected transmit frame-synchronization pulse during normal operation of the serial port with intervals between the data packets.

NOTE: The unexpected transmit frame-synchronization pulse does not influence the data transmit process, being ignored by the data transmit state-machine.

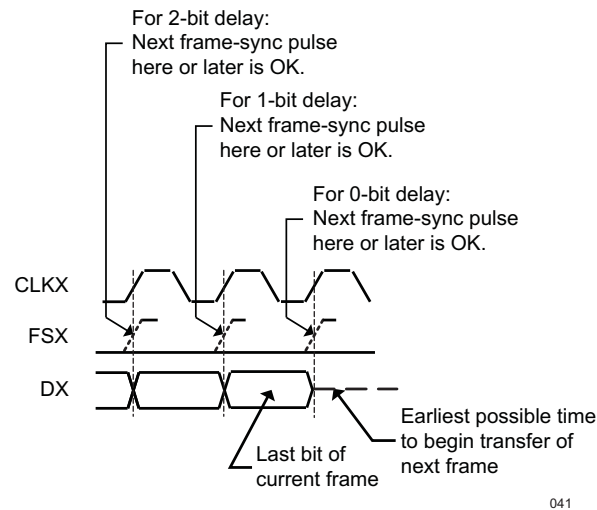

Figure 18-45. Unexpected Frame-sync Pulse During a McBSP Transmission

040

18.4.4.6.3 Preventing Unexpected Transmit Frame-sync Pulses

Each frame transfer can be delayed by 0, 1, or 2 CLKX cycles, depending on the value in the McBSPi.MCBSPLP_XCR2_REG[1:0] XDATDLY field. For each possible data delay, Figure 18-46 shows when a new frame-synchronization pulse on FSX can safely occur relative to the last bit of the current frame.

Figure 18-46. Proper Positioning of Transmit Frame-sync Pulses

18.4.4.7 Overflow in the Transmitter

The McBSP module indicates a transmitter overflow condition by setting the `McBSPi.MCBSPLP_IRQSTATUS_REG[12]` `XOVFLSTAT` bit. This error occurs when sDMA controller or MPU/IVA2.2 subsystem write data to a full XB (this may happen only if the MPU/IVA2.2 subsystem or sDMA controller does not respect the DMA length, does not wait for DMA request or does not check the buffer status before writing data). According to the `McBSPi.MCBSPLP_IRQENABLE_REG` register settings this condition can generate the `McBSPi_IRQ` line to be asserted low. Writing 1 to the corresponding bit in status register clears the interrupt.

18.4.5 McBSP DMA Configuration

The McBSP receive and transmit data DMA requests are active after the receive `McBSPi.MCBSPLP_SPCR1_REG[0]` `RRST` and transmit `McBSPi.MCBSPLP_SPCR2_REG[0]` `XRST` are released. After reset the default DMA threshold (and length) is one.

The receive and transmit DMA requests can be individually disabled by setting the `McBSPi.MCBSPLP_RCCR_REG[3]` `RDMAEN`, `McBSPi.MCBSPLP_XCCR_REG[3]` `XDMAEN` bits to 0. When disabling the DMA, the DMA request line is de-asserted even if a DMA transfer is pending and the DMA state-machine is not reset.

The DMA threshold and length configuration is done through `McBSPi.MCBSPLP_THRSH1_REG` and `McBSPi.MCBSPLP_THRSH2_REG` registers as follows:

- `(THRSH1_REG + 1)` value represents the required receive DMA request length (the length of the transfer is the same as the threshold value plus one). As long as the RB occupied locations level is above or equal to the `THRSH1_REG` value + 1, the DMA request is asserted. After transferring the configured `(THRSH1_REG + 1)` number of words, the receive DMA request is de-asserted and reasserted as soon as the conditions are met again.
- `(THRSH2_REG + 1)` value represents the required transmit DMA request length (the length of the transfer is the same as the threshold value plus one). As long as the XB free locations level is above or equal to the `THRSH2_REG` value + 1, the DMA request is asserted. After transferring the configured `(THRSH2_REG + 1)` number of words, the transmit DMA request is de-asserted and reasserted as soon as the conditions are met again.

NOTE: The MPU/IVA2.2 subsystem can decide not to use the DMA to transfer the data. In this case, the DMA must be disabled (or the DMA request can be ignored by MPU/IVA2.2 subsystem) and the common interrupt line (McBSPi_IRQ) can be used. The McBSPi.MCBSPLP_SPCR1_REG[1] RRDY bit for receive and McBSPi.MCBSPLP_SPCR2_REG[1] XRDY bit for transmit will indicate when the threshold values are reached. Also, by reading the receive buffer status McBSPi.MCBSPLP_RBUFFSTAT_REG register and transmit buffer status McBSPi.MCBSPLP_XBUFFSTAT_REG register, the MPU/IVA2.2 subsystem can decide to transfer data even if the threshold is not reached. This mechanism is useful on the last transfer on receive side when the threshold value is bigger than the occupied locations inside the receive buffer and the MPU/IVA2.2 subsystem needs to read this data. Since no interrupt or DMA request is asserted the only option in this case is to read the RB status register value and to transfer the remaining data without using the DMA or interrupt indication.

18.4.6 Multichannel Selection Modes

18.4.6.1 Channels, Blocks, and Partitions

A McBSP channel is a time slot for shifting in/out the bits of one serial word. The McBSP module supports up to 128 channels for reception and 128 channels for transmission. In the receiver and in the transmitter, the 128 available channels are divided into eight blocks that contain 16 contiguous channels each:

- Block 0: Channels 0–15
- Block 1: Channels 16–31
- Block 2: Channels 32–47
- Block 3: Channels 48–63
- Block 4: Channels 64–79
- Block 5: Channels 80–95
- Block 6: Channels 96–111
- Block 7: Channels 112–127

The blocks are assigned to partitions according to the selected partition mode. In the two-partition mode described in [Section 18.4.6.6](#), you assign one even-numbered block (0, 2, 4, or 6) to partition A and one odd-numbered block (1, 3, 5, or 7) to partition B. In the 8-partition mode [Section 18.4.6.4](#), blocks 0 through 7 are automatically assigned to partitions A through H, respectively.

The number of partitions for reception and the number of partitions for transmission are independent of each other. For example, it is possible to use two receive partitions (A and B) and eight transmit partitions (A–H).

18.4.6.2 Multichannel Selection

When a McBSP module uses a time-division multiplexed (TDM) data stream while communicating with other McBSP modules or serial devices, the McBSP module may need to receive and/or transmit on only a few channels. To save memory and bus bandwidth, you can use a multichannel selection mode to prevent data flow in some of the channels.

Each channel partition has a dedicated channel enable register. If the appropriate multichannel selection mode is on, each bit in the register controls whether data flow is allowed or prevented in one of the channels that is assigned to that partition.

The McBSP module has one receive multichannel selection mode [Section 18.4.6.5](#), and three transmit multichannel selection modes [Section 18.4.6.7](#).

18.4.6.3 Configuring a Frame for Multichannel Selection

Before enabling a multichannel selection mode, make sure you properly configure the data frame:

- Select a single-phase frame (McBSPi.MCBSPLP_RCR2_REG[15] RPHASE bit and McBSPi.MCBSPLP_XCR2_REG[15] XPHASE bit = 0). Each frame represents a TDM data stream.

- Set a frame length (in McBSPi.MCBSPLP_RCR1_REG[14:8] RFRLEN1 field and in McBSPi.MCBSPLP_XCR1_REG[14:8] XFRLEN1 field) that includes the highest-numbered channel to be used. For example, if you plan to use channels 0, 15, and 39 for reception, the receive frame length must be at least 40 (RFRLEN1 = 39). If RFRLEN1 = 39 in this case, the receiver creates 40 time slots per frame but only receives data during time slots 0, 15, and 39 of each frame.

18.4.6.4 Using Eight Partitions

For multichannel selection operation in the receiver and/or the transmitter, you can use eight partitions or two partitions (as previously described). If you choose the 8-partition mode (McBSPi.MCBSPLP_MCR1_REG[9] RMCME = 1 for reception, McBSPi.MCBSPLP_MCR2_REG[9] XMCME = 1 for transmission), McBSP channels are activated in the following order: A, B, C, D, E, F, G, H.

In response to a frame-synchronization pulse, the receiver or transmitter begins with the channels in partition A and then continues with the other partitions in order until the complete frame has been transferred. When the next frame-synchronization pulse occurs, the next frame is transferred, beginning with the channels in partition A.

In the 8-partition mode, the McBSPi.MCBSPLP_MCR1_REG[6:5] RPABLK and McBSPi.MCBSPLP_MCR2_REG[6:5] XPABLK, and McBSPi.MCBSPLP_MCR1_REG[8:7] RPBBLK and McBSPi.MCBSPLP_MCR2_REG[8:7] XPBBLK bit fields are ignored, and the 16 channel blocks are assigned to the partitions as shown in Table 18-20 through Table 18-21. These assignments cannot be changed. The tables also show the registers used to control the channels in the partitions.

Table 18-20. Eight Partitions – Receive Channel Assignment and Control

| Receive Partition | Assigned Block of Receive Channels | Register Used for Channel Control |
|-------------------|------------------------------------|-----------------------------------|
| A | Block 0: Channels 0 through 15 | McBSPi.MCBSPLP_RCERA_REG |
| B | Block 1: Channels 16 through 31 | McBSPi.MCBSPLP_RCERB_REG |
| C | Block 2: Channels 32 through 47 | McBSPi.MCBSPLP_RCERC_REG |
| D | Block 3: Channels 48 through 63 | McBSPi.MCBSPLP_RCERD_REG |
| E | Block 4: Channels 64 through 79 | McBSPi.MCBSPLP_RCERE_REG |
| F | Block 5: Channels 80 through 95 | McBSPi.MCBSPLP_RCERF_REG |
| G | Block 6: Channels 96 through 111 | McBSPi.MCBSPLP_RCERG_REG |
| H | Block 7: Channels 112 through 127 | McBSPi.MCBSPLP_RCERH_REG |

Table 18-21. Eight Partitions – Transmit Channel Assignment and Control

| Transmit Partition | Assigned Block of Receive Channels | Register Used for Channel Control |
|--------------------|------------------------------------|-----------------------------------|
| A | Block 0: Channels 0 through 15 | McBSPi.MCBSPLP_XCERA_REG |
| B | Block 1: Channels 16 through 31 | McBSPi.MCBSPLP_XCERB_REG |
| C | Block 2: Channels 32 through 47 | McBSPi.MCBSPLP_XCERC_REG |
| D | Block 3: Channels 48 through 63 | McBSPi.MCBSPLP_XCERD_REG |
| E | Block 4: Channels 64 through 79 | McBSPi.MCBSPLP_XCERE_REG |
| F | Block 5: Channels 80 through 95 | McBSPi.MCBSPLP_XCERF_REG |
| G | Block 6: Channels 96 through 111 | McBSPi.MCBSPLP_XCERG_REG |
| H | Block 7: Channels 112 through 127 | McBSPi.MCBSPLP_XCERH_REG |

Figure 18-47 shows an example of the McBSP using the 8-partition mode. In response to a frame-synchronization pulse, the McBSP module begins a frame transfer with partition A and then activates B, C, D, E, F, G, and H to complete a 128-word frame.

Figure 18-47. McBSP Data Transfer in 8-Partition Mode

18.4.6.5 Receive Multichannel Selection Mode

The `McBSPi.MCBSPLP_MCR1_REG[0]` RMCME bit determines whether all channels or only selected channels are enabled for reception.

- When RMCME = 0, all 128 receive channels are enabled and cannot be disabled.
- When RMCME = 1, the receive multichannel selection mode is enabled. In this mode:
 - Channels can be individually enabled or disabled. The enabled channels are those selected in the appropriate receive channel enable registers (`McBSPi.MCBSPLP_RCERA_REG` to `McBSPi.MCBSPLP_RCERH_REG`). The channels are assigned to the `McBSPi.MCBSPLP_RCERA_REG` to `McBSPi.MCBSPLP_RCERH_REG` registers depends on the number of receive channel partitions (2 or 8), as defined by the `McBSPi.MCBSPLP_MCR1_REG[9]` RMCME bit.
 - If a receive channel is disabled, any bits received in that channel are not transferred to the RB, and as a result, the receiver ready bit (RRDY) is not set. Therefore, no DMA synchronization event is generated and, if the receiver interrupt mode depends on RRDY (`McBSPi.MCBSPLP_SPCR1_REG[5:4]` RINTM = 0b00), no interrupt is generated.

As an example of how the McBSP module behaves in the receive multichannel selection mode, suppose you enable only channels 0, 15, and 39 and that the frame length is 40. The McBSP module:

1. Accepts bits shifted in from the `mcbspi_dr` pin in channel 0
2. Ignores bits received in channels 1–14
3. Accepts bits shifted in from the `mcbspi_dr` pin in channel 15
4. Ignores bits received in channels 16–38
5. Accepts bits shifted in from the `mcbspi_dr` pin in channel 39

18.4.6.6 Using Two Partitions (Legacy Only)

For multichannel selection operation in the receiver and/or the transmitter, you can use two partitions or eight partitions. If you choose the 2-partition mode (`McBSPi.MCBSPLP_MCR1_REG[9]` RMCME = 0 for reception, `McBSPi.MCBSPLP_MCR2_REG[9]` XMCME = 0 for transmission), McBSP channels are activated using an alternating scheme. In response to a frame-synchronization pulse, the receiver or transmitter begins with the channels in partition A and then alternates between partitions B and A until the complete frame has been transferred. When the next frame-synchronization pulse occurs, the next frame is transferred beginning with the channels in partition A.

For reception, any two of the eight receive-channel blocks can be assigned to receive partitions A and B, which means up to 32 receive channels can be enabled at any given point. Similarly, any two of the eight transmit-channel blocks (up to 32 enabled transmit channels) can be assigned to transmit partitions A and B.

For reception:

- Assign an even-numbered channel block (0, 2, 4, or 6) to receive partition A by writing to the `McBSPi.MCBSPLP_MCR1_REG[6:5]` RPABLK field. In the receive multichannel selection mode, the channels in this partition are controlled by receive channel enable register A (`McBSPi.MCBSPLP_RCERA_REG`).

- Assign an odd-numbered block (1, 3, 5, or 7) to receive partition B with the McBSPi.MCBSPLP_MCR1_REG[8:7] RPBLK field. In the receive multichannel selection mode, the channels in this partition are controlled by receive channel enable register B (McBSPi.MCBSPLP_RCERB_REG).

For transmission:

- Assign an even-numbered channel block (0, 2, 4, or 6) to transmit partition A by writing to the McBSPi.MCBSPLP_MCR2_REG[6:5] XPABLK fields. In one of the transmit multichannel selection modes, the channels in this partition are controlled by transmit channel enable register A (McBSPi.MCBSPLP_XCERA_REG).
- Assign an odd-numbered block (1, 3, 5, or 7) to transmit partition B with the McBSPi.MCBSPLP_MCR1_REG[8:7] XPBLK field. In one of the transmit multichannel selection modes, the channels in this partition are controlled by transmit channel enable register B (McBSPi.MCBSPLP_XCERB_REG).

Figure 18-48 shows an example of alternating between the channels of partition A and the channels of partition B. Channels 0–15 have been assigned to partition A, and channels 16–31 have been assigned to partition B. In response to a frame-synchronization pulse, the McBSP module begins a frame transfer with partition A and then alternates between partitions B and A until the complete frame is transferred.

Figure 18-48. Alternating Between Partitions A and B Channels

18.4.6.7 Transmit Multichannel Selection Modes

The McBSPi.MCBSPLP_MCR2_REG[1:0] XMCM field determine whether all channels or only selected channels are enabled and unmasked for transmission. The McBSP module has three transmit multichannel selection modes (XMCM = 0b01, XMCM = 0b10, and XMCM = 0b11), which are described in Table 18-22.

Table 18-22. Selecting a Transmit Multichannel Selection Mode With the XMCM Bit Field

| XMCM | Transmit Multichannel Selection Mode |
|------|--|
| 0b00 | No transmit multichannel selection mode is on. All channels are enabled and unmasked. No channels can be disabled or masked. |
| 0b01 | All channels are disabled unless they are selected in the appropriate transmit channel enable registers (McBSPi.MCBSPLP_XCERA_REG/McBSPi.MCBSPLP_XCERH_REG). If enabled, a channel in this mode is also unmasked. The McBSPi.MCBSPLP_MCR2_REG[9] XMCME bit determines whether 32 channels or 128 channels are selectable in the McBSPi.MCBSPLP_XCERA_REG/McBSPi.MCBSPLP_XCERH_REG registers. |
| 0b10 | All channels are enabled, but they are masked unless they are selected in the appropriate transmit channel enable registers (McBSPi.MCBSPLP_XCERA_REG/McBSPi.MCBSPLP_XCERH_REG). The McBSPi.MCBSPLP_MCR2_REG[9] XMCME bit determines whether 32 channels or 128 channels are selectable in the McBSPi.MCBSPLP_XCERA_REG/McBSPi.MCBSPLP_XCERH_REG registers. |
| 0b11 | This mode is used for symmetric transmission and reception. All channels are disabled for transmission unless they are enabled for reception in the appropriate receive channel enable registers (McBSPi.MCBSPLP_RCERA_REG/McBSPi.MCBSPLP_RCERH_REG). Once enabled, they are masked unless they are also selected in the appropriate transmit channel enable registers (McBSPi.MCBSPLP_XCERA_REG/McBSPi.MCBSPLP_XCERH_REG). The McBSPi.MCBSPLP_MCR2_REG[9] XMCME bit determines whether 32 channels or 128 channels are selectable in McBSPi.MCBSPLP_RCERA_REG/McBSPi.MCBSPLP_RCERH_REG registers and McBSPi.MCBSPLP_XCERA_REG/McBSPi.MCBSPLP_XCERH_REG registers. |

As an example of how the McBSP module behaves in a transmit multichannel selection mode, suppose that XMCM = 0b01 (all channels disabled unless individually enabled) and that you have enabled only channels 0, 15, and 39. Suppose also that the frame length is 40. The McBSP module:

1. Shifts data to the mcbspi_dx pin in channel 0
2. Places the mcbspi_dx pin in the high impedance state in channels 1–14
3. Shifts data to the mcbspi_dx pin in channel 15
4. Places the mcbspi_dx pin in the high impedance state in channels 16–38
5. Shifts data to the mcbspi_dx pin in channel 39

18.4.6.7.1 Disabling/Enabling Versus Masking/Unmasking

For transmission, a channel can be:

- Enabled and unmasked (transmission can begin and can be completed)
- Enabled but masked (transmission can begin but cannot be completed)
- Disabled (transmission cannot occur)

The definitions in [Table 18-23](#) explain the channel control options:

Table 18-23. McBSP Channel Control Options

| | |
|-------------------------|--|
| Enabled channel | A channel that can begin transmission by passing data from the data transmit register (McBSPi.MCBSPLP_DXR_REG) to the XSR through XB. |
| Masked channel | A channel that cannot complete transmission. The mcbspi_dx pin is held in the high impedance state; data cannot be shifted out on the mcbspi_dx pin. In systems where symmetric transmit and receive provide software benefits, this feature allows transmit channels to be disabled on a shared serial bus. A similar feature is not needed for reception because multiple receptions cannot cause serial bus contention. |
| Disabled channel | A channel that is not enabled. A disabled channel is also masked. Because no DXR-to-XB copy occurs, the McBSPi.MCBSPLP_SPCR2_REG[1] XRDY bit is not set. Therefore, no DMA synchronization event is generated, and if the transmit interrupt mode depends on XRDY (McBSPi.MCBSPLP_SPCR2_REG[5:4] XINTM=00b), no interrupt is generated. The McBSPi.MCBSPLP_SPCR2_REG[2] XEMPTY bit is not affected. |
| Unmasked channel | A channel that is not masked. Data in the XSR(s) is shifted out on the mcbspi_dx pin. |

18.4.6.7.2 Activity on McBSP Pins for Different Values of XMCM

[Figure 18-49](#) shows the activity on the McBSP pins for the various McBSPi.MCBSPLP_MCR2_REG[1:0] XMCM values. In all cases, the transmit frame is configured as follows:

- XPHASE=0: Single-phase frame (required for multichannel selection modes)
- XFRLEN1=0b0000011: 4 words per frame
- XWDLEN1=0b000: 8 bits per word
- XMCME=0: 2-partition mode (only partitions A and B used)

In the case where McBSPi.MCBSPLP_MCR2_REG[1:0] XMCM=0b11, transmission and reception are symmetric, which means the corresponding bits for the receiver (RPHASE, RFRLEN1, RWDLEN1, and RMCME) must have the same values as XPHASE, XFRLEN1, and XWDLEN1, respectively.

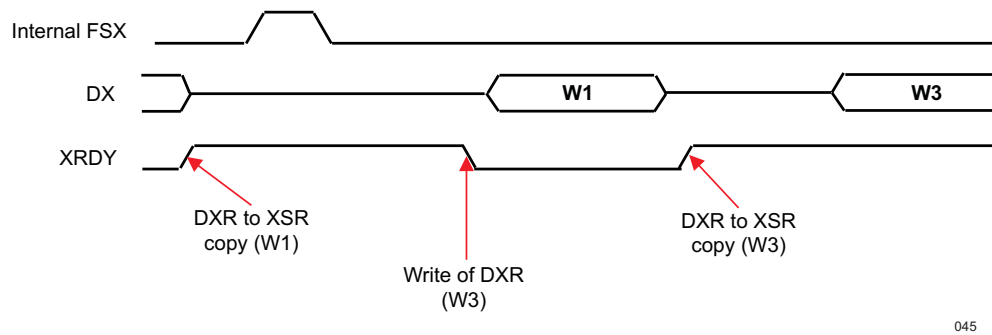

In [Figure 18-49](#), the arrows showing where the various events occur are only sample indications. Wherever possible, there is a time window in which these events can occur.

Figure 18-49. Activity on McBSP Pins When XMCM=0b00

If XMCM = 0b00, all channels are enabled and unmasked. Words W0, W1, W2, and W3 are written to the XB, then, from the XB, there are transferred by mcbspi_dx.

Figure 18-50. Activity on McBSP Pins When XMCM=0b01

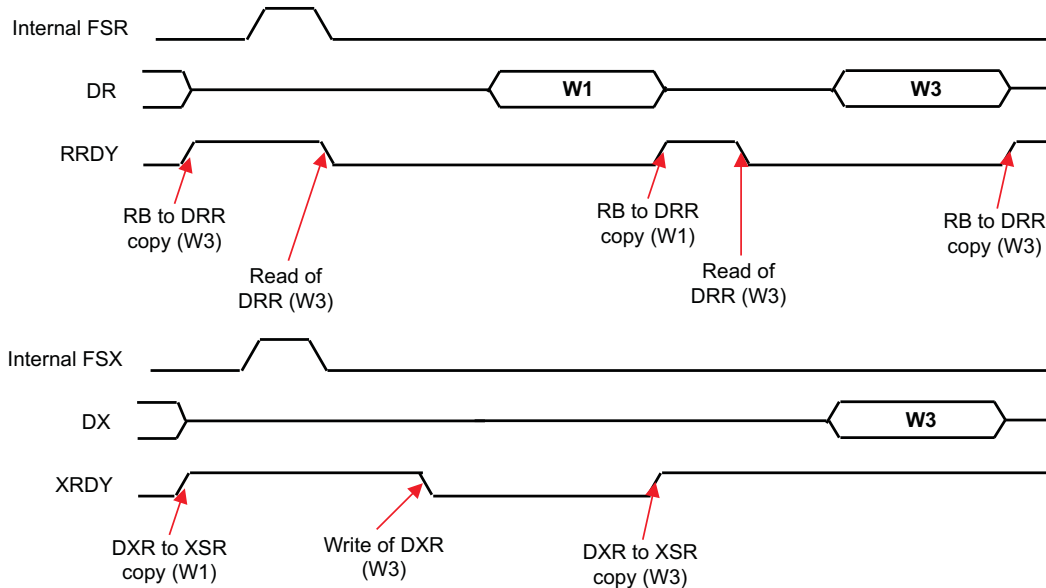

In [Figure 18-50](#) if XMCM = 0b01, XPABLK = 0b00, and XCERA = 0b1010, only channels 1 and 3 are enabled and unmasked. Words W1 and W3 are written to the XB, then, from the XB, there are transferred by mcbspi_dx.

Figure 18-51. Activity on McBSP Pins When XMCM=0b10

In [Figure 18-51](#) if XMCM = 0b10, XPABLK = 0b00, and XCERA = 0b1010, all channels are enabled, only 1 and 3 unmasked. Words W0, W1, W2, and W3 are written to the XB, but only W1 and W3, from the XB, there are transferred by mcbspi_dx.

Figure 18-52. Activity on McBSP Pins When XMCM=0b11

047

In [Figure 18-52](#) if XMCM = 0b11, RPABLK = 0b00, XPABLK = 0bX, RCERA = 0b1010 and XCERA = 0b1000, channels 1 and 3 are enabled in receive and transmit mode, but only 3 unmasked. Words W1 and W3 are written to the XB, but only W3, from the XB, there are transferred by mcbspi_dx.

18.4.7 SIDETONE Mode (ALP)

18.4.7.1 Introduction

In multimedia-rich mobile communication devices, loopback signals from audio inputs to audio outputs are renamed. A traditional example is the telephone SIDETONE (that is, the telephone user expects to also hear his own voice in the earpiece).

Some of the features using the loopback have strict delay requirements.

It is required that two of the audio input channels be looped back, filtered, and mixed to the corresponding two audio output channels. The SIDETONE mode filters and applies gain to each sample received.

18.4.7.2 SIDETONE Interface

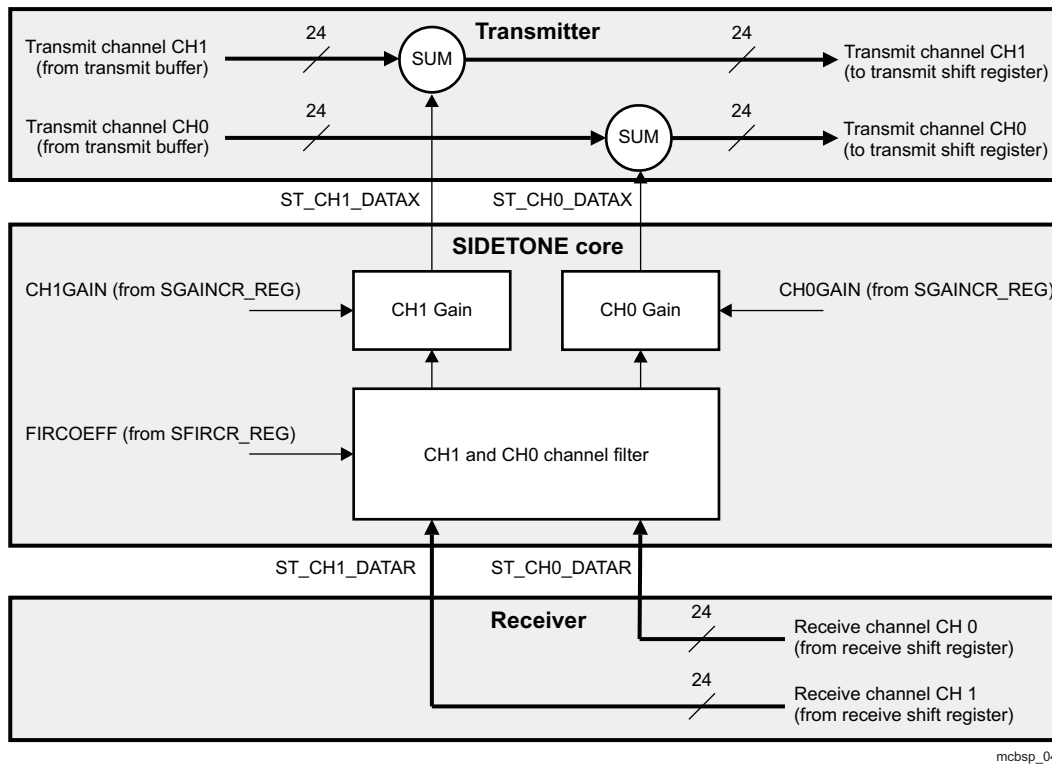

The data from digital microphone, two (out of four) channels, can be configured to be input in the external SIDETONE core. After filtering, the data from digital microphone data is mixed and sent out to the speaker output channels using two (out of eight) configured output channels (separate configuration bits are used). The McBSP module synchronizes the incoming data (filtered by the external SIDETONE core). The transmit and receive part of the McBSP module are not required to operate on the same functional frequency.

The SIDETONE interface offers the following features:

- Send out two 24-bit data channels for the configured SIDETONE received channels (channels can be the same)
- Send out two control signals to indicate to the SIDETONE module that the data is valid (toggle signals which are changing the value from 0 to 1 or 1 to 0 each time a new data is available)
- Receive two 24-bit filtered data channels from the external SIDETONE module and send these channels to the configured transmit channels after mixing the data with the incoming data (from the L4 interface). The sum between the incoming data and SIDETONE loopback data is a saturated sum.
- Receive two control signals to indicate that the SIDETONE module filtered data is available (toggle signals which are changing the value from 0 to 1 or 1 to 0 each time a new data is available).

Figure 18-53 shows the SIDETONE external module data path:

Figure 18-53. SIDETONE Data Path

Before you enable a SIDETONE selection mode, make sure you properly configure the data frame for multichannel and SIDETONE mode:

- Select a single-phase frame (McBSPi.MCBSPLP_RCR2_REG[15] RPHASE bit and McBSPi.MCBSPLP_XCR2_REG[15] XPHASE bit=0). Each frame represents a TDM data stream.
- Set McBSPi.MCBSPLP_MCR1_REG[0] RMCM=1 to select multichannel mode enable.
- Set a frame length (in McBSPi.MCBSPLP_RCR1_REG[14:8] RFLEN1 bit field and in McBSPi.MCBSPLP_XCR1_REG[14:8] XFLEN1 bit field) that includes the highest-numbered channel to be used (a maximum of 4 channels can be used in this configuration).
- Set a word length (in McBSPi.MCBSPLP_RCR1_REG[7:5] RWDLEN1 bit field and in McBSPi.MCBSPLP_XCR1_REG[7:5] XWDLEN1 bit field) to be either 16, 24 or 32 (see note).
- Select the input/output channels configured as SIDETONE channels and enable SIDETONE by setting the McBSPi.MCBSPLP_SSELCR_REG[1:0] ICH0ASSIGN/McBSPi.MCBSPLP_SSELCR_REG[6:4] OCH0ASSIGN, McBSPi.MCBSPLP_SSELCR_REG[3:2] ICH1ASSIGN/McBSPi.MCBSPLP_SSELCR_REG[9:7] OCH1ASSIGN fields (2 out of 4 channels external SIDETONE assignment) and McBSPi.MCBSPLP_SSELCR_REG[10] SIDETONEEN bit to 1.

NOTE: Word width in the loop is 24 bits. If input channel word width is less than 24 bits, LSBs of the samples are zero padded. If input channel word width is more than 24 bits, samples are truncated.

Figure 18-54 describes the data exchange protocol between McBSP module and SIDETONE core:

Figure 18-54. McBSP to SIDETONE Data Exchange

Figure 18-55 describes the data exchange protocol between SIDETONE core and McBSP module:

Figure 18-55. SIDETONE to McBSP Data Exchange

NOTE: To use the same input channel as source for both SIDETONE output channels the McBSPi.MCBSPLP_SSELCR_REG[1:0] ICH0ASSIGN should be equal to McBSPi.MCBSPLP_SSELCR_REG[3:2] ICH1ASSIGN. The McBSP module does not support two input channels to be assigned to only one SIDETONE output channel.

18.4.7.3 Data Processing Path

The SIDETONE core receives the data to be processed through two 24-bits parallel data interfaces, one for each audio channel. When enabled through McBSPi.ST_SSELCR_REG[0] SIDETONEEN bit-field, the module applies the filtering and gain functions to each data item (frame) and outputs it through two similar 24-bits parallel data interfaces.

Figure 18-56 below describes how the data is sampled and output through the dedicated data interfaces.

Figure 18-56. SIDETONE Processed Data Interfaces

051

NOTE: The processing time needed is 132 clock cycles (SIDETONE enabled). The total number of cycles needed for outputting the new processed data upon arrival of a sample is maximum 135 (including synchronizations). When not enabled, the data response takes maximum 5 clock cycles.

The ST_CH0_VALIDR and ST_CH1_VALIDR are 1 bit inputs and their toggling information is used to signal that new data is valid for sampling from ST_CH0_DATAR / ST_CH1_DATAR.

The ST_CH0_VALIDX and ST_CH1_VALIDX are 1 bit outputs and their toggling information is used to signal that new data is valid on the output data bus ST_CH0_DATAX / ST_CH1_DATAX.

18.4.7.4 Data Processing

The processing consists in 2 stages filtering and applying gain to signal. The whole process takes 132 clock cycles.

If a new frame comes too early causing the interrupt assertion, the current frame will be completely processed and this new frame will be ignored. Consequent frames will also be ignored until the current frame processing has ended.

18.4.7.4.1 Filtering

A 128 length FIR filter scheme is used. The module must process the two channels in parallel so two instances of filter will work in parallel sharing only the same coefficients.

Samples data are signed values in interval (-1..1) in Q23 format, negative values are expressed in 2's complement. Coefficients are also signed values in interval (-1..1) in Q15 format, negative values are expressed in 2's complement too.

The module handles overflows in the sums of the product but the user should choose the coefficients with the sum of magnitudes in absolute value is smaller than 1, otherwise the user must ensure that gain applying brings the samples value below |1|, to avoid saturation.

$$|C0| + |C1| + \dots + |C127| < 1$$

CAUTION

The coefficients cannot be loaded while the filtering is active (SIDETONE enabled).

18.4.7.4.2 Applying Gain

Each output sample will be multiplied with the gain value specified in the McBSPi.ST_SGAINCR_REG. The gain is independent for each channel and can be modified anytime through L4-interface with immediate effect. Gain values are in the interval (-2..2) in Q1.14 format, negative values are expressed in 2's complement.

The user must choose the gain's value according to the magnitude of the samples to avoid overflow in the final product between the FIR data and gain value. If an overflow occurs, the output data is saturated.

18.4.7.4.3 Enabling SIDETONE

When the SIDETONE operation is enabled (McBSPi.ST_SSELCR_REG[0] SIDETONEEN is 1), the module starts collecting samples received through the data interface without returning any sample or toggling any of the ST_CH0/CH1_VALIDX outputs. The first 127 samples for each channel are only accumulated, no processed data is provided. The first processed frame comes after receiving the 128th sample (with the specific delay).

When the SIDETONE operation is disabled, data is output through the data interface as it comes on the data input interface with the resynchronization latency of maximum 5 clock cycles. Re-enabling it requires waiting another 128 samples before providing new processed samples (each transition of McBSPi.ST_SSELCR_REG[0] SIDETONEEN from 0 to 1 triggers this initialization process).

NOTE: After reset, the McBSPi.ST_SSELCR_REG[0] SIDETONEEN bit is 0.

18.4.7.4.4 FIR Accuracy

All the arithmetic inside the module is performed without any truncation/saturation until the last stage – the gain applying, where the result of the product between gain and FIR value is saturated to +/-1 if overflow occurs and the LSBs are truncated.

18.4.7.5 Interrupt Operation

The SIDETONE core has a single interrupt line and a single event that may trigger the interrupt. The event (an error one) occurs when the input interface data rate overflows the processing ability of the module. As described in the data processing path section, the SIDETONE core completes a frame processing in 132 cycles. If the input frame rate for any channel exceeds 1 frame/132 x interface clock period while SIDETONE is enabled, the McBSPi.ST_IRQSTATUS_REG[0] OVRERROR bit is set and, if McBSPi.ST_IRQENABLE_REG[0] OVRERROREN bit is set to 1, the interrupt line is asserted.

18.5 McBSP Basic Programming Model

This section describes the programming model of typical McBSP module and SIDETONE core applications.

18.5.1 McBSP Core

CAUTION

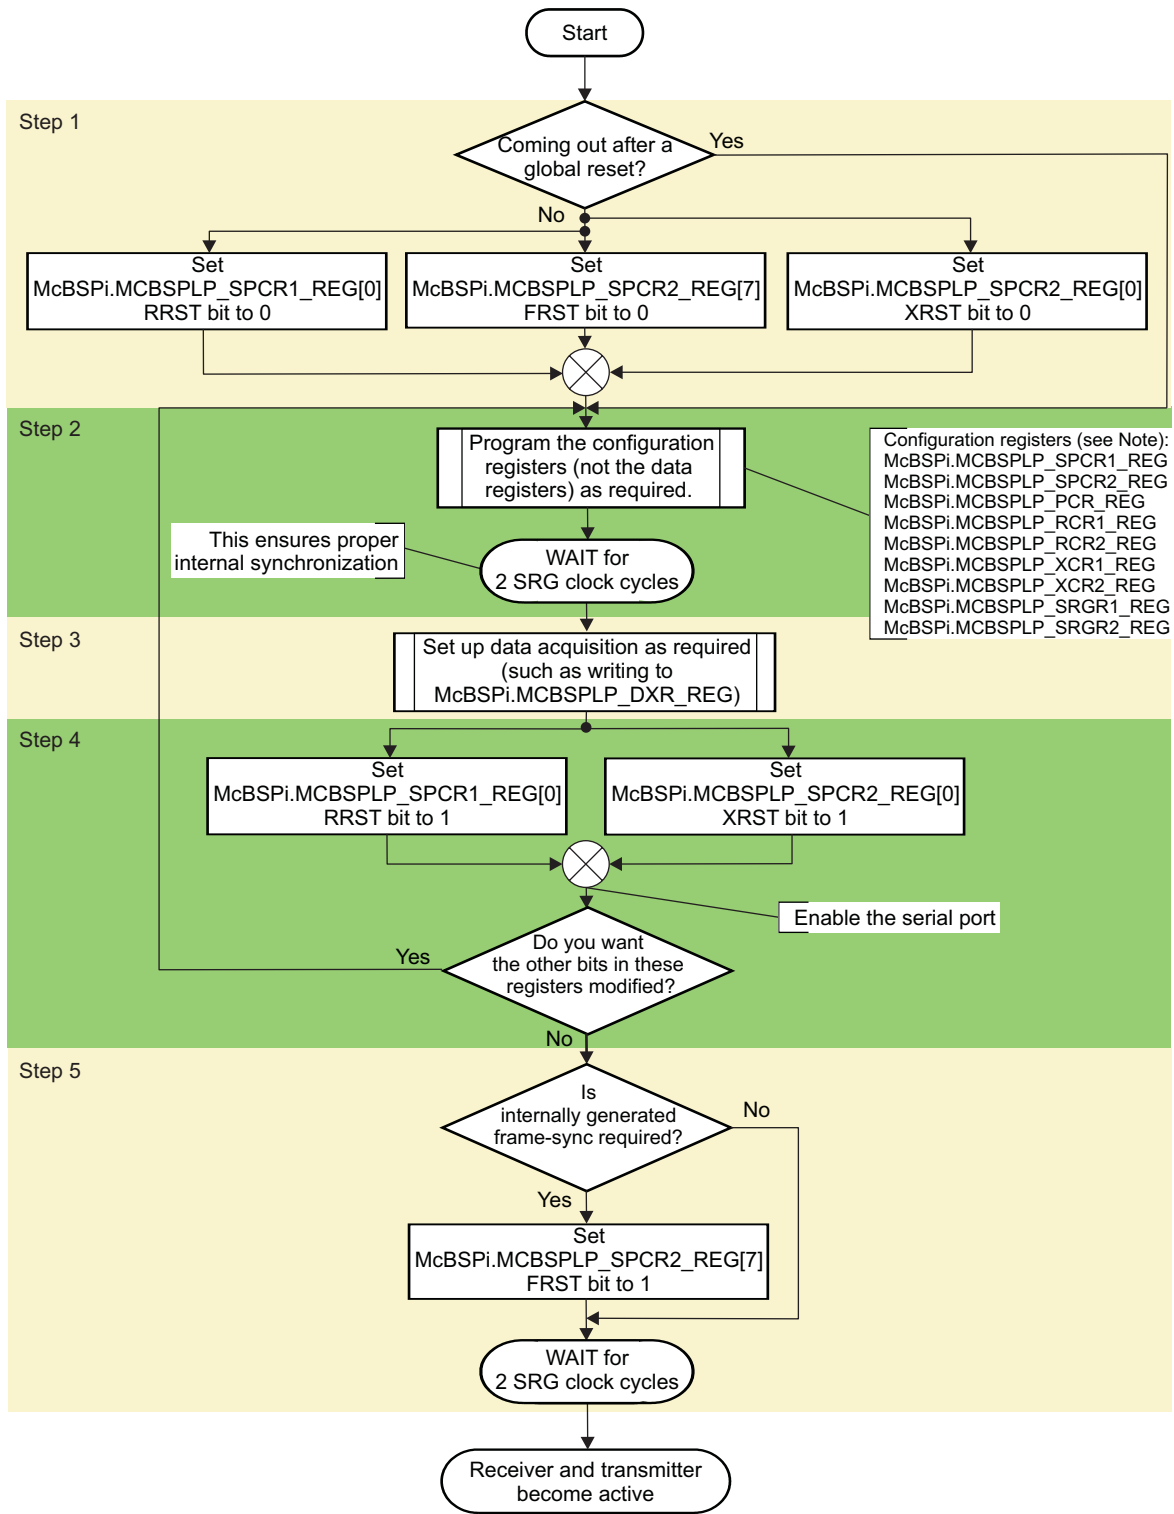

For all descriptions in this section, the McBSPi.MCBSPLP_XCCR_REG[11] XFULL_CYCLE bit and the McBSPi.MCBSPLP_RCCR_REG[11] RFULL_CYCLE bit are their reset value (XFULL_CYCLE bit=0 and RFULL_CYCLE bit=1).

18.5.1.1 McBSP Initialization Procedure

This procedure for reset/initialization can be applied in general when the Receiver or Transmitter has to be reset during its normal operation, and also when the Sample Rate Generator is not used for either operation.

[Figure 18-57](#) shows the serial port initialization procedure for master mode.

Figure 18-57. Flow Diagram of McBSP Initialization Procedure for Master Mode

mcbsp-062

Alternatively, on write (step 1 or 4), the transmitter and receiver can be placed in or taken out of reset by modifying the McBSPi.MCBSPLP_SPCR2_REG[0] XRST bit and the McBSPi.MCBSPLP_SPCR1_REG[0] RRST bit, respectively.

Figure 18-58 shows the flow diagram of the McBSP initialization procedure for slave mode.

Figure 18-58. Flow Diagram of McBSP Initialization Procedure for Slave Mode

mcbasp-074

NOTE:

- The necessary duration of the active-low period of XRST or Rrst is at least two CLKR/CLKX cycles.
- The appropriate bits in serial port configuration registers (McBSPi.MCBSPLP_SPCR1_REG, McBSPi.MCBSPLP_SPCR2_REG, McBSPi.MCBSPLP_PCR_REG, McBSPi.MCBSPLP_RCR1_REG, McBSPi.MCBSPLP_RCR2_REG, McBSPi.MCBSPLP_XCR1_REG, McBSPi.MCBSPLP_XCR2_REG, McBSPi.MCBSPLP_THRSH2_REG, McBSPi.MCBSPLP_XCCR_REG, McBSPi.MCBSPLP_SYSCONFIG_REG, McBSPi.MCBSPLP_SRGR1_REG, and McBSPi.MCBSPLP_SRGR2_REG) should only be modified when the affected portion of the serial port is in its reset state.
- In most cases, the data transmit register (McBSPi.MCBSPLP_DXR_REG) should be loaded by the MPU/IVA2 subsystem or the sDMA controller only when the transmitter is enabled (McBSPi.MCBSPLP_SPCR2_REG[0] XRST = 1). An exception to this rule is when these registers are used for loopback internal data.
- The bits of the channel control registers (McBSPi.MCBSPLP_MCR1_REG, McBSPi.MCBSPLP_MCR2_REG, McBSPi.MCBSPLP_RCER{A-H}_REG and McBSPi.MCBSPLP_XCER{A-H}_REG) can be modified at any time as long as they are not being used by the current reception/transmission in a multichannel selection mode.
- The SRG is reset by setting McBSPi.MCBSPLP_SPCR2_REG[6] GRST bit to 0.
- It is not necessary to wait if SRG is not used.
- Modification on-the-fly has no effect if a reset is not done first.

18.5.1.2 Reset and Initialization Procedure for the Sample Rate Generator

To reset and initialize the Sample Rate Generator:

- Place the McBSP Sample Rate Generator in RESET.

During a Global RESET, the Sample Rate Generator, the Receiver, and the Transmitter reset bits (GRST, Rrst, and XRST) are automatically forced to '0'. Otherwise, during normal operation, the Sample Rate Generator can be reset by making McBSPi.MCBSPLP_SPCR2_REG[6] GRST=0, provided that CLKG and/or FSG internal signal is not used by any portion of the McBSP module. Depending on the system needs, the software may also to reset the Receiver (McBSPi.MCBSPLP_SPCR1_REG[0] Rrst=0) and reset the Transmitter (McBSPi.MCBSPLP_SPCR2_REG[0] XRST bit =0).

- Program the registers that affect the Sample Rate Generator.

Program the Sample Rate Generator registers (McBSPi.MCBSPLP_SPCR1_REG and McBSPi.MCBSPLP_SPCR2_REG) as required for your application. Refer to [Figure 18-59](#).

If necessary, other control registers can be loaded with desired values provided the respective portion of the McBSP module (the Receiver or Transmitter) is in reset. [Table 18-24](#) presents the McBSP configuration when one of the clock sources is selected, but others registers can be impacted in function of the user application.

Table 18-24. McBSP Configuration in Function of the SRG Clock Source Selected

| SRG Clock Source Selected | Module Configuration | McBSPi.MCBSPLP_PCR_REG Configuration | | | |
|---------------------------|---------------------------------------|--------------------------------------|-----------|-------------------------|----------|
| | | CLKRM bit ⁽¹⁾ | CLKXM bit | FSRM bit ⁽¹⁾ | FSXM bit |
| McBSPi_ICLK or CLKS | Master Transmitter and Slave Receiver | 0 | 1 | 0 | 1 |
| | Master Receiver and Slave Transmitter | 1 | 0 | 1 | 0 |
| | Master Transmitter and Receiver | 1 | 1 | 1 | 1 |
| CLKR | Master Transmitter and Slave Receiver | 0 | 1 | 0 | 1 |

⁽¹⁾ This configuration is correct if McBSPi.MCBSPLP_XCCR_REG[5] DLB bit=0x0. When the DLB bit is set to 1, the CLKR clock (not the mcbspi_clkr pin) is driven by the CLKX clock, which is based on the CLKXM bit.

Table 18-24. McBSP Configuration in Function of the SRG Clock Source Selected (continued)

| SRG Clock Source Selected | Module Configuration | McBSPi.MCBSPLP_PCR_REG Configuration | | | |
|---------------------------|---------------------------------------|--------------------------------------|-----------|-------------------------|----------|
| | | CLKRM bit ⁽¹⁾ | CLKXM bit | FSRM bit ⁽¹⁾ | FSXM bit |
| CLKX | Master Receiver and Slave Transmitter | 1 | 0 | 1 | 0 |

After the Sample Rate Generator registers are programmed, wait for 2 CLKSRG cycles. This ensures proper synchronization internally.

- Enable the Sample Rate Generator (take it out of reset).
Set McBSPi.MCBSPLP_SPCR2_REG[6] GRST bit to 1 to enable the Sample Rate Generator.
After the Sample Rate Generator is enabled, wait for 2 CLKG cycles for the Sample Rate Generator logic to stabilize.
On the next rising edge of CLKSRG, the CLKG signal transitions to '1' and starts clocking with a frequency equal to (input clock frequency)/(CLKGDV + 1).
- If necessary, enable the receiver and/or the transmitter.
If necessary, remove the receiver and/or transmitter from reset by setting McBSPi.MCBSPLP_SPCR1_REG[0] RRST bit and/or McBSPi.MCBSPLP_SPCR2_REG[0] XRST = 1.

Figure 18-59. Flow Diagram for the SRG Registers Programming

MCBSP_073

The input clock is selected with the McBSPi.MCBSP_SPLP_PCR_REG[7] SCLKME bit and the McBSPi.MCBSP_SPLP_SRGR2_REG[13] CLKSM bit in one of the following configurations (see Table 18-25):

Table 18-25. Input Clock Selection for Sample Rate Generator

| SCLKME bit | CLKSM bit | Input Clock for Sample Rate Generator |
|------------|-----------|---------------------------------------|
| 0 | 0 | Signal on mcbsp_clks pin |
| 0 | 1 | McBSPi_ICLK clock |
| 1 | 0 | Signal on mcbsp_clkr pin |
| 1 | 1 | Signal on mcbsp_clkx pin |

18.5.1.3 Data Transfer DMA Request Configuration

To configure the McBSP receive/transmit data DMA requests (McBSPi_DMA_RX and McBSPi_DMA_TX), perform the following procedure:

- Write the receive McBSPi.MCBSPLP_THRSH1_REG register with the required receive DMA request length (the length of the transfer is the same as the threshold value + 1). As long as the RB occupied locations level is above or equal to the THRSH1_REG value + 1, the DMA request will be asserted. After transferring the configured THRSH1_REG value + 1 number of words, the receive DMA request will be de-asserted and reasserted as soon as the conditions are met again.

NOTE: In case of a number of transfers that exceed the number of the programmed DMA length the McBSP module will respond to the command, and will perform the transfer regardless of the receive buffer empty condition. When the receive buffer is empty a data transfer access will trigger a receive underflow interrupt, if enabled by McBSPi.MCBSPLP_IRQENABLE_REG[4] RUNDLEN bit.

- Write the transmit McBSPi.MCBSPLP_THRSH2_REG register with the required transmit DMA request length (the length of the transfer is the same as the threshold value + 1). As long as the XB free locations level is above or equal to the THRSH2_REG value + 1, the DMA request will be asserted. After transferring the configured THRSH2_REG value + 1 number of words, the transmit DMA request will be de-asserted and reasserted as soon as the conditions are met again.

NOTE: In case of a number of transfers that exceed the number of the programmed DMA length the McBSP module will respond to the command, and will perform the transfer regardless of the transmit buffer full condition. When the transmit buffer is full a data transfer access will trigger a transmit overflow interrupt, if enabled by McBSPi.MCBSPLP_IRQENABLE_REG[12] XOVLEN bit.

18.5.1.4 Interrupt Configuration

The McBSP module offers two interrupt schemes:

- L4 compliant interrupt request scheme using a common receive/transmit interrupt request line
- The legacy interrupt compliant scheme using 3 interrupt lines: one for receive, one for transmit and the common interrupt line.

18.5.1.4.1 L4-Compliant Interrupt Line

The L4-compliant interrupt line can be configured by using the McBSPi.MCBSPLP_IRQENABLE_REG register. When the McBSPi.MCBSPLP_IRQSTATUS_REG bit is set and the corresponding McBSPi.MCBSPLP_IRQENABLE_REG bit is set to one, the interrupt line is asserted. Writing one to a bit in McBSPi.MCBSPLP_IRQSTATUS_REG register clears the bit.

There are several conditions, which can be configured to generate an interrupt as follows:

- Transmit buffer empty at end of frame (McBSPi.MCBSPLP_IRQSTATUS_REG[14] XEMPTYEOF bit is set to one when a complete frame was transmitted and the transmit buffer is empty).
- Transmit buffer overflow (McBSPi.MCBSPLP_IRQSTATUS_REG[12] XOVFLSTAT bit is set to one when transmit buffer overflow; the data written while overflow condition is discarded).
- Transmit buffer underflow (McBSPi.MCBSPLP_IRQSTATUS_REG[11] XUNDFLSTAT bit is set to one when the transmit data buffer is empty, new data needs to be transmitted).

4. Transmit buffer threshold reached (McBSPi.MCBSPLP_IRQSTATUS_REG[10] XRDY bit is set to one when the transmit buffer free locations are equal or above the [THRSH2_REG + 1] value).
5. Transmit end of frame (McBSPi.MCBSPLP_IRQSTATUS_REG[9] XEOF is set to one when a complete frame was transmitted).
6. Transmit frame synchronization (McBSPi.MCBSPLP_IRQSTATUS_REG[8] XFSX bit is set to one when a new transmit frame synchronization is asserted).
7. Transmit frame synchronization Error (McBSPi.MCBSPLP_IRQSTATUS_REG[7] XSYNCERR is set to one when a transmit frame synchronization error is detected).
8. Receive buffer overflow (McBSPi.MCBSPLP_IRQSTATUS_REG[5] ROVFLSTAT bit is set to one when receive buffer overflow; the data which is written while overflow condition is discarded).
9. Receive buffer underflow (McBSPi.MCBSPLP_IRQSTATUS_REG[4] RUNDFLSTAT bit is set to one when read operation is performed to the receive data register while receive buffer is empty; data read while underflow condition is undefined).
10. Receive buffer threshold Reached (McBSPi.MCBSPLP_IRQSTATUS_REG[3] RRDY bit is set to one when the receive buffer occupied locations are equal or above the [THRSH1_REG + 1] value).
11. Receive end of frame (McBSPi.MCBSPLP_IRQSTATUS_REG[2] REOF is set to one when a complete frame was received).
12. Receive frame synchronization (McBSPi.MCBSPLP_IRQSTATUS_REG[1] RFSR bit is set to one when a new receive frame synchronization is asserted).
13. Receive frame synchronization error (McBSPi.MCBSPLP_IRQSTATUS_REG[0] RSYNCERR is set to one when a receive frame synchronization error is detected).

18.5.1.4.2 Legacy Interrupt Line

McBSPi_IRQ_TX and McBSPi_IRQ_RX are legacy interrupts. Not to be used for new development. McBSPi_IRQ (common interrupt line) should be preferred.

18.5.1.4.2.1 Set the receive interrupt line (legacy only)

The McBSPi.MCBSPLP_SPCR1_REG[5:4] RINTM bit field determines which event generates a receive interrupt request, McBSPi_IRQ_RX, to the MPU/IVA2.2 subsystem.

The receive interrupt informs the MPU/IVA2.2 subsystem of changes to the serial port status. Four options exist for configuring this interrupt.

- RINTM=0b00: The receive interrupt generated when the McBSPi.MCBSPLP_SPCR1_REG[1] RRDY bit changes from 0 to 1. Interrupt on every serial word by tracking the McBSPi.MCBSPLP_SPCR1_REG[1] RRDY bit. Regardless of the value of RINTM, RRDY bit can be read to detect the RRDY=1 condition.
- RINTM = 0b01: The receive interrupt generated by an end-of-frame condition in the receive multichannel selection mode. In any other serial transfer case, this setting is not applicable and, therefore, no interrupts are generated.
- RINTM = 0b10: The receive interrupt generated by a new receive frame-synchronization pulse. Interrupt on detection of receive frame-synchronization pulses. This generates an interrupt even when the receiver is in its reset state. This is done by synchronizing the incoming frame-synchronization pulse to the McBSPi_ICLK clock and sending it to the MPU/IVA2.2 subsystem via the receive interrupt.
- RINTM = 0b11: The receive interrupt generated when McBSPi.MCBSPLP_SPCR1_REG[3] RSYNCERR is set. Interrupt on frame-synchronization error. Regardless of the value of RINTM, RSYNCERR can be read to detect this condition. For information on using RSYNCERR, see [Section 18.4.4.3](#).

The McBSP module also provides a common interrupt line McBSPi_IRQ, which can be used by setting the McBSPi.MCBSPLP_IRQENABLE register. All the above settings have equivalent enable bits in the McBSPi.MCBSPLP_IRQENABLE register to enable the common interrupt line:

- RRDYEN is equivalent with RINTM = 0 setting
- REOFEN is equivalent with RINTM = 0b01 setting (the interrupt is generated by an end-of-frame condition regardless of the multichannel selection mode)

- RFSREN is equivalent with RINTM = 0b10 setting
- RSYNCERREN is equivalent with RINTM = 0b11 setting

This interrupt line has its own status register, [McBSPi.MCBSPLP_IRQSTATUS_REG](#).

18.5.1.4.2.2 Set the transmit interrupt line (legacy only)

The [McBSPi.MCBSPLP_SPCR2_REG\[5:4\]](#) XINTM bit field determines which event generates a transmit interrupt request ([McBSPi_IRQ_TX](#)) to the MPU/IVA2.2 subsystem.

The transmit interrupt informs the MPU/IVA2.2 subsystem of changes to the serial port status. Four options exist for configuring this interrupt.

- XINTM = 0b00: The transmit interrupt generated when the [McBSPi.MCBSPLP_SPCR2_REG\[1\]](#) XRDY bit changes from 0 to 1. Interrupt on every serial word by tracking the XRDY bit. Regardless of the value of XINTM, XRDY bit can be read to detect the XRDY=1 condition.
- XINTM = 0b01: The transmit interrupt generated by an end-of-frame condition in the transmit multichannel selection mode. In any other serial transfer case, this setting is not applicable and, therefore, no interrupts are generated.
- XINTM = 0b10: The transmit interrupt generated by a new transmit frame-synchronization pulse. Interrupt on detection of transmit frame-synchronization pulses. This generates an interrupt even when the transmitter is in its reset state. This is done by synchronizing the incoming frame-synchronization pulse to the [McBSPi_ICLK](#) clock and sending it to the MPU/IVA2.2 subsystem via transmit interrupt.
- XINTM = 0b11: The transmit interrupt generated when [McBSPi.MCBSPLP_SPCR2_REG\[3\]](#) XSYNCERR is set. Interrupt on frame-synchronization error. Regardless of the value of XINTM, XSYNCERR bit can be read to detect this condition. For information on using XSYNCERR bit, see [Section 18.4.4.6](#).

The McBSP module provides also a common interrupt line [McBSPi_IRQ](#), which can be used by setting the [McBSPi.MCBSPLP_IRQENABLE](#) register. All the above settings have equivalent enable bits in the [McBSPi.MCBSPLP_IRQENABLE](#) register to enable the common interrupt line:

- XDYEN is equivalent with XINTM = 0b00 setting
- XEOFEN is equivalent with XINTM = 0b01 setting (the interrupt is generated by an end-of-frame condition regardless of the multichannel selection mode)
- XFSXEN is equivalent with XINTM = 0b10 setting
- XSYNCERREN is equivalent with XINTM = 0b11 setting

This interrupt line has its own status register, [McBSPi.MCBSPLP_IRQSTATUS_REG](#).

18.5.1.5 Receiver Configuration

To configure the McBSP receiver, perform the following procedure:

1. Place the McBSP receiver in reset .
2. Program the McBSP registers for the desired receiver operation.
3. Take the receiver out of reset.

These 3 steps are detailed in the following subsections.

18.5.1.5.1 Resetting (Step 1) and Enabling (Step 3) the Receiver

The first step of the receiver configuration procedure is to reset the receiver, and the last step is to enable the receiver (to take it out of reset).

The serial port can be reset in the following 2 ways:

1. A global reset places the receiver, transmitter, and SRG in reset. When the device reset is removed, [McBSPi.MCBSPLP_SPCR2_REG\[6\]](#) GRST, [McBSPi.MCBSPLP_SPCR2_REG\[7\]](#) FRST, [McBSPi.MCBSPLP_SPCR1_REG\[0\]](#) RRST and [McBSPi.MCBSPLP_SPCR2_REG\[0\]](#) XRST bits = 0, which keeps the entire serial port in the reset state.

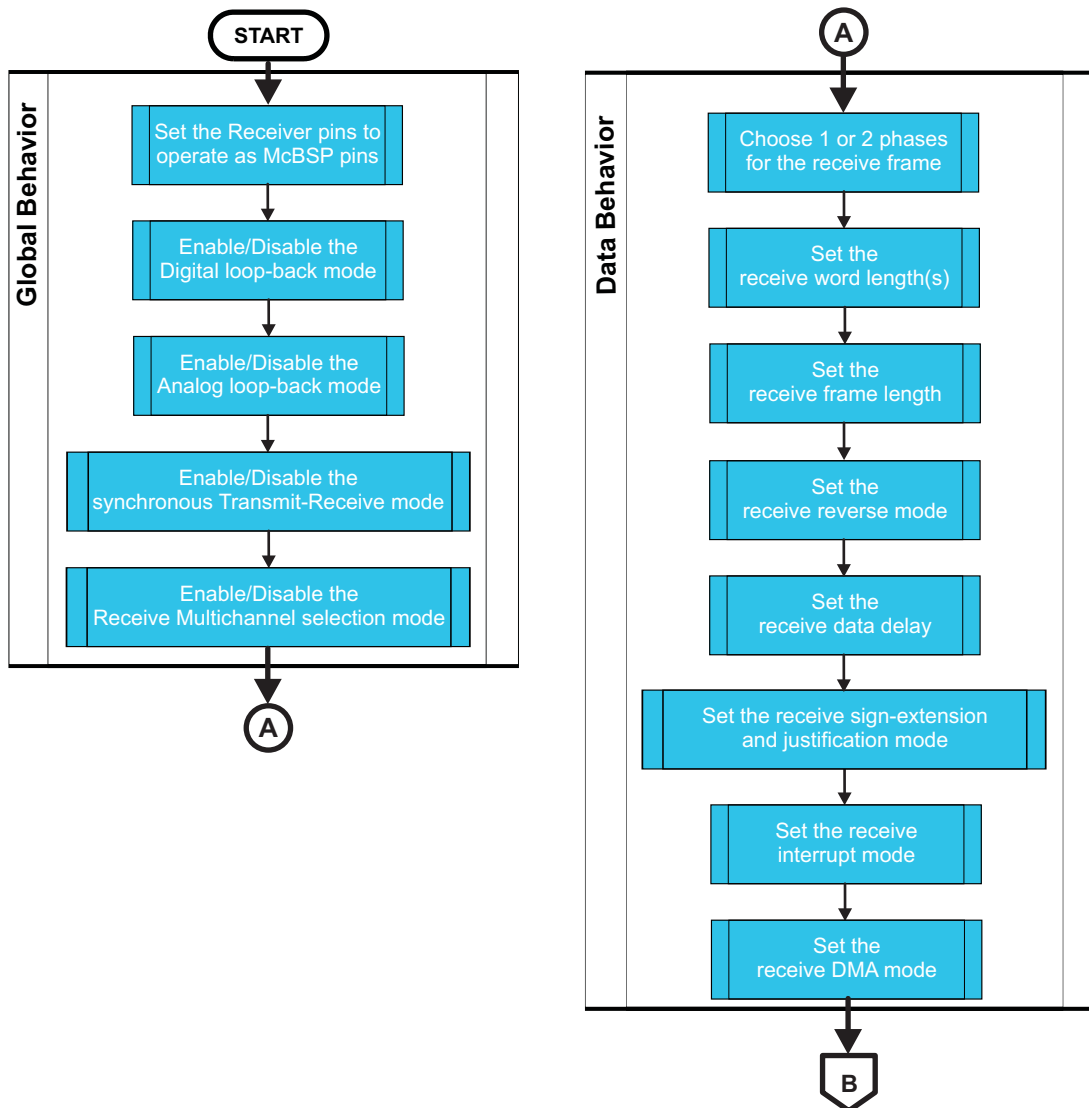

- The serial port receiver can be reset directly using the `McBSPi.MCBSPLP_SPCR1_REG[0]` RRST bit. If the SRG needs to be used, SRG must be reset directly using the `McBSPi.MCBSPLP_SPCR2_REG[6]` GRST bit. Similar operations with frame synchronization generator also require using the `McBSPi.MCBSPLP_SPCR2_REG[7]` FRST bit when the frame-sync signal must be generated.

To enable the receiver, the preceding bits, cleared to 0, must be set to 1.

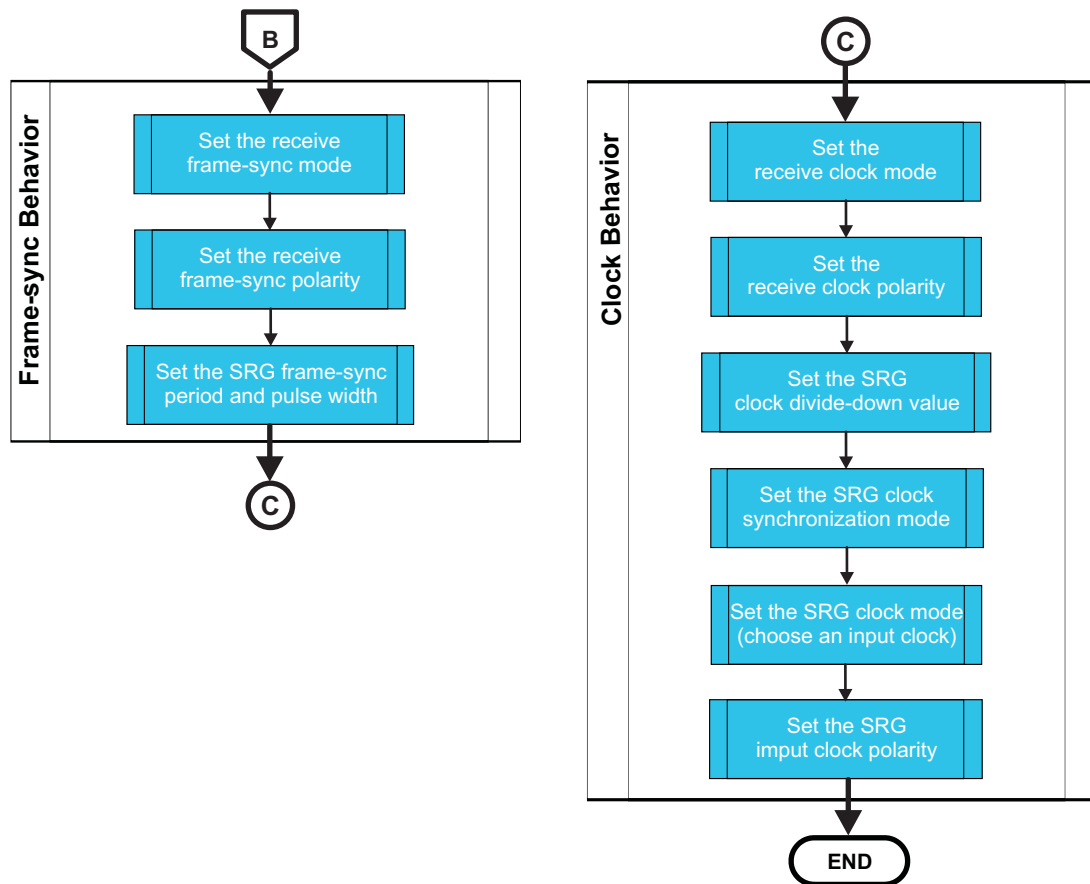

18.5.1.5.2 Programming the McBSP Registers for the Desired Receiver Configuration (Step 2)

Figure 18-60 and Figure 18-61 lists important tasks to be performed when the software is configuring the McBSP receiver. Each task corresponds to one or more McBSP register bit fields.

Figure 18-60. Important Tasks to Configure the McBSP Receiver (Part 1)

063

Figure 18-61. Important Tasks to Configure the McBSP Receiver (Part 2)

064

18.5.1.5.2.1 Global Behavior

18.5.1.5.2.1.1 Set the Receiver Pins to Operate as McBSP Pins

The McBSPi.MCBSPLP_PCR_REG[12] RIOEN bit determines whether the receiver pins are McBSP pins (RIOEN bit=0) or general-purpose I/O pins (RIOEN bit=1).

Please refer to [Section 18.5.1.7](#) which describes how to use McBSP pins as GPIO pins.

18.5.1.5.2.1.2 Enable/Disable the Digital Loop Back Mode

The McBSPi.MCBSPLP_XCCR_REG[5] DLB bit determines whether the digital loopback mode is on or off.

In the digital loopback mode, the receive signals are connected internally through multiplexers to the corresponding transmit signals:

- DR signal is connected on DX signal to receive the transmitted data
- FSR is connected to FRX output signal
- CLKR is connected to the CLKX output signal

This mode allows testing of serial port; the McBSP module receives the data it transmits. This loopback mode is not done through pads, all output signals being disabled.

NOTE: That in digital loopback mode the SRG and the frame synchronization generator need to be enabled to generate the CLKX and FSX signals.

18.5.1.5.2.1.3 Enable/Disable the Analog Loopback Mode

The McBSPi.MCBSPLP_SPCR1_REG[15] ALB bit determines whether the analog loopback mode is on or off.

In the analog loopback mode, the receive signals are connected internally through multiplexers to the corresponding transmit loop back signals:

- DR is connected to transmit loop back data on DX input pin
- FSR is connected to FRX input pin
- CLKR is connected to the CLKX input pin

This Analog Loopback mode is also done to test the Input/Output buffers, through pads.

18.5.1.5.2.1.4 Enable/disable the synchronous transmit-receive mode (McBSP1 only)

The control registers of the System Control Module is used to configure the synchronous transmit-receive mode.

The McBSP1_CLKR bit of the CONTROL_DEVCONF0[3] register is used to select the McBSP1 module CLKR signal source:

- When set to '0', the CLKR source is from the CLKR input signal
- When set to '1', the CLKR source is from the CLKX input signal

The McBSP1_FSR bit of the CONTROL_DEVCONF0[4] register is used to select the McBSP1 module FSR signal source:

- When set to '0', the FSR source is from the FSR input signal
- When set to '1', the FSR source is from the FSX input signal

18.5.1.5.2.1.5 Enable/Disable the Receive Multichannel Selection Mode

The McBSPi.MCBSPLP_MCR1_REG[0] RMCM bit determines whether the receive multichannel selection mode is on or off.

For further details, see [Section 18.4.6.5](#).

18.5.1.5.2.2 Data Behavior

18.5.1.5.2.2.1 Choose 1 or 2 Phases for the Receive Frame

The McBSPi.MCBSPLP_RCR2_REG[15] RPHASE bit determines whether the receive data frame has one (Single phase) or two phases (Dual phase). When dual-phase is selected the number of words per phase must be set to one.

18.5.1.5.2.2.2 Set the Receive Word Length(s)

The McBSPi.MCBSPLP_RCR1_REG[7:5] RWDLEN1 and McBSPi.MCBSPLP_RCR2_REG[7:5] RWDLEN2 bit fields determine how many bits are in each serial word in phase 1 and in phase 2, respectively, of the receive data frame.

If a single-phase frame is selected, RWDLEN1 selects the length for every serial word received in the frame.

If a dual-phase frame is selected, RWDLEN1 and RWDLEN2 must be set to select the both length. These both bits can have values different.

18.5.1.5.2.2.3 Set the Receive Frame Length

The receive frame length is the number of serial words in the receive frame.

The McBSPi.MCBSPLP_RCR1_REG[14:8] RFRLLEN1 and McBSPi.MCBSPLP_RCR2_REG[14:8] RFRLLEN2 bit fields determine how many serial words are in phase 1 and in phase 2, respectively, of the receive data frame.

If a dual-phase frame is selected (RPHASE=1), the frame length must be two words(one word for phase 1 plus the one word for phase 2). Others values must not be used.

The 7-bit RFLEN1 field allows up to 128 words per phase when single-phase frame. See [Table 18-26](#) below for a summary of how to calculate the frame length. This length corresponds to the number of words or logical time slots or channels per frame-synchronization pulse.

Program the RFLEN fields with [W - 1], where W represents the number of words per phase. For example, to get a phase length of 128 words in phase 1, load 127 words into RFLEN1.

Table 18-26. How to Calculate the Length of the Receive Frame

| RPHASE | RFLEN1 | RFLEN2 | Frame Length |
|--------|------------------|------------|------------------------|
| 0 | 0 ≤ RFLEN1 ≤ 127 | Don't care | (RFLEN1value +1) words |
| 1 | RFLEN1 = 0 | RFLEN2 = 0 | 2 words |

18.5.1.5.2.2.4 Set the Receive Reverse Mode

The McBSPi.MCBSPLP_RCR2_REG[4:3] RREVERSE bit field determines whether reverse (LSB first) data transfer option is chosen for McBSP reception.

For further information about reverse mode, see [Section 18.4.2.2](#).

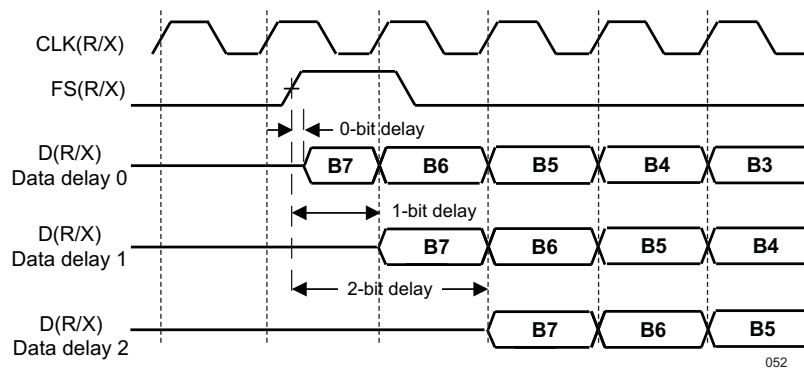

18.5.1.5.2.2.5 Set the Receive Data Delay

The McBSPi.MCBSPLP_RCR2_REG[1:0] RDATDLY bit field determines the length of the data delay for the receive frame.

The start of a frame is defined by the first clock cycle in which frame synchronization is active. The beginning of actual data reception or transmission with respect to the start of the frame can be delayed if required. This delay is called data delay.

McBSPi.MCBSPLP_RCR2_REG[1:0] RDATDLY specifies the data delay for reception. The range of programmable data delay is zero to two bit-clocks (RDATDLY=0b00–0b10), as shown in [Figure 18-62](#) below. In this figure, the data transferred is an 8-bit value with bits labeled B7, B6, B5, and so on. Typically a 1-bit delay is selected, because data often follows a 1-cycle active frame-synchronization pulse.

Figure 18-62. Range of Programmable Data Delay

18.5.1.5.2.2.5.1 0-Bit Data Delay

Normally, a frame-synchronization pulse is detected or sampled with respect to an edge of internal serial clock CLK(R/X). Thus, on the following cycle or later (depending on the data delay value), data may be received or transmitted. However, in the case of 0-bit data delay, the data must be ready for reception and/or transmission on the same serial clock cycle.

For reception, this problem is solved because receive data is sampled on the first falling edge of CLKR

where an active-high internal FSR is detected. However, data transmission must begin on the rising edge of the internal CLKX clock that generated the frame synchronization. Therefore, the first data bit is assumed to be present in XSR, and thus on mcbasp_dx. The transmitter then asynchronously detects the frame-synchronization signal (FSX) going active high and immediately starts driving the first bit to be transmitted on the mcbasp_dx pin.

18.5.1.5.2.2.5.2 2-Bit Data Delay

A data delay of two bit periods allows the serial port to interface to different types of T1 framing devices where the data stream is preceded by a framing bit. During reception of such a stream with data delay of two bits (framing bit appears after a 1-bit delay and data appears after a 2-bit delay), the serial port essentially discards the framing bit from the data stream, as shown in Figure 18-63. In this figure, the data transferred is an 8-bit value with bits labeled B7, B6, B5, and so on.

Figure 18-63. 2-Bit Data Delay Used to Skip a Framing Bit

053

18.5.1.5.2.2.6 Set the Receive Sign-Extension and Justification Mode

The McBSPi.MCBSPLP_SPCR1_REG[14:13] RJUST bit field determines whether data received by the McBSP module is sign-extended or not and how it is justified.

RJUST bit selects whether data in RB is right- or left-justified (with respect to the MSB) in McBSPi.MCBSPLP_DRR_REG register and whether unused bits in McBSPi.MCBSPLP_DRR_REG are filled with zeroes or with sign bits.

Table 18-27 and Table 18-28 show the effects of various RJUST values; the effect on an example 12-bit receive-data value 0xABC, and the effect on an example 20-bit receive-data value 0xABCDE, respectively.

Table 18-27. Example: Use of RJUST Bit Field With 12-bit Data Value 0xABC

| RJUST | Justification | Extension | Value in DRR_REG |
|-------|---------------|----------------------------|------------------|
| 0b00 | Right | Zero fill MSBs | 0x0000 0ABC |
| 0b01 | Right | Sign extend data into MSBs | 0xFFFF FABC |
| 0b10 | Left | Zero fill LSBs | 0xABC0 0000 |
| 0b11 | Reserved | Reserved | Reserved |

Table 18-28. Example: Use of RJUST Bit Field With 20-bit Data Value 0xABCDE

| RJUST | Justification | Extension | Value in DRR_REG |
|-------|---------------|----------------------------|------------------|
| 0b00 | Right | Zero fill MSBs | 0x000A BCDE |
| 0b01 | Right | Sign extend data into MSBs | 0xFFFF BCDE |
| 0b10 | Left | Zero fill LSBs | 0xABCD E000 |
| 0b11 | Reserved | Reserved | Reserved |

18.5.1.5.2.2.7 Set the Receive Interrupt Mode

Please refer to [Section 18.5.1.4.2.1](#).

18.5.1.5.2.2.8 Set the Receive DMA Mode

The McBSP receive-data DMA requests (McBSPi_DMA_RX) are active after the McBSPi.MCBSPLP_SPCR1_REG [0] RRST bit is released. After reset, the default DMA threshold (and length) is 1.

The receive DMA requests can be disabled by setting the McBSPi.MCBSPLP_RCCR_REG[3] RDMAEN bit to 0. When disabling the DMA, the DMA request line is deasserted even if a DMA transfer is pending, and the DMA state-machine is not reset.

To configure the McBSP receive data DMA requests, perform the following:

- Write the receive McBSPi.MCBSPLP_THRSH1_REG register with the required receive DMA request length (the length of the transfer is the same as the threshold value + 1).
- As long as the occupied locations level in the RB is above or equal to the THRSH1_REG value + 1, the DMA request is asserted.
- After transferring the configured (THRSH1_REG value + 1) number of words, the receive DMA request is deasserted, and then reasserted as soon as the conditions are met again.

18.5.1.5.2.3 Frame-Sync Behavior

18.5.1.5.2.3.1 Set the Receive Frame-Sync Mode

McBSPi.MCBSPLP_PCR_REG[10] FSRM bit, McBSPi.MCBSPLP_SRGR2_REG[15] GSYNC bit, McBSPi.MCBSPLP_SPCR1_REG[15] ALB bit and McBSPi.MCBSPLP_XCCR_REG[5] DLB bit field are used to determine the source for receive frame synchronization and the function of the mcbasp_fsr pin.

[Table 18-29](#) below shows how you can select various sources to provide the receive frame-synchronization signal and the effect on the mcbasp_fsr pin. The polarity of the signal on the mcbasp_fsr pin is determined by the McBSPi.MCBSPLP_PCR_REG[2] FSRP bit.

Table 18-29. FSRM and GSYNC Effects on Frame-Sync Signal and mcbasp_fsr Pin

| FSRM | GSYNC | Source of Receive Frame Synchronization | MCBSPLP.FSR Pin Status |
|------|--------|---|--|
| 0 | 0 or 1 | An external frame synchronization signal enters the McBSP module through the mcbasp_fsr pin. The signal is then inverted as determined by FSRP bit before being used as internal FSR. | Input |
| 1 | 0 | Internal FSR is driven by the SRG frame-synchronization signal (FSG). | Output. FSG is inverted as determined by FSRP bit before being driven out on the mcbasp_fsr pin. |
| 1 | 1 | Internal FSR is driven by the SRG frame-synchronization signal (FSG). | Input. The external frame-synchronization input on the mcbasp_fsr pin is used to synchronize CLKG and generate FSG pulses. |

In digital loop-back mode (DLB=1), the transmit frame-synchronization signal is used as the receive frame-synchronization signal.

Also in the analog loop back mode (ALB=1), the internal receive clock signal (CLKR), and the internal receive frame-synchronization signal (FSR) are internally connected to their transmit counterparts, CLKX and FSX.

For more details on clock and frame-sync configuration, see [Section 18.4.3](#).

18.5.1.5.2.3.2 Set the Receive Frame-Sync Polarity

The McBSPi.MCBSPLP_PCR_REG[2] FSRP bit determines whether frame-synchronization pulses are active high or active low on the mcbasp_fsr pin.

Receive frame-synchronization pulses can be generated internally by the SRG or driven by an external source. The source of frame synchronization is selected by programming the `McBSPi.MCBSPLP_PCR_REG[10]` FSRM bit. FSR is also affected by the `McBSPi.MCBSPLP_SRGR2_REG[15]` GSYNC bit. For information about the effects of FSRM and GSYNC, see [Section 18.5.1.5.2.3.1](#), *Set the Receive Frame-Sync Mode*.

When FSR and FSX are inputs ($FSXM = FSRM = 0$, external frame-synchronization pulses), the McBSP module detects them on the internal falling edge of clock, internal CLKR, and internal CLKX, respectively. The receive data arriving at the `mcbspi_dr` pin is also sampled on the falling edge of internal CLKR. These internal clock signals are either derived from an external source via CLK(R/X) pins or driven by the SRG clock (CLKG) internal to the McBSP module.

When FSR and FSX are outputs, implying that they are driven by the SRG, they are generated (transition to their active state) on the rising edge of the internal clock, CLK(R/X). Similarly, data on the `mcbbsp_dx` pin is output on the rising edge of internal CLKX.

FSRP, FSXP, CLKRP, and CLKXP bit fields in the pin control register (`McBSPi.MCBSPLP_PCR_REG`) configure the polarities of the FSR, FSX, CLKR, and CLKX signals, respectively. All frame-synchronization signals (internal FSR, internal FSX) that are internal to the serial port are active high. If the serial port is configured for external frame synchronization (FSR/FSX are inputs to McBSP), and $FSRP = FSXP = 1$, the external active-low frame-synchronization signals are inverted before being sent to the receiver (internal FSR) and transmitter (internal FSX). Similarly, if internal synchronization (FSR/FSX are output pins and $GSYNC = 0$) is selected, the internal active-high frame-synchronization signals are inverted, if the polarity bit $FS(R/X)P = 1$, before being sent to the $FS(R/X)$ pin.

[Figure 18-64](#) shows how data clocked by an external serial device using a rising edge can be sampled by the McBSP receiver on the falling edge of the same clock.

Figure 18-64. Data Externally Clocked on a Rising Edge and Sampled on a Falling Edge

18.5.1.5.2.3.3 Set the SRG Frame-Sync Period and Pulse Width

The SRG can produce a clock signal, CLKG, and FSG. If the SRG is supplying receive or transmit frame synchronization, you must program the bit fields FPER and FWID.

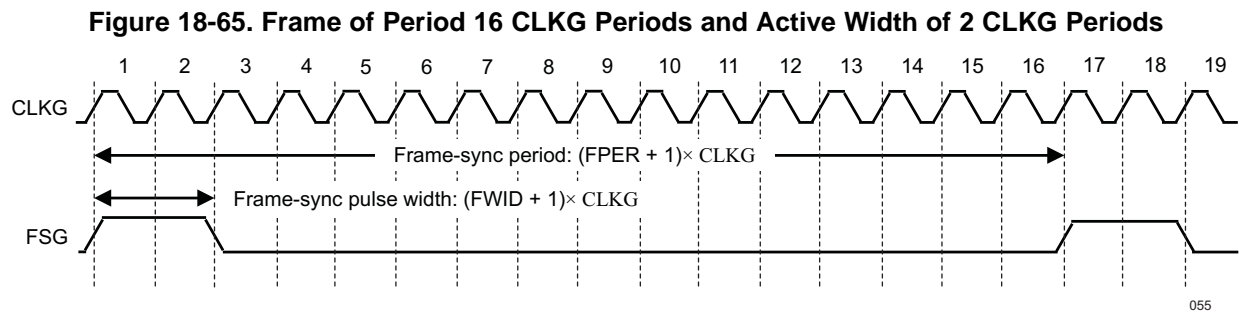

`McBSPi.MCBSPLP_SRGR2_REG[11:0]` FPER bit field is used to set the SRG frame-sync period and `McBSPi.MCBSPLP_SRGR1_REG[15:8]` FWID bit field is used to set the SRG pulse width.

On FSG, the period from the start of a frame-synchronization pulse to the start of the next pulse is $(FPER+1)$ CLKG cycles. The 12 bits of FPER allow a frame-synchronization period of 1 to 4096 CLKG cycles, which allows up to 4096 data bits per frame. When $GSYNC=1$, FPER is a don't care value.

Each pulse on FSG has a width of $(FWID+1)$ CLKG cycles. The eight bits of FWID allow a pulse width of 1 to 256 CLKG cycles. It is recommended that FWID be programmed to a value less than the programmed word length.

The values in FPER and FWID are loaded into separate down-counters. The 12-bit FPER counter counts down the generated clock cycles from the programmed value (4095 maximum) to 0. The 8-bit FWID counter counts down from the programmed value (255 maximum) to 0.

[Figure 18-65](#) shows a frame-synchronization period of 16 CLKG periods ($FPER=15$ or 00001111b) and a frame-synchronization pulse with an active width of 2 CLKG periods ($FWID=1$).

When the SRG comes out of reset, FSG is in its inactive state. Then, when GRST=1 and FSGM=1, a frame-synchronization pulse is generated. The frame width value (FWID+1) is counted down on every CLKG cycle until it reaches 0, at which time FSG goes low. At the same time, the frame period value (FPER+1) is also counting down. When this value reaches 0, FSG goes high, indicating a new frame.

18.5.1.5.2.4 Clock Behavior

18.5.1.5.2.4.1 Set the receive clock mode

McBSPi.MCBSPLP_PCR_REG[8] CLKRM bit, McBSPi.MCBSPLP_SPCR1_REG[15] ALB bit and McBSPi.MCBSPLP_XCCR_REG[5] DLB bit are used to set the receive clock mode.

Table 18-30 shows how to select various sources to provide the receive clock signal and affect the mcbbsp_clkr pin. The McBSPi.MCBSPLP_PCR_REG[0] CLKRP bit determines the polarity of the signal on the mcbbsp_clkr pin.

Table 18-30. CLKRM Effect on Receive Clock Signal and mcbbsp_clkr Pin

| CLKRM | Source of Receive Clock | mcbbsp_clkr Pin Status |
|-------|--|--|
| 0 | The mcbbsp_clkr pin is an input driven by an external clock. The external clock signal is inverted as determined by CLKRP bit before being used. | Input |
| 1 | The SRG clock (CLKG) drives internal CLKR. | Output. CLKG, inverted as determined by CLKRP, is driven out on the mcbbsp_clkr pin. |

In the digital loop-back mode (DLB=1) or analog loop-back mode (ALB = 1), the transmit clock signal is used as the receive clock signal. For more details on clock configuration, see [Section 18.4.3.1](#).

18.5.1.5.2.4.2 Set the Receive Clock Polarity

McBSPi.MCBSPLP_PCR_REG[0] CLKRP bit is used to set the receive clock polarity.

The receive clock polarity bit, CLKRP, sets the edge used to sample received data. The receive data is always sampled on the falling edge of internal CLKR. Therefore, if CLKRP=1 and external clocking is selected (CLKRM=0 and CLKR is an input pin), the external rising-edge triggered input clock on CLKR is inverted to a falling-edge triggered clock before being sent to the receiver. If CLKRP=1 and internal clocking is selected (CLKRM=1), the internal falling-edge triggered clock is inverted to a rising-edge triggered clock before being sent out on the mcbbsp_clkr pin.

NOTE: CLKRP=CLKXP in a system where the same clock (internal or external) is used to clock the receiver and transmitter. The receiver uses the opposite edge as the transmitter to ensure valid setup and hold of data around this edge.

18.5.1.5.2.4.3 Set the SRG Clock Divide-Down Value

McBSPi.MCBSPLP_SRGR1_REG[7:0] CLKGDV bit field is used to set the SRG clock divide-down value.

The first divider stage generates the serial data bit clock from the input clock. This divider stage utilizes a counter, preloaded by CLKGDV, that contains the divide ratio value.

The output of the first divider stage is the data bit clock, which is output as CLKG and which serves as the input for the second and third stages of the divider.

CLKG has a frequency equal to $1/(\text{CLKGDV}+1)$ of SRG input clock. Thus, the sample generator input clock frequency is divided by a value between 1 and 256. The CLKG duty cycle is 50%.

18.5.1.5.2.4.4 Set the SRG Clock Synchronization Mode

McBSPi.MCBSPLP_SRGR2_REG[15] GSYNC bit is used to set the SRG clock synchronization mode.

For more information about the clock synchronization feature, see [Section 18.4.3](#).

18.5.1.5.2.4.5 Set the SRG Clock Mode (Choose an Input Clock)

McBSPi.MCBSPLP_PCR_REG[7] SCLKME bit and McBSPi.MCBSPLP_SRGR2_REG[13] CLKSM bit are used to set the SRG clock mode.

The SRG can produce a clock signal (CLKG) for use by the receiver, the transmitter, or both, but CLKG is derived from an input clock.

For further details about the clock synchronization feature, see [Section 18.4.3](#).

18.5.1.5.2.4.6 Set the SRG Input Clock Polarity

McBSPi.MCBSPLP_SRGR2_REG[14] CLKSP bit, McBSPi.MCBSPLP_PCR_REG[1] CLKXP bit and McBSPi.MCBSPLP_PCR_REG[0] CLKRP bit are used to set the SRG input clock polarity.

The SRG can produce a clock signal (CLKG) and a frame-synchronization signal (FSG) for use by the receiver, the transmitter, or both. To produce CLKG and FSG, the SRG must be driven by an input clock signal derived from the McBSP_FCLK clock or from an external clock on the mcbbsp_clks, mcbbsp_clkx, or mcbbsp_clkr pin. If you use a pin, choose a polarity for that pin by using the appropriate polarity bit (CLKSP for the mcbbsp_clks pin, CLKXP for the mcbbsp_clkx pin, CLKRP for the mcbbsp_clkr pin). The polarity determines whether the rising or falling edge of the input clock generates transitions on CLKG and FSG.

18.5.1.6 Transmitter Configuration

To configure the McBSP transmitter, perform the following procedure:

1. Place the McBSP transmitter in reset
2. Program the McBSP registers for the desired transmitter operation
3. Take the transmitter out of reset

These 3 steps are described in more details in the sub-sections below.

18.5.1.6.1 Resetting (Step 1) and Enabling (Step 3) the Transmitter

The first step of the transmitter configuration procedure is to reset the transmitter, and the last step is to enable the transmitter (to take it out of reset).

The serial port can be reset in the following two ways:

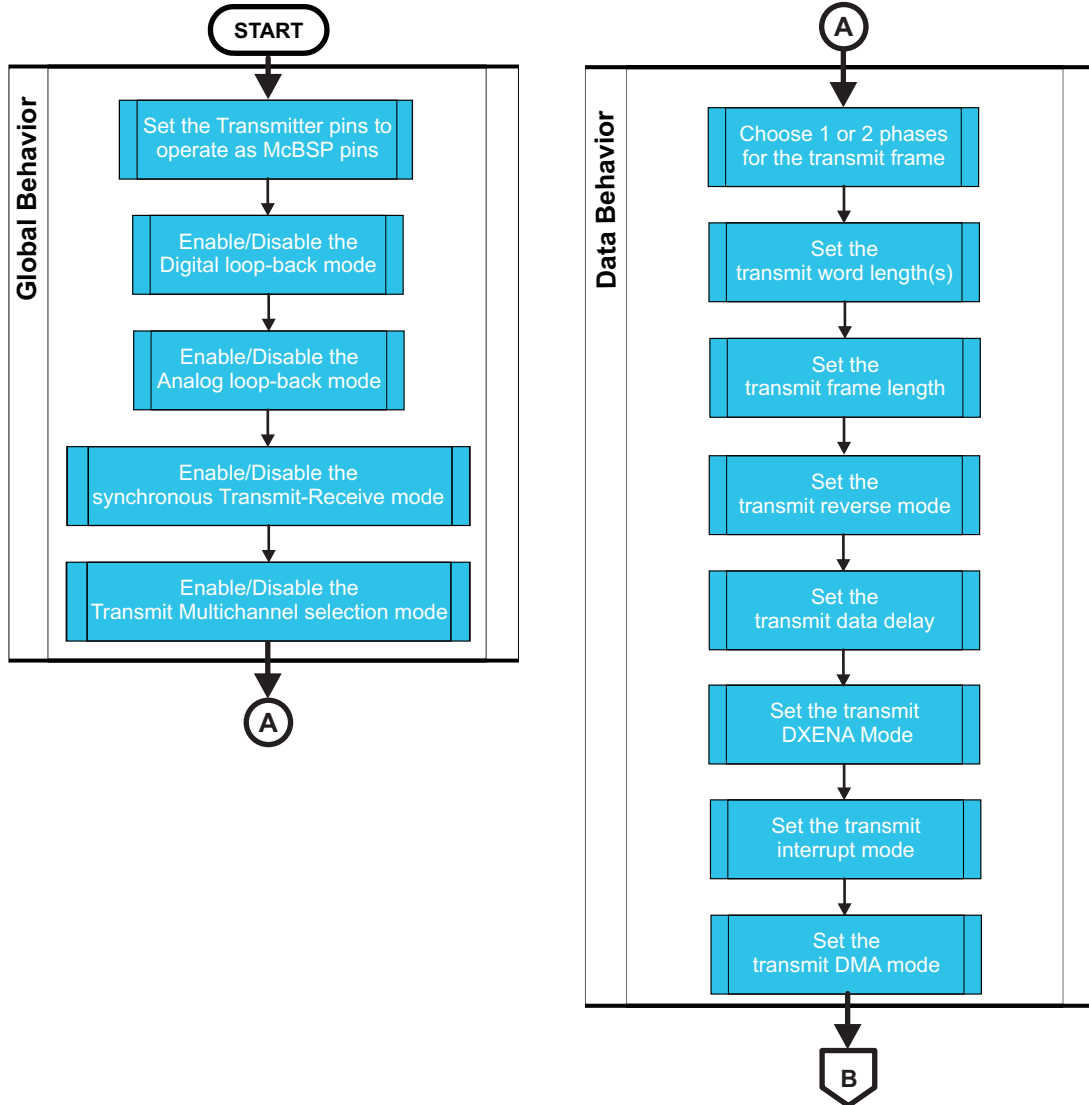

1. A global reset places the receiver, transmitter, and SRG in reset. When the device reset is removed, McBSPi.MCBSPLP_SPCR2_REG[6] GRST, McBSPi.MCBSPLP_SPCR2_REG[7] FRST, McBSPi.MCBSPLP_SPCR1_REG[0] RRST and McBSPi.MCBSPLP_SPCR2_REG[0] XRST bits = 0, which keeps the entire serial port in the reset state.
2. The serial port receiver can be reset directly using the McBSPi.MCBSPLP_SPCR2_REG[0] XRST bit. If the SRG needs to be used, SRG must be reset directly using the McBSPi.MCBSPLP_SPCR2_REG[6] GRST bit. Similar operation with the Frame Synchronization Generator also requires using the McBSPi.MCBSPLP_SPCR2_REG[7] FRST bit when the frame-sync signal must be generated.

To enable the transmitter, the preceding bits, cleared to 0, must be set to 1.

18.5.1.6.2 Programming the McBSP Registers for the Desired Transmitter Operation (Step 2)

Figure 18-66 and Figure 18-67 list important tasks to be performed when configuring the McBSP transmitter. Each task corresponds to one or more McBSP register bit fields.

Figure 18-66. Important Tasks to Configure the McBSP Transmitter (Part 1)

065

Figure 18-67. Important Tasks to Configure the McBSP Transmitter (Part 2)

066

18.5.1.6.2.1 Global Behavior

18.5.1.6.2.1.1 Set the Transmitter Pins to Operate as McBSP Pins

McBSPi.MCBSPLP_PCR_REG[13] XIOEN bit determines whether the transmitter pins are McBSP pins (XIOEN=0) or general-purpose I/O pins (XIOEN=1).

Refer to [Section 18.5.1.7](#) which describes how to use McBSP pins as GPIO pins.

18.5.1.6.2.1.2 Enable/Disable the Digital Loop-Back Mode

Refer to it, [Section 18.5.1.5.2.1.2](#).

18.5.1.6.2.1.3 Enable/Disable the Analog Loop-Back Mode

Refer to it, [Section 18.5.1.5.2.1.3](#).

18.5.1.6.2.1.4 Enable/Disable the Synchronous Transmit-Receive Mode (McBSP1 only)

Refer to it, [Section 18.5.1.5.2.1.4](#).

18.5.1.6.2.1.5 Enable/Disable the Transmit Multichannel Selection

McBSPi.MCBSPLP_MCR2_REG[1:0] XMCM bit field determines whether the transmit multichannel selection mode is on or off.

Refer to [Section 18.4.6.7](#).

18.5.1.6.2.2 Data Behavior

18.5.1.6.2.2.1 Choose 1 or 2 Phases for the Transmit Frame

McBSPi.MCBSPLP_XCR2_REG[15] XPHASE bit determines whether the transmit data frame has one (Single phase) or two phases (Dual phase). When dual-phase is selected the number of words per phase must be set to one.

18.5.1.6.2.2.2 Set the Transmit Word Length(s)

McBSPi.MCBSPLP_XCR1_REG[7:5] XWDLEN1 and McBSPi.MCBSPLP_XCR2_REG[7:5] XWDLEN2 bit fields determine how many bits are in each serial word in phase 1 and in phase 2, respectively, of the transmit data frame.

If a single-phase frame is selected, XWDLEN1 selects the length for every serial word received in the frame.

If a dual-phase frame is selected, XWDLEN1 and XWDLEN2 must be set to select the both length. These both bits can have values different.

18.5.1.6.2.2.3 Set the Transmit Frame Length

The transmit frame length is the number of serial words in the transmit frame.

McBSPi.MCBSPLP_XCR1_REG[14:8] XFRLEN1 and McBSPi.MCBSPLP_XCR2_REG[14:8] XFRLEN2 bit fields determine how many serial words are in phase 1 and in phase 2, respectively, of the transmit data frame.

If a dual-phase frame is selected (XPHASE=1), the frame length is 2 words, the length of phase 1 (one word) plus the length of phase 2 (one word). Others values must not be used.

The 7-bit XFRLEN fields allow up to 128 words per phase. See [Table 18-31](#) for a summary of how to calculate the frame length. This length corresponds to the number of words or logical time slots or channels per frame-synchronization pulse.

Program the XFRLEN fields with [W minus 1], where W represents the number of words per phase. For the example, if you want a phase length of 128 words in phase 1, load 127 into XFRLEN1.

Table 18-31. How to Calculate the Length of the Transmit Frame

| XPHASE | XFRLEN1 | XFRLEN2 | Frame Length |
|--------|----------------------------------|-------------|-------------------------|
| 0 | $0 \leq \text{XFRLEN1} \leq 127$ | Don't care | (XFRLEN1value +1) words |
| 1 | XFRLEN1= 0 | XFRLEN2 = 0 | 2 words |

18.5.1.6.2.2.4 Set the Transmit Reverse Mode

McBSPi.MCBSPLP_XCR2_REG[4:3] XREVERSE bit field determines whether reverse (LSB first) data transfer option is chosen for McBSP reception.

For additional information about reverse mode, see [Section 18.4.2.2](#).

18.5.1.6.2.2.5 Set the Transmit Data Delay

McBSPi.MCBSPLP_XCR2_REG[1:0] XDATDLY bit field determines the length of the data delay for the transmit frame.

The start of a frame is defined by the first clock cycle in which frame synchronization is found to be active. The beginning of actual data transmission with respect to the start of the frame can be delayed if required. This delay is called data delay.

XDATDLY specifies the data delay for reception. The range of programmable data delay is zero to two bit-clocks (XDATDLY=00b–10b), as shown in [Figure 18-68](#). In this figure, the data transferred is an 8-bit value with bits labeled B7, B6, B5, and so on.

NOTE: Typically a 1-bit delay is selected, because data often follows a 1-cycle active frame-synchronization pulse.

Figure 18-68. Range of Programmable Data Delay

18.5.1.6.2.2.5.1 0-Bit Data Delay:

Normally, a frame-synchronization pulse is detected or sampled with respect to an edge of internal serial clock CLK(R/X). Thus, on the following cycle or later (depending on the data delay value), data may be received or transmitted. However, in the case of 0-bit data delay, the data must be ready for reception and/or transmission on the same serial clock cycle.

For reception, this problem is solved because receive data is sampled on the first falling edge of CLKR where an active-high internal FSR is detected. However, data transmission must begin on the rising edge of the internal CLKX clock that generated the frame synchronization. Therefore, the first data bit is assumed to be present in XSR1, and thus on mcbspi_dx. The transmitter then asynchronously detects the frame-synchronization signal (FSX) going active high and immediately starts driving the first bit to be transmitted on the mcbbsp_dx pin.

18.5.1.6.2.2.5.2 2-Bit Data Delay:

A data delay of two bit periods allows the serial port to interface to different types of T1 framing devices where the data stream is preceded by a framing bit. During reception of such a stream with data delay of two bits (framing bit appears after a 1-bit delay and data appears after a 2-bit delay), the serial port essentially discards the framing bit from the data stream, as shown in Figure 18-69. The data transferred is an 8-bit value with bits labeled B7, B6, B5, and so on.

Figure 18-69. 2-Bit Data Delay Used to Skip a Framing Bit

18.5.1.6.2.2.6 Set the Transmit DXENA Mode

McBSPi.MCBSPLP_SPCR1_REG[7] DXENA bit is used to set the transmit DXENA (DX delay enable) mode.

The DXENA bit controls the delay enabler on the mcbbsp_dx pin. Set DXENA to enable an extra delay for

turn-on time. This bit does not control the data itself, so only the first bit is delayed (the delay is given by a combinatorial delay buffer). The inserted delay: 813 ns, 1418 ns (default), 2024 ns or 2830 ns can be set using the `McBSPi.MCBSPLP_XCCR_REG[13:12]` DXENDLY field. If you tie together the `mcbasp_dx` pins of multiple McBSP modules, make sure `DXENA=1`, to avoid having more than one McBSP transmitting on the data line at one time.

18.5.1.6.2.2.7 Set the Transmit Interrupt Mode

Refer to [Section 18.5.1.4.2.2](#).

18.5.1.6.2.2.8 Set the Transmit DMA Mode

The McBSP transmit data DMA requests (`McBSPi_DMA_TX`) are active after the transmit `McBSPi.MCBSPLP_SPCR2_REG[0]` XRST bit is released. After reset, the default DMA threshold (and length) is 1.

The transmit DMA requests can be disabled by setting the `McBSPi.MCBSPLP_XCCR_REG[3]` XDMAEN bit to 0. When disabling the DMA, the DMA request line is deasserted even if a DMA transfer is pending, and the DMA state-machine is not reset.

To configure the McBSP transmit data DMA requests, follow this procedure:

- Write the transmit `McBSPi.MCBSPLP_THRSH2_REG` register with the required transmit DMA request length (the length of the transfer is the same as the threshold value + 1).
- As long as the free locations level in XB is above or equal to the `THRSH2_REG` value + 1, the DMA request is asserted.
- After transferring the configured (`THRSH2_REG` value + 1) number of words, the transmit DMA request is deasserted, and then reasserted as soon as the conditions are met again.

18.5.1.6.2.3 Frame-Synchronization Behavior

18.5.1.6.2.3.1 Set the Transmit Frame-Sync Mode

`McBSPi.MCBSPLP_PCR_REG[11]` FSXM bit and `McBSPi.MCBSPLP_SRGR2_REG[12]` FSGM bit are used to set the transmit frame-sync mode.

[Table 18-32](#) shows how FSXM and FSGM select the source of transmit frame-synchronization pulses. The three choices are:

1. External frame-synchronization input
2. Sample rate generator frame-synchronization signal (FSG)
3. Sample rate generator frame-synchronization signal (FSG) gated by the transmit buffer XB empty condition.

[Table 18-32](#) also shows the effect of each bit setting on the `mcbasp_fsx` pin. The FSXP bit determines the polarity of the signal on the `mcbasp_fsx` pin.

Table 18-32. How FSXM and FSGM Select the Source of Transmit Frame-Sync Pulses

| FSXM | FSGM | Source of Transmit Frame Synchronization | mcbasp_fsx Pin Status |
|------|--------|--|---|
| 0 | 0 or 1 | An external FSG enters the McBSP through the <code>mcbasp_fsx</code> pin. The signal is then inverted by FSXP bit before being used as internal FSX. | Input |
| 1 | 1 | Internal FSX is driven by the SRG FSG. | Output. FSG is inverted by FSXP bit before being driven out on <code>mcbasp_fsx</code> pin. |
| 1 | 0 | A XB empty condition causes the McBSP not to generate a transmit frame-synchronization pulse. The frame synchronization is generated taking into account the FWID and FPER bits as long as the transmit buffer is not empty. When the buffer is empty the generated frame synchronization signal is gated. | Output. The generated frame-synchronization pulse is inverted as determined by FSXP bit before being driven out on <code>mcbasp_fsx</code> pin. |

If the SRG creates a frame-synchronization signal (FSG) that is derived from an external input clock, the GSYNC bit determines whether FSG is kept synchronized with pulses on the `mcbsp_fsr` pin. For more details, see [Section 18.4.3.3](#).

In the digital loopback mode (DLB=1) or analog loopback mode (ALB = 1), the transmit frame synchronization signal is used as the receive frame synchronization signal. For more details on frame-sync configuration, see [Section 18.4.3.2](#).

18.5.1.6.2.3.2 Set the Transmit Frame-Sync Polarity

`McBSPi.MCBSPLP_PCR_REG[3]` FSXP bit determines whether frame-synchronization pulses are active high or active low on the `mcbsp_fsx` pin.

Transmit frame-synchronization pulses can be generated internally by the SRG or driven by an external source. The source of frame synchronization is selected by programming the `McBSPi.MCBSPLP_PCR_REG[11]` FSXM bit. FSX is also affected by the `McBSPi.MCBSPLP_SRGR2_REG[12]` FSGM bit. For information about the effects of FSXM and FSGM, see [Section 18.5.1.6.2.3.1](#).

When FSR and FSX are inputs (FSXM=FSRM=0, external frame-synchronization pulses), the McBSP module detects them on the internal falling edge of clock, internal CLKR, and internal CLKX, respectively. The receive data arriving at the `mcbsp_dr` pin is also sampled on the falling edge of internal CLKR. These internal clock signals are either derived from external source via CLK(R/X) pins or driven by the SRG clock (CLKG) internal to the McBSP module.

When FSR and FSX are outputs, implying that they are driven by the SRG, they are generated (transition to their active state) on the rising edge of internal clock, CLK(R/X). Similarly, data on the `mcbsp_dx` pin is output on the rising edge of internal CLKX.

FSRP, FSXP, CLKRP, and CLKXP in the pin control register (PCR_REG) configure the polarities of the FSR, FSX, CLKR, and CLKX signals, respectively. All FSG (internal FSR, internal FSX) that are internal to the serial port are active high. If the serial port is configured for external frame synchronization (FSR/FSX are inputs to McBSP) and FSRP=FSXP=1, the external active-low frame-synchronization signals are inverted before being sent to the receiver (internal FSR) and transmitter (internal FSX). Similarly, if internal synchronization (FSR/FSX are output pins and GSYNC=0) is selected and the polarity bit FS(R/X)P=1, the internal active-high FSG are inverted before being sent to the FS(R/X) pin.

18.5.1.6.2.3.3 Set the SRG Frame-Sync Period and Pulse Width

See [Section 18.5.1.5.2.3.3](#).

18.5.1.6.2.4 Clock Behavior

18.5.1.6.2.4.1 Set the Transmit Clock Mode

The `McBSPi.MCBSPLP_PCR_REG[9]` CLKXM bit is used to set the transmit clock mode.

[Table 18-33](#) shows how the CLKXM bit selects the transmit clock and the corresponding status of the `mcbsp_clkx` pin. The CLKXP bit determines the polarity of the signal on the `mcbsp_clkx` pin.

Table 18-33. CLKXM Bit Effect on Transmit Clock and MCBSPLP.CLKX Pin

| CLKXM | Source of Transmit Clock | mcbsp_clkx Pin Status |
|-------|---|---|
| 0 | Internal CLKX is driven by an external clock on the <code>mcbsp_clkx</code> pin. CLKX is inverted as determined by CLKXP before being used. | Input |
| 1 | Internal CLKX is driven by the SRG clock, CLKG. | Output. CLKG, inverted as determined by CLKXP, is driven out on <code>mcbsp_clkx</code> . |

If the SRG creates a clock signal (CLKG) that is derived from an external input clock, the GSYNC bit determines whether CLKG is kept synchronized with pulses on the mcbbsp_fsr pin.

In the digital loopback mode (DLB=1) or analog loopback mode (ALB = 1), the transmit frame synchronization signal is used as the receive frame synchronization signal. For more details on clock configuration, see [Section 18.4.3.1](#).

18.5.1.6.2.4.2 Set the Transmit Clock Polarity

The McBSPi.MCBSPLP_PCR_REG[1] CLKXP bit is used to set the transmit clock polarity.

On the transmit side, the transmit clock polarity bit, CLKXP, sets the edge used to shift and clock out transmit data. Data is always transmitted on the rising edge of internal CLKX. If CLKXP=1 and external clocking is selected (CLKXM=0 and CLKX is an input), the external falling-edge triggered input clock on CLKX is inverted to a rising-edge triggered clock before being sent to the transmitter. If CLKXP=1 and internal clocking is selected (CLKXM=1 and CLKX is an output pin), the internal (rising-edge triggered) clock, internal CLKX, is inverted before being sent out on the mcbbsp_clkx pin.

Similarly, the receiver can reliably sample data that is clocked with a rising edge clock (by the transmitter). The receive clock polarity bit, CLKRP, sets the edge used to sample received data. The receive data is always sampled on the falling edge of internal CLKR. Therefore, if CLKRP=1 and external clocking is selected (CLKRM=0 and CLKR is an input pin), the external rising-edge triggered input clock on CLKR is inverted to a falling-edge triggered clock before being sent to the receiver. If CLKRP=1 and internal clocking is selected (CLKRM=1), the internal falling-edge triggered clock is inverted to a rising-edge triggered clock before being sent out on the mcbbsp_clkr pin.

NOTE: CLKRP=CLKXP in a system where the same clock (internal or external) is used to clock the receiver and transmitter. The receiver uses the opposite edge as the transmitter to ensure valid setup and hold of data around this edge.

18.5.1.6.2.4.3 Set the SRG Clock Divide-Down Value

See [Section 18.5.1.5.2.4.3](#).

18.5.1.6.2.4.4 Set the SRG Clock Synchronization Mode

See [Section 18.5.1.5.2.4.4](#).

18.5.1.6.2.4.5 Set the SRG Clock Mode (Choose an Input Clock)

See [Section 18.5.1.5.2.4.5](#).

18.5.1.6.2.4.6 Set the SRG Input Clock Polarity

See [Section 18.5.1.5.2.4.6](#).

18.5.1.7 General-Purpose I/O on the McBSP Pins (Legacy Only)

[Table 18-34](#) summarizes how to use the McBSP pins as general-purpose I/O pins. All the bits mentioned in the table except XRST and RRST bits are in the pin control register (McBSPi.MCBSPLP_PCR_REG). McBSPi.MCBSPLP_SPCR2_REG[0] XRST bit and McBSPi.MCBSPLP_SPCR1_REG[0] RRST bit are in the serial port control registers.

To use receiver pins mcbbsp_clkr, mcbbsp_fsr, and mcbbsp_dr as general-purpose I/O pins rather than as serial port pins, you must set two conditions:

1. The receiver of the serial port is in reset (McBSPi.MCBSPLP_SPCR1_REG[0] RRST bit =0).
2. General-purpose I/O is enabled for the serial port receiver (McBSPi.MCBSPLP_PCR_REG[12] RIOEN=1).

The `mcbasp_clkr` and `mcbasp_fsr` pins can be individually configured as either input or output pins with the `CLKRM` and `FSRM` bits, respectively. The `mcbasp_dr` pin can only be an input pin. Table 18-34 shows, which bits in `McBSPi.MCBSPLP_PCR_REG` are used to read from/write to these pins.

For the transmitter pins `mcbasp_clkx`, `mcbasp_fsx`, and `mcbasp_dx`, you must meet two conditions:

1. The transmitter of the serial port is in reset (`McBSPi.MCBSPLP_SPCR2_REG[0] XRST=0`).
2. General-purpose I/O is enabled for the serial port transmitter (`McBSPi.MCBSPLP_PCR_REG[12] XIOEN=1`).

The `mcbasp_clkx` and `mcbasp_fsx` pins can be individually configured as input or output pins with the `CLKXM` and `FSXM` bits, respectively. The `mcbasp_dx` pin can only be an output pin. Table 18-34 shows the bits in `McBSPi.MCBSPLP_PCR_REG` used to read from/write to these pins.

For the `mcbasp_clks` pin (common to all McBSP modules), all of the reset and I/O enable conditions must be met:

1. Both the receiver and transmitter of the serial port are in reset (`RRST=0` and `XRST=0`).
2. General-purpose I/O is enabled for both the receiver and the transmitter (`RIOEN=1` and `XIOEN=1`).

The `mcbasp_clks` pin can only be an input pin. To read the status of the signal on the `mcbasp_clks` pin, read the `McBSPi.MCBSPLP_PCR_REG[6] CLKS_STAT` bit.

Table 18-34. Using McBSP Pins for General-Purpose I/O

| Pin | General-Purpose use enabled by this bit combination | Selected as output when | Output value driven from this bit | Selected as input when | Input value read from this bit |
|--------------------------|--|-------------------------|-----------------------------------|------------------------|--------------------------------|
| <code>mcbasp_clkx</code> | <code>XRST = 0</code> <code>XIOEN = 1</code> | <code>CLKXM = 1</code> | <code>CLKXP</code> | <code>CLKXM = 0</code> | <code>CLKXP</code> |
| <code>mcbasp_fsx</code> | <code>XRST = 0</code> <code>XIOEN = 1</code> | <code>FSXM = 1</code> | <code>FSXP</code> | <code>FSXM = 0</code> | <code>FSXP</code> |
| <code>mcbasp_dx</code> | <code>XRST = 0</code> <code>XIOEN = 1</code> | Always | <code>DX_STAT</code> | Never | Does not apply |
| <code>mcbasp_clkr</code> | <code>RRST = 0</code> <code>RIOEN = 1</code> | <code>CLKRM = 1</code> | <code>CLKRP</code> | <code>CLKRM = 0</code> | <code>CLKRP</code> |
| <code>mcbasp_fsr</code> | <code>RRST = 0</code> <code>RIOEN = 1</code> | <code>FSRM = 1</code> | <code>FSRP</code> | <code>FSRM = 0</code> | <code>FSRP</code> |
| <code>mcbasp_dr</code> | <code>RRST = 0</code> <code>RIOEN = 1</code> | Never | Does not apply | Always | <code>DR_STAT</code> |
| <code>mcbasp_clks</code> | <code>RRST = XRST = 0</code> <code>RIOEN = XIOEN = 1</code> | Never | Does not apply | Always | <code>CLKS_STAT</code> |

18.5.1.8 Data Packing Examples

This section describes two ways to implement data packing in the McBSP: Using frame length and word length, and using word length and ignoring frame sync pulses.

18.5.1.8.1 Data Packing Using Frame Length and Word Length

Frame length and word length can be manipulated to pack data effectively. For example, four 8-bit words are transferred in a single-phase frame, as shown in Figure 18-70. In this case:

- (R/X)PHASE = 0: Single-phase frame
- (R/X)FRLLEN1 = 00011b: 4-word frame
- (R/X)WDLEN1 = 101b: 32-bit words

Four 8-bit data words are transferred to and from the McBSP by the MPU/IVA2.2 subsystems or the sDMA controller. Thus, four reads from `McBSPi.MCBSPLP_DRR_REG` and four writes to `McBSPi.MCBSPLP_DXR_REG` are necessary for each frame.

Figure 18-70. Four 8-bit Data Words Transferred To/From McBSP Module

This data can also be treated as a single-phase frame consisting of one 32-bit data word, as shown in [Figure 18-71](#). In this case:

- (R/X)PHASE = 0: Single-phase frame
- (R/X)FRLLEN1 = 0000000b: 1-word frame
- (R/X)WDLEN1 = 000b: 8-bit words

Two 16-bit data words are transferred to and from the McBSP by the MPU/IVA2.2 subsystems or the sDMA controller. Thus, two reads from `McBSPi.MCBSPLP_DRR_REG` and two writes to `McBSPi.MCBSPLP_DXR_REG` are necessary for each frame. This results in only half the number of transfers, as compared to the previous case. This manipulation reduces the percentage of bus time required for serial port data movement.

Figure 18-71. One 32-bit Data Word Transferred To/From McBSP Module

18.5.1.8.2 Data Packing Using Word Length and the Frame-Sync Ignore Function

When there are multiple words per frame, data can be packed by increasing the word length (defining a serial word with more bits) and by ignoring frame-sync pulses. [Figure 18-72](#) shows the McBSP operating at the maximum packet frequency. Here, each frame has only one 8-bit word. Notice the frame-sync pulse that initiates each frame transfer for reception and for transmission. For reception, this configuration requires one read operation for each word. For transmission, this configuration requires one write operation for each word.

Figure 18-72. 8-bit Data Words Transferred at Maximum Packet Frequency

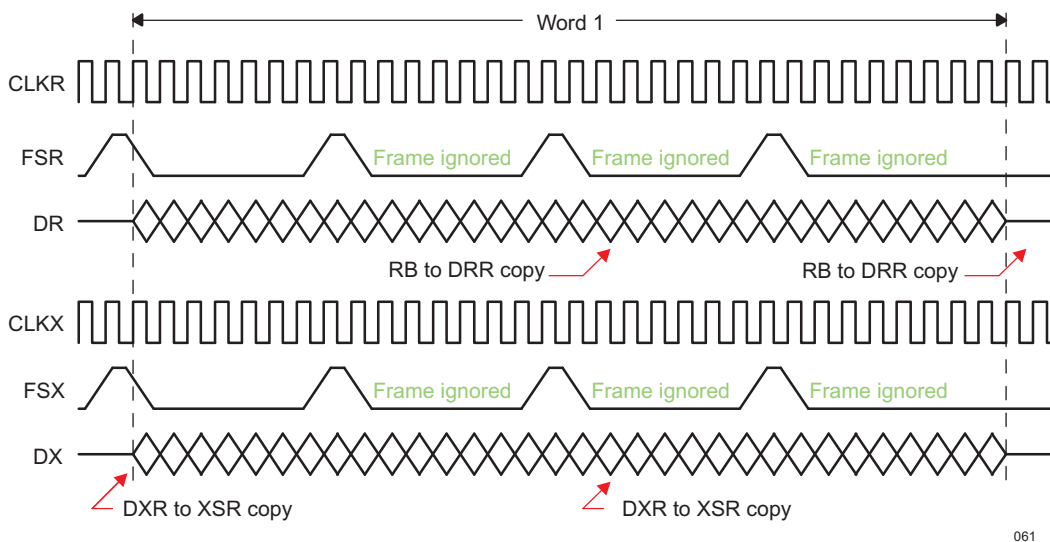

Figure 18-73 shows the McBSP configured to treat this data stream as a continuous 32-bit word. In this example, the McBSP responds to an initial frame-sync pulse. However, the McBSP ignores subsequent pulses. Only one read transfer or one write transfer is required every 32 bits. This configuration effectively reduces the required bus bandwidth to one-fourth the bandwidth needed to transfer four 8-bit words.

Figure 18-73. Configuring the Data Stream as a Continuous 32-bit Word

18.5.2 SIDETONE Feature

18.5.2.1 SIDETONE Activation Procedure

Before you enable a SIDETONE selection mode, make sure you properly configure the data frame for multichannel mode of the McBSP module:

- Select a single-phase frame (McBSPi.MCBSPLP_RCR2_REG[15] RPHASE bit and McBSPi.MCBSPLP_XCR2_REG[15] XPHASE bit=0). Each frame represents a TDM data stream.
- Set to 1 the McBSPi.MCBSPLP_MCR1_REG[0] RMCM bit, to select multichannel mode enable.
- Set a frame length (McBSPi.MCBSPLP_RCR1_REG[14:8] RFLEN1 bit field and McBSPi.MCBSPLP_XCR1_REG[14:8] XFLEN1 bit field) that includes the highest-numbered channel to be used (a maximum of 4 channels can be used in this configuration).
- Set a word length (McBSPi.MCBSPLP_RCR1_REG[7:5] RWDLEN1 bit field and McBSPi.MCBSPLP_XCR1_REG[7:5] XWDLEN1 bit field) to be either 16, 24 or 32 (see the note below).

- Select the input/output channels configured as SIDETONE channels by setting the following bit fields listed in [Table 18-35](#):

Table 18-35. Selection of the SIDETONE Input and Output Channels

| Bit field | Description |
|--|--|
| McBSPi.MCBSPLP_SSELCR_REG[9:7] OCH1ASSIGN | Map the CH1 data for the speaker out channels to one of the McBSP channels (1 out of 8 channels) |
| McBSPi.MCBSPLP_SSELCR_REG[6:4] OCH0ASSIGN | Map the CH0 data for the speaker out channels to one of the McBSP channels (1 out of 8 channels) |
| McBSPi.MCBSPLP_SSELCR_REG[3:2] ICH1ASSIGN | Map the CH1 data from the digital microphone channels to one of the McBSP channels (1 out of 4 channels) |
| McBSPi.MCBSPLP_SSELCR_REG[1:0] ICH0ASSIGN | Map the CH0 data from the digital microphone channels to one of the McBSP channels (1 out of 4 channels) |

- Enable SIDETONE by setting 2 bits to 1:
 1. In McBSP module, the McBSPi.MCBSPLP_SSELCR_REG[10] SIDETONEEN bit
 2. In SIDETONE core, the McBSPi.ST_SSELCR_REG[0] SIDETONEEN bit

NOTE: Word width in the loop is 24 bits. If input channel word width is less than 24 bits, LSBs of the samples are zero padded. If input channel word width is more than 24 bits, samples are truncated.

18.5.2.2 SIDETONE Initialization Procedure

The SIDETONE core initialization procedure is as follows:

1. Write 1 in McBSPi.ST_SSELCR_REG[1] COEFFWREN bit to enable loading of the FIR coefficients.
2. Load one by one the FIR coefficients performing 128 write accesses to McBSPi.ST_SFIRCR_REG[15:0] FIRCOEFF bit field, the McBSPi.ST_SFIRCR_REG[0] FIRCOEFF bit is loaded first. To ensure the completion of loading, check the status bit-field, McBSPi.ST_SSELCR_REG[2] COEFFWRDONE bit.
3. Set-up gain values for both channels writing desired values inside McBSPi.ST_SGAINCR_REG[31:16] CH1GAIN bit field for the second sidetone channel and McBSPi.ST_SGAINCR_REG[15:0] CH0GAIN bit field for the first sidetone channel.

18.5.2.3 SIDETONE FIR Coefficients Writing

Writing the coefficients is only possible when the SIDETONE is disabled.

1. Write 1 in McBSPi.ST_SSELCR_REG[1] COEFFWREN bit to enable writing of the FIR coefficients, or write 0, and then write 1 in the COEFFWREN bit to reset the write process.
2. Perform 128 write accesses in 32/16 LSB bit mode on the McBSPi.ST_SFIRCR_REG[15:0] FIRCOEFF bit field. The first write action following the previous step sets the coefficient index 0.
3. Check that the write is done by reading McBSPi.ST_SSELCR_REG[2] COEFFWRDONE bit (it becomes 1 after the 128th coefficient is written).

18.5.2.4 SIDETONE FIR Coefficients Reading

Reading the coefficients is only possible when the SIDETONE is disabled.

- Write 0 in McBSPi.ST_SSELCR_REG[1] COEFFWREN bit to enable reading of the FIR coefficients, or write 1, and then write 0 in the COEFFWREN bit to reset the read process.
- Perform 128 read accesses from McBSPi.ST_SFIRCR_REG[15:0] FIRCOEFF bit field. Each read returns coefficients one by one. The first read following previous step returns coefficient index 0.

18.6 McBSP Register Manual

[Table 18-36](#) shows the base address and address space for the device module instances.

Table 18-36. Device Instance Summary

| Module Name | Base Address (hex) | Size |
|-----------------|--------------------|----------|
| McBSP1 | 0x4807 4000 | 4K bytes |
| McBSP5 | 0x4809 6000 | 4K bytes |
| McBSP2 | 0x4902 2000 | 4K bytes |
| McBSP3 | 0x4902 4000 | 4K bytes |
| McBSP4 | 0x4902 6000 | 4K bytes |
| SIDETONE_McBSP2 | 0x4902 8000 | 4K bytes |
| SIDETONE_McBSP3 | 0x4902 A000 | 4K bytes |

18.6.1 McBSP Register Mapping Summary

CAUTION

The McBSP data registers (that is, DXR_REG for data transmit and DRR_REG for data receive) support 8/16/32-bit data accesses. All other McBSP registers are limited to 32-bit data accesses. 16-bit and 8-bit data accesses are not allowed and can corrupt register contents.

Table 18-37. McBSP1 Registers Mapping Summary

| Register Name | Type | Register Width (Bits) | Address Offset | Physical Address |

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| RESERVED | | | | | | | | | | | | | | | | | | | | | | | FREE | SOFT | FRST | GRST | XINTM | XSYNCERR | XEMPTY | XRDY | XRST |

| Bits | Field Name | Description | Type | Reset |
|-------|------------|--|------|----------|
| 31:10 | RESERVED | Read returns 0x0. | R | 0x000000 |
| 9 | FREE | Free Running Mode (When this bit is set, the module ignores the Msuspend input) 0x0: Free running mode is disabled 0x1: Free running mode is enabled | RW | 0x0 |
| 8 | SOFT | Soft Bit 0x0: SOFT Mode is disabled: the McBSP module stops its activity immediately following MSuspend assertion. 0x1: SOFT Mode is enabled: the McBSP module freezes its state after completion of the current operation when MSuspend is asserted. | RW | 0x0 |
| 7 | FRST | Frame-Sync Generator Reset 0x0: Frame-synchronization logic is reset. Frame-sync signal FSG is not generated by the sample-rate generator 0x1: Frame-sync signal FSG is generated after (FPER+1) number of CLKG clocks; i.e., all frame counters are loaded with their programmed values | RW | 0x0 |
| 6 | GRST | Sample-Rate Generator Reset 0x0: SRG is reset 0x1: SRG is pulled out of reset. CLKG is driven as per programmed value in SRG registers (SRGR[1,2]) | RW | 0x0 |
| 5:4 | XINTM | Transmit Interrupt Mode (legacy) 0x0: Transmit interrupt is driven by XRDY 0x1: Transmit interrupt generated by end-of-frame 0x2: Transmit interrupt generated by a new frame synchronization 0x3: Transmit interrupt generated by XSYNCERR | RW | 0x0 |
| 3 | XSYNCERR | Transmit Synchronization Error (writing 0 to this bit clear the legacy transmit interrupt if asserted due to XSYNCERROR condition) 0x0: No synchronization error 0x1: Synchronization error detected by McBSP | RW | 0x0 |
| 2 | XEMPTY | Transmit Shift Register XSR Empty 0x0: XSR is empty 0x1: XSR is not empty | R | 0x0 |
| 1 | XRDY | Transmitter ready 0x0: Transmitter is not ready. 0x1: Transmitter is ready for new data in DXR | R | 0x0 |
| 0 | XRST | Transmitter reset. This resets and enables the transmitter. 0x0: The serial port transmitter is disabled and in reset state. 0x1: The serial port transmitter is enabled. | RW | 0x0 |

| RESERVED | | | | | | | | | | | | | | | | GSYNC | CLKSP | CLKSM | FSGM | FPER | | | | | | | | | | | |

| Bits | Field Name | Description | Type | Reset |
|-------|------------|---|------|--------|
| 31:16 | RESERVED | Read returns 0x0. | R | 0x0000 |
| 15 | GSYNC | Sample Rate Generator Synchronization Only used when the external clock (CLKS) drives the SRG clock (CLKSM=0) 0x0: The SRG clock (CLKG) is free running. 0x1: The SRG clock (CLKG) is running. But CLKG is resynchronized and frame-sync signal (FSG) is generated only after detecting the receive frame-synchronization signal (FSR). Also, frame period, FPER, is a don't care because the period is dictated by the external frame-sync pulse. | RW | 0x0 |
| 14 | CLKSP | CLKS Polarity Clock Edge Select Only used when the external clock CLKS drives the SRG clock (CLKSM=0). 0x0: Rising edge of CLKG and FSG. 0x1: Falling edge of CLKG and FSG. | RW | 0x0 |
| 13 | CLKSM | McBSP SRG Clock Mode 0x0: SCLKME=0: SRG clock derived from the CLKS pin. SCLKME=1: SRG clock derived from the CLKR input pin. 0x1: SCLKME=0: SRG clock derived from the McBSPi_ICLK clock. SCLKME=1: SRG clock derived from the CLKX input pin. | RW | 0x1 |
| 12 | FSGM | Sample Rate Generator Transmit Frame-Synchronization Mode Used when FSXM=1 in the PCR. 0x0: Transmit frame-sync signal (FSX) is generated when transmit buffer is not empty. When FSGM=0, FPER and FWID are used to determine the frame synchronization period and width (external FSX is gated by the buffer empty condition). 0x1: Transmit frame-sync signal driven by the SRG frame-sync signal, FSG. | RW | 0x0 |
| 11:0 | FPER | Frame Period. This value + 1 determines when the next frame-sync signal becomes active. Range: 1 to 4096 CLKG periods | RW | 0x000 |

| 4:2 | RESERVED | Reserved | R | 0x0 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|--|------|-------|
| 1:0 | XMCM | Transmit Multichannel Selection Enable 0x0: All channels enabled without masking (DX is always driven during transmission of data). 0x1: All channels disabled and therefore masked by default. Required channels are selected by enabling XP(A/B)BLK and XCER(A/B) appropriately. Also, these selected channels are not masked and therefore DX is always driven. 0x2: All channels enabled, but masked. Selected channels enabled via XP(A/B)BLK and XCER(A/B) are unmasked. 0x3: All channels disabled and therefore masked by default. Required channels are selected by enabling RP(A/B)BLK and RCER(A/B) appropriately. Selected channels can be unmasked by RP(A/B)BLK and XCER(A/B). This mode is used for symmetric transmit and receive operation. | RW | 0x0 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|--|------|-------|
| 7 | SCLKME | The frequency of CLKG is: $CLKG \text{ frequency} = (\text{Input clock frequency}) / (\text{CLKGDV} + 1)$ SCLKME is used in conjunction with the CLKSM bit to select the input clock: 0x0: CLKSM = 0: Signal on CLKS pin CLKSM = 1: McBSPi_ICLK clock 0x1: CLKSM = 0: Signal on CLKR pin CLKSM = 1: Signal on CLKX pin | RW | 0x0 |
| 6 | CLKS_STAT | CLKS pin status. Reflects value on CLKS pin when selected as a general purpose input. (legacy) 0x0: The signal on the CLKS pin is low 0x1: The signal on the CLKS pin is high | R | 0x0 |
| 5 | DX_STAT | DX pin status. Reflects value driven on to DX pin when selected as a general purpose output. (legacy) 0x0: Drive the signal on the DX pin low 0x1: Drive the signal on the DX pin high | RW | 0x0 |
| 4 | DR_STAT | DR pin status. Reflects value on DR pin when selected as a general purpose input. (legacy) 0x0: The signal on DR pin is low 0x1: The signal on DR pin is high | R | 0x0 |
| 3 | FSXP | Transmit Frame-Synchronization Polarity 0x0: Frame-synchronization pulse FSX is active high 0x1: Frame-synchronization pulse FSX is active low | RW | 0x0 |
| 2 | FSRP | Receive Frame-Synchronization Polarity 0x0: Frame-synchronization pulse FSR is active high 0x1: Frame-synchronization pulse FSR is active low | RW | 0x0 |
| 1 | CLKXP | Transmit Clock Polarity 0x0: Transmit data driven on rising edge of CLKX 0x1: Transmit data driven on falling edge of CLKX | RW | 0x0 |
| 0 | CLKRP | Receive Clock Polarity 0x0: Receive data sampled on falling edge of CLKR 0x1: Receive data sampled on rising edge of CLKR | RW | 0x0 |

| 31:15 | RESERVED | Read returns 0x0. | R | 0x00000 |
| 14 | XEMPTYEOF | <p>Transmit Buffer Empty at end of frame (XEMPTYEOF is set to one when a complete frame was transmitted and the transmit buffer is empty). Writing 1 to this bit clears the bit.</p> <p>0x0: Transmit buffer NOT Empty at end of frame 0x1: Transmit buffer Empty at end of frame; Writing 1 to this bit clears the bit.</p> | RW | 0x0 |
| 13 | RESERVED | Read returns 0x0. | R | 0x0 |
| 12 | XOVFLSTAT | <p>Transmit Buffer Overflow (XOVFLSTAT bit is set to one when transmit buffer overflow; the data which is written while overflow condition is discarded). Writing 1 to this bit clears the bit.</p> <p>0x0: Transmit buffer NOT overflow 0x1: Transmit buffer overflow; Writing 1 to this bit clears the bit.</p> | RW | 0x0 |
| 11 | XUNDFLSTAT | <p>Transmit Buffer Underflow (XUNDFLSTAT bit is set to one when the transmit data buffer is empty new data is required to be transmitted). Writing 1 to this bit clears the bit.</p> <p>0x0: the transmit data buffer is NOT empty new data is required to be transmitted. 0x1: the transmit data buffer is empty new data is required to be transmitted. Writing 1 to this bit clears the bit.</p> | RW | 0x0 |
| 10 | XRDY | <p>Transmit Buffer Threshold Reached (XRDY bit is set to one when the transmit buffer free locations are equal or above the THRSH2_REG value). Writing 1 to this bit clears the bit.</p> <p>0x0: Transmit buffer occupied locations are below the THRSH2_REG value). 0x1: Transmit buffer occupied locations are equal or above the THRSH2_REG value). Writing 1 to this bit clears the bit.</p> | RW | 0x0 |
| 9 | XEOF | <p>Transmit End Of Frame (XEOF is set to one when a complete frame was transmitted). Writing 1 to this bit clears the bit.</p> <p>0x0: complete frame was NOT transmitted 0x1: complete frame was transmitted; Writing 1 to this bit clears the bit.</p> | RW | 0x0 |
| 8 | XFSX | <p>Transmit Frame Synchronization (XFSX bit is set to one when a new transmit frame synchronization is asserted). Writing 1 to this bit clears the bit.</p> <p>0x0: new transmit frame synchronization is NOT asserted 0x1: new transmit frame synchronization is asserted; Writing 1 to this bit clears the bit.</p> | RW | 0x0 |
| 7 | XSYNCERR | <p>Transmit Frame Synchronization Error (XSYNCERR is set to one when a transmit frame synchronization error is detected). Writing 1 to this bit clears the bit.</p> <p>0x0: Transmit frame synchronization error is NOT detected 0x1: Transmit frame synchronization error is detected. Writing 1 to this bit clears the bit.</p> | RW | 0x0 |
| 6 | RESERVED | Read returns 0x0. | R | 0x0 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|--|------|-------|
| 5 | ROVFLSTAT | Receive Buffer Overflow (ROVFLSTAT bit is set to one when receive buffer overflow; the data which is written while overflow condition is discarded). Writing 1 to this bit clears the bit. 0x0: receive buffer NOT overflow 0x1: receive buffer overflow; Writing 1 to this bit clears the bit. | RW | 0x0 |
| 4 | RUNDFLSTAT | Receive Buffer Underflow (RUNDFLSTAT bit is set to one when read operation is performed to the receive data register while receive buffer is empty; data read while underflow condition is undefined). Writing 1 to this bit clears the bit. 0x0: read operation is performed to the receive data register while receive buffer is NOT empty 0x1: read operation is performed to the receive data register while receive buffer is empty; Writing 1 to this bit clears the bit. | RW | 0x0 |
| 3 | RRDY | Receive Buffer Threshold Reached (RRDY bit is set to one when the receive buffer occupied locations are equal or above the THRSH1_REG value). Writing 1 to this bit clears the bit. 0x0: receive buffer occupied locations are below the THRSH1_REG value). 0x1: receive buffer occupied locations are equal or above the THRSH1_REG value). Writing 1 to this bit clears the bit. | RW | 0x0 |
| 2 | REOF | Receive End Of Frame (REOF is set to one when a complete frame was received). Writing 1 to this bit clears the bit. 0x0: complete frame was NOT received 0x1: complete frame was received; Writing 1 to this bit clears the bit. | RW | 0x0 |
| 1 | RFSR | Receive Frame Synchronization (RFSR bit is set to one when a new receive frame synchronization is asserted). Writing 1 to this bit clears the bit. 0x0: new receive frame synchronization is NOT asserted 0x1: new receive frame synchronization is asserted; Writing 1 to this bit clears the bit. | RW | 0x0 |
| 0 | RSYNCERR | Receive Frame Synchronization Error (RSYNCERR is set to one when a receive frame synchronization error is detected). Writing 1 to this bit clears the bit. 0x0: receive frame synchronization error is NOT detected 0x1: receive frame synchronization error is detected. Writing 1 to this bit clears the bit. | RW | 0x0 |

| RESERVED | | | | | | | | | | | | | | | | EXTCLKGATE | PPCONNECT | DXENDLY | XFULL_CYCLE | RESERVED | | | | | | DLB | RESERVED | XDMAEN | RESERVED | XDISABLE | |

| Bits | Field Name | Description | Type | Reset |
|-------|------------|--|------|--------|
| 31:16 | RESERVED | Read returns 0x0. | R | 0x0000 |
| 15 | EXTCLKGATE | External clock gating enable (CLKX and FSX master only). When this bit is set and the transmit clock and FSX are set as output, the CLKX is enabled when FSX is active plus 3 clock cycles after (clock is provided for FWID + 4 clock cycles, assuming that the FSX width, active, is FWID + 1 clock cycles); outside this window the external transmit clock is gated. The receive use the same gated transmit clock and transmit frame synchronization signals regardless of the CLKRM/FSRM settings. When using this mode the frame synchronization signal must be active during reception of the entire frame (FWID must be programmed accordingly) to ensure the proper receive process, which requires at least 3 cycles after the frame complete to transfer the data into the receive buffer. 0x0: External clock gating disabled. 0x1: External clock gating enable. | RW | 0x0 |
| 14 | PPCONNECT | Pair to pair connection. When set the DXENO pin is always set to 0, regardless of the frame boundary, setting the tree state buffer as output. 0x0: non Pair-to-pair connection. The DX pin will go to high-impedance state when there is no frame to transmit. 0x1: Pair-to-pair connection. When set, the DXENO pin is always set to 0, regardless of the frame boundary, setting the tree state buffer as output. This means the DX pin will be driven outside valid frame window. In that case, data sent by McBSP module during inactive channel are not guaranteed. | RW | 0x0 |
| 13:12 | DXENDLY | When McBSPi.MCBSPLP_SPCR1_REG[7] DXENA bit is set to one, this field selects the added delay as follow: 0x0: 813 ns 0x1: 1418 ns (default) 0x2: 2024 ns 0x3: 2830 ns | RW | 0x1 |

| Bits | Field Name | Description | Type | Reset |
|------|-------------|--|------|-------|
| 11 | XFULL_CYCLE | Transmit full cycle mode select: 0x0: McBSP module operates in transmit half-cycle mode (transmit frame synchronization is sampled by the opposite edge of the clock used to drive transmit data) 0x1: McBSP module operates in transmit full-cycle mode (transmit frame synchronization is sampled by the same edge of the clock used to drive transmit data) | RW | 0x0 |
| 10:6 | RESERVED | Read returns 0x0. | R | 0x00 |
| 5 | DLB | Digital Loop-Back 0x0: No DLB 0x1: DLB | RW | 0x0 |
| 4 | RESERVED | Read returns 0x0. | R | 0x0 |
| 3 | XDMAEN | Transmit DMA Enable bit. When set to zero this bit will gate the external transmit DMA request, without resetting the DMA state machine. It is recommended to change this bit value only during transmit reset. 0x0: When set to zero this bit will gate the external transmit DMA request, 0x1: When set to one this bit will NOT gate the external transmit DMA request, | RW | 0x1 |
| 2:1 | RESERVED | Read returns 0x0. | R | 0x0 |
| 0 | XDISABLE | Transmit Disable bit. When this bit is set the transmit process will stop at the next frame boundary. 0x0: The transmit process will NOT stop at the next frame boundary. 0x1: The transmit process will stop at the next frame boundary. | RW | 0x0 |

MMC/SD/SDIO Card Interface

This chapter describes the features and functions of the multimedia card/SD/SD I/O (MMC/SDIO) card interface.

NOTE: Some features may not be available or supported in your particular device. For more information, see Chapter 1, the Device Family section, and your device-specific data manual.

| Topic | Page |
|--|------|
| 19.1 MMC/SD/SDIO Overview | 2132 |
| 19.2 MMC/SD/SDIO Environment | 2135 |
| 19.3 MMC/SD/SDIO Integration | 2143 |
| 19.4 MMC/SD/SDIO Functional Description | 2151 |
| 19.5 MMC/SD/SDIO Basic Programming Model | 2160 |
| 19.6 MMC/SD/SDIO Use Cases and Tips | 2175 |
| 19.7 MMC/SD/SDIO Register Manual | 2188 |

19.1 MMC/SD/SDIO Overview

The multimedia card high-speed/SD/SD I/O (MMC/SD/SDIO) host controller provides an interface between a local host (LH) such as a microprocessor unit (MPU) or digital signal processor (DSP) and either MMC, SD memory cards, or SDIO cards and handles MMC/SD/SDIO transactions with minimal LH intervention.

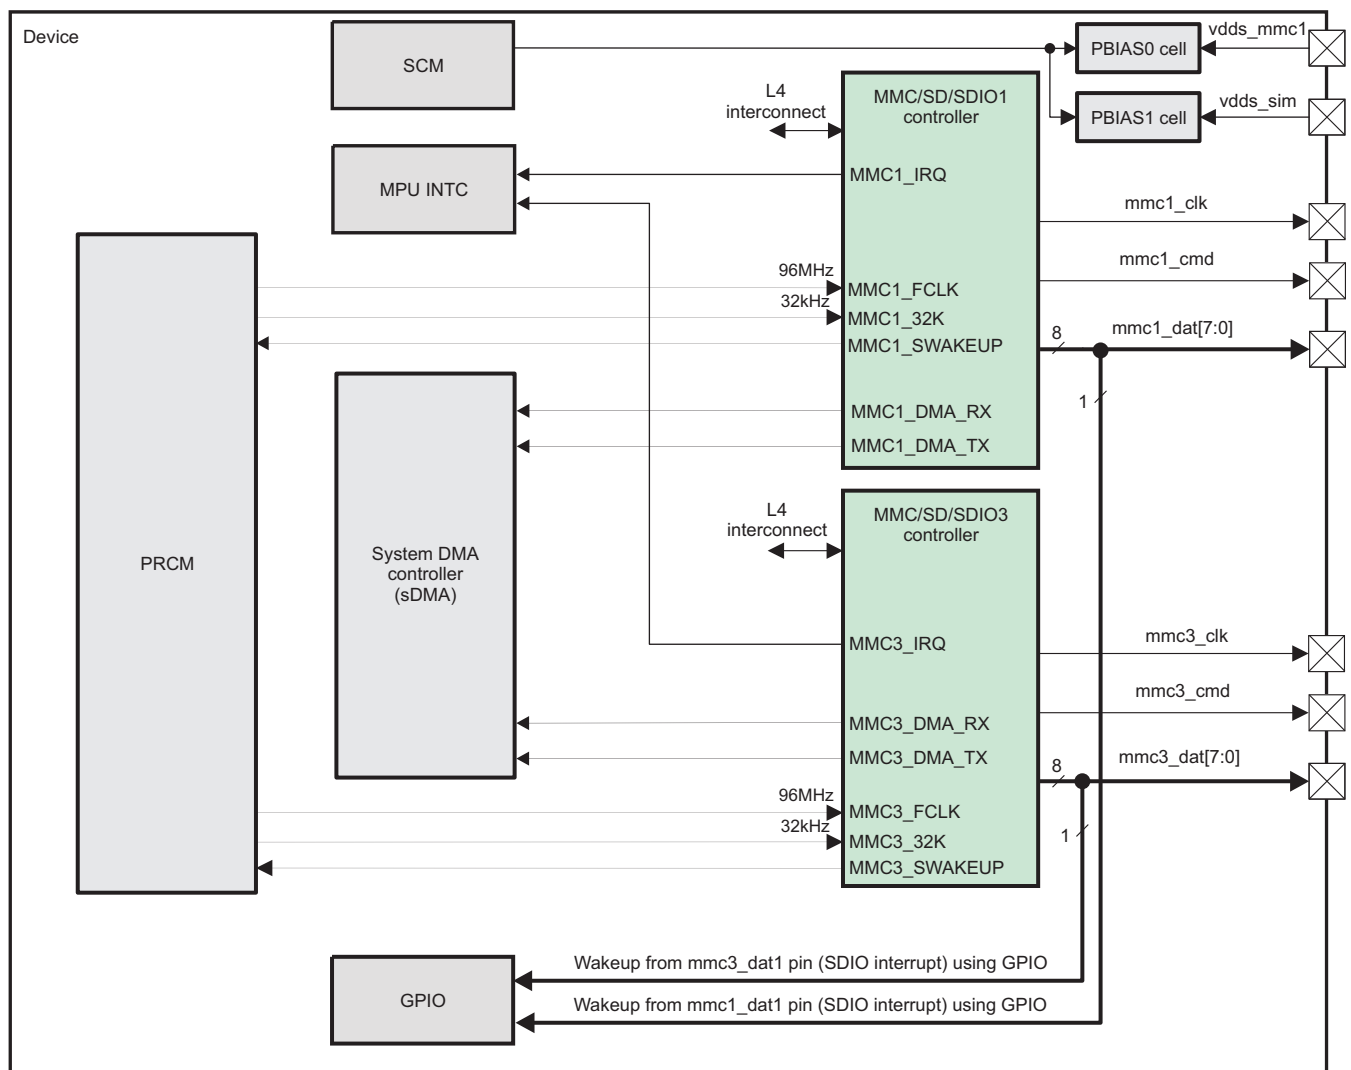

The application interface manages transaction semantics. The MMC/SD/SDIO host controller deals with MMC/SD/SDIO protocol at transmission level, data packing, adding cyclic redundancy checks (CRC), start/end bit, and checking for syntactical correctness.

The application interface can send every MMC/SD/SDIO command and either poll for the status of the adapter or wait for an interrupt request, which is sent back in case of exceptions or to warn of end of operation.

The application interface can read card responses or flag registers. It can also mask individual interrupt sources. All these operations can be performed by reading and writing control registers. The MMC/SD/SDIO host controller also supports two DMA channels.

There are three MMC/SD/SDIO host controllers inside the device: [Figure 19-1](#) gives an overview of the MMC/SD/SDIO controller instances 1 and 3, and [Figure 19-2](#) gives an overview of the MMC/SD/SDIO2 controller instance.

Figure 19-1. MMC/SD/SDIO1 and 3 Overview

mmchs-001

Figure 19-2. MMC/SD/SDIO2 Overview

19.1.1 MMC/SD/SDIO Features

The main features of the MMC/SD/SDIO host controller are:

- Full compliance with MMC command/response sets as defined in the *Multimedia Card System Specification*, v4.2 including high-capacity (size > 2GB) cards HC MMC.
- Full compliance with SD command/response sets as defined in the *SD Memory Card Specifications*, v2.0 including high-capacity SDHC cards up to 32 GB.
- Full compliance with SDIO command/response sets and interrupt/read-wait mode as defined in the *SDIO Card Specification, Part E1*, v1.10
- Compliance with sets as defined in the *SD Card Specification, Part A2, SD Host Controller Standard Specification*, v1.00
- Full compliance with MMC bus testing procedure as defined in the *Multimedia Card System Specification*, v4.2
- Full compliance with CE-ATA command/response sets as defined in the *CE-ATA Standard Specification*
- Full compliance with ATA for MMCA specification
- Flexible architecture allowing support for new command structure
- Support:
 - 1-bit or 4-bit transfer mode specifications for SD and SDIO cards
 - 1-bit, 4-bit, or 8-bit transfer mode specifications for MMC cards
- Built-in 1024-byte buffer for read or write
- 32-bit-wide access bus to maximize bus throughput
- Single interrupt line for multiple interrupt source events
- Two slave DMA channels (1 for TX, 1 for RX)
- Designed for low power
- Programmable clock generation

- Support SDIO Read Wait and Suspend/Resume functions
- Support Stop at block gap
- Support command completion signal (CCS) and command completion signal disable (CCSD) management as specified in the *CE-ATA Standard Specification*

The known limitations are as follows:

- No built-in hardware support for error correction codes (ECC). See the *Multimedia Card System Specification*, v4.2, and the *SD Memory Card Specifications*, v2.0, for details about ECC.
- The maximum block size defined in the *SD Memory Card Specifications*, v2.0, that the host driver can read and write to the buffer in the host controller is 2048 bytes. MMC supports a maximum block size of 1024 bytes. Up to 512 byte transfers, the buffer in MMC is considered as a double buffering with ping-pong management; half of the buffer can be written while the other part is read. For 512 to 1024 byte transfers, the entire buffer is dedicated to the transfer (read only or write only).

The differences between the MMC/SD/SDIO host controllers and a Standard SD host controller are defined by the *SD Card Specification, Part A2, SD Host Controller Standard Specification*, v1.00, as follows:

- The MMC/SD/SDIO host controllers support MMC cards.
- The MMC/SD/SDIO host controller is defined as a DMA slave device. Standard SD host controller is defined as DMA master controller that can start and stop a DMA transfer. MMC/SD/SDIO host controllers support DMA transfers through slave DMA requests.
- The clock divider in MMC/SD/SDIO host controller supports a wider range of frequency than specified in the *SD Memory Card Specifications*, v2.0. The MMC/SD/SDIO host controller supports odd and even clock ratio.
- The MMC/SD/SDIO host controller supports configurable busy timeout.

19.2 MMC/SD/SDIO Environment

One MMC/SD/SDIO host controller can support one MMC memory card, one SD memory card, or one SDIO card.

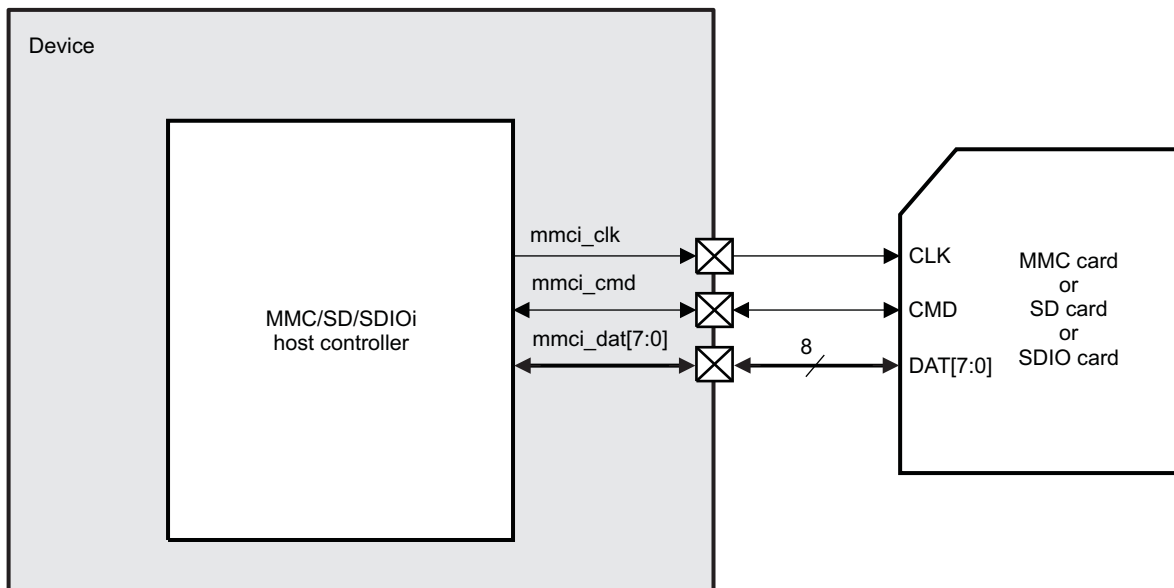

Other combinations (for example, two SD cards, one MMC card, and one SD card) are not supported through a single controller.

- The first controller (MMC/SD/SDIO1) integrates an internal transceiver that allows a direct connection to the MMC/SD/SDIO card (1.8 and 3V), without external transceiver.
- The second controller (MMC/SD/SDIO2) allows connecting MMC/SD/SDIO cards (only 1.8V cards) or an external device that uses the MMC/SD/SDIO interface (WLAN device for example). The second instance also supports an external transceiver and provides direction signals for data and command. Using an external transceiver device precludes 8-bit transfer mode.
- The third controller (MMC/SD/SDIO3) allows connecting MMC/SD/SDIO cards (only 1.8V cards) or an external device that uses the MMC/SD/SDIO interface (Wireless USB card for example). This interface is used without external transceiver.

19.2.1 MMC/SD/SDIO Connected to an MMC, an SD, or an SDIO Card

Figure 19-3 shows MMC/SD/SDIO_i host controller, instance 1, 2 or 3, connected to an MMC, an SD, or an SDIO card and its related external connections.

Figure 19-3. MMC/SD/SDIO Connected to an MMC, an SD, or an SDIO Card Without External Transceiver

mmchs-002

19.2.2 MMC/SD/SDIO Connected to an MMC, an SD, or an SDIO Card Through an External Transceiver Device

This connection is supported only by the MMC/SD/SDIO2 host controller. Figure 19-4 shows the MMC/SD/SDIO2 host controller connected to an MMC, an SD, or an SDIO card through an external transceiver device.

Figure 19-4. MMC/SD/SDIO2 Connected to an MMC, an SD, or an SDIO Card with External Transceiver

mmchs-003

19.2.3 MMC/SD/SDIO Functional Interfaces

19.2.3.1 Basic MMC/SD/SDIOi Pins Without External Transceiver

Figure 19-5 shows the MMC/SD/SDIOi host controller interface signals (instance 1, 2 or 3).

Figure 19-5. MMC/SD/SDIOi Interface Signals

mmchs-004

Table 19-1 describes the MMC/SD/SDIOi inputs/outputs.

Table 19-1. MMC/SD/SDIOi I/O Description

| Signal Name | I/O ⁽¹⁾ | Description | Reset Value |
|---------------|--------------------|--|-------------|
| mmci_clk | O | External clock for MMC/SD/SDIO card ⁽²⁾ | 0 |
| mmci_cmd | I/O | Command signal | 0 |
| mmci_dat[7:0] | I/O | Data signals | 0 |

⁽¹⁾ I = Input; O = Output

⁽²⁾ This output signal is also used as re-timing input.

19.2.3.2 Basic MMC/SD/SDIO2 Pins with External Transceiver

Figure 19-6 shows the MMC/SD/SDIO2 host controller interface signals.

Figure 19-6. MMC/SD/SDIO2 Interface Signals

Table 19-2 describes the MMC/SD/SDIO2 inputs/outputs.

Table 19-2. MMC/SD/SDIO2 I/O Description

| Signal Name | I/O | Description | Reset Value |
|---------------|-----|--|-------------|
| mmc2_clk | O | External clock for MMC/SD/SDIO card | 0 |
| mmc2_clkin | I | Input clock from MMC/SD/SDIO card | 0 |
| mmc2_cmd | I/O | Command signal | 0 |
| mmc2_dir_cmd | O | Direction control for mmc2_cmd signal case an external transceiver is used (high when transmit, low when receive) | 0 |
| mmc2_dat[3:0] | I/O | Data signals | 0 |
| mmc2_dir_dat0 | O | Direction control for mmc2_dat0 signal when an external transceiver is used (high when transmit, low when receive) | 0 |
| mmc2_dir_dat1 | O | Direction control for mmc2_dat1 and mmc2_dat3 signal when an external transceiver is used (high when transmit, low when receive) | 0 |
| mmc2_dir_dat2 | O | Direction control for mmc2_dat2 signal when an external transceiver is used (high when transmit, low when receive) | 0 |
| mmc2_dir_dat3 | O | Direction control for mmc2_dat[7:4] signal when an external transceiver is used (high when transmit, low when receive). Unusable on the device because mmci_dat[7:4] are muxed with other direction control signals. See Chapter 6, System Control Module for further details on the pin multiplexing. | 0 |

19.2.3.3 MMC/SD/SDIO Protocol and Data Format

The bus protocol between the MMC/SD/SDIOi host controller and the card is message-based. Each message is represented by one of the following parts:

Command: a command starts an operation. The command is transferred serially from the MMC/SD/SDIO host controller to the card on the mmci_cmd line.

Response: a response is an answer to a command. The response is sent from the card to the MMC/SD/SDIO host controller. It is transferred serially on the mmci_cmd line.

Data: data are transferred from the MMC/SD/SDIOi host controller to the card or from a card to the MMC/SD/SDIO host controller using the DATA lines.

Busy: the mmci_dat0 signal is maintained low by the card as far as it is programming the data received.

CRC status: CRC result is sent by the card through the mmci_dat0 line when executing a write transfer. In the case of transmission error, occurring on any of the active data lines, the card sends a negative CRC status on mmci_dat0. In the case of successful transmission, over all active data lines, the card sends a positive CRC status on mmci_dat0 and starts the data programming procedure.

19.2.3.3.1 Protocol

There are two types of data transfer:

- Sequential operation
- Block-oriented operation

There are specific commands for each type of operation (sequential or block-oriented).

See the *Multimedia Card System Specification, v4.2*, the *SD Memory Card Specifications, v2.0*, and the *SDIO Card Specification, Part E1, August 2004*, for details about commands and programming sequences supported by the MMC, SD, and SDIO cards.

Figure 19-7 and Figure 19-8 show how sequential operations are defined. Sequential operation is only for 1-bit transfer and initiates a continuous data stream. The transfer terminates when a stop command follows on the mmci_cmd line.

CAUTION
Stream commands are supported only by MMC cards.

Figure 19-7. Sequential Read Operation (MMC Cards Only)

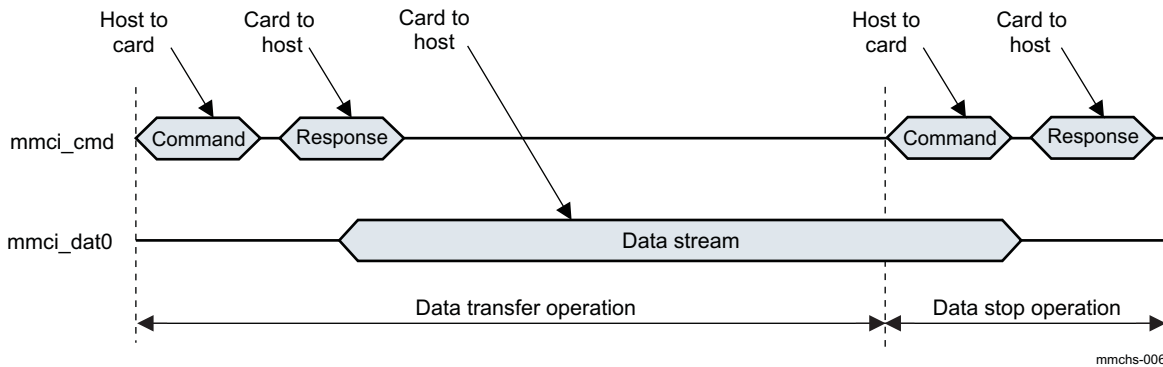

Figure 19-8. Sequential Write Operation (MMC Cards Only)

Figure 19-9 and Figure 19-10 show how multiple block-oriented operations are defined. A multiple block-oriented operation sends a data block plus CRC bits. The transfer terminates when a stop command follows on the mmci_cmd line. These operations are available for all kinds of cards.

Figure 19-9. Multiple Block Read Operation

mmchs-008

Figure 19-10. Multiple Block Write Operation with Card Busy Signal

mmchs-009

NOTE:

1. The card busy signal is not always generated by the card; the previous examples show a particular case.
2. It is software responsibility to do a software reset (set `MMCI_MMCHS_SYSCTL[26]` SRD bit to 0x1) after data timeout to ensure `mmci_clk` is stopped
3. For multiblock transfer, and especially for MMC cards, you can abort a transfer without using a stop command. Use a `CMD23` before data transfer to define the number of blocks that will be transferred, then the transfer stops automatically after the last block (if the MMC card supports this feature).

19.2.3.3.2 Data Format

Coding Scheme for Command Token

Command tokens always start with 0 and end with 1. The second bit is a transmitter bit: 1 for a host command. The content is the command index (coded by 6 bits) and an argument (for example, an address), coded by 32 bits. The content is protected by 7-bit CRC checksum (see [Figure 19-11](#)).

Figure 19-11. Command Token Format

Coding Scheme for Response Token

Response tokens always start with 0 and end with a 1. The second bit is a transmitter bit: 0 for a card response. The content is different for each type of response (R1, R2, R3, R4, and R5 R6 [for SDIO]) and the content is protected by 7-bit CRC checksum (see [Figure 19-12](#) and [Figure 19-13](#)). Depending on the type of commands sent to the card, the `MMCHS_CMD` register must be configured differently to avoid false CRC or index errors to be flagged on command response (see [Table 19-3](#)). For more details about response types, see the *Multimedia Card System Specification, v4.2*, the *SD Memory Card Specifications, v2.0*, or the *SDIO Card Specification, Part E1, v1.10*.

Figure 19-12. Response Token Format (R1, R3, R4, R5, R6)

Figure 19-13. Response Token Format (R2)

Table 19-3. Relation Between Configuration and Name of Response Type⁽¹⁾

| Response Type MMCi.MMCHS_CMD[17:16] RSP_TYPE | Index Check Enable MMCi.MMCHS_CMD[20] CICE | CRC Check Enable MMCi.MMCHS_CMD[19] CCCE | Name of Response Type |
|--|--|--|-----------------------|
| 00 | 0 | 0 | No Response |
| 01 | 0 | 1 | R2 |
| 10 | 0 | 0 | R3 (R4 for SD cards) |
| 10 | 1 | 1 | R1, R6, R5 |
| 11 | 1 | 1 | R1b, R5b |

⁽¹⁾ The MMC/SD/SDIOi host controller assumes that both clocks may be switched off, whatever the value set in the MMcI.MMCHS_SYSCONFIG[9:8] CLOCKACTIVITY bit.

Coding Scheme for Data Token

Data tokens always start with 0 and end with 1 (see Figure 19-14, Figure 19-15, and Figure 19-16).

19.3 MMC/SD/SDIO Integration

Figure 19-17 shows the internal connections between the three instances of the MMC/SD/SDIO host controller and the other modules

Figure 19-17. MMC/SD/SDIO1 Integration

mmchs-016

19.3.1 Clocking, Reset, and Power-Management Scheme

19.3.1.1 Clocks

19.3.1.1.1 Module Clocks

The MMC/SD/SDIO receives three clocks:

- A fixed functional clock of 96 MHz (the MMCi_FCLK) independent of the device external clock frequency
- An interface clock (the MMCi_ICLK) for interfacing with L4 interconnects (register accesses)
- A debounce clock, the MMCi_32K for reset process only

All these clocks are generated and controlled by the power, reset, and clock manager (PRCM) module (see , *Power Reset and Clock Management* for more information).

19.3.1.1.2 Power Management

The MMC/SD/SDIO host controller can enter into different modes and save power:

- Normal mode
- Idle mode

The two modes are mutually exclusive (the module can be in normal mode or in idle mode). The MMC/SD/SDIO host controller is compliant with the PRCM module handshake protocol.

Normal Mode

The autogating of interface and functional clocks occurs when the following conditions are met:

- The MMCI.MMCHS_SYSCONFIG[0] AUTOIDLE bit is set to 1 (1 = 1 for MMC/SD/SDIO1, 2 for MMC/SD/SDIO2 and 3 for MMC/SD/SDIO3 instances).
- There is no transaction on the MMC interface.

The autogating of interface and functional clocks stops when the following conditions are met:

- A register access occurs through the L4 interconnect.
- A wake-up event occurs (an interrupt from a SDIO card).
- A transaction on the MMC/SD/SIO interface starts.

Then the MMC/SD/SDIO host controller enters in low-power state (MMCI_ICLK clock autogated) even if MMCI.MMCHS_SYSCONFIG[0] AUTOIDLE is set to 0.

The functional clock is internally switched off and only interconnect read and write accesses are allowed.

Idle Mode

The MMCI_ICLK and MMCI_FCLK clocks provided to MMC/SD/SDIO are switched off upon a PRCM module request. They are switched back upon module request.

The MMC/SD/SDIO host controller complies with the PRCM module handshaking protocol:

- Idle request from the system power manager
- Idle acknowledgment from the MMC/SD/SDIO host controller
- Wake-up request from the MMC/SD/SDIO host controller

The idle acknowledgment varies according to the MMCI.MMCHS_SYSCONFIG[4:3] SIDLEMODE bit field:

- 0x0: Force-idle mode. The MMC/SD/SDIO host controller acknowledges the system power manager request unconditionally.
- 0x1: No-idle mode. The MMC/SD/SDIO host controller ignores the system power manager request and behaves normally as if the request was not asserted.
- 0x2: Smart-idle mode. The MMC/SD/SDIO host controller acknowledges the system power manager request according to its internal state.

During the smart-idle mode period, the MMC/SD/SDIO host controller acknowledges that the MMCI_ICLK and MMCI_FCLK clocks may be switched off whatever the value set in the MMCI.MMCHS_SYSCONFIG[9:8] CLOCKACTIVITY field.

Transition from Normal Mode to Smart-Idle Mode

Smart-idle mode is enabled when the MMCI.MMCHS_SYSCONFIG[4:3] SIDLEMODE bit field is set to 0x2.

The MMC/SD/SDIOi host controller goes into idle mode when the PRCM issues an idle request, according to its internal activity.

During normal to idle mode transition, any access to the registers of the MMC/SD/SDIOi host controller generates an error as long as the MMCI_ICLK clock is alive. The PRCM.CM_IDLEST1_CORE[25] ST_MMC2 and (respectively the PRCM.CM_IDLEST1_CORE[24] ST_MMC1 bit) is set to 0x0 when the MMC/SD/SDIO2 module (respectively the MMC/SD/SDIO1 module) can be accessed.

The MMC/SD/SDIO host controller acknowledges the idle request from the PRCM after ensuring the following:

- The current multi/single-block transfer is completed.
- Any interrupt or DMA request is asserted.
- There is no card interrupt on `mmci_dat[1]` signal.

As long as the MMC/SD/SDIOi controller do not acknowledge the idle request, if an event occurs, the MMC/SD/SDIOi host controller can still generate an interrupt or a DMA request. In this case, the module ignores the idle request from the PRCM.

As soon as the MMC/SD/SDIOi controller acknowledges the idle request from the PRCM, the module does not assert any new interrupt or DMA request.

Wake-Up Event in Smart-Idle Mode

The wake-up feature is enabled when the following enable wake-up bits are set:

- `MMCi.MMCHS_SYSCONFIG[2]` ENAWAKEUP bit is set to 0x1
- `MMCi.MMCHS_HCTL[24]` IWE bit is set to 0x1
- `MMCi.MMCHS_IE[8]` CIRQ_ENABLE bit is set to 0x1

The wakeup is generated only in smart-idle mode only, when module is in idle mode.

Table 19-4 lists the supported cases in smart-idle mode.

Table 19-4. Smart Idle Mode and Wake-Up Capabilities

| Mode | MMCi_ICLK clock | MMCi_FCLK clock | Wake-up Event |
|----------------|------------------------------------|------------------------------------|--|
| Card interrupt | May be switched off ⁽¹⁾ | May be switched off ⁽¹⁾ | The module sends an asynchronous wake-up request on detection of a card interrupt on <code>mmci_dat[1]</code> signal |

⁽¹⁾ The MMC/SD/SDIOi host controller assumes that both clocks may be switched off, whatever the value set in the `MMCi.MMCHS_SYSCONFIG[9:8]` CLOCKACTIVITY bit.

Transition from Smart-Idle Mode to Normal Mode

The MMC/SD/SDIO host controller detects the end of the idle period when the PRCM deasserts the idle request.

For the wake-up event, there is a corresponding interrupt status in the `MMCi.MMCHS_STAT` register. The MMC/SD/SDIOi host controller operates the conversion between wake-up and interrupt (or DMA request) upon exit from smart-idle mode if the associated enable bit is set in the `MMCi.MMCHS_ISE` register.

Interrupts and wake-up events have independent enable/disable controls, accessible through the `MMCi.MMCHS_HCTL` and `MMCi.MMCHS_ISE` registers. The overall consistency must be ensured by software.

The interrupt status register `MMCi.MMCHS_STAT` is updated with the event that caused the wake-up in the CIRQ bit when the `MMCi.MMCHS_IE[8]` CIRQ_ENABLE associated bit is enabled.

Then, the wake-up event at the origin of the transition from smart-idle mode to normal mode is converted into its corresponding interrupt or DMA request. (The `MMCi.MMCHS_STAT` register is updated and the status of the interrupt signal changes.)

When the idle request from the PRCM is deasserted, the module switches back to normal mode. The module is fully operational.

Force-Idle Mode

Force-idle mode is enabled when the `MMCi.MMCHS_SYSCONFIG[4:3]` SIDLEMODE bit field is set to 0x0.

Force-idle mode is an idle mode where the MMC/SD/SDIOi host controller responds unconditionally to the idle request from the PRCM. Moreover, in this mode, the MMC/SD/SDIOi host controller unconditionally deasserts interrupts and DMA request lines asserted.

The transition from normal mode to force-idle mode does not affect the bits of the MMCi.MMCHS_STAT register.

In force-idle mode, the interrupt and DMA request lines are deasserted. MMCi_ICLK and MMCi_FCLK can be switched off.

CAUTION

In force-idle mode, an idle request from the PRCM during a command or a data transfer can lead to an unexpected and unpredictable result. When the module is idle, any access to the module generates an error as long as the MMCi_ICLK clock is alive.

The module exits the force-idle mode when the PRCM deasserts the idle request. Then the module switches back to normal mode. The module is fully operational. Interrupt and DMA request lines are optionally asserted one clock cycle later.

19.3.1.2 Resets

19.3.1.2.1 Hardware Reset

The module is reinitialized by the hardware when the active-low reset signal (CORE_RST), synchronous to the MMCi_ICLK clock is asserted on the input pin MMCi_RESET (see , *Power, Reset, and Clock Management* for more information).

A global status bit RESETDONE is provided in the status register MMCi.MMCHS_SYSSTATUS[0]. This bit is set to 1 when all the different clock domain resets (interface domain, functional domain, and 32K domain) have been released.

The MMCi.MMCHS_SYSSTATUS[0] RESETDONE bit can be monitored by the software to check if the module is ready-to-use after a hardware reset.

NOTE: Functional clock MMCi_FCLK, interface clock MMCi_ICLK, and debounce clock MMCi_32K must be provided to the module to allow the RESETDONE status bit to be set.

This hardware reset signal has a global reset action on the module. All configuration registers and all state-machines are reset in all clock domains.

19.3.1.2.2 Software Reset

The module is reinitialized by software through the MMCi.MMCHS_SYSCONFIG[1] SOFTRESET bit. This bit has the same action on the module logic as the hardware MMCi_RESET signal except for:

- Debounce logic
- MMCi.MMCHS_PSTATE, MMCi.MMCHS_CAPA, and MMCi.MMCHS_CUR_CAPA registers (see corresponding register descriptions)

The SOFTRESET bit is active high. The bit is automatically reinitialized to 0 by the hardware. The MMCi.MMCHS_SYSCTL[24] SRA bit has the same action as the SOFTRESET bit on the design.

The MMCi.MMCHS_SYSSTATUS[0] RESETDONE bit can be monitored by the software to check if the module is ready-to-use after a software reset.

Moreover, two partial software reset bits are provided:

- MMCi.MMCHS_SYSCTL[26] SRD bit
- MMCi.MMCHS_SYSCTL[25] SRC bit

These two reset bits are useful to reinitialize data or command processes respectively in case of line conflict. When set to 1, a reset process is automatically released when the reset completes:

- The MMCi.MMCHS_SYSCTL[26] SRD bit resets all finite state-machines and status management that handle data transfers on both the interface and functional side.

- The MMCI.MMCHS_SYSCTL[25] SRC bit resets all finite state-machines and status management that handle command transfers on both the interface and functional side.

19.3.1.3 Power Domain

MMC/SD/SDIOi power is supplied by the CORE power domain (see , *Power Reset and Clock Management* for more information).

When the MMC/SD/SDIOi power domain is off, the only way to wake up the power domain and different MMC/SD/SDIOi clocks is to monitor mmci_dat[1] input pin state via a different GPIO line for each MMC/SD/SDIO interface (see [Chapter 21](#), *General-Purpose Interface*, for more information).

19.3.2 Hardware Requests

19.3.2.1 DMA Requests

The MMC/SD/SDIOi host controller can be interfaced with a DMA controller. At system level, the advantage is to discharge the LH of the data transfers. The module does not support wide DMA access (above 1024 bytes) for SD cards as specified in the *SD Card Specification, Part A2, SD Host Controller Standard Specification, v1.00*.

The DMA request is issued if the three following conditions are met:

- The MMCI.MMCHS_CMD[0] DE bit is set to 1 to trigger the initial DMA request (the write must be done when running the data transfer command).
- A command was emitted on the mmci_cmd line.
- There is enough space in the buffer of the MMC/SD/SDIOi host controller to write an entire block (BLEN writes).

DMA request lines are connected on the system DMA (sDMA) inputs:

- S_DMA_60 (MMC1_DMA_TX)
- S_DMA_61 (MMC1_DMA_RX)
- S_DMA_46 (MMC2_DMA_TX)
- S_DMA_47 (MMC2_DMA_RX)
- S_DMA_76 (MMC3_DMA_TX)
- S_DMA_77 (MMC3_DMA_RX)

19.3.2.1.1 DMA Receive Mode

In a DMA block read operation (single or multiple), the request signal MMCI_DMA_RX is asserted to its active level when a complete block is written in the buffer. The block size transfer is specified in the MMCI.MMCHS_BLK[10:0] BLEN field.

The MMCI_DMA_RX signal is deasserted to its inactive level when the sDMA has read one single word from the buffer.

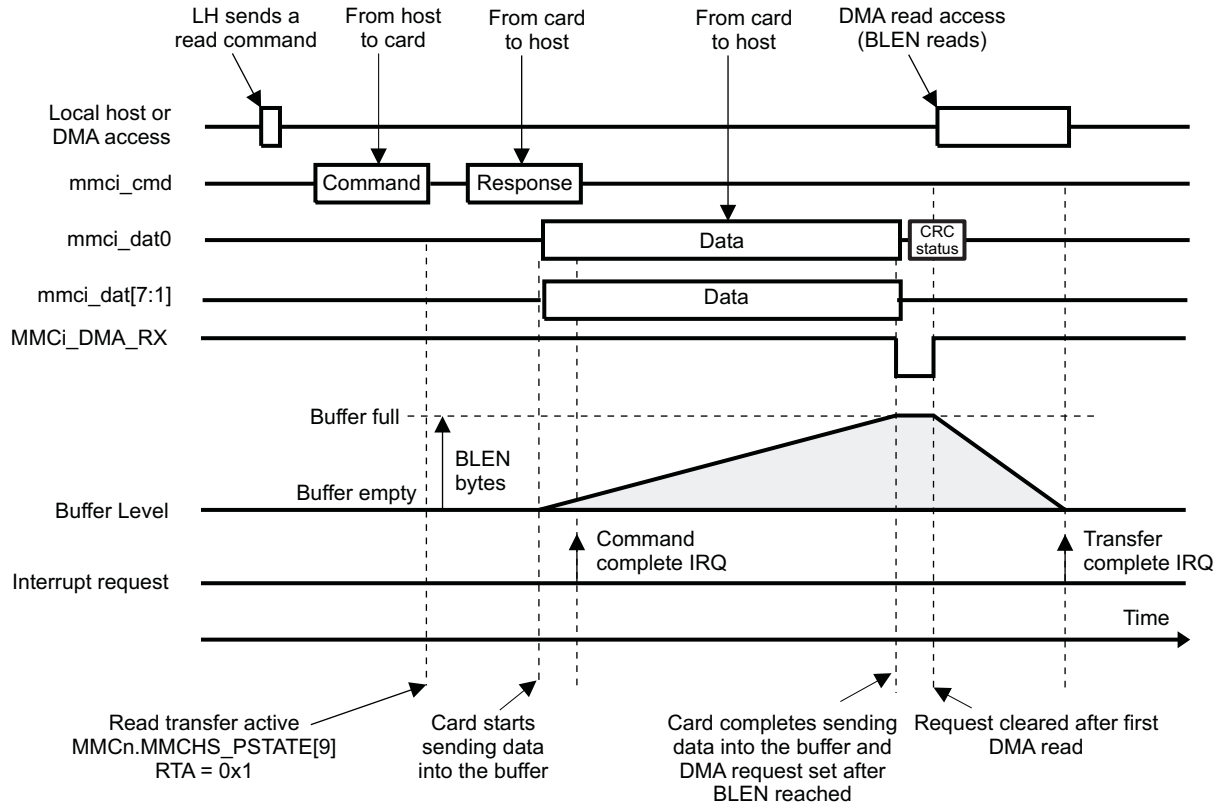

Only one request is sent per block; the DMA controller can make a 1-shot read access or several DMA bursts, in which case the DMA controller must manage the number of burst accesses, according to block size BLEN field.

New DMA requests are internally masked if the sDMA has not read exactly BLEN bytes and a new complete block is not ready. As DMA accesses are in 32-bit, then the number of sDMA read is $\text{Integer}(\text{BLEN}/4)+1$.

The receive buffer never overflows. In multiple block transfers for block size above 512 bytes, when the buffer gets full, the mmci_clk clock signal (provided to the card) is momentarily stopped until the sDMA or the MPU performs a read access, which reads a complete block in the buffer.

Summary (see [Figure 19-18](#)):

- DMA transfer size = BLEN buffer size (maximum 1024 32-bit words) in one shot or by burst
- One DMA request per block

Figure 19-18. DMA Receive Mode

mmchs-018

19.3.2.1.2 DMA Transmit Mode

In a DMA block write operation (single or multiple), the request signal `MMCi_DMA_TX` is asserted to its active level when a complete block is to be written to the buffer. The block size transfer is specified in the `MMCi.MMCHS_BLK[10:0]` BLEN field.

The `MMCi_DMA_TX` signal is deasserted to its inactive level when the sDMA has written one single word to the buffer.

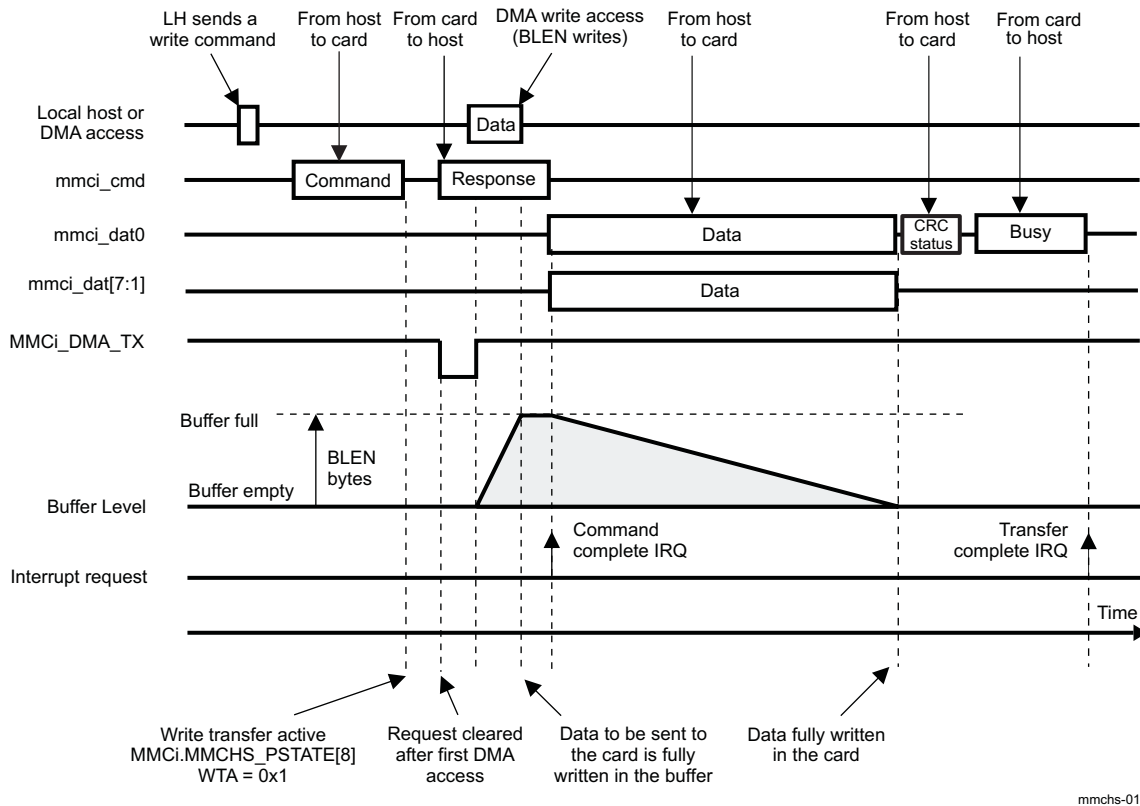

Only one request is sent per block; the DMA controller can make a 1-shot write access or multiple write DMA bursts, in which case the DMA controller must manage the number of burst accesses, according to block size BLEN field.

New DMA requests are internally masked if the sDMA has not written exactly BLEN bytes (as DMA accesses are in 32-bit, then the number of sDMA read is $\text{Integer}(\text{BLEN}/4)+1$) and if there is not enough memory space to write a complete block in the buffer.

Summary (see Figure 19-19):

- DMA transfer size = BLEN buffer size (maximum 1024 32-bit words) in one shot or by burst
- One DMA request per block

Figure 19-19. DMA Transmit Mode

mmchs-019

19.3.2.2 Interrupt Requests

Several internal module events can generate an interrupt. Each interrupt has a status bit, an interrupt enable bit, and a signal status enable:

- The status of each type of interrupt is automatically updated in the `MMCi.MMCHS_STAT` register; it indicates which service is required.
- The interrupt status enable bits of the `MMCi.MMCHS_IE` register enable/disable the automatic update of the `MMCi.MMCHS_STAT` register on an event-by-event basis.
- The interrupt signal enable bits of the `MMCi.MMCHS_ISE` register enable/disable the transmission of an interrupt request on the interrupt line `MMCi_IRQ` (from the MMC/SD/SDIOi host controller to the MPU subsystem interrupt controller) on an event-by-event basis.

If an interrupt status is disabled in the `MMCi.MMCHS_IE` register, then the corresponding interrupt request is not transmitted, and the value of the corresponding interrupt signal enable in the `MMCi.MMCHS_ISE` register is ignored.

When an interrupt event occurs, the corresponding status bit is automatically set to 0x1 (the MMC/SD/SDIOi host controller updates the status bit) in the `MMCi.MMCHS_STAT` register. If later a mask is applied on the interrupt in the `MMCi.MMCHS_ISE` register, the interrupt request is deactivated.

When the interrupt source has not been serviced, if the interrupt status is cleared in the `MMCi.MMCHS_STAT` register and the corresponding mask is removed from the `MMCi.MMCHS_ISE` register, the interrupt status is not asserted again in the `MMCi.MMCHS_STAT` register and the MMC/SD/SDIOi host controller does not transmit an interrupt request.

CAUTION

If the buffer write ready interrupt (BWR) or the buffer read ready only interrupt (BRR) are not serviced and are cleared in the MMCi.MMCHS_STAT register, and the corresponding mask is removed, then the MMC/SD/SDIOi host controller will wait for the service of the interrupt without updating the status MMCi.MMCHS_STAT or transmitting an interrupt request.

The MMC/SD/SDIOi host controller supports interrupt-driven operation and polling.

There are one interrupt line for each instance of the MMC/SD/SDIOi host controller:

- MMC1_IRQ is connected to M_IRQ_83 for MMC/SD/SDIO1 instance.
- MMC2_IRQ is connected to M_IRQ_86 for MMC/SD/SDIO2 instance.
- MMC3_IRQ is connected to M_IRQ_94 for MMC/SD/SDIO3 instance.

19.3.2.2.1 Interrupt-Driven Operation

An interrupt enable bit must be set in the MMCi.MMCHS_IE register to enable the module internal source of interrupt.

When an interrupt event occurs, the single interrupt line is asserted and the LH must:

- Read the MMCi.MMCHS_STAT register to identify which event occurred.
- Write 1 into the corresponding bit of the MMCi.MMCHS_STAT register to clear the interrupt status and release the interrupt line (if a read is done after this write, this would return 0).

NOTE: In the MMCi.MMCHS_STAT register, Card Interrupt (CIRQ) and Error Interrupt (ERRI) bits cannot be cleared.
 The MMCi.MMCHS_STAT[8] CIRQ status bit must be masked by disabling the MMCi.MMCHS_IE[8] CIRQ_ENABLE bit (set to 0x0), then the interrupt routine must clear SDIO interrupt source in SDIO card common control register (CCCR). See [Chapter 5, Interconnect](#) for more information.
 The MMCi.MMCHS_STAT[15] ERRI bit is automatically cleared when all status bits in MMCi.MMCHS_STAT[31:16] are cleared.

19.3.2.2.2 Polling

When the interrupt capability of an event is disabled in the MMCi.MMCHS_ISE register, the interrupt line is not asserted:

- Software can poll the status bit in the MMCi.MMCHS_STAT register to detect when the corresponding event occurs.
- Writing 1 into the corresponding bit of the MMCi.MMCHS_STAT register clears the interrupt status and does not affect the interrupt line state.

NOTE: Refer to the previous note concerning CIRQ and ERRI bits clearing.

19.4 MMC/SD/SDIO Functional Description

19.4.1 Description

MMC/SD/SDIOi host controller is partitioned into two clock domains:

- The interface L4 clock domain
- The functional clock domain

Any two domains are considered asynchronous to each other, and exchanges between the two domains are synchronized through a synchronization stage and an asynchronous buffer. Data are transferred from one domain to other through the buffer (2*512 RAM).

[Figure 19-20](#) shows a block diagram of the MMC/SD/SDIO host controller.

Figure 19-20. MMC/SD/SDIO Diagram

mmchs-020

In the L4 clock domain, the user can:

- Control the transfer (configure parameters for the transfer)
- Control clock activities and reset
- Manage interrupts and hardware requests

- Consult different status:
 - Bus
 - Buffer
 - Interrupts
 - Errors
- Transmit and receive data through the buffer

In the functional clock domain, the internal mechanisms perform the transfers of data and commands.

For more detail see the command response registers (MMCi.MMCHS_RSPn registers: [Table 19-52](#), [Table 19-54](#), [Table 19-56](#), and [Table 19-58](#)).

CAUTION

Read access to the command response registers is allowed only when the command process is completed.

19.4.2 Mode Selection

The MMC/SD/SDIO host controller can be use in two modes: MMC and SD/SDIO modes. It has been designed to be the most transparent with the type of card.

The type of the card connected is differentiated by the software initialization procedure. Software identifies the type of card connected during software initialization. For each given card type, there are corresponding commands. Some commands are not supported by all cards. See the *Multimedia Card System Specification, v4.2*, the *SD Memory Card Specifications, v2.0*, and the *SDIO Card Specification, Part E1, v1.10*, for more details.

The purpose of the module is to transfer commands and data, to whatever card is connected, respecting the protocol of the connected card.

Writes and reads to the card must respect the appropriate protocol of that card.

19.4.3 Buffer Management

19.4.3.1 Data Buffer

The MMC/SD/SDIOi host controller uses a data buffer divided into two 512-byte portions that are 32 bits wide by 128 words deep. This buffer transfers data from one data bus (Interconnect) to another data bus (SD SDIO or MMC card bus) and vice versa.

The buffer is the heart of the interface and ensures the transfer between the two interfaces (L4 and the card).

To enhance performance, the data buffer is completed by a prefetch register and a post-write buffer that are not accessible by the host controller.

The read access time of the prefetch register is faster than the one of the data buffer. The prefetch register allows data to be read from the data buffer at an increased speed by preloading data into the prefetch register.

The entry point of the data buffer for the two portions, the prefetch buffer and the post-write buffer, is the 32-bit register MMCI.MMCHS_DATA. A write access to the MMCI.MMCHS_DATA register followed by a read access from the MMCI.MMCHS_DATA register corresponds to a write access to the post-write buffer followed by a read access to the prefetch buffer. As a consequence, it is normal that the data of the write access to the MMCI.MMCHS_DATA register and the data of the read access to the MMCI.MMCHS_DATA register are different.

The number of 32-bit accesses to the MMCI.MMCHS_DATA register that are needed to read (or write) a data block with a size of MMCI.MMCHS_BLK[10:0] BLEN, and equals the rounded up result of BLEN divided by 4.

The maximum block size supported by the host controller is 1024 bytes. This value is hard-coded in the register MMCI.MMCHS_CAPA[17:16] MBL field and cannot be changed.

A read access to the MMCI.MMCHS_DATA register is allowed only when the buffer read enable status is set to 1 (MMCI.MMCHS_PSTATE[11] BRE); otherwise, a bad access (MMCI.MMCHS_STAT[29] BADA) is signaled.

A write access to the MMCI.MMCHS_DATA register is allowed only when the buffer write enable status is set to 1 (MMCI.MMCHS_PSTATE[10] BWE); otherwise, a bad access (MMCI.MMCHS_STAT[29] BADA) is signaled and the data is not written.

The data buffer has two modes of operation to store and read of the first and second portions of the data buffer:

- When the size of the data block to transfer is less than or equal to 512 bytes, meaning the value written in BLEN is less than or equal to 0x200, two data transfers can occur from one data bus to the other data bus and vice versa at the same time. The MMC/SD/SDIOi host controller uses the two portions of the data buffer in a ping pong manner so that storing and reading of the first and second portions of the data buffer are automatically interchanged from time to time so that data may be read from one portion (for instance, through a DMA read access on the interconnect bus) while data (for instance, from the card) is being stored into the other portion and vice versa. When BLEN is less than, or equal to 0x200 (that is, less than, or equal to 512 bytes), each of the two portions of the buffer that can be used have a size of BLEN (that is, 32 bits x BLEN div by 4). Do not use a size greater than 2 times this value.

CAUTION

The MMCI.MMCHS_CMD[4] DDIR bit must be configured before a transfer to indicate the direction of the transfer.

Figure 19-21 and Figure 19-22 show the buffer management for a write and for a read, respectively.

Figure 19-21. Buffer Management for a Write

mmchs-047

Figure 19-22. Buffer Management for a Read

- When the size of the data block to transfer is larger than 512 bytes, meaning the value written in BLEN is 0x201 or larger, only one data transfer can occur from one data bus to the other data bus at a time. The MMC/SD/SDIOi host controller uses the entire data buffer as a single 1024-byte portion. In this mode, a bad access (MMCi.MMCHS_STAT[29] BADA) is signaled when two data transfers occur from one data bus to the other data bus and vice versa at the same time.

19.4.3.1.1 Data Buffer Status

The data buffer status is defined in the following interrupt status register and status register:

- Interrupt status registers (see Table 19-68):
 - MMCi.MMCHS_STAT[29] BADA: Bad access to data space
 - MMCi.MMCHS_STAT[5] BRR: Buffer read ready
 - MMCi.MMCHS_STAT[4] BWR: Buffer write ready
- Status registers (see Table 19-62):
 - MMCi.MMCHS_PSTATE[11] BRE: Buffer read enable
 - MMCi.MMCHS_PSTATE[10] BWE: Buffer write enable

19.4.4 Transfer Process

The process of a transfer is dependent on the type of command. It can be with or without a response, with or without data.

19.4.4.1 Different Types of Commands

Different types of commands are specific to MMC, SD, or SDIO cards. See the *Multimedia Card System Specification*, v4.2, the *SD Memory Card Specifications*, v2.0, the *SDIO Card Specification, Part E1*, v1.10, or the *SD Card Specification, Part A2, SD Host Controller Standard Specification*, v1.00, for more details.

19.4.4.2 Different Types of Responses

Different types of responses are specific to MMC, SD, or SDIO cards. See the *Multimedia Card System Specification*, v4.2, the *SD Memory Card Specifications*, v2.0, the *SDIO Card Specification, Part E1*, v1.10, or the *SD Card Specification, Part A2, SD Host Controller Standard Specification*, v1.00, for more details.

Table 19-5 shows how the MMC, SD, and SDIO responses are stored in the MMCHS_RSPxx registers.

Table 19-5. MMC, SD, SDIO responses in the MMCHS_RSPxx registers

| Kind of Response | Response Field | Response Register |
|--|----------------------------|--|
| R1, R1b (normal response), R3, R4, R5, R5b, R6 | RESP[39:8] ⁽¹⁾ | MMCHS_RSP10[31:0] |
| R1b (Auto CMD12 response) | RESP[39:8] ⁽¹⁾ | MMCHS_RSP76[31:0] |
| R2 | RESP[127:0] ⁽¹⁾ | MMCHS_RSP76[31:0] MMCHS_RSP54[31:0] MMCHS_RSP32[31:0] MMCHS_RSP10[31:0] |

⁽¹⁾ RESP refers to the command response format described in the specifications mentioned above.

When the host controller modifies part of the MMCHS_RSPxx registers, it preserves the unmodified bits.

The host controller stores the Auto CMD12 response in the MMCHS_RSP76[31:0] register because the Host Controller may have a multiple block data DAT line transfer executing concurrently with a command. This allows the host controller to avoid overwriting the Auto CMD12 response with the command response stored in MMCHS_RSP10 register and vice versa.

19.4.5 Transfer or Command Status and Errors Reporting

Flags in the MMC/SD/SDIOi host controller show status of communication with the card:

- A timeout (of a command, a data, or a response)
- A CRC

Error conditions generate interrupts. See Table 19-6 and register description for more details.

Table 19-6. CC and TC Values Upon Error Detected

| Error hold in the MMCi.MMCHS_STAT register | CC | TC | Comments |
|--|----|----|--|
| 29 BADA | | | No dependency with CC nor TC BADA is related to MMCHS_DATA register accesses. Its assertion is not dependent of the ongoing transfer. |
| 28 CERR | 1 | | CC is set upon CERR. |
| 22 DEB | | 1 | TC is set upon DEB. |
| 21 DCRC | | 1 | TC is set upon DCRC. |
| 20 DTO | | | DTO and TC are mutually exclusive DCRC and DEB cannot occur with DTO. |
| 19 CIE | 1 | | CC is set upon CIE. |
| 18 CEB | 1 | | CC is set upon CEB. |
| 17 CCRC | 1 | | CC can be set upon CCRC - See CTO comment |

Table 19-6. CC and TC Values Upon Error Detected (continued)

| Error hold in the MMCi.MMCHS_STAT register | CC | TC | Comments |
|--|-----|----|---|
| 16 | CTO | | CTO and CC are mutually exclusive. CIE, CEB and CERR cannot occur with CTO. CTO can occur at the same time as CCRC: it indicates a command abort due to a contention on CMD line. In this case no CC appears. |

19.4.6 Transfer Stop

Whenever a transfer is initiated, the transmission may be willed to stop whereas it is still not finished. Several cases can be faced depending on the transfer type:

- Multiple blocks oriented transfers (for which transfer length is known)
- Continuous stream transfers (which have an infinite length)

NOTE: Since the MMC/SD/SDIOi controller manages transfers based on a block granularity, the buffer will accept a block only if there is enough space to completely store it. Consequently, if a block is pending in the buffer, no command will be sent to the card because the card clock will be shut off by the controller.

The MMC/SD/SDIOi controller includes two features which makes a transfer stop more convenient and easier to manage:

- Auto CMD12 (for MMC and SD only).
This feature is enabled by setting the MMCi.MMCHS_CMD[2] ACEN bit to 0x1 (this setting is relevant for a MMC/SD transfer with a known number of blocks to transfer). When the Auto CMD12 feature is enabled, the MMC/SD/SDIOi controller will automatically issue a CMD12 command when the expected number of blocks has been exchanged.
- Stop at block gap
This feature is enabled by setting the MMCi.MMCHS_HCTL[16] SBGR bit to 0x1. When enabled, this capability holds the transfer on until the end of a block boundary. If a stop transmission is needed, software can use this pause to send a CMD12 to the card.

NOTE: For MMC and SD cards, the stop at block gap feature is not supported in READ mode.

For SDIO cards, this setting can be supported in READ mode if the card has a read wait capability.

Table 19-7 shows the common way to stop a transfer, indicating command to send and features to enable.

Table 19-7. MMC/SD/SDIOi Controller Transfer Stop Command Summary

| | | WRITE transfer | | READ transfer | |
|--------------------------------------|---|---|--|---|---|
| | | SD / MMC | SDIO | SD / MMC | SDIO |
| Single block | | Transfer ends automatically Wait TC | Transfer ends automatically Wait TC | Transfer ends automatically Wait TC | Transfer ends automatically Wait TC |
| Multi blocks (finite or infinite) | Before the programmed block boundary | Send CMD12 Wait TC | Send CMD52 Wait TC | Send CMD12 Wait TC | Send CMD52 Wait TC |
| | Stop at the end of the transfer (finite transfer only) | Auto CMD12 active Transfer ends automatically Wait TC | Set MMCi.MMCHS_HC TL[16] SBGR bit to 0x1. Send CMD52 Wait TC | Auto CMD12 active Transfer ends automatically Wait TC | If READ_WAIT supported Stop at block gap Wait TC If READ_WAIT not supported Send CMD52 Wait TC |

NOTE: The MMC/SD/SDIOi controller will send the stop command to the card on a block boundary, regardless the moment the command was written to the controller registers.

19.4.7 MMC CE-ATA Command Completion Disable Management

The MMC/SD/SDIOi host controller supports CE-ATA features, in particular the detection of command completion token. When a command that requires a command completion signal ([MMCHS_CON\[12\]](#) CEATA and [MMCHS_CMD\[2\]](#) ACEN set to 1) is launched, host system is no longer allowed to emit a new command in parallel of data transfer unless it is a command completion disable.

The settings to emit a command completion disable token follow:

- [MMCHS_CON\[12\]](#) CEATA is set to 1.
- [MMCHS_CON\[2\]](#) HR set to 1.
- Clear the [MMCHS_ARG](#) register.
- Write into [MMCHS_CMD](#) register with value 0x00000000.

When a command completion disable token was emitted (that is, [MMCHS_STAT\[0\]](#) CC received), the host system is again allowed to emit another type of command (for example a transfer abort command CMD12 to abort transfer).

A critical case can be met when command completion signal disable (CCSD) is emitted during the last data block transfer, the sequence on command line could be sent very close to command completion signal (CCS) token sent by the card.

Three cases can be met:

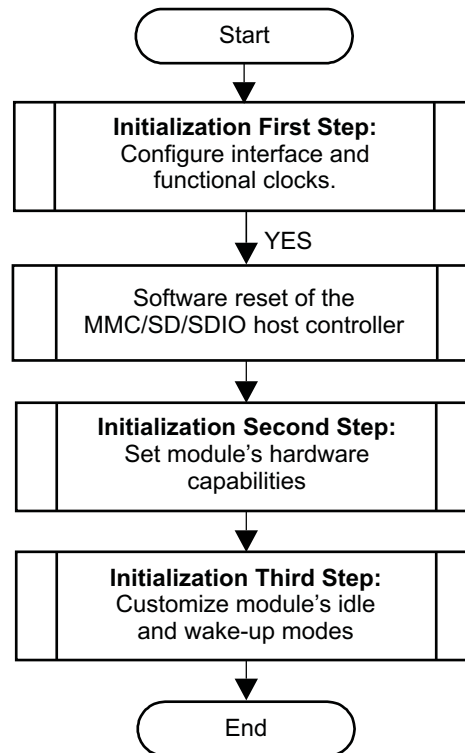

- CCS is receive just before CCSD is emitted:
An interrupt CIRQ is generated with CCS detection, CCSD is transmitted to card then an interrupt CC is generated when CCSD ends. In this case, card consider the CCSD sequence.
- CCS is not generated or generated during the CCSD transfer:
The CCS bit cannot be detected (conflict is not possible as they drive the same level on command line, then no CIRQ interrupt is generated; besides CC interrupt is generated when CCSD ends).
- CCS is generated without CCSD token required:
Only the interrupt CIRQ is generated when CCS is detected.

19.5 MMC/SD/SDIO Basic Programming Model

19.5.1 MMC/SD/SDIO Host Controller Initialization Flow

Figure 19-23 shows the general boot process.

Figure 19-23. MMC/SD/SDIO Controller Meta Initialization Steps

mmchs-024

19.5.1.1 Enable Interface and Functional clock for MMC Controller

Prior to any MMCHS register access one must enable MMCHS interface clock and functional clock in PRCM module registers PRCM.CM_ICLKEN1_CORE and PRCM.CM_FCLKEN1_CORE. Please refer to , *Power, Reset, and Clock Management*.

19.5.1.2 MMCHS Soft Reset Flow

Figure 19-24 shows the soft reset process of MMCHS controller.

Figure 19-24. MMC/SD/SDIO Controller Software Reset Flow

mmchs-025

19.5.1.3 Set MMCHS Default Capabilities

Software must read capabilities (in boot ROM for instance) and is allowed to set (write) `MMCi.MMCHS_CAPA[26:24]` and `MMCi.MMCHS_CUR_CAPA[23:0]` registers before the MMC/SD/SDIO host driver is started.

19.5.1.4 Wake-Up Configuration

Figure 19-25 details MMCHS controller wake-up configuration.

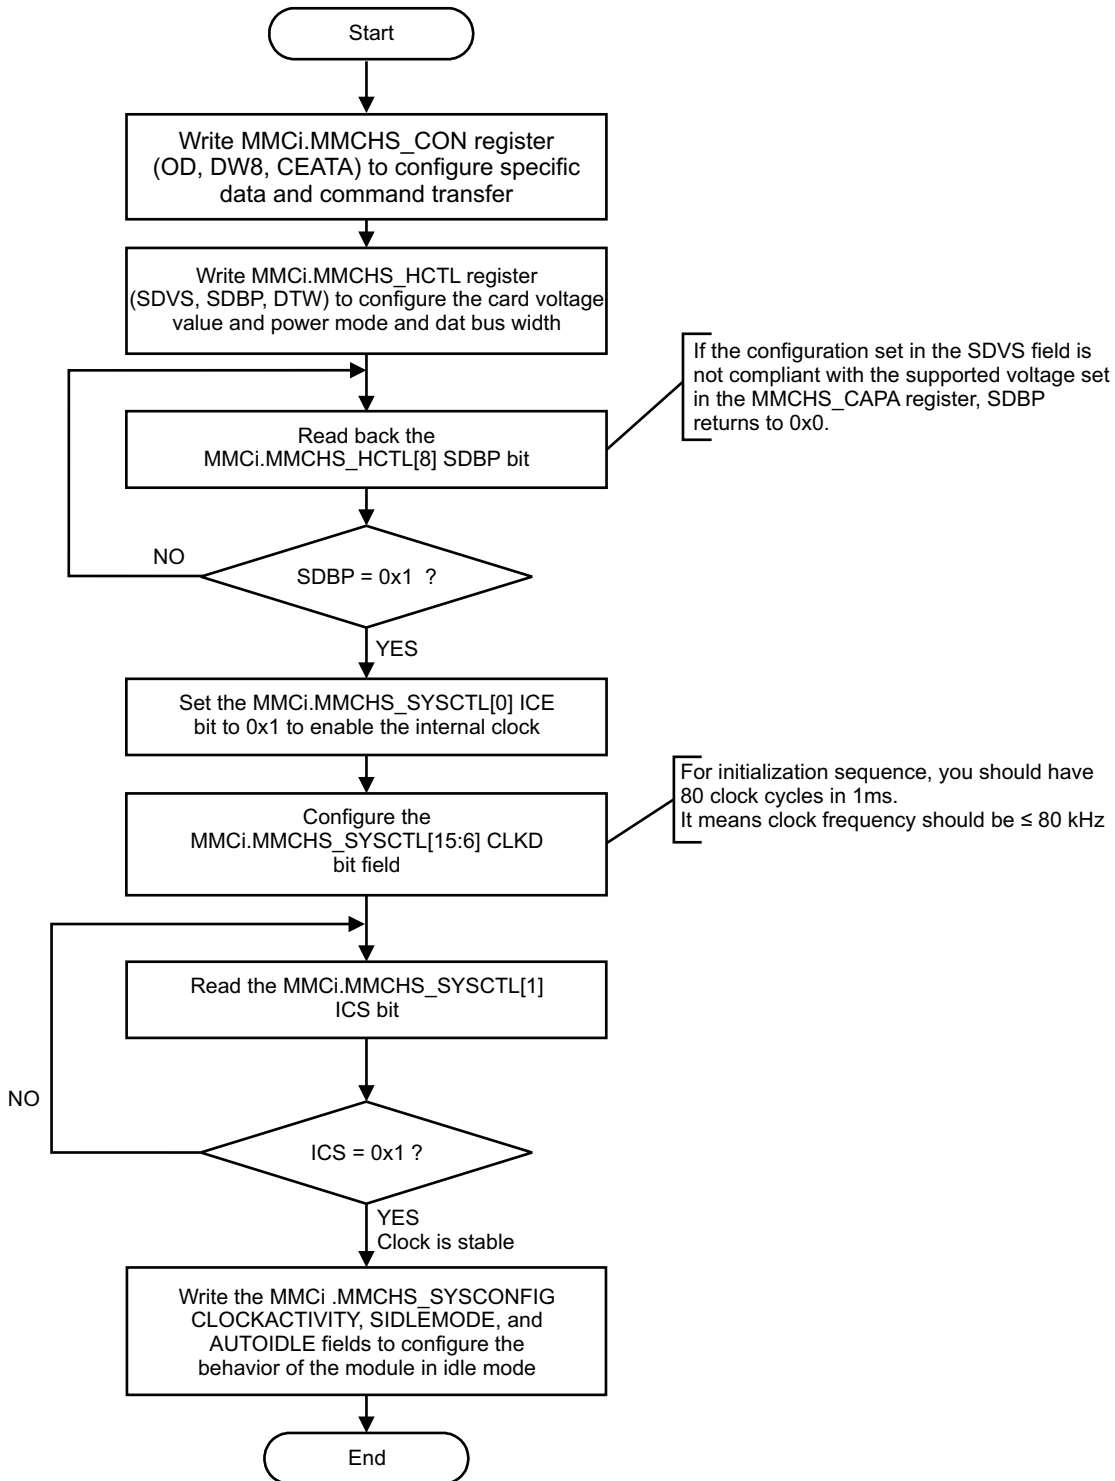

Figure 19-25. MMC/SD/SDIO Controller Wake-Up Configuration

mmchs-027

19.5.1.5 MMC Host and Bus Configuration

Figure 19-26 details MMC bus configuration process.

Figure 19-26. MMC/SD/SDIO Controller Bus Configuration

mmchs-028

19.5.2 Basic Operations for MMC/SD/SDIO Host Controller

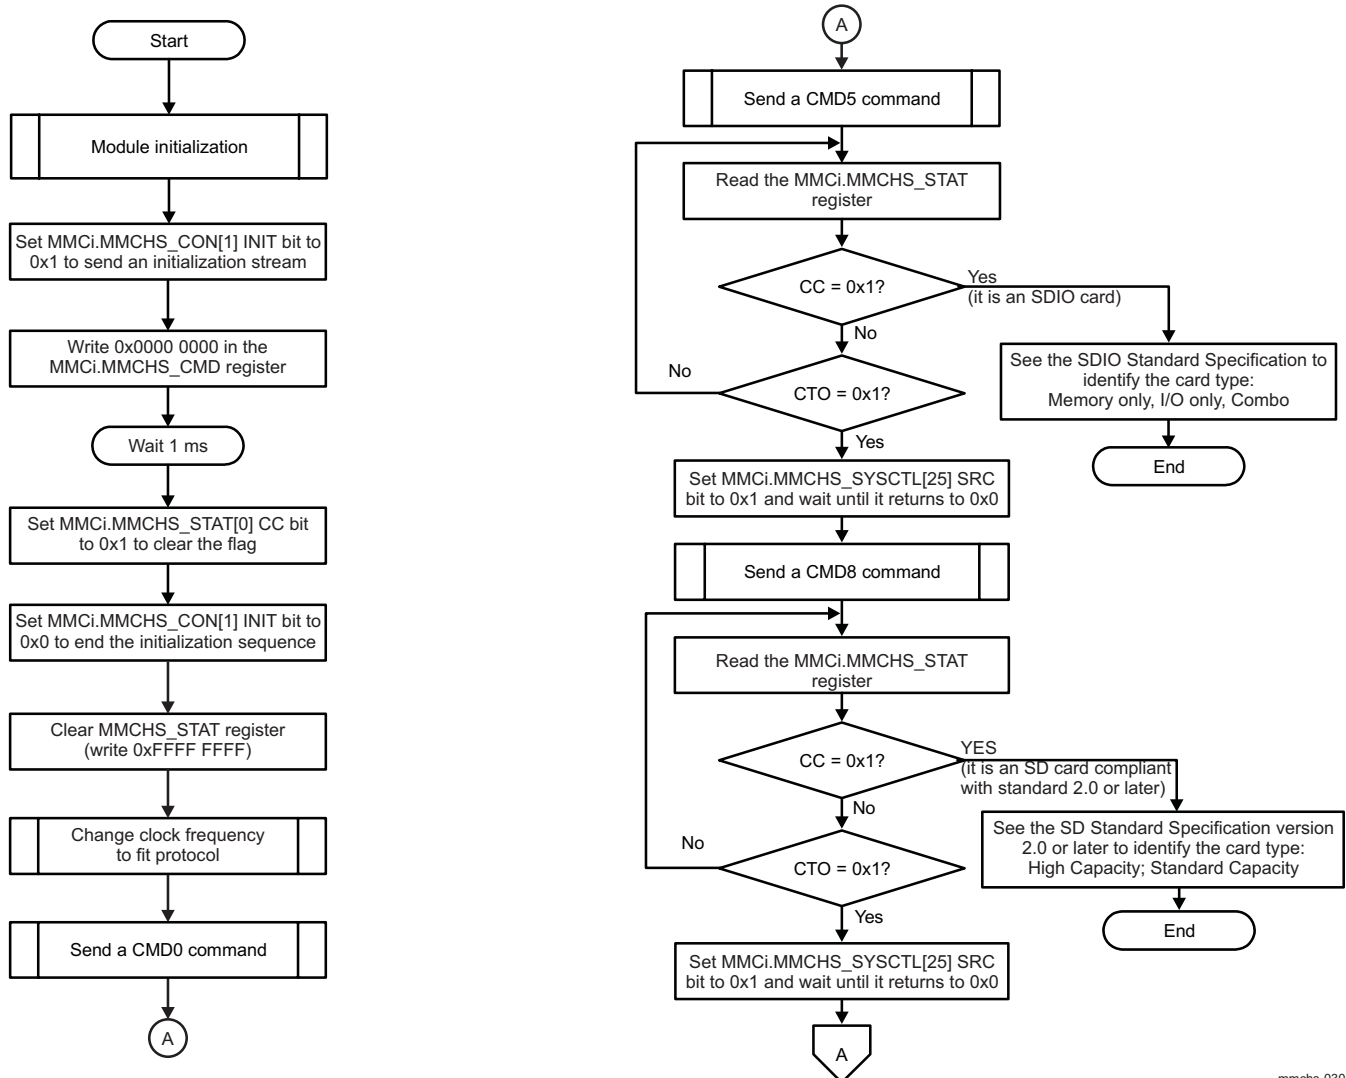

The MMC/SD/SDIO host controller performs data transfers: data to card (referred to as write transfers) and data from card (referred to as read transfers).

The host controller requires transfers to run on a block-by-block basis, rather than on a DMA burst size basis. A single DMA request (or block request interrupt) is signaled for each block. Pipelining is supported as long as the block size is less than one half of the memory buffer size.

19.5.2.1 Card Detection, Identification, and Selection

Figure 19-27 and Figure 19-28 show the card identification and selection process.

Figure 19-27. MMC/SD/SDIO Controller Card Identification and Selection - Part 1

mmchs-030

Figure 19-28. MMC/SD/SDIO Controller Card Identification and Selection - Part 2

*With OCR 0.
In case of a CMD1 with OCR=0, a second CMD1 must be sent to the card with the "negotiated" voltage.

19.5.2.2 Read/Write Transfer Flow in DMA Mode with Interrupt

Figure 19-29 describes the read and write protocol in DMA mode with interrupt signaling. Refer to Chapter 7, DMA, for more information on the DMA settings.

Figure 19-29. MMC/SD/SDIO Controller Read/Write Transfer Flow in DMA Mode with Interrupt

mmchs-032

19.5.2.3 Read/Write Transfer Flow in DMA Mode with Polling

Figure 19-30 describes the read and write protocol in DMA mode. Refer to Chapter 7, DMA, for more information on the DMA settings.

Figure 19-30. MMC/SD/SDIO Controller Read/Write Transfer Flow in DMA Mode with Polling

mmchs-033

19.5.2.4 Read/Write Transfer Flow without DMA with Polling

Figure 19-31 describes a read/write transfer without using the DMA and with polling.

Figure 19-31. MMC/SD/SDIO Controller Read/Write Transfer Flow without DMA with Polling

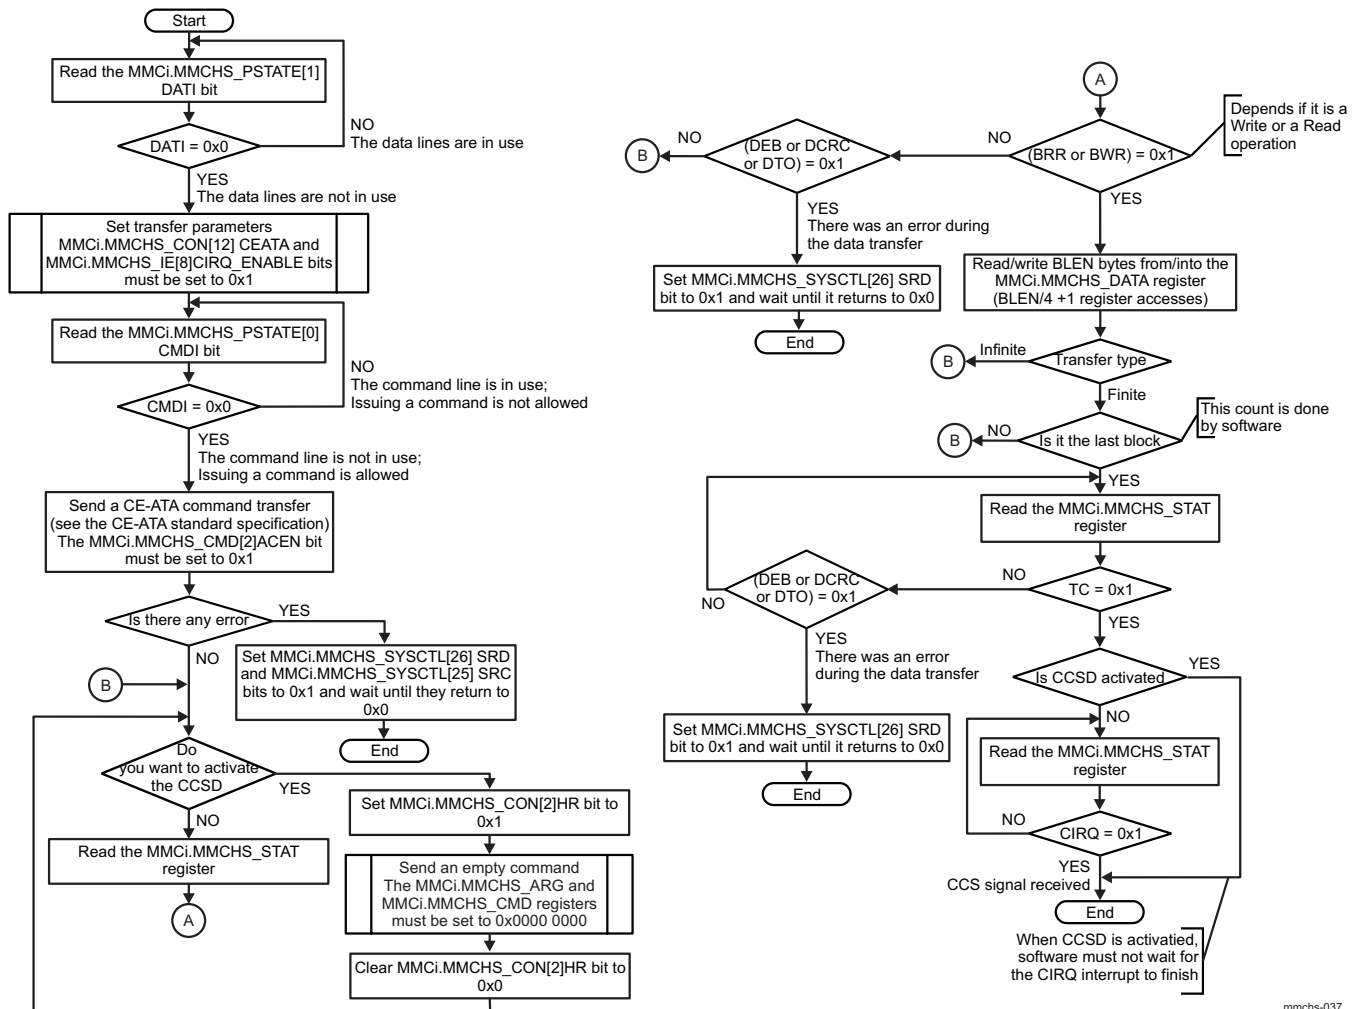

mmchs-034

19.5.2.5 Read/Write Transfer Flow in CE-ATA Mode

Figure 19-32 describes the read and write CE-ATA protocol when in Polling mode.

Figure 19-32. MMC/SD/SDIO Controller Read/Write in CE-ATA Mode

mmchs-037

CAUTION

CE-ATA protocol is only supported by MMC cards.

In CE-ATA mode, issuing command during the transfer (except a CCSD command) is not allowed

In CE-ATA mode, infinite transfers are not allowed, only finite transfers are permitted.

19.5.2.6 Suspend-Resume Flow

The suspend and resume feature is only supported by SDIO cards.

19.5.2.6.1 Suspend Flow

Figure 19-33 describes the suspend flow for SDIO cards.

Figure 19-33. MMC/SD/SDIO Controller Suspend Flow

mmchs-038

19.5.2.6.2 Resume Flow

Figure 19-34 describes the resume flow for SDIO cards.

Figure 19-34. MMC/SD/SDIO Controller Resume Flow

mmchs-039

19.5.2.7 Basic Operations - Steps Detailed

19.5.2.7.1 Command Transfer Flow

Figure 19-35 describes how to send a command to the card using polling instead of interrupts for event signaling.

Figure 19-35. MMC/SD/SDIO Controller Command Transfer Flow with Polling

Figure 19-36 describes how to send a command to the card using interrupts for event signaling.

Figure 19-36. MMC/SD/SDIO Controller Command Transfer Flow with Interrupts

19.5.2.7.2 MMCHS Clock Frequency Change

Figure 19-37 describes the different steps that allow to change the MMC/SD/SDIO output clock frequency.

Figure 19-37. MMC/SD/SDIO Controller Clock Frequency Change Flow

mmchs-042

19.5.3 MMC/SD/SDIO1 Bus Voltage Selection

The MMC/SD/SDIO1 controller can operate with two types of card voltages: 1.8 V and 3.0 V. For this reason, dual voltage pads are implemented on this interface. For technological concerns those pads must have an internal bias voltage reference to operate. The PBIAS_LITE module supplies this bias voltage, depending on the CONTROL.CONTROL_PBIAS_LITE register settings.

See , *Extended-Drain I/O Pin and PBIAS Cell*, for more information about the PBIAS_LITE cell.

, *Extended-Drain I/Os and PBIAS Cell Basic Programming Guide*, describes the steps involved in transitioning from 1.8 V to 3.0 V and from 3.0 V to 1.8 V, applicable to the MMC/SD/SDIO1 controller.

CAUTION

The BIAS voltage must be set using the procedure described in , *Extended-Drain I/Os and PBIAS Cell Basic Programming Guide*. Failure to follow this procedure can damage the MMCHS interface.

19.6 MMC/SD/SDIO Use Cases and Tips

19.6.1 MMCHS Controller Usage

19.6.1.1 Overview

The MMCHS controller is in charge of managing raw data storage in a MMC memory card. The MMCHS controller transfers data between DDRAM and MMC card. [Figure 19-38](#) gives an overview of MMCHS controller position in the use case.

Figure 19-38. Overview

mmchs_050

For the Camcorder use case, the MMCHS controller is configured to operate with the following features :

- High speed mode with a card clock frequency of 48 MHz.
- 8 data lines.

- 1.8 V and 3.0 V voltage capabilities.

MMC card power supply is not provided by the MMCHS controller itself but rather by the companion device. please refer to I2C TRM output to learn how to set these voltage levels.

Only MMC1 controller is used in this configuration. Hence this document describes the output of the test carried out with MMC1 controller.

19.6.1.2 Environment

In order to operate in the correct manner, the MMCHS controller needs the System Control Module (SCM) to be configured with the right muxing mode and with the right pull up state. The MMC card needs to be powered with the right power level and this is done with the companion device. [Figure 19-39](#) gives the environment picture of the MMCHS controller.

Figure 19-39. Environment

mmchs_F98-001

19.6.1.2.1 Command and Data Transfer Formats

When communicating with a MMC card, The MMCHS controller is always the master. The communication between the MMCHS controller and the MMC card always starts by sending a command. Both command and data transfers are started with a command.

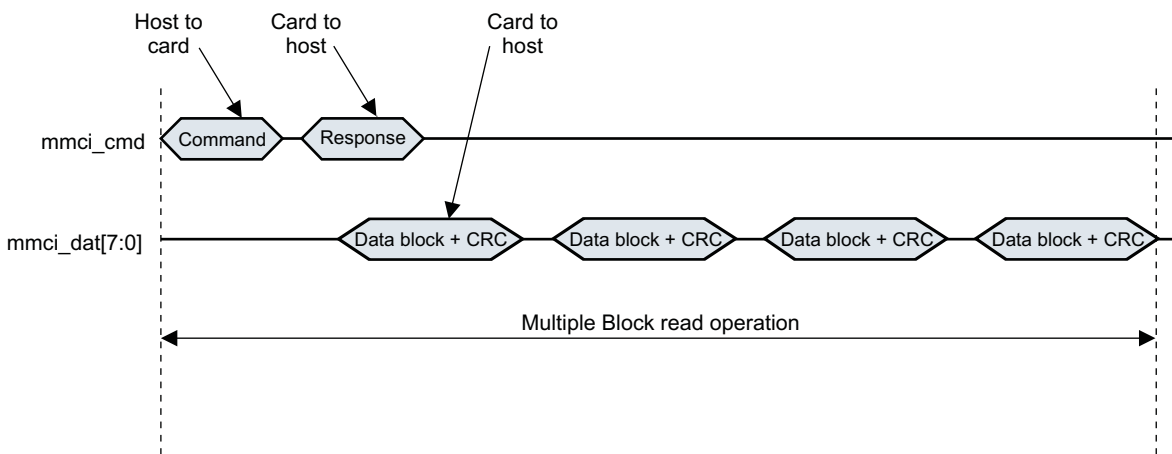

The data transfer type used by the MMCHS controller is a finite multiple block transfer. [Figure 19-40](#) illustrates a command transfer without data. [Figure 19-41](#) and [Figure 19-42](#) illustrate a multiple block transfer between the MMCHS controller and the MMC card.

Figure 19-40. Command Transfer

mmchs_052

Figure 19-41. Data Read Transfer

mmchs_053

Figure 19-42. Data Write Transfer

mmchs_054

19.6.1.3 Programming Flow

19.6.1.3.1 Initial Configuration

The initialization of the MMCHS controller is done through these steps :

1. MMCHS controller interface and functional clocks enabling.

2. MMCHS controller software reset.
3. MMCHS controller voltage capabilities initialization.
4. MMCHS controller default initialization.
5. MMCHS controller INIT procedure start.
6. MMCHS controller pre-card identification configuration.

For more information about different steps the MMCHS controller goes through during initial configuration refer to [Section 19.5, MMC/SD/SDIO Basic Programming Model](#).

19.6.1.3.1.1 MMCHS Controller Interface and Functional Clocks Enabling

To enable the interface and functional clocks of the MMCHS1 controller, the following steps must be done:

1. Enable the interface clock for the MMCHS1 controller (set the PRCM.CM_ICLKEN1_CORE[24] EN_MMCHS1).
2. Enable the functional clock for the MMCHS1 module (set the PRCM.CM_FCLKEN1_CORE[24] EN_MMCHS1).

[Table 19-8](#) shows all PRCM registers to be configured to enable interface and functional clocks for MMCHS1 controller.

Table 19-8. Register Print for the MMCHS1 controller's clocks Initialization

| Register Name | Register Address | Value | Value Description |
|----------------------|------------------|------------|---------------------------------|
| PRCM.CM_ICLKEN1_CORE | 0x4800 4A10 | 0x01000000 | MMCHS1 interface clock enabled |
| PRCM.CM_FCLKEN1_CORE | 0x4800 4A00 | 0x01000000 | MMCHS1 functional clock enabled |

19.6.1.3.1.2 MMCHS Controller Software Reset

In order to software reset the MMCHS1 controller, the following steps must be done:

1. Write 0x2 in MMCHS1.MMCHS_SYSCONFIG register.
2. Wait until MMCHS1.MMCHS_SYSSTATUS[0] RESETDONE turns 1.

| Register Name | Register Address | Value | Value Description |
|------------------------|------------------|------------|-------------------------|
| MMCHS1.MMCHS_SYSCONFIG | 0x4809 C010 | 0x00000002 | Activate software reset |
| MMCHS1.MMCHS_SYSSTATUS | 0x4809 C014 | 0x00000001 | Reset is over. |

19.6.1.3.1.3 MMCHS Controller Voltage Capabilities Initialization

MMCHS1 controller's voltage capabilities should be set in MMCHS1.MMCHS_CAPA. Refer to [Table 19-9](#).

Table 19-9. MMCHS Controller Voltage Capabilities Initialization

| Register Name | Register Address | Value | Value Description |
|-------------------|------------------|----------------------------|--|
| MMCHS1.MMCHS_CAPA | 0x4809 C140 | current_value 0x06000000 | Activate VS18 and VS30 in MMCHS_CAPA register. |

19.6.1.3.1.4 MMCHS Controller Default Initialization

Before sending any command, the MMCHS controller is configured with default values :

1. Default voltage support is set to 1.8 v in MMCHS1.MMCHS_HCTL[11:9] SDVS.
2. MMC bus is set to open drain in MMCHS1.MMCHS_CON[0] OD.
3. MMC data bus width is set to 1 in MMCHS1.MMCHS_HCTL[1] DTW.
4. MMC Card's power is off.
5. MMC Card's clock is on in MMCHS1.MMCHS_SYSCTL[0] ICE and MMCHS1.MMCHS_SYSCTL[2] CEN.

6. MMCHS controller bus power up in MMCHS1.MMCHS_HCTL[8] SDBP.
7. MMC card's clock frequency is set to 150 KHz in MMCHS1.MMCHS_SYSCTL[15:6] CLKD.

Table 19-10 shows the values that should be written in the right register pool.

Table 19-10. MMC Controller Default Initialization Values

| Register Name | Register Address | Value | Value Description |
|---------------------|------------------|------------|--|
| MMCHS1.MMCHS_HCTL | 0x4809C128 | 0x00000b00 | data bus width = 1, voltage = 1.8v, MMC bus power is on (not card's power) |
| MMCHS1.MMCHS_SYSCTL | 0x4809C12C | 0x0000a007 | card's clock enable and card's clock frequency divider. |
| MMCHS1.MMCHS_CON | 0x4809C02C | 0x00000001 | Set MMC bus mode to open drain. |

A small notice about MMCHS1.MMCHS_HCTL. Even if the value written in it is 0x00000b00, the value read from it is equal to 0x00000a00. This is due to the fact that the MMCHS controller is not in a card state mode which sets automatically MMCHS_HCTL[8] SDBP bit to 0.

19.6.1.3.1.5 MMCHS Controller INIT Procedure Start

Prior to issuing any command, the MMCHS controller has to execute a special INIT procedure. The MMCHS controller has to generate a clock during 1ms. During the INIT procedure, the MMCHS controller generates 80 clock periods. In order to keep the 1ms gap, the MMCHS controller should be configured to generate a clock whose frequency is smaller or equal to 80 KHz.

The INIt procedure is executed by setting MMCHS1.MMCHS_CON[1] INIT bit field to 1 and by sending a dummy command, writing 0x00000000 in MMCHS1.MMCHS_CMD register.

Table 19-11 shows the values that should be written in the right register pool.

Table 19-11. MMCHS Controller INIT Procedure Start

| Register Name | Register Address | Value | Value Description |
|------------------|------------------|----------------------------|------------------------------------|
| MMCHS1.MMCHS_CON | 0x4809C02C | current_value 0x00000002 | sets MMCHS1.MMCHS_CON[1] INIT to 1 |
| MMCHS1.MMCHS_CMD | 0x4809C10C | 0x00000000 | sends dummy command. |

19.6.1.3.1.6 MMCHS Controller Pre-card Identification Configuration

Before card identification starts, the MMCHS controller's configuration should change. MMC card's clock should now be 400 KHz according to MMC system spec requirements. Table 19-12 shows the values that should be written in the right register pool.

Table 19-12. MMCHS Controller Pre-Card Identification Configuration

| Register Name | Register Address | Value | Value Description |
|---------------------|------------------|------------|--|
| MMCHS1.MMCHS_HCTL | 0x4809C128 | 0x00000b00 | data bus width = 1, voltage = 1.8v, MMC bus power is on (not card's power) |
| MMCHS1.MMCHS_SYSCTL | 0x4809C12C | 0x00003C07 | card's clock enable and card's clock frequency divider. |
| MMCHS1.MMCHS_CON | 0x4809C02C | 0x00000001 | Set MMC bus mode to open drain. |

19.6.1.3.2 MMC Card Identification

MMC card identification is performed by issuing many MMC commands. Each command imposes certain configuration values in a pool of registers. The status of command transfer is read in MMCHS1.MMCHS_STAT register and command response if any is read from MMCHS1.MMCHS_RSP10, MMCHS1.MMCHS_RSP32, MMCHS1.MMCHS_RSP54 and MMCHS1.MMCHS_RSP76.

This TRM output describes a use case where interrupts are used to signal MMCHS controller status changes.

For more details about the card identification sequence, please refer to [Section 19.5 MMC/SD/SDIO Basic Programming Model](#).

19.6.1.3.2.1 Sending CMD0

This command resets the MMC card (see [Table 19-13](#)).

Table 19-13. Sending CMD0

| Register Name | Register Address | Value | Value Description |
|------------------|------------------|------------|---|
| MMCHS1.MMCHS_CON | 0x4809C02C | 0x00000001 | MMC bus is still in open drain state for broadcast. |
| MMCHS1.MMCHS_IE | 0x4809C134 | 0x00040001 | Enables CC and CEB events to occur. |
| MMCHS1.MMCHS_ISE | 0x4809C138 | 0x00040001 | Enables CC and CEB interrupts to rise. |
| MMCHS1.MMCHS_CMD | 0x4809C10C | 0x00000000 | Sends CMD0 whose opcode is 0. |

19.6.1.3.2.2 Sending CMD5

This command asks a SDIO card to send its operating conditions (see [Table 19-14](#)). This command will fail if there is no SDIO card. In case of success the response will be in MMCHS1.MMCHS_RSP10 register.

Table 19-14. Sending CMD5

| Register Name | Register Address | Value | Value Description |
|------------------|------------------|------------|--|
| MMCHS1.MMCHS_CON | 0x4809C02C | 0x00000001 | MMC bus is still in open drain state for broadcast. |
| MMCHS1.MMCHS_IE | 0x4809C134 | 0x00050001 | Enables CC, CTO and CEB events to occur. |
| MMCHS1.MMCHS_ISE | 0x4809C138 | 0x00050001 | Enables CC, CTO and CEB interrupts to rise. |
| MMCHS1.MMCHS_CMD | 0x4809C10C | 0x05020000 | Sends CMD5 whose opcode is 5 and response type is 48 bits. |

19.6.1.3.2.2.1 Sending CMD8

This command asks a SD card version 2.X to send its operating conditions (see [Table 19-15](#)). This command will fail if there is no SD card version 2.X. In case of success the response will be in MMCHS1.MMCHS_RSP10 register.

Table 19-15. Sending CMD8

| Register Name | Register Address | Value | Value Description |
|------------------|------------------|------------|--|
| MMCHS1.MMCHS_CON | 0x4809C02C | 0x00000001 | MMC bus is still in open drain state for broadcast. |
| MMCHS1.MMCHS_IE | 0x4809C134 | 0x100f0001 | Enables CERR, CIE, CCRC, CC, CTO and CEB events to occur. |
| MMCHS1.MMCHS_ISE | 0x4809C138 | 0x100f0001 | Enables CERR, CIE, CCRC, CC, CTO and CEB interrupts to rise. |
| MMCHS1.MMCHS_CMD | 0x4809C10C | 0x81a0000 | Sends CMD8 whose opcode is 8, response type is 48 bits with CICE and CCCE enabled. |

19.6.1.3.2.3 Sending CMD55

This is a special command used to prevent the card that the following command is going to be an application one (see [Table 19-16](#)). This is used to prepare the issuing of ACMD41 (opcode = 41) that usually asks a SD card version 1.X to send its operating conditions. If no SD card version 1.X is connected to the MMCHS controller this command will fail. In case of success, the response will be received in MMCHS1.MMCHS_RSP10 register.

Table 19-16. Sending CMD55

| Register Name | Register Address | Value | Value Description |
|------------------|------------------|------------|--|
| MMCHS1.MMCHS_CON | 0x4809C02C | 0x00000001 | MMC bus is still in open drain state for broadcast. |
| MMCHS1.MMCHS_IE | 0x4809C134 | 0x100f0001 | Enables CERR, CIE, CCRC, CC, CTO and CEB events to occur. |
| MMCHS1.MMCHS_ISE | 0x4809C138 | 0x100f0001 | Enables CERR, CIE, CCRC, CC, CTO and CEB interrupts to rise. |
| MMCHS1.MMCHS_CMD | 0x4809C10C | 0x371a0000 | Sends CMD55 whose opcode is 55, response type is 48 bits with CICE and CCCE enabled. |

19.6.1.3.2.4 Sending CMD1

Once the card response is available in register MMCHS1.MMCHS_RSP10, the software is responsible to compare Card OCR and Host OCR, and then send a second CMD1 command with the cross-checked OCR.

This way, the card is notified of the Operating Voltage to work with.

Table 19-17. Sending CMD1

| Register Name | Register Address | Value | Value Description |
|------------------|------------------|------------|--|
| MMCHS1.MMCHS_CON | 0x4809C02C | 0x00000001 | MMC bus is still in open drain state for broadcast. |
| MMCHS1.MMCHS_IE | 0x4809C134 | 0x00050001 | Enables CC, CTO and CEB events to occur. |
| MMCHS1.MMCHS_ISE | 0x4809C138 | 0x00050001 | Enables CC, CTO and CEB interrupts to rise. |
| MMCHS1.MMCHS_CMD | 0x4809C10C | 0x01020000 | Sends CMD1 whose opcode is 1 and response type is 48 bits. |

Once the card response is available in register MMCHS1.MMCHS_RSP10, the software should compare card OCR and host OCR, and then send a second CMD1 command with the cross-checked OCR. This tells the card what operating voltage to use.

19.6.1.3.2.5 Sending CMD2

This command asks the MMC card to send its CID register's content (see [Table 19-18](#)). The response is 128 bit wide and is received in MMCHS1.MMCHS_RSP10, MMCHS1.MMCHS_RSP32, MMCHS1.MMCHS_RSP54 and MMCHS1.MMCHS_RSP76 registers.

Table 19-18. Sending CMD2

| Register Name | Register Address | Value | Value Description |
|------------------|------------------|------------|---|
| MMCHS1.MMCHS_CON | 0x4809C02C | 0x00000001 | MMC bus is still in open drain state for broadcast. |
| MMCHS1.MMCHS_IE | 0x4809C134 | 0x00070001 | Enables CERR, CIE, CCRC, CC, CTO and CEB events to occur. |

Table 19-18. Sending CMD2 (continued)

| Register Name | Register Address | Value | Value Description |
|------------------|------------------|------------|--|
| MMCHS1.MMCHS_ISE | 0x4809C138 | 0x00070001 | Enables CERR, CIE, CCRC, CC, CTO and CEB interrupts to rise. |
| MMCHS1.MMCHS_CMD | 0x4809C10C | 0x02090000 | Sends CMD2 whose opcode is 2, response type is 136 bits with CCCE enabled. |

19.6.1.3.2.6 Sending CMD3

This command sets MMC card address (see [Table 19-19](#)). Useful when MMCHS controller switches to addressed mode.

Table 19-19. Sending CMD3

| Register Name | Register Address | Value | Value Description |
|------------------|------------------|------------|---|
| MMCHS1.MMCHS_CON | 0x4809C02C | 0x00000001 | MMC bus is still in open drain state for broadcast. |
| MMCHS1.MMCHS_IE | 0x4809C134 | 0x100f0001 | Enables CERR, CIE, CCRC, CC, CTO and CEB events to occur. |
| MMCHS1.MMCHS_ISE | 0x4809C138 | 0x100f0001 | Enables CERR, CIE, CCRC, CC, CTO and CEB interrupts to rise. |
| MMCHS1.MMCHS_CMD | 0x4809C10C | 0x031a0000 | Sends CMD3 whose opcode is 3, response type is 48 bits with CICE and CCCE enabled. |
| MMCHS1.MMCHS_ARG | 0x4809C108 | 0x00010000 | MMCHS_ARG register carries MMC card's address. We choose to assign address 1 any other 16 bit wide value is valid. |

19.6.1.3.3 MMC Bus Setting Change After Card Identification

After CMD3 command transfer is completed successfully, an auto-negotiation on voltage value an start. This is the frontier when the MMCHS controller should switch from identification mode to transfer mode. This impacts the controller in a way that it should change its bus state from open drain to push-pull. [Table 19-20](#) gives several registers and their values.

Table 19-20. MMC Bus Setting Change Table

| Register Name | Register Address | Value | Value Description |
|---------------------|------------------|------------|---|
| MMCHS1.MMCHS_CON | 0x4809C02C | 0x00000000 | Bus is now in push-pull mode. |
| MMCHS1.MMCHS_HCTL | 0x4809C128 | 0x00000B00 | Bus power is on, 1.8V is selected. |
| MMCHS1.MMCHS_SYSCTL | 0x4809C12C | 0x00003C07 | MMCHS controller's internal clock is stable and enabled, MMC card's clock is on. Divider value is 240 which means that MMCHS controller is still supplying a 400 KHz clock. |

19.6.1.3.4 Reading the CSD Register of a MMC Card

After settling on a voltage value, additional information must be read from the MMC card. This data is stored in MMC card CSD register. The card sends CSD register content after receiving CMD9 command. The CSD register holds important information on the card, MMC system specification version support, maximum clock speed support, memory capacity, minimum block length, read and write transfer latency timings.

19.6.1.3.4.1 Sending CMD9

This command asks the card to send its csd register's content (see [Table 19-21](#)). The 136 bit (128 bits are valid payload) response is received in MMCHS1.MMCHS_RSP10, MMCHS1.MMCHS_RSP32, MMCHS1.MMCHS_RSP54 and MMCHS1.MMCHS_RSP76 registers. CMD9 is an addressed command which means that card's address must be written in MMCHS1.MMCHS_ARG register before the command is issued.

Table 19-21. Sending CMD9

| Register Name | Register Address | Value | Value Description |
|------------------|------------------|------------|--|
| MMCHS1.MMCHS_CON | 0x4809C02C | 0x00000000 | MMC bus is in push-pull mode. |
| MMCHS1.MMCHS_IE | 0x4809C134 | 0x00070001 | Enables CCRC, CC, CTO and CEB events to occur. |
| MMCHS1.MMCHS_ISE | 0x4809C138 | 0x00070001 | Enables CCRC, CC, CTO and CEB interrupts to rise. |
| MMCHS1.MMCHS_CMD | 0x4809C10C | 0x09090000 | Sends CMD9 whose opcode is 9, response type is 136 bits with CCCE enabled. |
| MMCHS1.MMCHS_ARG | 0x4809C108 | 0x00010000 | MMCHS_ARG register carries MMC card's address. We choose to assign address 1 any other 16 bit wide value is valid. |

After receiving and parsing CMD9 response, MMC card clock speed must change to take advantage to card's maximum speed. This has an impact on MMC bus as we should perform a clock frequency change. At this stage the maximum clock frequency will be 20 MHz (please refer to MMC system specification from www.mmca.org).

Clock frequency change procedure is performed in several steps. Please refer to [Section 19.5](#), MMC/SD/SDIO Basic Programming Model, [Section 19.5.2.7.2](#), *MMCHS Clock Frequency Change*.

[Table 19-22](#) shows the value written in MMCHS1.MMCHS_SYSCTL register.

Table 19-22. MMCHS_SYSCTL Value

| Register Name | Register Address | Value | Value Description |
|---------------------|------------------|------------|---|
| MMCHS1.MMCHS_SYSCTL | 0x4809C12C | 0x00000147 | MMCHS controller's internal clock is stable and enabled, MMC card's clock is on. Divider value is 5 which means that MMCHS controller is supplying a 19.2 MHz clock < 20 MHz. |

Another important parameter read from CSD register is MMC system specification version. If this parameter points to a value greater than or equal to 4, the MMC card is capable of a speed up to 52 MHz and a bus width up to 8 (1, 4 or 8 are the possible options). In order to enable these two extra features, MMCHS controller must issue a CMD6 command with specific argument.

A CMD6 command is issued in the data transfer mode after MMC card is selected. MMC card selection consists of sending CMD7 command with MMC card's address in command argument.

[Table 19-23](#) shows the set of register impacted by CMD7 issue action.

Table 19-23. Sending CMD7

| Register Name | Register Address | Value | Value Description |
|------------------|------------------|------------|--|
| MMCHS1.MMCHS_CON | 0x4809C02C | 0x00000000 | MMC bus is in push-pull mode. |
| MMCHS1.MMCHS_IE | 0x4809C134 | 0x100f0001 | Enables CERR, CIE, CCRC, CC, CTO and CEB events to occur. |
| MMCHS1.MMCHS_ISE | 0x4809C138 | 0x100f0001 | Enables CERR, CIE, CCRC, CC, CTO and CEB interrupts to rise. |

Table 19-23. Sending CMD7 (continued)

| Register Name | Register Address | Value | Value Description |
|------------------|------------------|------------|--|
| MMCHS1.MMCHS_CMD | 0x4809C10C | 0x071a0000 | Sends CMD7 whose opcode is 7, response type is 48 bits with CICE and CCCE enabled. |
| MMCHS1.MMCHS_ARG | 0x4809C108 | 0x00010000 | MMCHS_ARG register carries MMC card's address. We choose to assign address 1 any other 16 bit wide value is valid. |

After a CMD7 transfer is complete, the MMC card is ready to receive a CMD6 command. CMD6 command is used to write a byte in MMC card extended CSD register (ext_csd). It is an IO access function. There are two write actions, the first one enables a specific data bus width in the card. For our use case we used maximum data bus width 8. The second one enables high speed feature in the card.

19.6.1.3.4.1.1 Setting Data Bus Width to 8

Table 19-24 shows the set of registers impacted by issuing CMD6.

Table 19-24. Setting Data Bus Width with CMD6

| Register Name | Register Address | Value | Value Description |
|------------------|------------------|------------|--|
| MMCHS1.MMCHS_CON | 0x4809C02C | 0x00000000 | MMC bus is in push-pull mode. |
| MMCHS1.MMCHS_IE | 0x4809C134 | 0x100f0001 | Enables CERR, CIE, CCRC, CC, CTO and CEB events to occur. |
| MMCHS1.MMCHS_ISE | 0x4809C138 | 0x100f0001 | Enables CERR, CIE, CCRC, CC, CTO and CEB interrupts to rise. |
| MMCHS1.MMCHS_CMD | 0x4809C10C | 0x061b0000 | Sends CMD6 whose opcode is 6, response type is 48 bits with busy, with CICE and CCCE enabled. |
| MMCHS1.MMCHS_ARG | 0x4809C108 | 0x03b70200 | $(3 \ll 24) (\text{byte_address} \ll 16) (\text{byte_value} \ll 8)$. byte_address is the byte address in ext_csd register. |

After issuing CMD6 completes successfully and MMC card leaves busy state, MMCHS controller should change its data bus width. This is done by changing MMCHS1.MMCHS_CON configuration value.

Table 19-25. MMCHS_CON Value

| Register Name | Register Address | Value | Value Description |
|------------------|------------------|------------|--|
| MMCHS1.MMCHS_CON | 0x4809C02C | 0x00000020 | MMCHS controller's data bus width is set to 8. |

19.6.1.3.4.1.2 Enable High Speed Feature

Table 19-26 shows the set of registers impacted by issuing CMD6 issuing.

Table 19-26. Enabling High Speed with CMD6

| Register Name | Register Address | Value | Value Description |
|------------------|------------------|------------|---|
| MMCHS1.MMCHS_CON | 0x4809C02C | 0x00000020 | MMC bus is in push-pull mode. DW8 is enabled. |
| MMCHS1.MMCHS_IE | 0x4809C134 | 0x100f0001 | Enables CERR, CIE, CCRC, CC, CTO and CEB events to occur. |

Table 19-26. Enabling High Speed with CMD6 (continued)

| Register Name | Register Address | Value | Value Description |
|------------------|------------------|------------|--|
| MMCHS1.MMCHS_ISE | 0x4809C138 | 0x100f0001 | Enables CERR, CIE, CCRC, CC, CTO and CEB interrupts to rise. |
| MMCHS1.MMCHS_CMD | 0x4809C10C | 0x061b0000 | Sends CMD6 whose opcode is 6, response type is 48 bits with busy, with CICE and CCCE enabled. |
| MMCHS1.MMCHS_ARG | 0x4809C108 | 0x03b90100 | $(3 \ll 24) (\text{byte_address} \ll 16) (\text{byte_value} \ll 8)$. byte_address is the byte address in ext_csd register. |

After issuing CMD6 completes successfully and MMC card leaves busy state, MMCHS controller should now change its output clock to bring it to 48 MHz. 52 MHz, max frequency value supported by MMC card version 4 and above, is not supported because 96 MHz, MMCHS controller functional clock, is not a multiple of 52 MHz. We fall off to 48 MHz.

Table 19-27. MMCHS_SYSCTL Value

| Register Name | Register Address | Value | Value Description |
|---------------------|------------------|------------|--|
| MMCHS1.MMCHS_SYSCTL | 0x4809C12C | 0x00000087 | MMCHS controller's internal clock is stable and enabled, MMC card's clock is on. Divider value is 2 which means that MMCHS controller is supplying a 48 MHz clock. |

19.6.1.3.5 MMC Write Transfer

Either data read or data write transfer uses DMA controller to perform memory (DDRAM) to/from MMCHS controller transfers. The DMA part is not described in this chapter, it is described in [Chapter 7, DMA](#).

Before any data transfer begins, the card must selected by issuing CMD7 command ([Table 19-23](#)).

A write transfer is a finite multiple block write transfer. In order to perform a write transfer, the following steps must be performed.

19.6.1.3.5.1 Send CMD16

Issuing CMD16 allows to set the block length. For our use case we decided to use a static block length of 512 bytes. The block length value is passed to the MMC card via MMCHS1.MMCHS_ARG register. The registers impacted by this operation are as follows:

Table 19-28. Setting Block Length

| Register Name | Register Address | Value | Value Description |
|------------------|------------------|------------|---|
| MMCHS1.MMCHS_CON | 0x4809C02C | 0x00000020 | MMC bus is in push-pull mode. DW8 is enabled. |
| MMCHS1.MMCHS_IE | 0x4809C134 | 0x100f0001 | Enables CERR, CIE, CCRC, CC, CTO and CEB events to occur. |
| MMCHS1.MMCHS_ISE | 0x4809C138 | 0x100f0001 | Enables CERR, CIE, CCRC, CC, CTO and CEB interrupts to rise. |
| MMCHS1.MMCHS_CMD | 0x4809C10C | 0x101a0000 | Sends CMD16 whose opcode is 16, response type is 48 bits, with CICE and CCCE enabled. |
| MMCHS1.MMCHS_ARG | 0x4809C108 | 0x00000200 | Block length is 512 = 0x200 |

19.6.1.3.5.2 Send CMD23

Issuing CMD23 allows to set the number of how many 512-byte blocks the MMC card should expect from the MMCHS controller. The number of blocks is passed to MMC card via MMCHS1.MMCHS_ARG register. The registers impacted by this operation are as follows:

Table 19-29. Setting Number of Blocks

| Register Name | Register Address | Value | Value Description |
|------------------|------------------|------------|---|
| MMCHS1.MMCHS_CON | 0x4809C02C | 0x00000020 | MMC bus is in push-pull mode. DW8 is enabled. |
| MMCHS1.MMCHS_IE | 0x4809C134 | 0x100f0001 | Enables CERR, CIE, CCRC, CC, CTO and CEB events to occur. |
| MMCHS1.MMCHS_ISE | 0x4809C138 | 0x100f0001 | Enables CERR, CIE, CCRC, CC, CTO and CEB interrupts to rise. |
| MMCHS1.MMCHS_CMD | 0x4809C10C | 0x171a0000 | Sends CMD23 whose opcode is 23, response type is 48 bits, with CICE and CCCE enabled. |
| MMCHS1.MMCHS_ARG | 0x4809C108 | 0x00000008 | Number of 512-byte blocks in 4 KB buffer is 8. |

19.6.1.3.5.3 Send CMD25

Issuing CMD25 starts the finite, multiple block write transfer. Before the transfer starts, DMA controller should be configured for this operation. For more details about DMA configuration please refer to [Chapter 7, DMA](#).

Table 19-30. CMD25 Issuing

| Register Name | Register Address | Value | Value Description |
|------------------|------------------|------------|--|
| MMCHS1.MMCHS_CON | 0x4809C02C | 0x00000020 | MMC bus is in push-pull mode. DW8 is enabled. |
| MMCHS1.MMCHS_IE | 0x4809C134 | 0x107f0013 | Enables CERR, CIE, CCRC, CC, TC, BWR, CTO, DTO, DCRC, DEB and CEB events to occur. |
| MMCHS1.MMCHS_ISE | 0x4809C138 | 0x107f0013 | Enables CERR, CIE, CCRC, CC, TC, BWR, CTO, DTO, DCRC, DEB and CEB interrupts to rise. |
| MMCHS1.MMCHS_CMD | 0x4809C10C | 0x193a0023 | Sends CMD25 whose opcode is 25, response type is 48 bits, with CICE, DP, MSBS, BCE, DE and CCCE enabled. |
| MMCHS1.MMCHS_ARG | 0x4809C108 | 0x00000000 | Not used. |
| MMCHS1.MMCHS_BLK | 0x4809C104 | 0x00080200 | (number_blocks << 16) (block_length) |

19.6.1.3.6 MMC Read Transfer

Either data read or data write transfer uses DMA controller to perform memory (DDRAM) to/from MMCHS controller transfers. The DMA part is not described in this document, it is described in [Chapter 7, DMA](#).

Before any data transfer begins, the card must selected by issuing CMD7 command ([Table 19-23](#)).

A read transfer is a finite multiple block write transfer. In order to perform a read transfer, the following steps must be performed.

19.6.1.3.6.1 Send CMD16

Issuing CMD16 allows to set the block length. For our use case we decided to use a static block length of 512 bytes. The block length value is passed to the MMC card via MMCHS1.MMCHS_ARG register. See [Table 19-28](#).

19.6.1.3.6.2 Send CMD23

Issuing CMD23 allows to set the number of how many 512-byte blocks the MMC card should expect from the MMCHS controller. The number of blocks is passed to MMC card via MMCHS1.MMCHS_ARG register. See [Table 19-29](#).

19.6.1.3.6.3 Send CMD18

Issuing CMD18 starts the finite, multiple block read transfer. Before the transfer starts, DMA controller should be configured for this operation. For more details about DMA configuration please refer to [Chapter 7, DMA](#).

Table 19-31. CMD18 Issuing

| Register Name | Register Address | Value | Value Description |
|------------------|------------------|------------|--|
| MMCHS1.MMCHS_CON | 0x4809C02C | 0x00000020 | MMC bus is in push-pull mode. DW8 is enabled. |
| MMCHS1.MMCHS_IE | 0x4809C134 | 0x107f0023 | Enables CERR, CIE, CCRC, CC, TC, BRR, CTO, DTO, DCRC, DEB and CEB events to occur. |
| MMCHS1.MMCHS_ISE | 0x4809C138 | 0x107f0023 | Enables CERR, CIE, CCRC, CC, TC, BRR, CTO, DTO, DCRC, DEB and CEB interrupts to rise. |
| MMCHS1.MMCHS_CMD | 0x4809C10C | 0x123a0033 | Sends CMD18 whose opcode is 18, response type is 48 bits, with CICE, DP, MSBS, BCE, DE, DDIR and CCCE enabled. |
| MMCHS1.MMCHS_ARG | 0x4809C108 | 0x00000000 | Not used. |
| MMCHS1.MMCHS_BLK | 0x4809C104 | 0x00080200 | (number_blocks << 16) (block_length) |

19.6.1.3.7 Dealing with High Capacity Cards

Unlike standard-capacity cards, memory addressing mode for high-capacity cards (SDHC and HC MMC) is in 512-byte block format instead of byte format. This means that byte and partial accesses are not allowed with high-capacity cards.

The 32-bit wide argument configured in the MMCHS_ARG register and sent in data transfer commands CMD17, CMD18, CMD24, and CMD25, carries the block index where the read/write should start and not the 32-bit byte address.

For high-capacity cards, the block size is fixed at 512 bytes. Any data transfer, when the data bus is involved, must be a multiple of 512 bytes.

The number of blocks for a high-capacity card, which determines the capacity of the card block_count x 512 bytes, is accessible through field C_SIZE in the card's CSD register version 2.0 for SD cards, or through the SEC_COUNT field in the card's EXT_CSD register for MMC cards compliant with MMC specification version 4.x.

To write/read a packet whose size is less than 512 bytes to/from a high-capacity card, write/read the whole 512-byte block that contains the range of bytes to modify/read.

19.7 MMC/SD/SDIO Register Manual

19.7.1 MMC/SD/SDIO Instance Summary

Table 19-32 lists the instance summary.

Table 19-32. Instance Summary

| Module Name | Base Address | Size |
|-------------|--------------|-----------|
| MMCHS1 | 0x4809 C000 | 512 bytes |
| MMCHS2 | 0x480B 4000 | 512 bytes |
| MMCHS3 | 0x480A D000 | 512 bytes |

19.7.2 MMC/SD/SDIO Registers Mapping Summary

Table 19-33 lists the MMC/SD/SDIO1 to MMC/SD/SDIO3 registers. Table 19-34 through Table 19-80 describe the register bits.

CAUTION

The MMC/SD/SDIOi registers are limited to 32-bit data accesses. 16-bit and 8-bit are not allowed and can corrupt register content.

Table 19-33. MMC/SD/SDIO1 Register Summary

| Register | Type | Register Width (Bits) | Offset Address | MMCHS1 Physical Address | MMCHS2 Physical Address | MMCHS3 Physical Address |

| Bits | Field Name | Description | Type | Reset |
|-------|------------|---|------|----------|
| 31:17 | Reserved | Reserved bit field. Do not write any value. Reads return 0. | R | 0x000000 |
| 16 | OBI | Out-Of-Band Interrupt (OBI) data value. | RW | 0 |
| | | 0x0: The Out-of-Band Interrupt pin is driven low. | | |
| | | 0x1: The Out-of-Band Interrupt pin is driven high. | | |
| 15 | SDCD | Card detect input signal (SDCD) data value | R | 0 |
| | | 0x0: The card detect pin is driven low. | | |
| | | 0x1: The card detect pin is driven high. | | |

| Bits | Field Name | Description | Type | Reset |
|------|------------|---|------|-------|
| 14 | SDWP | Write protect input signal (SDWP) data value. 0x0: The write protect pin SDWP is driven low. 0x1: The write protect pin SDWP is driven high. | R | 0 |
| 13 | WAKD | Wake request output signal data value. Read 0x0: No action. Returns 0. Write 0x0: The pin SWAKEUP is driven low. Read 0x1: No action. Returns 1. Write 0x1: The pin SWAKEUP is driven high. | RW | 0 |
| 12 | SSB | Set status bit This bit must be cleared prior attempting to clear a status bit of the interrupt status register (MMCi.MMCHS_STAT). Read 0x0: No action. Returns 0. Write 0x0: Clear this SSB bit field. Writing 0 does not clear already set status bits. Read 0x1: No action. Returns 1. Write 0x1: Force to 1 all status bits of the interrupt status register (MMCi.MMCHS_STAT) only if the corresponding bit field in the Interrupt signal enable register (MMCi.MMCHS_ISE) is set. | RW | 0 |
| 11 | D7D | DAT7 input/output signal data value. Read 0x0: If MMCi.MMCHS_SYSTEST[3] DDIR bit = 1 (input mode direction), returns the value on the DAT7 line (low). If MMCi.MMCHS_SYSTEST[3] DDIR bit = 0 (output mode direction), returns 0. Write 0x0: If MMCi.MMCHS_SYSTEST[3] DDIR bit = 0 (output mode direction), the DAT7 line is driven low. If MMCi.MMCHS_SYSTEST[3] DDIR bit = 1 (input mode direction), no effect. Read 0x1: If MMCi.MMCHS_SYSTEST[3] DDIR bit = 1 (input mode direction), returns the value on the DAT7 line (high) If MMCi.MMCHS_SYSTEST[3] DDIR bit = 0 (output mode direction), returns 1. Write 0x1: If MMCi.MMCHS_SYSTEST[3] DDIR bit = 0 (output mode direction), the DAT7 line is driven high. If MMCi.MMCHS_SYSTEST[3] DDIR bit = 1 (input mode direction), no effect. | RW | 0 |
| 10 | D6D | DAT6 input/output signal data value. Read 0x0: If MMCi.MMCHS_SYSTEST[3] DDIR bit = 1 (input mode direction), returns the value on the DAT6 line (low). If MMCi.MMCHS_SYSTEST[3] DDIR bit = 0 (output mode direction), returns 0. Write 0x0: If MMCi.MMCHS_SYSTEST[3] DDIR bit = 0 (output mode direction), the DAT6 line is driven low. If MMCi.MMCHS_SYSTEST[3] DDIR bit = 1 (input mode direction), no effect. Read 0x1: If MMCi.MMCHS_SYSTEST[3] DDIR bit = 1 (input mode direction), returns the value on the DAT6 line (high) If MMCi.MMCHS_SYSTEST[3] DDIR bit = 0 (output mode direction), returns 1. Write 0x1: If MMCi.MMCHS_SYSTEST[3] DDIR bit = 0 (output mode direction), the DAT6 line is driven high. If MMCi.MMCHS_SYSTEST[3] DDIR bit = 1 (input mode direction), no effect. | RW | 0 |
| 9 | D5D | DAT5 input/output signal data value. | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|---|------|-------|
| | | <p>Read 0x0: If MMCi.MMCHS_SYSTEST[3] DDIR bit = 1 (input mode direction), returns the value on the DAT5 line (low). | | | CDP | MIT |
| | | DW8 | MODE |
| | | STR | HR |
| | | INIT | OD |

| Bits | Field Name | Description | Type | Reset |
|-------|------------|---|------|---------|
| 31:17 | Reserved | Reserved bit field. Do not write any value | R | 0x00000 |
| 16 | CLKEXTFREE | <p>External clock free running. This register is used to maintain card clock out of transfer transaction to enable slave module (for example to generate a synchronous interrupt on mmci_dat[1]). The Clock will be maintain only if MMCI.MMCHS_SYSCTL[2] CEN bit is set.</p> <p>0x0: External card clock is cut off outside active transaction period.</p> <p>0x1: External card clock is maintain even out of active transaction period only if MMCI.MMCHS_SYSCTL[2] CEN bit is set.</p> | RW | 0 |
| 15 | PADEN | <p>Control Power for MMC Lines. This register is only useful when MMC PADS contain power saving mechanism to minimize its leakage power. It works as a GPIO that directly control the ACTIVE pin of PADS. Excepted for mmci_dat[1], the signal is also combine outside the module with the dedicated power control MMCI.MMCHS_CON[11] CTPL bit.</p> <p>0x0: ADPIDLE module pin is not forced, it is automatically generated by the MMC fsms.</p> <p>0x1: ADPIDLE module pin is forced to active state.</p> | RW | 0 |
| 14 | OBIE | <p>Out-of-Band Interrupt Enable (MMC cards only). This bit enables the detection of Out-of-Band Interrupt on MMCOBI input pin. The usage of the Out-of-Band signal (OBI) is optional and depends on the system integration.</p> <p>0x0: Out-of-Band interrupt detection disabled.</p> <p>0x1: Out-of-Band interrupt detection enabled.</p> | RW | 0 |
| 13 | OBIP | <p>Out-of-Band Interrupt Polarity (MMC cards only). This bit selects the active level of the out-of-band interrupt coming from MMC cards. The usage of the Out-of-Band signal (OBI) is optional and depends on the system integration.</p> <p>0x0: active high level.</p> <p>0x1: active low level.</p> | RW | 0 |
| 12 | CEATA | <p>CE-ATA control mode (MMC cards compliant with CE-ATA): By default, this bit is set to 0. It is use to indicate that next commands are considered as specific CE-ATA commands that potentially use 'command completion' features.</p> <p>0x0: Standard MMC/SD/SDIO mode.</p> <p>0x1: CE-ATA mode. Next commands are considered as CE-ATA commands.</p> | RW | 0 |
| 11 | CTPL | <p>Control Power for mmci_dat[1] line (MMC and SD cards): By default, this bit is set to 0 and the host controller automatically disables all the input buffers outside of a transaction to minimize the leakage current.</p> <p>SDIO cards: When this bit is set to 1, the host controller automatically disables all the input buffers except the buffer of mmci_dat[1] outside of a transaction in order to detect asynchronous card interrupt on mmci_dat[1] line and minimize the leakage current of the buffers.</p> <p>0x0: Disable all the input buffers outside of a transaction.</p> <p>0x1: Disable all the input buffers except the buffer of mmci_dat[1] outside of a transaction.</p> | RW | 0 |
| 10:9 | DVAL | <p>Debounce filter value (All cards) This register is used to define a debounce period to filter the card detect input signal (SDCD). The usage of the card detect input signal (SDCD) is optional and depends on the system integration and the type of the connector housing that accommodates the card.</p> <p>0x0: 33 us debounce period.</p> <p>0x1: 231 us debounce period.</p> | RW | 0x3 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|--|------|-------|
| | | 0x2: 1 ms debounce period. 0x3: 8.4 ms debounce period. | | |
| 8 | WPP | Write protect polarity (SD and SDIO cards only) This bit selects the active level of the write protect input signal (SDWP). The usage of the write protect input signal (SDWP) is optional and depends on the system integration and the type of the connector housing that accommodates the card. 0x0: Active high level. 0x1: Active low level. | RW | 0 |
| 7 | CDP | Card detect polarity (All cards) This bit selects the active level of the card detect input signal (SDCD). The usage of the card detect input signal (SDCD) is optional and depends on the system integration and the type of the connector housing that accommodates the card. 0x0: Active high level. 0x1: Active low level. | RW | 0 |
| 6 | MIT | MMC interrupt command (Only for MMC cards.) This bit must be set to 1, when the next write access to the command register (MMCi.MMCHS_CMD) is for writing a MMC interrupt command (CMD40) requiring the command timeout detection to be disabled for the command response. 0x0: Command timeout enabled 0x1: Command timeout disabled | RW | 0 |
| 5 | DW8 | 8-bit mode MMC select For SD/SDIO cards, this bit must be set to 0. For MMC card, this bit must be set following a valid SWITCH command (CMD6) with the correct value and extend CSD index written in the argument. Prior to this command, the MMC card configuration register (CSD and EXT_CSD) must be verified for compliancy with MMC standard specification. 0x0: 1-bit or 4-bit Data width (mmci_dat[0] or mmci_dat[3:0] used, MMC, SD cards) 0x1: 8-bit Data width (mmci_dat[7:0] used, MMC cards) | RW | 0 |
| 4 | MODE | Mode select (All cards) These bits select the functional mode. 0x0: Functional mode. Transfers to the MMC/SD/SDIO cards follow the card protocol. MMC clock is enabled. MMC/SD transfers are operated under the control of the MMCi.MMCHS_CMD register. 0x1: SYSTEST mode. The signal pins are configured as general-purpose input/output and the 1024-byte buffer is configured as a stack memory accessible only by the local host or system DMA. The pins retain their default type (input, output or in-out). SYSTEST mode is operated under the control of the SYSTEST register. | RW | 0 |
| 3 | STR | Stream command (Only for MMC cards). This bit must be set to 1 only for the stream data transfers (read or write) of the adtc commands. Stream read is a class 1 command (CMD11: READ_DAT_UNTIL_STOP). Stream write is a class 3 command (CMD20: WRITE_DAT_UNTIL_STOP). 0x0: Block oriented data transfer. 0x1: Stream oriented data transfer. | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|--|------|-------|
| 2 | HR | <p>Broadcast host response (Only for MMC cards). This register is used to force the host to generate a 48-bit response for bc command type. It can be used to terminate the interrupt mode by generating a CMD40 response by the core. In order to have the host response to be generated in open drain mode, the register MMCHS_CON[OD] must be set to 1. When MMCi.MMCHS_CON[12] CEATA bit is set to 1 and MMCi.MMCHS_ARG set to 0x00000000, when writing 0x00000000 into MMCi.MMCHS_CMD register, the host controller performs a 'command completion signal disable' token (i.e. <code>mmci_cmd</code> line held to '0' during 47 cycles followed by a 1).</p> <p>0x0: The host does not generate a 48-bit response instead of a command.</p> <p>0x1: The host generates a 48-bit response instead of a command or a command completion signal disable token.</p> | RW | 0 |
| 1 | INIT | <p>Send initialization stream (All cards). When this bit is set to 1, and the card is idle, an initialization sequence is sent to the card. An initialization sequence consists of setting the <code>mmci_cmd</code> line to 1 during 80 clock cycles. The initialization sequence is mandatory - but it is not required to do it through this bit - this bit makes it easier. Clock divider (MMCi.MMCHS_SYSCTL[15:6] CLKD bits) should be set to ensure that 80 clock periods are greater than 1ms. Note: in this mode, there is no command sent to the card and no response is expected. A command complete interrupt will be generated once the initialization sequence is completed. MMCi.MMCHS_STAT[0] CC bit can be polled.</p> <p>0x0: The host does not send an initialization sequence.</p> <p>0x1: The host sends an initialization sequence.</p> | RW | 0 |
| 0 | OD | <p>Card open drain mode (Only for MMC cards). This bit must be set to 1 for MMC card commands 1, 2, 3 and 40, and if the MMC card bus is operating in open-drain mode during the response phase to the command sent. Typically, during card identification mode when the card is either in idle, ready or ident state. It is also necessary to set this bit to 1, for a broadcast host response (see Broadcast host response register MMCi.MMCHS_CON[2] HR bit)</p> <p>0x0: No Open Drain</p> <p>0x1: Open Drain or Broadcast host response</p> | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|-------|------------|---|------|--------|
| 31:16 | NBLK | <p>Blocks count for current transfer. This register is enabled when Block count Enable (MMCi.MMCHS_CMD[1] BCE bit) is set to 1 and is valid only for multiple block transfers. Setting the block count to 0 results no data blocks being transferred. Note: The host controller decrements the block count after each block transfer and stops when the count reaches zero. This register can be accessed only if no transaction is executing (i.e., after a transaction has stopped). Read operations during transfers may return an invalid value and write operation will be ignored. In suspend context, the number of blocks yet to be transferred can be determined by reading this register. When restoring transfer context prior to issuing a Resume command, The local host shall restore the previously saved block count.</p> <p>0x0: Stop count 0x1: 1 block 0x2: 2 blocks 0xFFFF: 65535 blocks</p> | RW | 0x0000 |
| 15:11 | Reserved | Reserved bit field. Do not write any value | R | 0x00 |
| 10:0 | BLLEN | <p>Transfer Block Size. This register specifies the block size for block data transfers. Read operations during transfers may return an invalid value, and write operations are ignored. When a CMD12 command is issued to stop the transfer, a read of the BLEN field after transfer completion (MMCi.MMCHS_STAT[1] TC bit set to 1) will not return the true byte number of data length while the stop occurs but the value written in this register before transfer is launched.</p> <p>0x0: No data transfer 0x1: 1 byte block length 0x2: 2 bytes block length 0x3: 3 bytes block length 0x1FF: 511 bytes block length 0x200: 512 bytes block length 0x3FF: 1023 bytes block length 0x400: 1024 bytes block length</p> | RW | 0x000 |

| Address Offset | 0x10C | | |
| Physical Address | 0x4809 C10C | Instance | MMCHS1 |
| | 0x480A D10C | | MMCHS3 |
| | 0x480B 410C | | MMCHS2 |
| Description | Command and transfer mode register MMCi.MMCHS_CMD[31:16] = the command register MMCi.MMCHS_CMD[15:0] = the transfer mode. This register configures the data and command transfers. A write into the most significant byte send the command. A write into MMCi.MMCHS_CMD[15:0] registers during data transfer has no effect. This register shall be used for any card. | | |
| Type | RW | | |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----------|------|----|----|----|----|----|----|----------|----|------|------|----------|----------|----------|----|----|----|----|----|----|----|---|---|------|------|----------|------|-----|----|---|---|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Reserved | INDX | | | | | | | CMD_TYPE | DP | CICE | CCCE | Reserved | RSP_TYPE | Reserved | | | | | | | | | | MSBS | DDIR | Reserved | ACEN | BCE | DE | | |

| Bits | Field Name | Description | Type | Reset |
|-------|------------|---|------|-------|
| 31:30 | Reserved | Reserved bit field. Do not write any value | R | 0x0 |
| 29:24 | INDX | Command index Binary encoded value from 0 to 63 specifying the command number send to card 0x0: CMD0 or ACMD0 0x1: CMD1 or ACMD1 0x3F: CMD63 or ACMD63 | RW | 0x00 |

| Bits | Field Name | Description | Type | Reset |
|-------|------------|---|------|-------|
| 23:22 | CMD_TYPE | Command type. This register specifies three types of special command: Suspend, Resume and Abort. These bits shall be set to 0b00 for all other commands. 0x0: Others Commands 0x1: Upon CMD52 "Bus Suspend" operation 0x2: Upon CMD52 "Function Select" operation 0x3: Upon CMD12 or CMD52 "I/O Abort" command | RW | 0x0 |
| 21 | DP | Data present select. This register indicates that data is present and mmci_dat line shall be used. It must be set to 0 in the following conditions: - Command using only mmci_cmd line -Command with no data transfer but using busy signal on mmci_dat[0] -Resume command 0x0: Command with no data transfer 0x1: Command with data transfer | RW | 0 |
| 20 | CICE | Command Index check enable. This bit must be set to 1 to enable index check on command response to compare the index field in the response against the index of the command. If the index is not the same in the response as in the command, it is reported as a command index error (MMCI.MMCHS_STAT[19] CIE bit set to 1) Note: The CICE bit cannot be configured for an Auto CMD12, then index check is automatically checked when this command is issued. 0x0: Index check disable 0x1: Index check enable | RW | 0 |
| 19 | CCCE | Command CRC check enable. This bit must be set to 1 to enable CRC7 check on command response to protect the response against transmission errors on the bus. If an error is detected, it is reported as a command CRC error (MMCI.MMCHS_STAT[17] CCRC bit set to 1). Note: The CCCE bit cannot be configured for an Auto CMD12, and then CRC check is automatically checked when this command is issued. 0x0: CRC7 check disable 0x1: CRC7 check enable | RW | 0 |
| 18 | Reserved | Reserved bit field. Do not write any value. | R | 0 |
| 17:16 | RSP_TYPE | Response type. This bits defines the response type of the command. 0x0: No response 0x1: Response Length 136 bits 0x2: Response Length 48 bits 0x3: Response Length 48 bits with busy after response | RW | 0x0 |
| 15:6 | Reserved | Reserved bit field. Do not write any value. | R | 0x000 |
| 5 | MSBS | Multi/Single block select. This bit must be set to 1 for data transfer in case of multi block command. For any others command this bit shall be set to 0. 0x0: Single block. If this bit is 0, it is not necessary to set the register MMCI.MMCHS_BLK[31:16] NBLK bits. 0x1: Multi block. When Block Count is disabled (MMCI.MMCHS_CMD[1] BCE bit is set to 0) in Multiple block transfers (MMCI.MMCHS_CMD[5] MSBS bit is set to 1), the module can perform infinite transfer. | RW | 0 |
| 4 | DDIR | Data transfer Direction. Select This bit defines either data transfer will be a read or a write. 0x0: Data Write (host to card) 0x1: Data Read (card to host) | RW | 0 |
| 3 | Reserved | Reserved bit field. Do not write any value. | R | 0 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|--|------|-------|
| 2 | ACEN | Auto CMD12 Enable. (SD cards only). When this bit is set to 1, the host controller issues a CMD12 automatically after the transfer completion of the last block. The Host Driver shall not set this bit to issue commands that do not require CMD12 to stop data transfer. For CE-ATA commands (MMCi.MMCHS_CON[12] CEATA bit set to 1), auto CMD12 is useless; therefore when this bit is set the mechanism to detect command completion signal, named CCS, interrupt is activated. 0x0: Auto CMD12 disable 0x1: Auto CMD12 enable or CCS detection enabled. | RW | 0 |
| 1 | BCE | Block Count Enable (Multiple block transfers only). This bit is used to enable the block count register (MMCHS_BLK[31:16] NBLK bits). When Block Count is disabled (MMCHS_CMD[1] BCE bit is set to 0) in Multiple block transfers (MMCHS_CMD[5] MSBS bits is set to 1), the module can perform infinite transfer. 0x0: Block count disabled for infinite transfer. 0x1: Block count enabled for multiple block transfer with known number of blocks | RW | 0 |
| 0 | DE | DMA Enable. This bit is used to enable DMA mode for host data access. 0x0: DMA mode disable 0x1: DMA mode enable | RW | 0 |

| | 0x480A D120 | | MMCHS3 | |
| | 0x480B 4120 | | MMCHS2 | |
| Description | Data Register This register is the 32-bit entry point of the buffer for read or write data transfers. The buffer size is 32bits x256(1024 bytes). Bytes within a word are stored and read in little endian format. This buffer can be used as two 512 byte buffers to transfer data efficiently without reducing the throughput. Sequential and contiguous access is necessary to increment the pointer correctly. Random or skipped access is not allowed. In little endian, if the local host accesses this register byte-wise or 16bit-wise, the least significant byte (bits [7:0]) must always be written/read first. The update of the buffer address is done on the most significant byte write for full 32-bit DATA register or on the most significant byte of the last word of block transfer. Example 1: Byte or 16-bit access Mbyteen[3:0]=0001 (1-byte) => Mbyteen[3:0]=0010 (1-byte) => Mbyteen[3:0]=1100 (2-bytes) OK Mbyteen[3:0]=0001 (1-byte) => Mbyteen[3:0]=0010 (1-byte) => Mbyteen[3:0]=0100 (1-byte) OK Mbyteen[3:0]=0001 (1-byte) => Mbyteen[3:0]=0010 (1-byte) => Mbyteen[3:0]=1000 (1-byte) Bad | | | |

| Bits | Field Name | Description | Type | Reset |
|-------|------------|---|------|-------|
| 31:25 | Reserved | Reserved bit field. Do not write any value. | R | 0x00 |
| 24 | CLEV | <p>mmci_cmd line signal level. This status is used to check the mmci_cmd line level to recover from errors, and for debugging. The value of this register after reset depends on the mmci_cmd line level at that time.</p> <p>Read 0x0: The mmci_cmd line level is 0. Read 0x1: The mmci_cmd line level is 1.</p> | R | - |
| 23:20 | DLEV | <p>mmci_dat[3:0] line signal level mmci_dat[3] => bit 23 mmci_dat[2] => bit 22 mmci_dat[1] => bit 21 mmci_dat[0] => bit 20 This status is used to check mmci_dat line level to recover from errors, and for debugging. This is especially useful in detecting the busy signal level from mmci_dat[0]. The value of these registers after reset depends on the mmci_dat lines level at that time.</p> | R | 0x- |
| 19 | Reserved | Reserved bit field. Do not write any value | R | 0 |
| 18 | Reserved | Reserved bit field. Do not write any value This bit is not affected by soft reset. | R | 1 |
| 17:16 | Reserved | Reserved bit field. Do not write any value The value of these bits after soft reset is 0x0. These bits will be automatically set to 0x3 after debounce time. Debounce time is fixed to 256 x32kHz clock cycles. | R | 00 |
| 15:12 | Reserved | Reserved bit field. Do not write any value | R | 0x0 |
| 11 | BRE | <p>Buffer read enable. This bit is used for non-DMA read transfers. It indicates that a complete block specified by MMCI.MMCHS_BLK[10:0] BLEN bits has been written in the buffer and is ready to be read. It is set to 0 when the entire block is read from the buffer. It is set to 1 when a block data is ready in the buffer and generates the Buffer read ready status of interrupt (MMCI.MMCHS_STAT[5] BRR bit).</p> <p>Read 0x0: Read BLEN bytes disable Read 0x1: Read BLEN bytes enable. Readable data exists in the buffer.</p> | R | 0 |
| 10 | BWE | <p>Buffer Write enable. This status is used for non-DMA write transfers. It indicates if space is available for write data.</p> <p>Read 0x0: There is no room left in the buffer to write BLEN bytes of data. Read 0x1: There is enough space in the buffer to write BLEN bytes of data.</p> | R | 0 |
| 9 | RTA | <p>Read transfer active. This status is used for detecting completion of a read transfer. It is set to 1 after the end bit of read command or by activating a continue request (MMCI.MMCHS_HCTL[17] CR bit) following a stop at block gap request. This bit is set to 0 when all data have been read by the local host after last block or after a stop at block gap request.</p> <p>Read 0x0: No valid data on the mmci_dat lines. Read 0x1: Read data transfer on going.</p> | R | 0 |
| 8 | WTA | <p>Write transfer active. This status indicates a write transfer active. It is set to 1 after the end bit of write command or by activating a continue request (MMCI.MMCHS_HCTL[17] CR bit) following a stop at block gap request. This bit is set to 0 when CRC status has been received after last block or after a stop at block gap request.</p> <p>Read 0x0: No valid data on the mmci_dat lines. Read 0x1: Write data transfer on going.</p> | R | 0 |
| 7:3 | Reserved | Reserved bit field. Do not write any value | R | 0x00 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|---|------|-------|
| 2 | DLA | <p>mmci_dat line active.</p> <p>This status bit indicates whether one of the mmci_dat line is in use. In the case of read transactions (card to host):</p> <p>This bit is set to 1 after the end bit of read command or by activating continue request MMCi.MMCHS_HCTL[17] CR bit. This bit is set to 0 when the host controller received the end bit of the last data block or at the beginning of the read wait mode. In the case of write transactions (host to card):</p> <p>This bit is set to 1 after the end bit of write command or by activating continue request MMCi.MMCHS_HCTL[17] CR bit.</p> <p>This bit is set to 0 on the end of busy event for the last block; host controller must wait 8 clock cycles with line not busy to really consider not "busy state" or after the busy block as a result of a stop at gap request.</p> <p>Read 0x0: mmci_dat Line inactive</p> <p>Read 0x1: mmci_dat Line active</p> | R | 0 |
| 1 | DATI | <p>Command inhibit (mmci_dat).</p> <p>This status bit is generated if either mmci_dat line is active (MMCi.MMCHS_PSTATE[2] DLA bit) or Read transfer is active (MMCi.MMCHS_PSTATE[9] RTA bit) or when a command with busy is issued. This bit prevents the local host to issue a command.</p> <p>A change of this bit from 1 to 0 generates a transfer complete interrupt (MMCi.MMCHS_STAT[1] TC bit).</p> <p>Read 0x0: Issuing of command using the mmci_dat lines is allowed</p> <p>Read 0x1: Issuing of command using mmci_dat lines is not allowed</p> | R | 0 |
| 0 | CMDI | <p>Command inhibit(mmci_cmd).</p> <p>This status bit indicates that the mmci_cmd line is in use.</p> <p>This bit is set to 0 when the most significant byte is written into the command register. This bit is not set when Auto CMD12 is transmitted.</p> <p>This bit is set to 0 in either the following cases:</p> <ul style="list-style-type: none"> - After the end bit of the command response, excepted if there is a command conflict error (MMCi.MMCHS_STAT[17] CCRC bit or MMCi.MMCHS_STAT[18] CEB bit set to 1) or a Auto CMD12 is not executed (MMCi.MMCHS_AC12[0] ACNE bit). - After the end bit of the command without response (MMCi.MMCHS_CMD[17:16] RSP_TYPE bits set to "00"). In case of a command data error is detected (MMCi.MMCHS_STAT[19] CTO bit set to 1), this register is not automatically cleared. <p>Read 0x0: Issuing of command using mmci_cmd line is allowed</p> <p>Read 0x1: Issuing of command using mmci_cmd line is not allowed</p> | R | 0 |

| Reserved | | | | OBWE | REM | INS | IWE | Reserved | | | | IBG | RWC | CR | SBGR | Reserved | | | SDVS | | SDBP | Reserved | | | | DTW | Reserved | | | | |

| Bits | Field Name | Description | Type | Reset |
|-------|------------|---|------|-------|
| 31:28 | Reserved | Reserved bit field. Do not write any value. | R | 0x00 |
| 27 | OBWE | Wake-up event enable for 'Out-of-Band' Interrupt. This bit enables wake-up events for 'Out-of-Band' assertion. Wakeup is generated if the wake-up feature is enabled (MMCi.MMCHS_SYSCONFIG[2] ENAWAKEUP bit). The write to this register is ignored when MMCi.MMCHS_CON[14] OBIE bit is not set. 0x0: Disable wakeup on 'Out-of-Band' Interrupt. 0x1: Enable wakeup on 'Out-of-Band' Interrupt. | RW | 0 |
| 26 | REM | Wake-up event enable on SD card removal. This bit enables wake-up events for card removal assertion. Wakeup is generated if the wake-up feature is enabled (MMCi.MMCHS_SYSCONFIG[2] ENAWAKEUP bit). 0x0: Disable wakeup on card removal. 0x1: Enable wakeup on card removal. | RW | 0 |
| 25 | INS | Wake-up event enable on SD card insertion. This bit enables wake-up events for card insertion assertion. Wakeup is generated if the wake-up feature is enabled (MMCi.MMCHS_SYSCONFIG[2] ENAWAKEUP bit). 0x0: Disable wakeup on card insertion. 0x1: Enable wakeup on card insertion. | RW | 0 |
| 24 | IWE | Wake-up event enable on SD card interrupt. This bit enables wake-up events for card interrupt assertion. Wakeup is generated if the wake-up feature is enabled (MMCi.MMCHS_SYSCONFIG[2] ENAWAKEUP bit) and enable status bit is set (MMCi.MMCHS_IE[8] CIRQ_ENABLE bit). 0x0: Disable wakeup on card interrupt 0x1: Enable wakeup on card interrupt | RW | 0 |
| 23:20 | Reserved | Reserved bit field. Do not write any value | R | 0x0 |
| 19 | IBG | Interrupt block at gap. This bit is valid only in 4-bit mode of SDIO card to enable interrupt detection in the interrupt cycle at block gap for a multiple block transfer. For MMC cards and for SD card this bit should be set to 0. 0x0: Disable interrupt detection at the block gap in 4-bit mode 0x1: Enable interrupt detection at the block gap in 4-bit mode | RW | 0 |
| 18 | RWC | Read wait control. The read wait function is optional only for SDIO cards. If the card supports read wait, this bit must be enabled, then requesting a stop at block gap (MMCi.MMCHS_HCTL[16] SBGR bit) generates a read wait period after the current end of block. Be careful, if read wait is not supported it may cause a conflict on mmc_i_dat line. | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|-------|------------|--|------|-------|
| | | 0x0: Disable Read Wait Control. Suspend/Resume cannot be supported. 0x1: Enable Read Wait Control | | |
| 17 | CR | Continue request. This bit is used to restart a transaction that was stopped by requesting a stop at block gap (MMCi.MMCHS_HCTL[16] SBGR bit). Set this bit to 1 restarts the transfer. The bit is automatically set to 0 by the host controller when transfer has restarted i.e. mmci_dat line is active (MMCi.MMCHS_PSTATE[2] DLA bit) or transferring data (MMCi.MMCHS_PSTATE[8] WTA bit). The Stop at block gap request must be disabled (MMCi.MMCHS_HCTL[16] SBGR bit =0) before setting this bit. 0x0: No affect 0x1: transfer restart | RW | 0 |
| 16 | SBGR | Stop at block gap request. This bit is used to stop executing a transaction at the next block gap. The transfer can restart with a continue request (MMCi.MMCHS_HCTL[17] CR bit) or during a suspend/resume sequence. In case of read transfer, the card must support read wait control. In case of write transfer, the host driver shall set this bit after all block data written. Until the transfer completion (MMCi.MMCHS_STAT[1] TC bit set to 1), the host driver shall leave this bit set to 1.If this bit is set, the local host shall not write to the data register (MMCi.MMCHS_DATA). 0x0: Transfer mode 0x1: Stop at block gap | RW | 0 |
| 15:12 | Reserved | Reserved bit field. Do not write any value. | R | 0x0 |
| 11:9 | SDVS | SD bus voltage select (All cards). The host driver should set these bits to select the voltage level for the card according to the voltage supported by the system (MMCi.MMCHS_CAPA[26] VS18 bit, MMcI.MMCHS_CAPA[25] VS30 bit, MMcI.MMCHS_CAPA[24] VS33 bit) before starting a transfer. 0x5: 1.8V (Typical) 0x6: 3.0V (Typical) 0x7: 3.3V (Typical) MMCHS2: This field must be set to 0x5. MMCHS3: This field must be set to 0x5. | RW | 0x0 |
| 8 | SDBP | SD bus power. Before setting this bit, the host driver shall select the SD bus voltage (MMCi.MMCHS_HCTL[11:9] SDVS bits). If the host controller detects the No card state, this bit is automatically set to 0. If the module is power off, a write in the command register (MMCi.MMCHS_CMD) will not start the transfer. A write to this bit has no effect if the selected SD bus voltage is not supported according to capability register (MMCi.MMCHS_CAPA[VS*]). 0x0: Power off 0x1: Power on | RW | 0 |
| 7:2 | Reserved | Reserved bit field. Do not write any value. | R | 0x00 |
| 1 | DTW | Data transfer width. For MMC card, this bit must be set following a valid SWITCH command (CMD6) with the correct value and extend CSD index written in the argument. Prior to this command, the MMC card configuration register (CSD and EXT_CSD) must be verified for compliance with <i>MMC standard specification 4.x</i> This register has no effect when the MMC 8-bit mode is selected (MMCi.MMCHS_CON[5] DW8 bit set to 1) For SD/SDIO cards, this bit must be set following a valid SET_BUS_WIDTH command (ACMD6) with the value written in bit 1 of the argument. Prior to this command, the SD card configuration register (SCR) must be verified for the supported bus width by the SD card. 0x0: 1-bit Data width (mmci_dat[0] used) 0x1: 4-bit Data width (mmci_dat[3:0] used) | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|---|------|-------|
| 0 | Reserved | Reserved bit field. Do not write any value. | R | 0 |

| Bits | Field Name | Description | Type | Reset |
|-------|------------|---|------|-------|
| 31:27 | Reserved | Reserved bit field. Do not write any value. | R | 0x00 |
| 26 | SRD | <p>Software reset for mmci_dat line. This bit is set to 1 for reset and released to 0 when completed. mmci_dat finite state machine in both clock domain are also reset.</p> <p>Here below are the registers cleared by the MMCHS_SYSCTL[26] SRD bit:</p> <p>MMCi.MMCHS_DATA MMCi.MMCHS_PSTATE: BRE, BWE, RTA, WTA, DLA and DATI MMCi.MMCHS_HCTL: SBGR and CR MMCi.MMCHS_STAT: BRR, BWR, BGE and TC Interconnect and MMC buffer data management is reinitialized.</p> <p>0x0: Reset completed 0x1: Software reset for mmci_dat line</p> | RW | 0 |
| 25 | SRC | <p>Software reset for mmci_cmd line. This bit is set to 1 for reset and released to 0 when completed. mmci_cmd finite state machine in both clock domain are also reset.</p> <p>Here below are the registers cleared by the MMCHS_SYSCTL[25] SRC bit:</p> <p>MMCi.MMCHS_PSTATE: CMDI MMCi.MMCHS_STAT: CC Interconnect and MMC command status management is reinitialized.</p> <p>0x0: Reset completed 0x1: Software reset for mmci_cmd line</p> | RW | 0 |
| 24 | SRA | <p>Software reset for all. This bit is set to 1 for reset, and released to 0 when completed. This reset affects the entire host controller except for the card detection circuit and capabilities registers.</p> <p>0x0: Reset completed 0x1: Software reset for all the design</p> | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|-------|------------|--|------|-------|
| 23:20 | Reserved | Reserved bit field. Do not write any value. | R | 0x0 |
| 19:16 | DTO | <p>Data timeout counter value and busy timeout. This value determines the interval by which mmci_dat lines timeouts are detected. The host driver needs to set this bit field based on</p> <ul style="list-style-type: none"> - the maximum read access time (NAC) (Refer to the SD Specification Part1 Physical Layer), - the data read access time values (TAAC and NSAC) in the card specific data register (CSD) of the card, - the timeout clock base frequency (MMCi.MMCHS_CAPA[5:0] TCF bits). <p>If the card does not respond within the specified number of cycles, a data timeout error occurs (MMCi.MMCHS_STAT[20] DTO bit). The MMCi.MMCHS_SYSCTL[19,16] DTO bit field is also used to check busy duration, to generate busy timeout for commands with busy response or for busy programming during a write command. Timeout on CRC status is generated if no CRC token is present after a block write.</p> <p>0x0: TCF x 2¹³ 0x1: TCF x 2¹⁴ 0xE: TCF x 2²⁷ 0xF: Reserved</p> | RW | 0x0 |
| 15:6 | CLKD | <p>Clock frequency select These bits define the ratio between a reference clock frequency (system dependant) and the output clock frequency on the mmci_clk pin of either the memory card (MMC, SD or SDIO).</p> <p>0x0: Clock Ref bypass 0x1: Clock Ref bypass 0x2: Clock Ref / 2 0x3: Clock Ref / 3 0x3FF: Clock Ref / 1023</p> | RW | 0x000 |
| 5:3 | Reserved | Reserved bit field. Do not write any value | R | 0x0 |
| 2 | CEN | <p>Clock enable. This bit controls if the clock is provided to the card or not.</p> <p>0x0: The clock is not provided to the card . Clock frequency can be changed .</p> <p>0x1: The clock is provided to the card and can be automatically gated when MMCi.MMCHS_SYSCONFIG[0] AUTOIDLE bit is set to 1 (default value) . The host driver shall wait to set this bit to 1 until the Internal clock is stable (MMCi.MMCHS_SYSCTL[1] ICS bit).</p> | RW | 0 |
| 1 | ICS | <p>Internal clock stable (status)This bit indicates either the internal clock is stable or not.</p> <p>Read 0x0: The internal clock is not stable.</p> <p>Read 0x1: The internal clock is stable after enabling the clock (MMCi.MMCHS_SYSCTL[0] ICE bit) or after changing the clock ratio (MMCi.MMCHS_SYSCTL[15:6] CLKD bits).</p> | R | 0 |
| 0 | ICE | <p>Internal clock enable. This register controls the internal clock activity. In very low power state, the internal clock is stopped. Note: The activity of the debounce clock (used for wake-up events) and the interface clock (used for reads and writes to the module register map) are not affected by this register.</p> <p>0x0: The internal clock is stopped (very low power state).</p> <p>0x1: The internal clock oscillates and can be automatically gated when MMCi.MMCHS_SYSCONFIG[0] AUTOIDLE bit is set to 1 (default value) .</p> | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|-------|------------|--|------|-------|
| 31:30 | Reserved | Reserved bit field. Do not write any value | R | 0x0 |
| 29 | BADA | Bad access to data space. This bit is set automatically to indicate a bad access to buffer when not allowed: - During a read access to the data register (MMCi.MMCHS_DATA) while buffer reads are not allowed (MMCi.MMCHS_PSTATE[11] BRE bit =0) - During a write access to the data register (MMCi.MMCHS_DATA) while buffer writes are not allowed (MMCi.MMCHS_PSTATE[10] BWE bit=0) Read 0x0: No Interrupt. Write 0x0: Status bit unchanged Read 0x1: Bad Access Write 0x1: Status is cleared | RW | 0 |
| 28 | CERR | Card error. This bit is set automatically when there is at least one error in a response of type R1, R1b, R6, R5 or R5b. Only bits referenced as type E (error) in status field in the response can set a card status error. An error bit in the response is flagged only if corresponding bit in card status response error MMCi.MMCHS_CSRE in set. There is no card error detection for autoCMD12 command. The host driver shall read MMCi.MMCHS_RSP76 register to detect error bits in the command response. Read 0x0: No Error Write 0x0: Status bit unchanged Read 0x1: Card error Write 0x1: Status is cleared | RW | 0 |
| 27:25 | Reserved | Reserved bit field. Do not write any value | R | 0x0 |
| 24 | ACE | Auto CMD12 error. This bit is set automatically when one of the bits in Auto CMD12 Error status register has changed from 0 to 1. Read 0x0: No Error Write 0x0: Status bit unchanged Read 0x1: AutoCMD12 error | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|--|------|-------|
| | | Write 0x1: Status is cleared | | |
| 23 | Reserved | Reserved bit field. Do not write any value | R | 0 |
| 22 | DEB | Data End Bit error. This bit is set automatically when detecting a 0 at the end bit position of read data on mmci_dat line or at the end position of the CRC status in write mode. Read 0x0: No Error Write 0x0: Status bit unchanged Read 0x1: Data end bit error Write 0x1: Status is cleared | RW | 0 |
| 21 | DCRC | Data CRC Error. This bit is set automatically when there is a CRC16 error in the data phase response following a block read command or if there is a 3-bit CRC status different of a position "010" token during a block write command. Read 0x0: No Error. Write 0x0: Status bit unchanged Read 0x1: Data CRC error Write 0x1: Status is cleared | RW | 0 |
| 20 | DTO | Data timeout error. This bit is set automatically according to the following conditions: - Busy timeout for R1b, R5b response type. - Busy timeout after write CRC status. - Write CRC status timeout. - Read data timeout. Read 0x0: No error Write 0x0: Status bit unchanged Read 0x1: Time out Write 0x1: Status is cleared | RW | 0 |
| 19 | CIE | Command index error. This bit is set automatically when response index differs from corresponding command index previously emitted. It depends on the enable bit (MMCi.MMCHS_CMD[20] CICE). Read 0x0: No error Write 0x0: Status bit unchanged Read 0x1: Command index error Write 0x1: Status is cleared | RW | 0 |
| 18 | CEB | Command end bit error. This bit is set automatically when detecting a 0 at the end bit position of a command response. Read 0x0: No error Write 0x0: Status bit unchanged Read 0x1: Command end bit error Write 0x1: Status is cleared | RW | 0 |
| 17 | CCRC | Command CRC Error. This bit is set automatically when there is a CRC7 error in the command response depending on the enable bit (MMCi.MMCHS_CMD[19] CCCE). Read 0x0: No Error Write 0x0: Status bit unchanged Read 0x1: Command CRC error Write 0x1: Status is cleared | RW | 0 |
| 16 | CTO | Command Timeout Error. This bit is set automatically when no response is received within 64 clock cycles from the end bit of the command. For commands that reply within 5 clock cycles - the timeout is still detected at 64 clock cycles. Read 0x0: No error | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|-------|------------|---|------|-------|
| | | Write 0x0: Status bit unchanged Read 0x1: Time Out Write 0x1: Status is cleared | | |
| 15 | ERRI | Error Interrupt. If any of the bits in the Error Interrupt Status register (MMCi.MMCHS_STAT[31:16]) are set, then this bit is set to 1. Therefore the host driver can efficiently test for an error by checking this bit first. Writes to this bit are ignored. Read 0x0: No Interrupt Read 0x1: Error interrupt event(s) occurred | R | 0 |
| 14:10 | Reserved | Reserved bit field. Do not write any value. | R | 0x00 |
| 9 | OBI | Out-Of-Band interrupt (This interrupt is only useful for MMC card). This bit is set automatically when MMc.MMCHS_CON[14] OBIE bit is set and an Out-of-Band interrupt occurs on OBI pin. The interrupt detection depends on polarity controlled by MMc.MMCHS_CON[13] OBIP bit. The Out-of-Band interrupt signal is a system specific feature for future use, this signal is not required for existing specification implementation. Read 0x0: No Out-Of-Band interrupt. Write 0x0: Status bit unchanged. Read 0x1: Interrupt Out-Of-Band occurs. Write 0x1: Status is cleared. | R | 0 |
| 8 | CIRQ | Card interrupt. This bit is only used for SD and SDIO cards. In 1-bit mode, interrupt source is asynchronous (can be a source of asynchronous wakeup). In 4-bit mode, interrupt source is sampled during the interrupt cycle. In CE-ATA mode, interrupt source is detected when the card drives mmci_cmd line to zero during one cycle after data transmission end. All modes above are fully exclusive. The controller interrupt must be clear by setting MMc.MMCHS_IE[8] CIRQ_ENABLE to 0, then the host driver must start the interrupt service with card (clearing card interrupt status) to remove card interrupt source. Otherwise the Controller interrupt will be reasserted as soon as MMc.MMCHS_IE[8] CIRQ_ENABLE is set to 1. Writes to this bit are ignored. Read 0x0: No card interrupt Read 0x1: Generate card interrupt | R | 0 |
| 7:6 | Reserved | Reserved bit field. Do not write any value. | RW | 00 |
| 5 | BRR | Buffer read ready. This bit is set automatically during a read operation to the card (see class 2 - block oriented read commands) when one block specified by the MMc.MMCHS_BLK[10:0] BLEN bit field is completely written in the buffer. It indicates that the memory card has filled out the buffer and that the local host needs to empty the buffer by reading it. Note: If the DMA receive-mode is enabled, this bit is never set; instead a DMA receive request to the main DMA controller of the system is generated. Read 0x0: Not Ready to read buffer Write 0x0: Status bit unchanged Read 0x1: Ready to read buffer Write 0x1: Status is cleared | RW | 0 |
| 4 | BWR | Buffer write ready. This bit is set automatically during a write operation to the card (see class 4 - block oriented write command) when the host can write a complete block as specified by MMc.MMCHS_BLK[10:0] BLEN. It indicates that the memory card has emptied one block from the buffer and that the local host is able to write one block of data into the buffer. Note: If the DMA transmit mode is enabled, this bit is never set; instead, a DMA transmit request to the main DMA controller of the system is generated. Read 0x0: Not Ready to write buffer | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|---|------|-------|
| | | Write 0x0: Status bit unchanged Read 0x1: Ready to write buffer Write 0x1: Status is cleared | | |
| 3 | Reserved | Reserved bit field. Do not write any value | R | 0 |
| 2 | BGE | Block gap event. When a stop at block gap is requested (MMCi.MMCHS_HCTL[16] SBGR bit), this bit is automatically set when transaction is stopped at the block gap during a read or write operation. This event does not occur when the stop at block gap is requested on the last block. In read mode, a 1-to-0 transition of the mmci_dat line active status (MMCi.MMCHS_PSTATE[2] DLA bit) between data blocks generates a Block gap event interrupt. Read 0x0: No block gap event Write 0x0: Status bit unchanged Read 0x1: Transaction stopped at block gap Write 0x1: Status is cleared | RW | 0 |
| 1 | TC | Transfer completed. This bit is always set when a read/write transfer is completed or between two blocks when the transfer is stopped due to a stop at block gap request (MMCi.MMCHS_HCTL[16] SBGR bit). This bit is also set when exiting a command in a busy state (if the command has a busy notification capability). In Read mode: This bit is automatically set on completion of a read transfer (MMCi.MMCHS_PSTATE[9] RTA bit). In write mode: This bit is set automatically on completion of the mmci_dat line use (MMCi.MMCHS_PSTATE[2] DLA bit). Read 0x0: No transfer complete Write 0x0: Status bit unchanged Read 0x1: Data transfer complete Write 0x1: Status is cleared | RW | 0 |
| 0 | CC | Command complete. This bit is set when a 1-to-0 transition occurs in the register command inhibit (MMCi.MMCHS_PSTATE[0] CMDI bit) If the command is a type for which no response is expected, then the command complete interrupt is generated at the end of the command. A command timeout error (MMCi.MMCHS_STAT[16] CTO bit) has higher priority than command complete (MMCi.MMCHS_STAT[0] CC bit). If a response is expected but none is received, then a command timeout error is detected and signaled instead of the command complete interrupt. Read 0x0: No Command complete Write 0x0: Status bit unchanged Read 0x1: Command complete Write 0x1: Status is cleared | RW | 0 |

MMCHS2 and 3: This bit must be left to 0. | RW | 0 |
| 24 | VS33 | Voltage support 3.3V Initialization of this register (via a write access to this register) depends on the system capabilities. The host driver shall not modify this register after the initialization. This register is only reinitialized by a hard reset (via MMCi_RESET signal) Read 0x0: 3.3 V Not Supported Write 0x0: 3.3 V Not supported Read 0x1: 3.3 V Supported Write 0x1: 3.3 V Supported MMCHS1, 2 and 3: This bit must be left to 0. | RW | 0 |
| 23 | SRS | Suspend/Resume support (SDIO cards only) This bit indicates whether the host controller supports Suspend/Resume functionality. Read 0x0: The Host controller does not Suspend/Resume functionality. Read 0x1: The Host controller supports Suspend/Resume functionality. | R | 1 |
| 22 | DS | DMA support. This bit indicates that the Host Controller is able to use DMA to transfer data between system memory and the Host Controller directly. Read 0x0: DMA Not Supported Read 0x1: DMA Supported | R | 1 |

| Bits | Field Name | Description | Type | Reset |
|-------|------------|--|------|-------|
| 21 | HSS | High speed support. This bit indicates that the host controller supports high speed operations and can supply an up-to-52 MHz clock to the card. Read 0x0: High Speed Not Supported Read 0x1: High Speed Supported | R | 1 |
| 20:18 | Reserved | Reserved bit field. Do not write any value. | R | 0x0 |
| 17:16 | MBL | Maximum block length. This value indicates the maximum block size that the host driver can read and write to the buffer in the host controller. The host controller supports 512 bytes and 1024 bytes block transfers. Read 0x0: 512 bytes Read 0x1: 1024 bytes Read 0x2: 2048 bytes | R | 0x1 |
| 15:14 | Reserved | Reserved bit field. Do not write any value | R | 0x0 |
| 13:8 | BCF | Base clock frequency for clock provided to the card. Read 0x0: The value indicating the base (maximum) frequency for the output clock provided to the card is system dependent and is not available in this register. Get the information via another method. See , <i>Power Reset and Clock Management</i> , for more information on the value of FUNC_96M_CLK clock signal. | R | 0x00 |
| 7 | TCU | Timeout clock unit. This bit shows the unit of base clock frequency used to detect Data Timeout Error (MMCi.MMCHS_STAT[20] DTO bit). Read 0x0: kHz Read 0x1: MHz | R | 1 |
| 6 | Reserved | Reserved. This bit is initialized to zero, and writes to it are ignored. | R | 0 |
| 5:0 | TCF | Timeout clock frequency. The timeout clock frequency is used to detect Data Timeout Error (MMCi.MMCHS_STAT[20] DTO bit). Read 0x0: The timeout clock frequency depends on the frequency of the clock provided to the card. The value of the timeout clock frequency is not available in this register. Note: You can have the timeout clock frequency by dividing FUNC_96M_CLK by the value of the MMcI.MMCHS_SYSCCTL[15:6] CLKD bit field. | R | 0x00 |

Universal Serial Bus (USB)

This chapter describes the high-speed USB On-The-Go (OTG) controller and the high-speed universal serial bus (USB) host subsystem.

Figure 20-1. USB Modules Overview

| Topic | Page |
|--|------|
| 20.1 High-Speed USB OTG Controller | 2228 |
| 20.2 High-Speed USB Host Subsystem | 2307 |

20.1 High-Speed USB OTG Controller

NOTE: The High-Speed USB OTG Controller is an instantiation of the MUSBMHDC from Mentor Graphics Corporation.

Mentor Graphics is a registered trademark of Mentor Graphics Corporation or its affiliated companies in the United States and other countries.

The High-Speed USB OTG Controller is an instantiation of the MUSBMHDC from Mentor Graphics Corporation.

20.1.1 Introduction

This chapter describes the high-speed universal serial bus (USB) host subsystem and the high-speed USB On-The-Go (OTG) controller. The controller complies with the USB 2.0 standard high-speed and full-speed functions and low-speed, full-speed, and high-speed limited host mode operations. It also includes support for the Session Request and Host Negotiation Protocols used in point-to-point communications, details of which are given in the USB On-the-Go supplement to the USB 2.0 specification. In addition, the four test modes for high-speed operation described in the USB 2.0 specification. It also allows options that allow it to be forced into full-speed mode, high-speed mode or host mode which may be used in helping debug PHY problems in hardware.

20.1.1.1 Purpose of the Peripheral

The USB controller supports data throughput rates up to 480 Mbps. It provides a mechanism for data transfer between USB devices and also supports host negotiation.

NOTE: Some features may not be available or supported in your particular device. For more information, see Chapter 1, and your device-specific data manual.

20.1.2 Features Supported

- Contains 1 usb20otg_f modules, with the following features:
 - Built around the Mentor USB 2.0 OTG core (musbmhdc)
 - Supports USB 2.0 peripheral at speeds HS (480 Mb/s) and FS (12 Mb/s)
 - Supports USB 2.0 Host or OTG at speeds HS (480 Mb/s), FS (12 Mb/s), and LS (1.5 Mb/s)
 - Supports all modes of transfers (control, bulk, interrupt, and isochronous)
 - Supports high bandwidth ISO mode
 - Supports 16 transmit (TX) and 16 receive (RX) endpoints including endpoint 0
 - Supports USB OTG extensions for session resume (SRP) and Host negotiation (HNP)
 - Includes a 32K endpoint FIFO RAM, and supports programmable FIFO sizes
 - Includes RNDIS mode for accelerating RNDIS type protocols using short packet termination over USB
 - Includes CDC Linux mode for accelerating CDC type protocols using short packet termination over USB
 - Included and RNDIS like mode for terminating RNDIS type protocols without using short packet termination for support of MSC applications
- Includes one USB2.0 OTG PHYs in GS60 process
- Connects to a standard charge pump for VBUS 5 V generation
- Interfaces to the CPU through a CBA 3.1 VBUSP slave port
- Includes a CPPI 4.1 compliant DMA controller sub-module with 15 RX and 15 TX simultaneous data connections
- Includes a CPPI 4.1 DMA scheduler
- DMA supports CPPI Host descriptor formats
- DMA supports stall on buffer starvation

- Supports data buffer sizes up to 4M bytes
- CPPI FIFO interface per TX/RX endpoint
- Provides a CPPI queue manager module with 96 queues for queuing/dequeuing packets

20.1.2.1 Features Not Supported

- 16-bit 30 MHz UTMI+ interface is not supported
- RNDIS, CDC, and Generic RNDIS mode acceleration for USB sizes that are not multiples of 64 bytes
- Endpoint max USB packet sizes that do not conform to the USB 2.0 spec (for FS/LS: 8, 16, 32, 64, and 1023 are defined; for HS: 64, 128, 512, and 1024 are defined)

20.1.3 Functional Description

20.1.3.1 Compliance to Standards

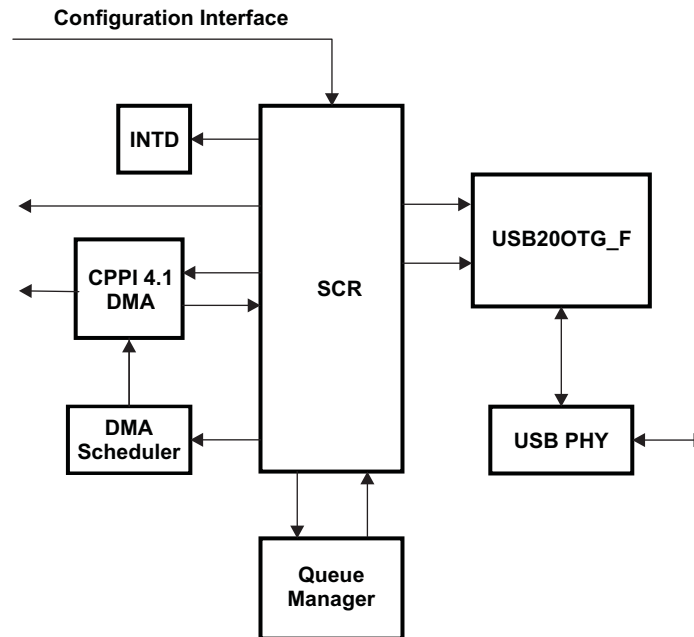

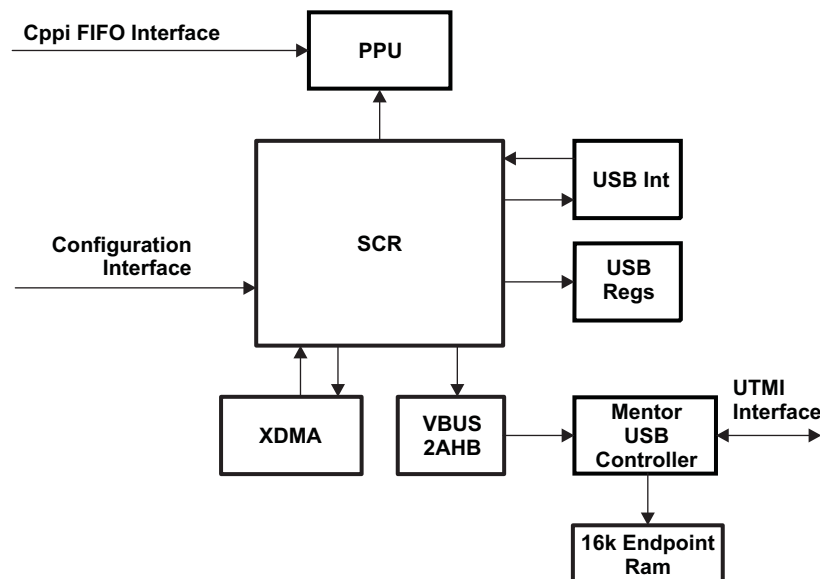

The module is compliant to the USB 2.0 specification as well as the OTG supplement. Refer to the Mentor specification for details.

20.1.3.2 Functional Operation

20.1.3.2.1 Overview

The USB 2.0 OTG subsystem consists of a CPPI 4.1 DMA controller and scheduler, an INTD interrupt distributor, a queue manager, a usb20otg_f USB controller subsystem, and a USB OTG PHY.

The USB 2.0 OTG F controller consists of the Mentor core, a packet processing unit, a switched central resource (SCR), and the bridge sub-modules. The core interfaces to the UTMI+ interface that is connected to a UTMI+ PHY. It also connects to the endpoint FIFO RAM. The module interfaces to a CPPI 4.1 compliant DMA controller through the Egress/Ingress CPPI FIFO interfaces in the PPU. The bridge sub-modules consist of additional new functions needed to connect the Mentor core and make the module PDR 3.5 compliant. The VBUSP to AHB (V2A) sub-module converts to the core's AHB slave port. The transfer (XFER) DMA sub-module controls transferring data from the endpoint FIFOs to the CPPI FIFOs. The interrupt sub-module implements PDR 3.5 compliant interrupts. The clock sub-module implements the CBA 3.1 compliant clocking protocols. The test sub-module implements the PDR 3.5 I/O test requirements. VBUSP retiming sub-modules are used to enhance VBUSP timing. And the SCR connects all the sub-modules together with the DMA state RAM. [Figure 20-2](#) shows the top level block diagram of the sub-modules and their connections. [Figure 20-3](#) shows the USB20OTG_F block diagram.

Figure 20-2. USB Subsystem Block Diagram

Figure 20-3. USB20OTG_F Block Diagram

20.1.3.2.2 Mentor Core

The core of the USB 2.0 OTG controller is the Mentor USB 2.0 high-speed multi-point dual-role controller, musbmhdc. This core is IP from Mentor and a detailed description of its operations is covered by the Mentor specification.

The Mentor core communicates to a UTMI+ PHY interface, an AHB slave interface, and a FIFO RAM interface, along with extra system signals. The connections for these interfaces and signals are described in [Section 20.1.4.3](#).

20.1.3.2.3 USB OTG PHY

The USB OTG Subsystem integrates a USB OTG PHY. The PHY interfaces to the Mentor OTG controller via the UTMI+ interface.

The integrated PHY has the following features:

- OTG compliant.
- Has UTMI-plus Level 3 functionality. (Host and OTG devices. HS/FS/LS and preamble packet.)
- Supports OTG, SRP and HNP protocols.
- 8-bit data interface on the UTMI with 60 MHz clock

The integrated PHY does not contain a charge pump, so it will not provide power to VBUS.

20.1.3.2.4 CPPI 4.1 DMA Controller

The CPPI DMA module supports the transmission and reception of USB packets. The CPPI DMA is designed to facilitate the segmentation and reassembly of CPPI compliant packets to/from smaller data blocks that are natively compatible with the specific requirements of each networking port. Multiple Tx and Rx channels are provided within the DMA that allow multiple segmentation or reassembly operations to be effectively performed in parallel (but not actually simultaneously). The DMA controller maintains state information for each of the channels which allows packet segmentation and reassembly operations to be time division multiplexed between channels in order to share the underlying DMA hardware. A DMA scheduler is used to control the ordering and rate at which this multiplexing occurs. The DMA controller has its mem1 port brought out to the top level of the subsystem as a VBUSP master interface. This is to allow simultaneous access by the DMA and the Queue manager to the external switch.

20.1.3.2.4.1 Tx Channel Allocation

A total of 30 Tx channels are provided within the DMA for concurrent packet transfers to the various ports. [Table 20-1](#) shows how the Tx channels are allocated.

Table 20-1. TX Channel Allocation

| DMA Channel | Function | Channel Type | Port | Channel In Port | Tx Queue Count | Tx Queue Arbitration Type | Start Tx QM # : Queue # | Packet Type(s) |
|-------------|-----------|--------------|------|-----------------|----------------|---------------------------|-------------------------|----------------|
| 0 | USB EP 1 | Endpt | 1 | 0 | 2 | Fixed Priority | 32 | USB |

| 13 | USB EP 14 | Endpt | 14 | 0 | 2 | Fixed Priority | 58 | USB |
| 14 | USB EP 15 | Endpt | 15 | 0 | 2 | Fixed Priority | 60 | USB |

20.1.3.2.4.2 CPPI DMA Transmit Operation

Packet transmission is accomplished within the DMA by moving data from structures that are located in external memory into the PPU module of the USB Subsystem. This movement of data is performed in blocks whose size varies based on the type of each packet and is performed in compliance with the CPPI 4.1 specification. USB packets are fetched by the Tx DMA in 64 byte blocks.

The DMA performs the following sequence on the Tx Port FIFO interface for each cell that is transferred:

1. Transfer specified number of payload bytes (1 to 64) to the Tx Port FIFO.
2. Write the channel number, packet type, SOP, EOP, and valid cell byte count to the cell information register in the Tx Port FIFO. The cell byte count is calculated by the DMA as the number of valid payload bytes in the cell for this packet type. Valid cell byte counts range from 1 to 64.
3. Write to the cell advance register in the Tx Port FIFO.

20.1.3.2.4.3 Rx Channel Allocation

A total of 30 Rx channels are provided within the DMA for concurrent packet transfers from the various ports. [Table 20-2](#) shows how the Rx channels are allocated.

Table 20-2. RX Channel Allocation

| DMA Channel | Function | Channel Type | Src Tag Port | Src Tag Channel | Src Tag Sub-Channel | Rx Queue Count | Packet Type(s) |
|-------------|-----------|--------------|--------------|-----------------|---------------------|----------------|----------------|
| 0 | USB EP 1 | Endpt | 1 | 0 | 0 | 1 | USB |
| 1 | USB EP 2 | Endpt | 2 | 0 | 0 | 1 | USB |
| 2 | USB EP 3 | Endpt | 3 | 0 | 0 | 1 | USB |
| 3 | USB EP 4 | Endpt | 4 | 0 | 0 | 1 | USB |
| 4 | USB EP 5 | Endpt | 5 | 0 | 0 | 1 | USB |
| 5 | USB EP 6 | Endpt | 6 | 0 | 0 | 1 | USB |
| 6 | USB EP 7 | Endpt | 7 | 0 | 0 | 1 | USB |
| 7 | USB EP 8 | Endpt | 8 | 0 | 0 | 1 | USB |
| 8 | USB EP 9 | Endpt | 9 | 0 | 0 | 1 | USB |
| 9 | USB EP 10 | Endpt | 10 | 0 | 0 | 1 | USB |
| 10 | USB EP 11 | Endpt | 11 | 0 | 0 | 1 | USB |
| 11 | USB EP 12 | Endpt | 12 | 0 | 0 | 1 | USB |
| 12 | USB EP 13 | Endpt | 13 | 0 | 0 | 1 | USB |
| 13 | USB EP 14 | Endpt | 14 | 0 | 0 | 1 | USB |
| 14 | USB EP 15 | Endpt | 15 | 0 | 0 | 1 | USB |

20.1.3.2.4.4 CPPI DMA Receive Operation

Packet reception is accomplished within the DMA by moving data from Rx Port FIFOs within the Jupiter session router subsystem into structures that are located in external memory. This movement of data is performed in blocks whose size varies based on the type of each packet and is in compliance with the CPPI 4.1 specification. USB packets are stored by the Rx DMA in 64 byte blocks.

The DMA performs the following sequence on the Rx Port FIFO interface of the PPU for each cell that is transferred:

1. Read the channel number, packet type, SOP, EOP, and valid cell byte count from the cell information registers in the Rx Port FIFO.
2. Transfer specified number of payload bytes (1 to 64) from the Rx Port FIFO.
3. Write to the cell advance register in the Rx Port FIFO.

20.1.3.2.5 CPPI DMA Scheduler

The CPPI DMA scheduler is responsible for controlling the rate and order between the different Tx and Rx threads that are provided in the CPPI DMA controller. The following sections describe the details of the scheduler functionality. The scheduler table RAM is a two port memory which is organized as 64 words with storage for 4 scheduler entries in each word.

20.1.3.2.5.1 Scheduler Initialization

Before the scheduler can be used, the Host is required to initialize and enable the block. This initialization is as follows:

- The Host initializes entries within an internal memory array in the scheduler. This array contains up to 256 entries and each entry consists of a DMA channel number and a bit indicating if this is a Tx or Rx opportunity. These entries represent both the order and frequency that various Tx and Rx channels will be processed. A table size of 256 entries allows channel bandwidth to be allocated with a maximum precision of 1/256th of the total DMA bandwidth. The more entries that are present for a given channel, the bigger the slice of the bandwidth that channel will be given. Larger tables can be accommodated to allow for more precision. This array can only be written by the Host, it cannot be read.
- The Host initializes an internal register in the scheduler that sets the actual size of the array; it can be less than 256 entries.
- The Host writes an internal register bit to enable the scheduler. The scheduler is not required to be disabled in order to change the scheduler array contents.

20.1.3.2.5.2 Scheduler Operation

Once the scheduler is enabled, it begins to process the entries in the table, and when appropriate, pass credits to the DMA controller to perform a Tx or Rx operation. The operation of the DMA controller is as follows:

1. After the DMA scheduler is enabled, it begins with the table index set to 0.
2. The scheduler reads the entry pointed to by the index and checks to see if the channel in question is currently in a state where a DMA operation can be accepted.
 - The DMA channel must be enabled, and
 - The CPPI FIFO that the channel talks to has free space on TX (FIFO full signal is not asserted) or a valid block on Rx (FIFO empty signal is not asserted).
3. If the DMA channel is capable of processing a credit to transfer a block, the DMA scheduler will issue that credit via the DMA scheduling interface, which is a point-to-point connection between the DMA scheduler and the DMA controller.
 - The DMA controller may not be ready to accept the credit immediately and is provided a `sched_ready` signal which is used to stall the scheduler until it can accept the credit. The DMA controller only asserts the `sched_ready` signal when it is in the IDLE state.
 - Once a credit has been accepted (indicated by `sched_req` and `sched_ready` both asserted), the scheduler will increment the index to the next entry and will start at step 2.
4. If the channel in question is not currently capable of processing a credit, the scheduler will increment the index in the scheduler table to the next entry and will start at step 2.
5. Note that when the scheduler attempts to increment its index to the value programmed in the table size register, the index will reset to 0.

20.1.3.2.6 CP_INTD

The `cp_intd` module controls the distribution of the USB subsystem interrupts to a single or multiple Hosts in a SoC. It combines the functions of many previous pieces of support IP into a single configurable module that allows a central method to control IP interrupts and system interrupts as well as complete customization to a particular SoC's need. The module eliminates the confusion of handling IP interrupts from a PDR IP module without knowledge of the support IP by building interfaces that connect directly to the IP and Interrupt controllers for each Host leaving the SoC to just connect the wires.

The `cp_intd` encompasses six functions that used to be separate (if even available) pieces of support IP or additional glue logic at the SoC level. These functions are: enabling, status capture, counting, combining or aggregation, pacing and synchronization. There are also polarity and type conversion and EOI functions to support legacy IP. The descriptions of these functions are detailed in the CP_INTD module specification.

Mapping of the USB interrupts to the `cp_intd` controller is described in [Section 20.1.4.2](#) of this document.

20.1.3.2.7 CPPI Queue Manager

The queue manager accelerates addition and deletion of descriptors from descriptor queues, tracking of queue emptiness, and queue diversion. The following sections describe various operations that the queue manager can do on the queues. See the CPPI 4.1 specification for more information on queues. The Queue Manager module in the USB subsystem provides 96 hardware queues.

Table 20-3. Queue Allocation

| Start | Count | Name |
|-------|-------|---------------------------------|
| 0 | 15 | Free Descriptor/Buffer Queues |
| 16 | 16 | Unassigned Queues |
| 32 | 2 | USB0 Endpoint 1 Transmit Queue |
| 34 | 2 | USB0 Endpoint 2 Transmit Queue |
| 36 | 2 | USB0 Endpoint 3 Transmit Queue |
| 38 | 2 | USB0 Endpoint 4 Transmit Queue |
| 40 | 2 | USB0 Endpoint 5 Transmit Queue |
| 42 | 2 | USB0 Endpoint 6 Transmit Queue |
| 44 | 2 | USB0 Endpoint 7 Transmit Queue |
| 46 | 2 | USB0 Endpoint 8 Transmit Queue |
| 48 | 2 | USB0 Endpoint 9 Transmit Queue |
| 50 | 2 | USB0 Endpoint 10 Transmit Queue |
| 52 | 2 | USB0 Endpoint 11 Transmit Queue |
| 54 | 2 | USB0 Endpoint 12 Transmit Queue |
| 56 | 2 | USB0 Endpoint 13 Transmit Queue |
| 58 | 2 | USB0 Endpoint 14 Transmit Queue |
| 60 | 2 | USB0 Endpoint 15 Transmit Queue |
| 62 | 2 | USB1 Endpoint 1 Transmit Queue |
| 64 | 30 | Unassigned |
| 92 | 4 | Completion Queues |

20.1.3.2.8 USB20OTG_F Packet Processing Unit

The packet processing unit (PPU) provides an interface and FIFO storage between the CPPI 4.1 DMA controller and the XDMA. The PPU interfaces to the DMA controller via a standard CFIFO interface. Full/empty flags are asserted to the DMA and XDMA depending on cell availability in the PPU FIFO. The PPU contains 30 logical FIFOs with a depth of 2 64-bytes cells each. One FIFO is allocated to each RX and TX channel and cannot be changed.

20.1.3.2.9 USB20OTG_F VBUSP to AHB (V2A)

The core is accessed through an AHB slave interface. There are a few operations that need to access this port: a CPU access from the VBUSP slave port, a register read by the Interrupt sub-module, or a FIFO access by the XFER DMA controller. The V2A will convert the VBUSP slave bus from the SCR to the AHB slave bus on the core. The AHB interface is a split transaction bus, with an address phase followed by a data phase, and successive transfers can overlap their address phases with the previous data phase (see the ARM AMBA Specification for more information on the AHB bus). The VBUSP interface is a single phase bus, so the address is presented until the slave is ready with the data (see the CBA 3.0 Specification for more information on the VBUSP bus). The V2A performs the two AHB phases while holding off the single phase on the VBUSP. When the second phase on the AHB is ready, then the VBUSP is ready and advances to the next phase. This allows a very simple implementation with minimal logic gates. For typical CPU accesses without bursts, there is no way to achieve better performance, and the DMA performance to the endpoint FIFOs should be sufficient for the required bandwidth.

The core is set to big endian mode to match the DMA expectation of data in the FIFOs. The DMA performs endian adjustment to match the system endian specified by the big_endian signal. To match this behavior, accesses to the core from the CPU through the VBUSP slave input will also adjust the data based on the system endian.

The V2A bridge as well as the VBUSP slave port only support bursts in linear incrementing mode. Any other modes cannot be used with the USB 2.0 OTG module.

20.1.3.2.10 USB20OTG_F Transfer (XFER) DMA

The XFER DMA receives DMA requests from the core and initiates the DMAs to the PPU. The first step is receiving the DMA request from the core. The core sends out 30 DMA_req signals, 15 for TX endpoints 1 to 15, and 15 for RX endpoints 1 to 15. For TX endpoints, the DMA_req goes high when a TX buffer for that endpoint is empty and can hold new data. The CPPI DMA performs the requested DMA for that channel, and the PPU indicates to the XDMA that data is available for that channel. Then, the XFER DMA reads from the PPU FIFO and writes the data into the endpoint FIFO inside the core. When the TX buffer in the core is full, the DMA_req goes low. After all the data is written to the endpoint FIFO, the XFER DMA writes the trigger bit in the core endpoint register to enable that TX endpoint for transfer.

For RX endpoints, the DMA_req goes high when an RX buffer holds a completed USB packet. The XFER DMA must check if the PPU FIFO is empty for that RX channel. If the PPU FIFO is empty on that RX channel, then the XFER DMA reads the RX count register in the core to obtain the size of the RX data, and reads the data from the core endpoint FIFOs and writes it to the PPU FIFO. The PPU FIFO signals the CPPI DMA that data is available. Then, the CPPI DMA writes the data out to main memory. The core lowers DMA_req once all the RX data is read from the endpoint FIFO. The XFER DMA also writes the trigger bit in the core endpoint register to enable the RX endpoint buffer for the next transfer.

20.1.3.2.10.1 RNDIS Mode

The USB 2.0 OTG controller also supports accelerating RNDIS type packets over USB. RNDIS mode allows the hardware to recognize and automate large packets being sent over USB, such as how RNDIS utilizes USB. When using transparent mode (the default with no acceleration) each DMA is equivalent to a single USB packet, so each DMA must be for at most the USB max packet size (i.e., 64 bytes for FS Bulk or 512 bytes for HS Bulk) and is a start-of-packet (SOP) and an end-of-packet (EOP) (see the CPPI 4.1 Specification for details on SOP and EOP) upon reception. Similarly, transmit CPPI packets can be no more than the USB max packet size.

RNDIS transfers over USB form a simple protocol to send larger packet sizes than those supported by USB 2.0 specifications. This is accomplished by breaking the larger packet into smaller packets, which are not larger than the max USB packet size. The protocol defines the end of the larger packet by using a USB packet that is not the max USB packet size (called a short packet). In the case where the larger packet size is an exact multiple of the max USB packet length, then the terminating short packet must be a zero length packet after the last data packet. The receiver combines the data packets and completes the RNDIS packet when it combines a short packet at the end.

The XFER DMA supports accelerating RNDIS packets over USB by automating the packing, unpacking, generation, and detection of these larger packets. In RNDIS mode, the CPPI packet refers to the larger packet, and the XFER DMA sends the entire packet out as a sequence of USB packets. For transmission, the CPPI packet data is sent as multiple USB packets of up to the max USB packet size. If the last data matches the max USB packet size, then the XFER DMA generates a zero length packet immediately after the last data packet. For receiving, USB packet data is sent to the same CPPI packet until a short packet is received. Only upon receiving the short packet will the XFER DMA indicate to the CPPI packet that it is now the end-of-packet.

To use RNDIS acceleration, the USB max packet size of any RNDIS mode enabled endpoints must be a multiple of 64 bytes. RNDIS acceleration should not be enabled for endpoints where the max packet size is not a multiple of 64 bytes. Only transparent mode should be used for such endpoints.

20.1.3.2.10.2 Linux CDC Mode

Linux CDC mode is supported. CDC packets act in the same manner as RNDIS packets, except for the case where the last data matches the max USB packet size. In transmit operation, if an endpoint is configured or CDC Linux mode, the XFER DMA then generates a packet containing 1 byte of data, whose

value is 0x00, to indicate the end of the transfer, similar to the manner in which the XDMA generates a zero length packet to terminate an RNDIS packet that exactly matches the max USB packet size. During receive operation, the XFER DMA recognizes the one byte zero packet as a termination of the USB packet, and sends a block of data with the EOP indicator set and a byte count of one to the CPPI DMA controller.

20.1.3.2.10.3 Generic RNDIS Mode

The USB 2.0 OTG controller supports a generic RNDIS mode over USB. This mode is identical to the normal RNDIS mode in nearly all respects, except for the exception case where data is being received or transmitted and the last packet of a segment exactly matches the max USB packet size. Normally, this mode receives USB packets in the same manner as RNDIS mode, closing the CPPI packet when a USB packet is received that is less than the endpoint size. Otherwise, the packet is closed when the value in the generic RNDIS EP size register is reached. Using this register, a packet of up to 64k bytes can be received. This is to allow the Host software to program the USB module to receive a packet that is an exact multiple of the endpoint size without having to send an additional short packet to terminate. In transmit operation, this mode behaves like RNDIS mode, except if the CPPI packet is an exact multiple of the endpoint size, a zero byte packet is not sent by the XDMA controller. The generic RNDIS EP size register must be programmed with a value that is an integer multiple of the endpoint size. For example, if the endpoint size is programmed with a value of 64, the generic RNDIS EP size register for that endpoint must be programmed with a value that is an integer multiple of 64, (e.g., 64, 128, 192, 256, etc.).

As in RNDIS mode, the USB max packet size of any generic RNDIS mode enabled endpoints must be a multiple of 64 bytes. Generic RNDIS acceleration should not be enabled for endpoints where the max packet size is not a multiple of 64 bytes. Only transparent mode should be used for such endpoints.

20.1.3.2.10.4 Zero Length Packets

A special case is the handling of zero length packets with the CPPI 4.1 compliant DMA controller. Upon receiving a zero length USB packet, the XFER DMA sends a data block to the DMA controller with the byte count of zero, the EOP bit set, and the zero byte packet bit of INFO Word 1 set. The DMA controller then performs normal EOP termination of the packet, without transferring data. To the packet transmission case, if a packet has the SOP and EOP packet has the zero byte packet bit of the INFO Word 1 of the CFIFO interface set, the XFER DMA ignores the CPPI packet size and sends a zero byte packet to the USB core. It is not valid to have the zero byte packet bit of the INFO Word 1 set without the SOP and EOP bits of INFO word 0 also being set.

20.1.3.2.10.5 Teardown

Teardown operation of an endpoint requires three operations. The teardown register in the CPPI DMA must be written, the corresponding endpoint bit in the teardown register of the USB module must be set, and the FlushFIFO bit in the Mentor USB controller CSR register must be set. Writing to the USB OTG controller teardown register resets the CPPI FIFO occupancy value and pointers to 0. It also resets the current state of the XDMA for the endpoint selected, after any current operations have been completed. Note that due to VBUSP bridge latency, the CPPI FIFO occupancy values are not reset immediately upon writing of the teardown register.

20.1.3.2.11 PDR Interrupts

The interrupt interface provided by the core is not PDR compliant. The core only provides one interrupt signal. The CPU would have to read registers inside the core to decide what the source of the interrupt actually is. While there are enable (mask) registers and the ability to clear interrupts, there is no ability to set interrupts as required by PDR. This sub-module creates a PDR compliant interrupt interface for the OTG module. The interrupt block accepts the core interrupt, reads the core registers to determine the source(s), and provides the required interface. This includes a new interrupt source set register, and the end-of-interrupt (EOI) register. The original interrupt from the core will also be sent out for those systems that do not need the PDR interrupt interface. These interrupts are in addition to those provided by the DMA controller. The interrupts that are output by this sub-module are then aggregated by the Intd module in a PDR compliant manner.

There is also an extra interrupt mode, for systems that do not need external interrupt aggregation logic or PDR interrupts altogether. The system can utilize the aggregator logic inside the Mentor core, and not use any part of the PDR interrupt style for the USB interrupts. All USB interrupt interaction must be with the Mentor core registers in this mode, since the PDR interrupt logic is disabled. This is only for the USB interrupts, though, as the DMA interrupts only support PDR mode.

20.1.3.2.12 VBUSP Retiming

To enhance the timing of the VBUSP interfaces to the system, a VBUSP retiming bridge is used to isolate the internal timings from the external system. This retiming bridge simply takes in a VBUSP bus and outputs a VBUSP bus. These bridges are located on the incoming VBUSP configuration slave bus and the outgoing Master from the module SCR.

20.1.3.2.13 PDR Clocking and IP Generics

This sub-module implements a PDR 3.5 compliant clock interface. This consists of a gated clock, clock stop request, and clock stop acknowledge signals. When a clock stop request is asserted, this block waits until all DMAs inside the module have ceased, and sends the clock stop acknowledge. Then the system may stop the gated clock. Software should disable all the necessary functions inside the DMA and core so that there is no continued activity when a clock stop is requested.

The module also performs the required PDR 3.5 emulation interface. Setting the emulation register sets the method the module uses to perform emulation stops based on the VBUSP emulation suspend signals.

There is a register bit in the control register that allows for fast responding to the clock stop request. If this bit is enabled, this module returns a clock stop ack in the next clock cycle and does not wait for current DMAs to finish. The system needs to be tolerant of a possible loss of the DMA request if this occurs.

20.1.3.2.14 Switched Central Resource (SCR)

SCRs allow connecting more than two VBUSP ports together onto a single bus. By using VBUSP ports for connecting not only to the system, but also to local RAMs or FIFOs, a generic interface is provided that can be upgraded without affecting the other sub-modules. An SCR is used to connect all the internal and external interfaces together. These interfaces include: the core's AHB slave through the V2A bridge, the XFER DMA, and all the configuration ports.

The USB 2.0 OTG SCR has been enhanced to allow the SSRAM port to be non-bursting, while the remainder support bursting.

20.1.4 Interrupt Conditions

20.1.4.1 CPU Interrupts

The following interrupts are generated by the USB 2.0 OTG controller:

Table 20-4. CPU Interrupts

| Interrupt | Description |
|---------------|---|
| TX_ENDP[15:1] | TX endpoint ready or error for endpoints 16 to 0 (endpoint 0 is for TX and RX) |
| RX_ENDP[15:1] | RX endpoint ready or error for endpoints 16 to 0 (there is no interrupt for endpoint 0) |
| USB[8:0] | Nine USB conditions |
| USB_INT | Single interrupt signal from the core |

20.1.4.2 Interrupt Description

20.1.4.2.1 USB Core PDR Interrupts

There are 4 general-purpose TX endpoints supported in addition to control endpoint 0, whose interrupt encapsulates both TX and RX readiness. The core generates a corresponding TX_ENDP interrupt when

that TX endpoint successfully completes transmitting a packet and the buffer is empty and ready to send another packet or when the TX endpoint had an error condition. If the TXCSR is setup as required for the DMA (with DMAReqEnab and DMAReqMode set), then the TX endpoint interrupt only generates error condition interrupts, and not packet completion interrupts, which would allow software to keep the interrupt enabled for monitoring error conditions. The TX endpoint interrupts are:

Table 20-5. TX Endpoint Interrupts

| Interrupt | Description |
|-------------|---|
| TX_ENDP[15] | TX endpoint ready or error for endpoint 15 |
| TX_ENDP[14] | TX endpoint ready or error for endpoint 14 |
| TX_ENDP[13] | TX endpoint ready or error for endpoint 13 |
| TX_ENDP[12] | TX endpoint ready or error for endpoint 12 |
| TX_ENDP[11] | TX endpoint ready or error for endpoint 11 |
| TX_ENDP[10] | TX endpoint ready or error for endpoint 10 |
| TX_ENDP[9] | TX endpoint ready or error for endpoint 9 |
| TX_ENDP[8] | TX endpoint ready or error for endpoint 8 |
| TX_ENDP[7] | TX endpoint ready or error for endpoint 7 |
| TX_ENDP[6] | TX endpoint ready or error for endpoint 6 |
| TX_ENDP[5] | TX endpoint ready or error for endpoint 5 |
| TX_ENDP[4] | TX endpoint ready or error for endpoint 4 |
| TX_ENDP[3] | TX endpoint ready or error for endpoint 3 |
| TX_ENDP[2] | TX endpoint ready or error for endpoint 2 |
| TX_ENDP[1] | TX endpoint ready or error for endpoint 1 |
| TX_ENDP[0] | TX or RX endpoint ready or error for endpoint 0 |

There are 4 general-purpose RX endpoints supported. The core generates a corresponding RX_ENDP interrupt when that RX endpoint successfully receives a packet and all the data is ready in the RX endpoint FIFO or when a receive error occurs. If the RXCSR is setup as required for the DMA (with DMAReqEnab set and DMAReqMode clear), then the RX endpoint interrupt only generates error condition interrupts, and not packet readiness interrupts, which would allow software to keep the interrupt enabled for monitoring error conditions. The RX endpoint interrupts are:

Table 20-6. RX Endpoint Interrupts

| Interrupt | Description |
|-------------|--|
| RX_ENDP[15] | RX endpoint ready or error for endpoint 15 |
| RX_ENDP[14] | RX endpoint ready or error for endpoint 14 |
| RX_ENDP[13] | RX endpoint ready or error for endpoint 13 |
| RX_ENDP[12] | RX endpoint ready or error for endpoint 12 |
| RX_ENDP[11] | RX endpoint ready or error for endpoint 11 |
| RX_ENDP[10] | RX endpoint ready or error for endpoint 10 |
| RX_ENDP[9] | RX endpoint ready or error for endpoint 9 |
| RX_ENDP[8] | RX endpoint ready or error for endpoint 8 |
| RX_ENDP[7] | RX endpoint ready or error for endpoint 7 |
| RX_ENDP[6] | RX endpoint ready or error for endpoint 6 |
| RX_ENDP[5] | RX endpoint ready or error for endpoint 5 |
| RX_ENDP[4] | RX endpoint ready or error for endpoint 4 |
| RX_ENDP[3] | RX endpoint ready or error for endpoint 3 |
| RX_ENDP[2] | RX endpoint ready or error for endpoint 2 |
| RX_ENDP[1] | RX endpoint ready or error for endpoint 1 |

The USB OTG module also generates 9 USB interrupts based on noteworthy USB conditions. The USB interrupts are:

Table 20-7. USB Interrupts

| Interrupt | Description |
|-----------|--|
| USB[8] | DRVVBUS level change |
| USB[7] | VBUS < VBUS valid threshold |
| USB[6] | SRP detected |
| USB[5] | Device disconnected (host mode) |
| USB[4] | Device connected (host mode) |
| USB[3] | SOF started |
| USB[2] | Reset signaling detected (peripheral mode) Babble detected (host mode) |
| USB[1] | Resume signaling detected |
| USB[0] | Suspend signaling detected |

Interrupts USB[0] to USB[7] are generated by the Mentor core, and converted to PDR 2.0 format by the PDR interrupt sub-module. For more details on these interrupts, see the Mentor core documentation. Interrupt USB[8] is generated outside the Mentor core by the PDR interrupt sub-module whenever the level of DRVVBUS changes. This is usually due to entering or leaving Host mode, or entering or leaving power saving mode.

The USB20OTG interrupts are also aggregated by the Interrupt Distributor module. The table below provides a list of USB Interrupts that INTD processes. Only one USB interrupt signals is provided on the outside and INTD provides the interrupt aggregation logic for all USB interrupts.

When the EOI register in the USB module is written to, the `eoi_wr` and `eoi_wr_vector` information is sent to INTD which in turn re-evaluates the interrupt and triggers it if necessary.

20.1.4.2.2 USB Core Non-PDR Interrupts

If the non-PDR interrupt mode is selected for the USB interrupts, then the previous list of USB PDR sources are not valid, and the core generates the CPU interrupt directly. The pin from the core is connected to the module output, `USB_INT`, and all interactions to clear and mask interrupts must be done with the core registers. This interrupt is an active high signal.

The additional USB interrupt for DRVVBUS level changes is not part of the core interrupt set, and therefore is not available when using non-PDR interrupt mode.

20.1.4.2.3 Completion Queue Interrupts

The pending bits for queues 92-95 are aggregated in the INTD controller. These bits correspond to dedicated completion queues used by the CDMA for returning completed transmit and receive packets. The pending signals are level sensitive and when low, indicate that there are no packets on the queue. When a packet is added to one of the completion queues, the pending bit goes to high, indicating packets are available on the queue. When the low to high transition occurs, an interrupt is generated by the INTD module on the `cdma_int` pin. The Host software must read the queue status register for the completion queues to determine which queue caused the interrupt. Once all packets have been removed from the queue, the corresponding pending signal returns to 0. Software may choose to use one of the unassigned queues if an interrupt is not wanted upon the completion of a packet.

20.1.4.3 Interrupt Condition Control

20.1.4.3.1 USB Core Interrupts

The USB core interrupts are originally generated inside the Mentor core. The core provides enable

registers for each of the three types of interrupts. The INTRTXE register allows enabling of each TX endpoint interrupt. The INTRRXE register allows enabling of each RX endpoint interrupt. The INTRUSBE register allows enabling of each general USB interrupt. Any enabled interrupt generates CPU interrupts in the form of the corresponding interrupt source, the module generated interrupt pulse, and the interrupt pulse from the Mentor core directly.

To comply with PDR interrupts, additional logic is built around the core. This adds a mask register along with mask set and mask clear registers. The USB Interrupt Mask register shows the current mask value, where each bit enables the corresponding interrupt source in the USB Interrupt Source register. The USB Interrupt Mask Set register allows writing a '1' in bit positions to enable the corresponding interrupt source. Those bits written with a '0' will not be modified. The USB Interrupt Mask Clear register allows writing a '1' in bit positions to disable the corresponding interrupt source. Those bit written with a '0' will not be modified. The mask is used to enable interrupt sources and generate the masked interrupt sources which are used to generate the CPU interrupt or by external logic to generate CPU interrupts.

20.1.4.4 Interrupt Handling

20.1.4.4.1 USB Core Interrupts

The Mentor core generates the interrupts and the additional logic generates the PDR 3.5 interrupt sources. In order to generate the interrupt sources, the additional logic must read the interrupt source registers inside the core. When these registers are read, the core clears all the interrupt source bits, so the CPU will not have to do this. Therefore, the CPU simply needs to handle the data for TX or RX endpoint interrupts, or the USB interrupts and acknowledge the interrupt in the usual method. The interrupt source can be cleared by writing a '1' in the corresponding bit position to the USB Interrupt Source Clear register. Also, the End of Interrupt register functions as required by PDR. To facilitate debugging, writing a '1' to bit positions in the USB Interrupt Source Set register sets the corresponding interrupt source even if it wasn't generated by the core.

20.1.5 I/O Description

20.1.5.1 Module I/O

20.1.5.1.1 Reset Interface

| Pin Name | Type | Function |
|------------------|------|---|
| vbusp_rst_n | In | Main reset for CDMA/Queue Manager/INTD |
| vbusp_usb0_rst_n | In | Main reset for USB controller 0 submodule |
| vbusp_usb1_rst_n | In | Main reset for USB controller 1 submodule |

20.1.5.1.2 Queue Manager Event Interface

| Pin Name | Type | Function |
|-----------------------|------|--|
| qmgr_event_queue[6:0] | Out | Queue on which a push/pop operation was performed. See CPPI 4.1.7 spec for hookup details. |
| qmgr_event_strobe | Out | Queue Event Valid Indicator. See CPPI 4.1.7 spec for hookup details. |
| qmgr_event_type | Out | Queue Push/Pop Type indicator with push operation indicated by a 1 and pop by a 0. See CPPI 4.1.7 spec for hookup details. |

20.1.5.1.3 USB Interface

| Pin Name | Type | Function |
|------------------------------|-------|---|
| PHY_DP | Inout | USB I/O pin |
| PHY_DM | Inout | USB I/O pin |
| PHY_VBUS | Inout | USB I/O pin |
| PHY_ID | Inout | USB I/O pin |
| PHY_UTMI_ DRVVBUS | Out | Drive VBUS connection to external charge pump |
| PHY_UTMI_ DRVVBUS_ E_N | Out | Output enable for drive VBUS |

20.1.5.1.4 Interrupt Interface

| Pin Name | Type | Function |
|----------|------|-------------------------------|
| Usb_int | Out | USB Interrupt request |
| cdma_int | Out | CDMA Starvation Interrupt Out |

20.1.5.2 External Pins

The only external pin is for an external charge pump. The controller outputs DRVVBUS to indicate whether the charge pump should drive the VBUS pin or not. This pin need not be present when using an internal charge pump. There are no timing requirements for DRVVBUS since it is basically a static signal that only changes at major USB actions, such as going into suspend mode, or becoming a Host.

20.1.5.2.1 External Pin Table

Table 20-8. External Pin Information

| Name | Dir | Description | I/O Type ⁽¹⁾ | Timing Parameter | Minimum Value | Maximum Value |
|----------------------|-----|-------------|-------------------------|------------------|---------------|---------------|
| PHY_UTMI_D RVVBUS | O | Drive VBUS | LV-TTL | | | |

⁽¹⁾ I/O Types: 5 V-Tol = 5 Volt Tolerant, TTL-3S = TTL Output Level Tri-Stateable, LV-TTL Low Voltage TTL

20.1.6 Teardown Procedure

In order to fully teardown a TX or RX channel, the following procedure must be followed. Software should guarantee that all steps have been completed before assuming teardown has completed successfully.

20.1.6.1 Transmit Teardown

First, the CPPI DMA teardown procedure must be implemented. This is to ensure that the DMA controller is aware of the teardown and can respond properly. See the CDMA and CPPI 4.1 specifications for more details on DMA transmit teardown.

Next, once the CDMA teardown is complete and any current packets the CDMA is transmitting on the channel have completed, the USB controller Teardown register must be written, setting the corresponding bit of the endpoint that is to be torn down set. This makes sure the CPPI FIFO interface is reset properly and no spurious data remains in the FIFOs.

Lastly, the FlushFIFO bit of the CSR Register of the endpoint that is to be torn down must be set. Make certain that the necessary bits are kept set if the entire register is written. See the Mentor core documentation for more information.

After these steps are complete, the DMA channel and endpoint must go through the normal reconfiguration procedure and then can resume normal operation.

20.1.6.2 Receive Teardown

Set the FlushFIFO bit of the CSR register of the endpoint that is to be torn down. See the Mentor core documentation for more detailed information.

Next, set the USB controller Teardown register for the designated endpoint. Lastly, initiate the CDMA receive teardown procedure as described in the CDMA specification. To ensure that no data corruption has occurred in the Mentor core FIFO, the FlushFIFO bit of the CSR register should be written a second time after the CDMA channel teardown. To ensure good operation, the Host should wait at least 100 VBUSP_CLK clock cycles after CDMA channel teardown and the second write of the FlushFIFO bit. At this time the endpoint has completed teardown and can be reinitialized according to the standard endpoint setup procedure and normal operation resumed.

20.1.7 USB Bus Reset Handling

After a USB bus reset, the Mentor core interrupts as well as clears many of its registers. This requires the software to teardown any TX DMA channels currently in use before setting up the DMA and core again. Failure to perform the teardown procedure as described previously may result in erratic behavior or unwanted TX data.

20.1.8 VBUSP Slave Port Bursting

The USB 2.0 OTG subsystem does not support bursting on the VBUSP slave port. All accesses should be single word (or smaller) accesses, and the first and last signals should always be high. Sending bursts to registers can result in unpredictable behavior.

20.1.9 Core Register Type Mixing

Software must take care when reading core registers larger than their original size to optimize reads. If the registers read are from different types (common, endpoint, or FIFO) then the core only reads the registers in the type of the initial address, and not the upper address registers in another type. An example is the DEVCTL common register at 0x460 with the TXFIFOSZ and RXFIFOSZ endpoint registers at 0x462 and 0x463. The core only reads the DEVCTL register in this case. To read the TXFIFOSZ and RXFIFOSZ registers, software must read starting at 0x462.

20.1.10 Zero Byte Packet Parameters

Zero-byte packets must be generated with the zero-byte bit of Info register 1 set (see the CPPI FIFO Info register 1) and the packet size should be 1 byte. The actual packet data is not used.

20.1.11 Interrupt Usage

The expected usage of the interrupts when using the DMA is as follows. The DMA generates interrupts after each CPPI packet is processed. With the expects TXCSR and RXCSR setup as required for the DMA, the TX endpoint and RX endpoint interrupts will only be generated when there is an error or stall condition from the core. Therefore, the CPU should not disable and ignore the endpoint interrupts unless error detection is not desired or polling is used.

20.1.12 Powerdown Handling

In order to safely powerdown the USB 2.0 OTG module, the SUSPENDM signal should be monitored. When low, the USB bus is going into suspend mode and the system can safely powerdown the OTG module. This includes disabling the clock, and disabling the PHY. Please refer to the PHY spec on how to safely powerdown the PHY.

In order to wakeup after suspend from a bus resume, the PHY must be powered on to drive the LINESTATE, VBUSVALID, and AVALID UTMI signals. The OTG controller uses these to asynchronously generate SUSPENDM, so it can drive SUSPENDM high even without a clock. When SUSPENDM goes high, the USB 2.0 OTG module and the PHY should be powered up again so that the USB operations can resume.

20.1.13 Clock Stop and Emulation Suspend

The USB module supports clock stop operation and CBA compliant emulation suspend. It should be noted that for clock stop operation, the UTMI clock is unaffected and the Mentor core continues to interact with the phy device unless the phy is powered down at the time. Similarly for emulation suspend, the XDMA state machine halts once the current packet processing is complete, but the Mentor controller is unaffected by the suspend unless the phy is also powered down at the same time.

The clock stop interface allows the DMA to be gracefully commanded to enter into a stopped clock state. When the *clkstop_req* input is asserted, the DMA suspend state is entered and, the DMA stops processing receive and transmit packets for each channel at the next packet boundary. Any packet currently in reception or transmission is completed normally without suspension. The *clkstop_ack* output is asserted when the DMA enters the IDLE state and all of the individual channels have indicated that they are stopped and are no longer in the middle of transmitting or receiving a packet. The *clkstop_ack* indicates that the clock, *vbusp_gclk*, may be stopped.

20.1.14 Registers

Table 20-9 lists the memory-mapped registers for the high speed universal serial bus (USB).

Table 20-9. Universal Serial Bus (USB) Registers

20.1.14.1 USB Control Register (Base Address + 0x0004)

The control register allows the CPU to control various aspects of the module.

The USB control register is shown in [Figure 20-4](#) and described in [Table 20-10](#).

Figure 20-4. USB Control Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 20-10. USB Control Register Field Descriptions

| Bit | Field | Value | Description |
|------|----------|-------|--|
| 31 | dis_deb | | Disable the VBUS debouncer circuit fix |
| 30 | dis_srp | | Disable the SRP a_valid circuit fix |
| 29-5 | Reserved | 0 | Always read as 0. Writes have no affect. |
| 4 | rndis | | Global RNDIS mode enable for all endpoints. |
| 3 | uint | | USB non-PDR interrupt enable |
| 2 | Reserved | 0 | Always read as 0. Writes have no effect. |
| 1 | clkfack | | Clock stop fast ack enable. |
| 0 | Reset | | Soft reset. Writing a 1 starts a module reset. |

20.1.14.2 USB Status Register (Base Address + 0x0008)

The status register allows the CPU to check various aspects of the module.

The USB status register is shown in [Figure 20-5](#) and described in [Table 20-11](#).

Figure 20-5. USB Status Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

| Bit | Field | Value | Description |
|------|----------|-------|--|
| 31-1 | Reserved | 0 | Always read as 0. Writes have no affect. |
| 0 | drvvbus | | Current DRVVBUS value |

20.1.14.3 USB Auto Req Register (Base Address + 0x0014)

The auto req register allows the CPU to enable an automatic IN token request generation for the Host mode RX operation per each RX endpoint. This feature has the DMA set the ReqPkt bit in the RXCSR when it clears the RxPktRdy bit after reading out a packet. The ReqPkt bit is used by the core to generate an IN token to receive data. By using this feature, the Host can automatically generate an IN token after the DMA finishes receiving data and empties an endpoint buffer, thus receiving the next data packet as soon as possible from the connected device. Without this feature, the CPU has to manually set the ReqPkt bit for every USB packet. There are two modes that Auto Req can function: always or all except an end of packet (EOP). The always mode sets the ReqPkt bit after every USB packet the DMA receives generating a new IN token after each USB packet. The EOP mode sets the ReqPkt bit after every USB packet that isn't an EOP in the CPPI descriptor. For RNDIS, CDC, and generic RNDIS modes, the auto req stops when the EOP is received (either via a short packet for RNDIS, CDC, and generic RNDIS or the count is reached for generic RNDIS), making it useful for starting a large RNDIS packet and having it auto generate IN tokens until the end of the RNDIS packet. For transparent mode, every USB packet is an EOP CPPI packet so the auto req never functions and acts like it is disabled.

The USB auto req register is shown in [Figure 20-6](#) and described in [Table 20-12](#).

20.1.14.4 USB Teardown Register (Base Address + 0x001C)

The teardown register controls the tearing down of rx and tx FIFOs in the USB controller. When a '1' is written to a valid bit in this register, the CPPI FIFO pointers for that endpoint are cleared. This register must be used in conjunction with the CPPI DMA teardown mechanism. The Host should also write the FlushFIFO bits in the TXCSR and RXCSR Mentor USB controller registers to ensure a complete teardown of the endpoint. See the Mentor specification for details.

The USB teardown register is shown in [Figure 20-7](#) and described in [Table 20-13](#).

Figure 20-7. USB Teardown Register

| | | | | | |
|----------|----|----------|----------|---|----------|
| 31 | 17 | 16 | 15 | 1 | 0 |
| tx_tdown | | Reserved | rx_tdown | | Reserved |
| R/W | | | R/W | | |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 20-13. USB Teardown Register Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|-------|---|
| 31-17 | tx_tdown | | Tx Endpoint Teardown. Write '1' to corresponding bit to set. Read as '0'. Bit 31 = Endpoint 15 ... Bit 17 = Endpoint 1 |
| 16 | Reserved | 0 | Always read as 0. Writes have no affect. |
| 15-1 | rx_tdown | | RX Endpoint Teardown. Write '1' to corresponding bit to set. Read as '0'. Bit 15 = Endpoint 15 ... Bit 1 = Endpoint 1 |
| 0 | Reserved | 0 | Always read as 0. Writes have no affect. |

20.1.14.5 USB Endpoint Interrupt Source Register (Base Address + 0x0020)

The USB interrupt source register contains the status of the interrupt sources generated by the USB core (not the DMA).

The USB endpoint interrupt source register is shown in [Figure 20-8](#) and described in [Table 20-14](#).

Figure 20-8. USB Endpoint Interrupt Source Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 20-14. USB Endpoint Interrupt Source Register Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|-------|--|
| 31-17 | rx | | RX endpoint interrupt sources (N+15 to N). |
| 16 | Reserved | 0 | Always read as 0. Writes have no affect. |
| 15-0 | tx | | TX endpoint interrupt sources (N+15 to N+1 plus endpoint 0). |

20.1.14.6 USB Endpoint Interrupt Source Set Register (Base Address + 0x0024)

The USB interrupt source set register allows the USB interrupt sources to be manually triggered. A read of this register returns the USB interrupt source register value.

The USB endpoint interrupt source set register is shown in [Figure 20-9](#) and described in [Table 20-15](#).

Figure 20-9. USB Endpoint Interrupt Source Set Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 20-15. USB Endpoint Interrupt Source Set Register Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|-------|---|
| 31-17 | rx | | Write a 1 to set equivalent RX endpoint interrupt source. |
| 16 | Reserved | 0 | Always read as 0. Writes have no affect. |
| 15-0 | tx | | Write a 1 to set equivalent TX endpoint interrupt source. |

20.1.14.7 USB Endpoint Interrupt Source Clear Register (Base Address + 0x0028)

The USB interrupt source clear register allows the CPU to acknowledge an interrupt source and turn it off. A read of this register returns the USB interrupt source register value.

The USB endpoint interrupt source clear register is shown in [Figure 20-10](#) and described in [Table 20-16](#).

Figure 20-10. USB Endpoint Interrupt Source Clear Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 20-16. USB Endpoint Interrupt Source Clear Register Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|-------|---|
| 31-17 | rx | | Write a 1 to clear equivalent RX endpoint interrupt source. |
| 16 | Reserved | 0 | Always read as 0. Writes have no affect. |
| 15-0 | tx | | Write a 1 to clear equivalent TX endpoint interrupt source. |

20.1.14.8 USB Endpoint Interrupt Mask Register (Base Address + 0x002C)

The USB interrupt mask register contains the masks of the interrupt sources generated by the USB core (not the DMA). These masks are used to enable or disable interrupt sources generated on the masked source interrupts (the raw source interrupts are never masked). The bit positions are maintained in the same position as the interrupt sources in the USB interrupt source register.

The USB endpoint interrupt mask register is shown in [Figure 20-11](#) and described in [Table 20-17](#).

Figure 20-11. USB Endpoint Interrupt Mask Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 20-17. USB Endpoint Interrupt Mask Register Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|-------|---|
| 31-17 | rx | | Write a 1 to clear equivalent RX endpoint interrupt source. |
| 16 | Reserved | 0 | Always read as 0. Writes have no affect. |
| 15-0 | tx | | Write a 1 to clear equivalent TX endpoint interrupt source. |

20.1.14.9 USB Endpoint Interrupt Mask Set Register (Base Address + 0x0030)

The USB interrupt mask set register allows the USB interrupt masks to be individually enabled. A read to this register returns the USB interrupt mask register value.

The USB endpoint interrupt mask set register is shown in [Figure 20-12](#) and described in [Table 20-18](#).

Figure 20-12. USB Endpoint Interrupt Mask Set Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 20-18. USB Endpoint Interrupt Mask Set Register Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|-------|---|
| 31-17 | rx | | Write a 1 to set equivalent RX endpoint interrupt mask. |
| 16 | Reserved | 0 | Always read as 0. Writes have no affect. |
| 15-0 | tx | | Write a 1 to set equivalent TX endpoint interrupt mask. |

20.1.14.10 USB Endpoint Interrupt Mask Clear Register (Base Address + 0x0034)

The USB interrupt mask clear register allows the USB interrupt masks to be individually disabled. A read to this register returns the USB interrupt mask register value.

The USB endpoint interrupt mask clear register is shown in [Figure 20-13](#) and described in [Table 20-19](#).

Figure 20-13. USB Endpoint Interrupt Mask Clear Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 20-19. USB Endpoint Interrupt Mask Clear Register Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|-------|---|
| 31-17 | rx | | Write a 1 to clear equivalent RX endpoint interrupt mask. |
| 16 | Reserved | 0 | Always read as 0. Writes have no affect. |
| 15-0 | tx | | Write a 1 to clear equivalent TX endpoint interrupt mask. |

20.1.14.11 USB Endpoint Interrupt Source Masked Register (Base Address + 0x0038)

The USB endpoint interrupt source masked register contains the status of the interrupt sources generated by the USB core masked by the USB interrupt mask register values.

The USB endpoint interrupt source masked register is shown in [Figure 20-14](#) and described in [Table 20-20](#).

Figure 20-14. USB Endpoint Interrupt Source Masked Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 20-20. USB Endpoint Interrupt Source Masked Register Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|-------|--|
| 31-17 | rx | | RX endpoint interrupt sources masked. |
| 16 | Reserved | 0 | Always read as 0. Writes have no affect. |
| 15-0 | tx | | TX endpoint interrupt sources masked. |

20.1.14.12 USB Core Interrupt Source Register (Base Address + 0x0040)

The USB interrupt source register contains the status of the interrupt sources generated by the USB core (not the DMA).

The USB core interrupt source register is shown in [Figure 20-15](#) and described in [Table 20-21](#).

Figure 20-15. USB Core Interrupt Source Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 20-21. USB Core Interrupt Source Register Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|-------|--|
| 31-25 | Reserved | 0 | Always read as 0. Writes have no affect. |
| 24-16 | usb | | USB interrupt sources. |
| 15-0 | Reserved | 0 | Always read as 0. Writes have no affect. |

20.1.14.13 USB Core Interrupt Source Set Register (Base Address + 0x0044)

The USB interrupt source set register allows the USB interrupt sources to be manually triggered. A read of this register returns the USB interrupt source register value.

The USB core interrupt source set register is shown in [Figure 20-16](#) and described in [Table 20-22](#).

Figure 20-16. USB Core Interrupt Source Set Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 20-22. USB Core Interrupt Source Set Register Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|-------|---|
| 31-25 | Reserved | 0 | Always read as 0. Writes have no affect. |
| 24-16 | usb | | Write a 1 to set equivalent USB interrupt source. |
| 15-0 | Reserved | 0 | Always read as 0. Writes have no affect. |

20.1.14.14 USB Core Interrupt Source Clear Register (Base Address + 0x0048)

The USB interrupt source clear register allows the CPU to acknowledge an interrupt source and turn it off. A read of this register returns the USB interrupt source register value.

The USB core interrupt source clear register is shown in [Figure 20-17](#) and described in [Table 20-23](#).

Figure 20-17. USB Core Interrupt Source Clear Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 20-23. USB Core Interrupt Source Clear Register Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|-------|---|
| 31-25 | Reserved | 0 | Always read as 0. Writes have no affect. |
| 24-16 | usb | | Write a 1 to clear equivalent USB interrupt source. |
| 15-0 | Reserved | 0 | Always read as 0. Writes have no affect. |

20.1.14.15 USB Core Interrupt Mask Register (Base Address + 0x004C)

The USB interrupt mask register contains the masks of the interrupt sources generated by the USB core (not the DMA). These masks are used to enable or disable interrupt sources generated on the masked source interrupts (the raw source interrupts are never masked). The bit positions are maintained in the same position as the interrupt sources in the USB interrupt source register.

The USB core interrupt mask register is shown in [Figure 20-18](#) and described in [Table 20-24](#).

Figure 20-18. USB Core Interrupt Mask Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 20-24. USB Core Interrupt Mask Register Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|-------|--|
| 31-25 | Reserved | 0 | Always read as 0. Writes have no affect. |
| 24-16 | usb | | USB interrupt source masks. |
| 15-0 | Reserved | 0 | Always read as 0. Writes have no affect. |

20.1.14.16 USB Core Interrupt Mask Set Register (Base Address + 0x0050)

The USB interrupt mask set register allows the USB interrupt masks to be individually enabled. A read to this register returns the USB interrupt mask register value.

The USB core interrupt mask set register is shown in [Figure 20-19](#) and described in [Table 20-25](#).

Figure 20-19. USB Core Interrupt Mask Set Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 20-25. USB Core Interrupt Mask Set Register Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|-------|---|
| 31-25 | Reserved | 0 | Always read as 0. Writes have no affect. |
| 24-16 | usb | | Write a 1 to set equivalent USB interrupt mask. |
| 15-0 | Reserved | 0 | Always read as 0. Writes have no affect. |

20.1.14.17 USB Core Interrupt Mask Clear Register (Base Address + 0x0054)

The USB interrupt mask clear register allows the USB interrupt masks to be individually disabled. A read to this register returns the USB interrupt mask register value.

The USB core interrupt mask clear register is shown in [Figure 20-20](#) and described in [Table 20-26](#).

Figure 20-20. USB Core Interrupt Mask Clear Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 20-26. USB Core Interrupt Mask Clear Register Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|-------|---|
| 31-25 | Reserved | 0 | Always read as 0. Writes have no affect. |
| 24-16 | usb | | Write a 1 to clear equivalent USB interrupt mask. |
| 15-0 | Reserved | 0 | Always read as 0. Writes have no affect. |

20.1.14.18 USB Core Interrupt Source Masked Register (Base Address + 0x0058)

The USB interrupt source masked register contains the status of the interrupt sources generated by the USB core masked by the USB interrupt mask register values.

The USB core interrupt source masked register is shown in [Figure 20-21](#) and described in [Table 20-27](#).

Figure 20-21. USB Core Interrupt Source Masked Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 20-27. USB Core Interrupt Source Masked Register Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|-------|--|
| 31-25 | Reserved | 0 | Always read as 0. Writes have no affect. |
| 24-16 | usb | | USB interrupt sources masked. |
| 15-0 | Reserved | 0 | Always read as 0. Writes have no affect. |

20.1.14.19 USB End of Interrupt Register (Base Address + 0x0060)

The USB end of interrupt register allows the CPU to acknowledge completion of an interrupt by writing to the EOI. An `eoi_write` signal is generated, the EOI vector is updated to the written value, and another interrupt is triggered if interrupt sources remain.

The USB end of interrupt register is shown in [Figure 20-22](#) and described in [Table 20-28](#).

Figure 20-22. USB End of Interrupt Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 20-28. USB End of Interrupt Register Field Descriptions

| Bit | Field | Value | Description |
|-----|------------|-------|--|
| 318 | Reserved | 0 | Always read as 0. Writes have no affect. |
| 7-0 | eoi_vector | | EOI vector |

20.1.14.20 USB MOP/SOP Interrupt Enable Register (Base Address + 0x0064)

This register must be set to enable the DMA buffer starvation interrupt. When bit for the mop or sop interrupt is enabled, the interrupt to the INTD module triggers the first time the DMA issues that interrupt and then automatically disables itself, blocking future interrupts until the Host re-enables via this register.

The USB MOP/SOP interrupt enable register is shown in [Figure 20-23](#) and described in [Table 20-29](#).

Figure 20-23. USB MOP/SOP Interrupt Enable Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 20-29. USB MOP/SOP Interrupt Enable Register Field Descriptions

| Bit | Field | Value | Description |
|------|----------|-------|--|
| 31-2 | Reserved | 0 | Always read as 0. Writes have no affect. |
| 1 | sop_en | | When 1, DMA sop starvation interrupt is enabled. |
| 0 | mop_en | | When 1, DMA mop starvation interrupt is enabled. |

20.1.14.21 USB Tx Mode Register (Base Address + 0x0070)

The mode register allows the CPU to individually enable RNDIS/generic/CDC modes for each endpoint. Using the global RNDIS enable in the control register overrides this register and enables RNDIS mode for all endpoints.

The USB Tx mode register is shown in [Figure 20-24](#) and described in [Table 20-30](#).

Figure 20-24. USB Tx Mode Register

| | | | | | | | |
|---------------|----|---------------|----|---------------|----|---------------|----|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 |

20.1.14.22 USB Rx Mode Register (Base Address + 0x0074)

The mode register allows the CPU to individually enable RNDIS/Generic/CDC modes for each endpoint. Using the global RNDIS enable in the control register overrides this register and enables RNDIS mode for all endpoints.

The USB Rx mode register is shown in [Figure 20-25](#) and described in [Table 20-31](#).

20.1.14.23 USB EP Count Mode Register (Base Address + 0x0078)

The EP count mode register is a special feature used only in conjunction with transparent mode that allows the XDMA to receive a preprogrammed number of USB packets and then halting until the count is reprogrammed. When the corresponding bit of this register is set and the endpoint is in transparent mode, the EP size register for that endpoint becomes a USB packet count register. After the XDMA receives a USB packet, it decrements this register by one. If auto request on all is enabled, it sets the packet request bit in the endpoint's CSR register in the Mentor controller. When the XDMA receives a packet and the count value is 1, the XDMA will not issue a packet request to the Mentor controller, but waits for the count value to be reprogrammed before continuing.

The USB EP count mode register is shown in [Figure 20-26](#) and described in [Table 20-32](#).

20.1.14.24 USB Generic RNDIS EP N Size Register (Base Address + 0x0080)

The generic RNDIS EP1 size register is programmed with a RNDIS packet size in bytes. When EP1 is in generic RNDIS mode, the received USB packets collected into a single CPPI packet that is completed when the number of bytes equal to the value of this register has been received, or a “short” packet is received. Note that this register must be programmed with a value that is an integer multiple of the endpoint size. The maximum value this register can be programmed with is 0x10000, or 65536. When the controller is set in transparent EP count mode, this register is known as the EP count register and the number programmed is the number of USB packets to receive before halting.

The USB generic RNDIS EP N size register is shown in [Figure 20-27](#) and described in [Table 20-33](#)??.

Figure 20-27. USB Generic RNDIS EP N Size Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 20-33. USB Generic RNDIS EP N Size Register Field Descriptions

| Bit | Field | Value | Description |
|-------|------------|-------|--|
| 31-17 | Reserved | 0 | Always read as 0. Writes have no affect. |
| 16-0 | Ep(N)_size | | Generic RNDIS packet size. |

20.1.14.25 USB Queue Interrupt Threshold Enable Register (Base Address + 0x00C0)

The queue interrupt threshold enable register enables the threshold counts that are available for two of the completion queues. When the bit is set, the interrupt threshold mechanism for that queue is enabled.

The USB queue interrupt threshold enable register is shown in [Figure 20-28](#) and described in [Table 20-34](#).

Figure 20-28. USB Queue Interrupt Threshold Enable Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 20-34. USB Queue Interrupt Threshold Enable Register Field Descriptions

| Bit | Field | Value | Description |
|------|------------|-------|--|
| 31-2 | Reserved | 0 | Always read as 0. Writes have no affect. |
| 1 | Queue65_en | 0 | Threshold Disabled for Completion Queue 65 |
| | | 1 | Threshold Enabled for Completion Queue 65 |
| 0 | Queue63_en | 0 | Threshold Disabled for Completion Queue 63 |
| | | 1 | Threshold Enabled for Completion Queue 63 |

20.1.14.26 USB Queue Threshold Register 0 (Base Address + 0x00C4)

The queue threshold register provides a programmable method to delay the completion interrupt until a number of interrupts have been detected. The Host software programs this register with a value between 1 and 255. When the DMA completes a packet designated for completion queue 63, an internal counter is incremented. When this counter reaches the value in this threshold register, an the interrupt and subsequent interrupts are enable to the INTD module, until the interrupt clear register is written and the internal count is reset.

The USB queue threshold register 0 is shown in [Figure 20-29](#) and described in [Table 20-35](#).

Figure 20-29. USB Queue Threshold Register 0

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 20-35. USB Queue Threshold Register 0 Field Descriptions

| Bit | Field | Value | Description |
|------|-----------|-------|--|
| 31-8 | Reserved | 0 | Always read as 0. Writes have no affect. |
| 7-0 | thrsh_q63 | | Programmable interrupt threshold. |

20.1.14.27 USB Interrupt Clear Register 0 (Base Address + 0x00C8)

When this register is written, the internal threshold count register is cleared. The Host should clear this register whenever the threshold count register value is reached, and an interrupt is generated.

The USB interrupt clear register 0 is shown in [Figure 20-30](#) and described in [Table 20-36](#).

Figure 20-30. USB Interrupt Clear Register 0

LEGEND: R/W = Read/Write; R = Read only; Write only; -n = value after reset

Table 20-36. USB Interrupt Clear Register 0 Field Descriptions

| Bit | Field | Value | Description |
|------|------------|-------|----------------------------------|
| 31-0 | Queue63_en | | Clears internal threshold count. |

20.1.14.28 USB Queue Threshold Register 1 (Base Address + 0x00D4)

The queue threshold register provides a programmable method to delay the completion interrupt until a number of interrupts have been detected. The Host software programs this register with a value between 1 and 255. When the DMA completes a packet designated for completion queue 65, an internal counter is incremented. When this counter reaches the value in this threshold register, an the interrupt and subsequent interrupts are enable to the INTD module, until the interrupt clear register is written and the internal count is reset.

The USB queue threshold register 1 is shown in [Figure 20-31](#) and described in [Table 20-37](#).

Figure 20-31. USB Queue Threshold Register 1

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 20-37. USB Queue Threshold Register 1 Field Descriptions

| Bit | Field | Value | Description |
|------|-----------|-------|--|
| 31-8 | Reserved | 0 | Always read as 0. Writes have no affect. |
| 7-0 | thrsh_q65 | | Programmable interrupt threshold. |

20.1.14.29 USB Interrupt Clear Register 1 (Base Address + 0x00D8)

When this register is written, the internal threshold count register is cleared. The Host should clear this register whenever the threshold count register value is reached, and an interrupt is generated.

The USB interrupt clear register 1 is shown in [Figure 20-32](#) and described in [Table 20-38](#).

Figure 20-32. USB Interrupt Clear Register 1

LEGEND: R/W = Read/Write; R = Read only; Write only; -n = value after reset

Table 20-38. USB Interrupt Clear Register 1 Field Descriptions

| Bit | Field | Value | Description |
|------|------------|-------|----------------------------------|
| 31-0 | Queue65_en | | Clears internal threshold count. |

20.1.14.30 USB Mentor Core Registers/FIFOs (Base Address + 0x400 – 0x59C)

A description of the Mentor core registers is available in the Mentor specification. The core registers are described starting at address 0x000, but they are located in the USB 2.0 OTG module starting at 0x400. To convert, just add 0x400 to the register address in the Mentor core specification.

20.1.14.30.1 CDMA Tx Channel N Global Configuration Register (Base Address + 0x0800 + 32*N)

The Tx channel configuration registers are used to initialize the behavior of each of the Tx DMA channels.

The CDMA Tx channel N global configuration register is shown in [Figure 20-33](#) and described in [Table 20-39](#).

Figure 20-33. CDMA Tx Channel N Global Configuration Register

| 31 | tx_enable | 0 1 | This field enables or disables the channel Channel is disabled Channel is enabled This field is cleared after a channel teardown is complete. |
| 30 | tx_teardown | | Setting this bit will request the channel to be torn down. This field remains set after a channel teardown is complete. |
| 29-14 | Reserved | 0 | Always read as 0. Writes have no affect. |
| 13-12 | tx_default_qmgr | | This field controls the default queue manager number that is used to queue teardown descriptors back to the Host. |
| 11-0 | tx_default_qnum | | This field controls the default queue number within the selected queue manager onto which teardown descriptors are queued back to the Host. |

20.1.14.30.2 CDMA Rx Channel N Global Configuration Register (Base Address + 0x0808 + 32*N)

The Rx channel global configuration registers are used to initialize the global (non descriptor type specific) behavior of each of the Rx DMA channels. If the enable bit is being set, the Rx channel global configuration register should only be written after all of the other Rx configuration registers have been initialized.

The CDMA Rx channel N global N configuration register is shown in [Figure 20-34](#) and described in [Table 20-40](#).

Figure 20-34. CDMA Rx Channel N Global Configuration Register

| | | | | | | | |

LEGEND: R/W = Read/Write; R = Read only; Write only; -n = value after reset

Table 20-40. CDMA Rx Channel N Global Configuration Register Field Descriptions

| Bit | Field | Value | Description |
|-------|-------------------|-------|--|
| 31 | rx_enable | | This field enables or disables the channel. |
| | | 0 | Channel is disabled |
| | | 1 | Channel is enabled |
| | | | This field is cleared after a channel teardown is complete. |
| 30 | rx_teardown | | This field indicates whether or not an Rx teardown operation is complete. This field should be cleared when a channel is initialized. This field is set after a channel teardown is complete. |
| 29-25 | Reserved | 0 | Always read as 0. Writes have no affect. |
| 24 | rx_error_handling | | This bit controls the error handling mode for the channel and is only used when channel errors (i.e., descriptor or buffer starvation occurs): |
| | | 0 | Starvation errors result in dropping packet and reclaiming any used descriptor or buffer resources back to the original queues/pools they were allocated to |
| | | 1 | Starvation errors result in subsequent re-try of the descriptor allocation operation. In this mode, the DMA returns to the IDLE state without saving it's internal operational state back to the internal state RAM and without issuing an advance operation on the FIFO interface. This results in the DMA re-initiating the FIFO block transfer at a later time with the intention that additional free buffers and/or descriptors will have been added. |
| | | | Regardless of the value of this bit, the DMA asserts the cdma_rx_sof_overrun (for SOP) or cdma_rx_mof_overrun (for non-SOP) when ?? |
| 23-16 | rx_sop_offset | | This field specifies the number of bytes that are to be skipped in the SOP buffer before beginning to write the payload. This value must be less than the minimum size of a buffer in the system. Valid values are 0 – 255 bytes. |

Table 20-40. CDMA Rx Channel N Global Configuration Register Field Descriptions (continued)

| Bit | Field | Value | Description |
|-------|----------------------|--|---|
| 15-14 | rx_default_desc_type | 0 Reserved 1 Host 2 Reserved 3 Reserved | This field indicates the default descriptor type to use: The actual descriptor type that is used for reception can be overridden by information provided in the CPPI FIFO data block. |
| 13-12 | rx_default_rq_mgr | | This field indicates the default receive queue manager that this channel should use. The actual receive queue manager index can be overridden by information provided in the CPPI FIFO data block. |
| 11-0 | rx_default_rq_qnum | | This field indicates the default receive queue that this channel should use. The actual receive queue that is used for reception can be overridden by information provided in the CPPI FIFO data block. |

20.1.14.30.3 CDMA Rx Channel N Host Packet Configuration Register A (Base Address + 0x080C + 32*N)

The Rx channel Host packet configuration registers are used to initialize the behavior of each of the Rx DMA channels for reception of Host type packets.

The CDMA Rx channel N Host packet configuration register A is shown in [Figure 20-35](#) and described in [Table 20-41](#).

Figure 20-35. CDMA Rx Channel N Host Packet Configuration Register A

Table 20-44. CDMA Scheduler Table Word N Registers Field Descriptions

| Bit | Field | Value | Description |
|-------|----------------|--------|--|
| 31 | entry3_rxtx | 0 1 | This bit indicates if this entry is for a Tx or an Rx channel and is encoded as follows: Tx Channel Rx Channel |
| 30-28 | Reserved | 0 | Always read as 0. Writes have no affect. |
| 27-24 | entry3_channel | | This field indicates the channel # that is to be given an opportunity to transfer data. If this is a Tx entry, the DMA is presented with a scheduling 'credit' for that exact Tx channel. If this is an Rx entry, the DMA is presented with a scheduling credit for the Rx FIFO that is associated with this channel. For Rx FIFOs which carry traffic for more than 1 Rx DMA channel, the exact channel number that is given in the Rx credit is the channel number that is currently on the head element of that Rx FIFO, which is not necessarily the channel number given in the scheduler table entry. |
| 23 | entry2_rxtx | 0 1 | This bit indicates if this entry is for a Tx or an Rx channel and is encoded as follows: Tx Channel Rx Channel |
| 22-20 | Reserved | 0 | Always read as 0. Writes have no affect. |
| 19-16 | entry2_channel | | This field indicates the channel # that is to be given an opportunity to transfer data. If this is a Tx entry, the DMA is presented with a scheduling 'credit' for that exact Tx channel. If this is an Rx entry, the DMA is presented with a scheduling credit for the Rx FIFO that is associated with this channel. For Rx FIFOs which carry traffic for more than 1 Rx DMA channel, the exact channel number that is given in the Rx credit is the channel number which is currently on the head element of that Rx FIFO, which is not necessarily the channel number given in the scheduler table entry. |
| 15 | entry1_rxtx | 0 1 | This bit indicates if this entry is for a Tx or an Rx channel and is encoded as follows: Tx Channel Rx Channel |
| 14-12 | Reserved | 0 | Always read as 0. Writes have no affect. |
| 11-8 | entry1_channel | | This field indicates the channel # that is to be given an opportunity to transfer data. If this is a Tx entry, the DMA is presented with a scheduling 'credit' for that exact Tx channel. If this is an Rx entry, the DMA is presented with a scheduling credit for the Rx FIFO that is associated with this channel. For Rx FIFOs which carry traffic for more than 1 Rx DMA channel, the exact channel number that is given in the Rx credit is the channel number which is currently on the head element of that Rx FIFO, which is not necessarily the channel number given in the scheduler table entry. |
| 7 | entry0_rxtx | 0 1 | This bit indicates if this entry is for a Tx or an Rx channel and is encoded as follows: Tx Channel Rx Channel |

Table 20-44. CDMA Scheduler Table Word N Registers Field Descriptions (continued)

| Bit | Field | Value | Description |
|-----|----------------|-------|--|
| 6-4 | Reserved | 0 | Always read as 0. Writes have no affect. |
| 3-0 | entry0_channel | | This field indicates the channel # that is to be given an opportunity to transfer data. If this is a Tx entry, the DMA is presented with a scheduling 'credit' for that exact Tx channel. If this is an Rx entry, the DMA is presented with a scheduling credit for the Rx FIFO that is associated with this channel. For Rx FIFOs which carry traffic for more than 1 Rx DMA channel, the exact channel number that is given in the Rx credit is the channel number which is currently on the head element of that Rx FIFO, which is not necessarily the channel number given in the scheduler table entry. |

20.1.14.31 INTD Revision Register (Base Address + 0x3000)

The revision register contains the ID and revision information.

The INTD revision register is shown in [Figure 20-39](#) and described in [Table 20-45](#).

Figure 20-39. INTD Revision Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 20-45. INTD Revision Register Field Descriptions

| Bit | Field | Value | Description |
|-------|--------|-------|---|
| 31-30 | scheme | | Always read as 1. Writes have no affect. |
| 29-16 | modID | | Module ID field. |
| 15-11 | revrtl | | RTL revision. Will vary depending on release. |
| 10-8 | revmaj | | Major revision. |
| 7-0 | revmin | | Minor revision. |

20.1.14.32 INTD EOI Register (Base Address + 0x3010)

The EOI register allows the software to perform an end of interrupt handshake to interrupts with an IP that does not have an EOI register. The EOI handshake allows system interrupts to be re-evaluated for the associate logic with the EOI vector value to allow multiple logic paths to re-evaluate individually without separate EOI registers. The EOI occurs the cycle after the register is written.

The INTD EOI register is shown in [Figure 20-40](#) and described in [Table 20-46](#).

Figure 20-40. INTD EOI Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 20-46. INTD EOI Register Field Descriptions

| Bit | Field | Value | Description |
|------|------------|-------|---|
| 31-8 | Reserved | 0 | Always read as 0. Writes have no affect. |
| 7-0 | eoi_vector | | EOI Vector value. This should be written with the value associate to the interrupt and Host combination given in the cp_intd configuration. |

20.1.14.33 INTD EOI Interrupt Vector Register (Base Address + 0x3014)

The EOI interrupt vector register captures the active and prioritized interrupts so that software can quickly read the values rather than check every bit in the IP interrupt source register. The exact definition of this register is configuration dependent.

The INTD EOI interrupt vector register is shown in [Figure 20-41](#) and described in [Table 20-47](#).

Figure 20-41. INTD EOI Interrupt Vector Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 20-47. INTD EOI Interrupt Vector Register

| Bit | Field | Value | Description |
|------|-------------|-------|---|
| 31-0 | intr_vector | | EOI interrupt vector value. This has the latest prioritized interrupt values. Dependent on configuration. |

20.1.14.34 INTD Status Register 0 (Base Address + 0x3200)

The status register indicates which IP interrupts are active for the Host. There is at least one register per Host for up to 32 interrupts. The exact interrupt mapping is determined by the configuration and then those registers, could be more than 1, are replicated for each Host. The mapping of bits in this register matches that of the enable registers. For level interrupts the status bit is read only and is always determined by the input interrupt level.

The INTD status register 0 is shown in [Figure 20-42](#) and described in [Table 20-48](#).

Figure 20-42. INTD Status Register 0

20.1.14.37 INTD Status Register 3 (Base Address + 0x320C)

The status register indicates which IP interrupts are active for the Host. There is at least one register per Host for up to 32 interrupts. The exact interrupt mapping is determined by the configuration and then those registers, could be more than 1, are replicated for each Host. The mapping of bits in this register matches that of the enable registers. For level interrupts the status bit is read only and is always determined by the input interrupt level.

The INTD status register 3 is shown in [Figure 20-45](#) and described in [Table 20-51](#).

Figure 20-45. INTD Status Register 3

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 20-51. INTD Status Register 3 Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|-------|--|
| 31-16 | Reserved | 0 | Always read as 0. Writes have no effect. |
| 15-14 | Comp_int | 0 | Completion Interrupts for Queues 66 and 65 Status Not pending |
| | | 1 | Pending |
| 13-2 | Reserved | 0 | Always read as 0. Writes have no effect. |
| 1-0 | Comp_int | 0 | Completion Interrupts for Queues 63 and 64 Status Not pending |
| | | 1 | Pending |

20.1.14.38 INTD Status Clear Register 0 (Base Address + 0x280)

The status clear register allows software to clear the pending status. This register is only valid and functional for pulsed interrupts and has no effect for level interrupts. There is at least one register per Host for up to 32 interrupts. The mapping of bits in this register matches that of the enable registers.

The INTD status clear register 0 is shown in [Figure 20-46](#) and described in [Table 20-52](#).

Figure 20-46. INTD Status Clear Register 0

| Bit | Field | Value | Description |
|------|------------|--------|---|
| 31-2 | Reserved | 0 | Always read as 0. Writes have no affect. |
| 1 | status_clr | 0 1 | RX MOP Descriptor interrupt status. Not pending Pending Write a 1 in a bit position to clear that bit. Writing a 0 has no effect. |
| 0 | status_clr | 0 1 | RX SOP Descriptor Starve interrupt status. Not pending Pending Write a 1 in a bit position to clear that bit. Writing a 0 has no effect. |

20.1.14.40 Queue Manager Queue Diversion Register (0x4008)

The queue diversion register is used to transfer the contents of one queue onto another queue. It does not support byte accesses.

The queue manager queue diversion register is shown in [Figure 20-48](#) and described in [Table 20-54](#).

Figure 20-48. Queue Manager Queue Diversion Register

LEGEND: R/W = Read/Write; R = Read only; Write only; -n = value after reset

Table 20-54. Queue Manager Queue Diversion Register Field Descriptions

| Bit | Field | Value | Description |
|-------|-------------|-------|---|
| 31 | head_tail | | head_tail indicates whether the queue contents should be merged onto the head or the tail of the destination queue. Clear this field for head and set for tail. |
| 30 | Reserved | 0 | Always read as 0. Writes have no effect. |
| 29-16 | dest_qnum | | Destination Queue Number |
| 15-14 | Reserved | 0 | Always read as 0. Writes have no effect. |
| 13-0 | source_qnum | | Source Queue Number |

20.1.14.41 Queue Manager Free Descriptor/Buffer Starvation Count Register 0 (0x4020)

The free descriptor/buffer queue starvation count register provides statistics about how many starvation events are occurring on the Rx free descriptor/buffer queues. It does not support byte accesses.

The queue manager free descriptor/buffer starvation count register is shown in [Figure 20-49](#) and described in [Table 20-55](#).

Figure 20-49. Queue Manager Free Descriptor/Buffer Starvation Count Register 0

| Bit | Field | Value | Description |
|-------|-------------------|-------|---|
| 31-24 | fdbq27_starve_cnt | | This field increments each time the Free Descriptor/Buffer Queue 27 is read while it is empty. This field is cleared when read. |
| 23-16 | fdbq26_starve_cnt | | This field increments each time the Free Descriptor/Buffer Queue 26 is read while it is empty. This field is cleared when read. |
| 15-8 | fdbq25_starve_cnt | | This field increments each time the Free Descriptor/Buffer Queue 25 is read while it is empty. This field is cleared when read. |
| 7-0 | fdbq24_starve_cnt | | This field increments each time the Free Descriptor/Buffer Queue 24 is read while it is empty. This field is cleared when read. |

20.1.14.48 Queue Manager Free Descriptor/Buffer Starvation Count Register 7 (0x403C)

The free descriptor/buffer queue starvation count register provides statistics about how many starvation events are occurring on the Rx free descriptor/buffer queues. It does not support byte accesses.

The queue manager free descriptor/buffer starvation count register 6 is shown in [Figure 20-56](#) and described in [Table 20-62](#).

Figure 20-56. Queue Manager Free Descriptor/Buffer Starvation Count Register 7

20.1.14.49 Queue Manager Linking RAM Region 0 Base Address Register (0x4080)

The linking RAM region 0 base address register is used to set the base address for the first portion of the linking RAM. This address must be 32-bit aligned. It is used by the queue manager to calculate the 32-bit linking address for a given descriptor index. It does not support byte accesses.

The queue manager linking RAM region 0 base address register is shown in [Figure 20-57](#) and described in [Table 20-63](#).

Figure 20-57. Queue Manager Linking RAM Region 0 Base Address Register

LEGEND: R/W = Read/Write; R = Read only; Write only; -n = value after reset

Table 20-63. Queue Manager Linking RAM Region 0 Base Address Register Field Descriptions

| Bit | Field | Value | Description |
|------|--------------|-------|--|
| 31-0 | region0_base | | This field stores the base address for the first region of the linking RAM. This can be anywhere in 32-bit address space but would be typically located in on-chip memory. |

20.1.14.50 Queue Manager Linking RAM Region 0 Size Register (0x4084)

The linking RAM region 0 size register is used to set the size of the array of linking pointers that are located in region 0 of linking RAM. The size specified the number of descriptors for which linking information is stored in this region. It does not support byte accesses.

The queue manager linking RAM region 0 size register is shown in [Figure 20-58](#) and described in [Table 20-64](#).

Figure 20-58. Queue Manager Linking RAM Region 0 Size Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 20-64. Queue Manager Linking RAM Region 0 Size Register Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|-------|---|
| 31-14 | Reserved | 0 | Always read as 0. Writes have no effect. |
| 13-0 | | | This field indicates the number of entries that are contained in the linking RAM region 0. A descriptor with index less than region0_size value has its linking location in region 0. A descriptor with index greater than region0_size has its linking location in region 1. The queue manager adds the index (left shifted by 2 bits) to the appropriate regionX_base_addr to get the absolute 32-bit address to the linking location for a descriptor. |

20.1.14.51 Queue Manager Linking RAM Region 1 Base Address Register (0x4088)

The linking RAM region 1 base address register is used to set the base address for the second portion of the linking RAM. This base address is used by the queue manager to calculate the 32-bit linking address from the descriptor index. All descriptors with index higher than that given in linking RAM 0 size register have linking information stored in linking RAM region 1. It does not support byte accesses.

The queue manager linking RAM region 1 base address register is shown in [Figure 20-59](#) and described in [Table 20-65](#).

Figure 20-59. Queue Manager Linking RAM Region 1 Base Address Register

| 31-0 | region1_base | | This field stores the base address for the second region of the linking RAM. This can be anywhere in 32-bit address space but would be typically located in on-chip memory. |

20.1.14.52 Queue Manager Queue Pending Register 0 (0x4090)

The queue pending register 0 can be read to find the pending status for queues 31 to 0. It does not support byte accesses.

The queue manager queue pending register 0 is shown in [Figure 20-60](#) and described in [Table 20-66](#).

Figure 20-60. Queue Manager Queue Pending Register 0

20.1.14.55 Queue Manager Memory Region R Base Address Register (0x5000 + 16xR)

The memory region R base address register is written by the Host to set the base address of memory region R. This memory region stores a number of descriptors of a particular size as determined by the memory region R control register. It does not support byte accesses.

The queue manager memory region R base address register is shown in [Figure 20-63](#) and described in [Table 20-69](#).

Figure 20-63. Queue Manager Memory Region R Base Address Register

LEGEND: R/W = Read/Write; R = Read only; Write only; -n = value after reset

20.1.14.56 Queue Manager Memory Region R Control Register (0x5000 + 16xR + 4)

The memory region R control register is written by the Host to configure various parameters of this memory region. It does not support byte accesses.

The queue manager memory region R control register is shown in [Figure 20-64](#) and described in [Table 20-70](#).

Figure 20-64. Queue Manager Memory Region R Control Register

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 20-70. Queue Manager Memory Region R Control Register Field Descriptions

| Bit | Field | Value | Description |
|-------|-------------|-------|--|
| 31-30 | Reserved | 0 | Always read as 0. Writes have no effect. |
| 29-16 | start_index | | This field indicates where in linking RAM does the descriptor linking information corresponding to memory region R starts. |
| 15-12 | Reserved | 0 | Always read as 0. Writes have no effect. |
| 11-8 | desc_size | | This field indicates the size of each descriptor in this memory region. It is an encoded value that specifies descriptor size as $2^{(5+desc_size)}$ number of bytes. The settings of desc_size from 9-15 are reserved. |
| 7-3 | Reserved | 0 | Always read as 0. Writes have no effect. |
| 2-0 | reg_size | | This field indicates the size of the memory region (in terms of number of descriptors). It is an encoded value that specifies region size as $2^{(5+reg_size)}$ number of descriptors. |

The following sections describe each of the four register locations that may be present for each queue in the queues region. For reasons of implementation and area efficiency, these registers are not actually implemented as a huge array of flip flops but are instead implemented as a single set of mailbox registers which use the LSBs of the provided address as a queue index. Due to this implementation all accesses to these registers need to be performed as a single burst write for each packet add or a single burst read for each packet pop operation. The length of a burst to add or pop a packet varies depending on the optional features that the queue supports which may be 4, 8, 12 or 16 bytes. Queue N register D must always be written/read in the burst but the preceding words are optional depending on the required queue functionality.

20.1.14.57 Queue Manager Queue N Register A (0x6000 + 16xN)

The queue N register A is an optional register that is only implemented for a queue if the queue supports entry/byte count feature. The entry count feature provides a count of the number of entries that are currently valid in the queue. It does not support byte accesses.

The queue manager queue N register is shown in [Figure 20-65](#) and described in [Table 20-71](#).

Figure 20-65. Queue Manager Queue N Register A

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 20-71. Queue Manager Queue N Register A Field Descriptions

| Bit | Field | Value | Description |
|-------|-------------------|-------|---|
| 31-14 | Reserved | 0 | Always read as 0. Writes have no effect. |
| 13-0 | queue_entry_count | | This field indicates how many packets are currently queued on the queue. This count is incremented by 1 whenever a packet is added to the queue. This count is decremented by 1 whenever a packet is popped from the queue. |

20.1.14.58 Queue Manager Queue N Register B (0x6000 + 16xN + 4)

The queue N register B is an optional register that is only implemented for a queue if the queue supports a total byte count feature. The total byte count feature provides a count of the total number of bytes in all of the packets that are currently valid in the queue. This register must be read prior to reading queue N register D during packet pop operation if the total size information is desired. It does not support byte accesses.

The queue manager queue N register B is shown in [Figure 20-66](#) and described in [Table 20-72](#).

Figure 20-66. Queue Manager Queue N Register B

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 20-72. Queue Manager Queue N Register B Field Descriptions

| Bit | Field | Value | Description |
|-------|------------------|-------|---|
| 31-28 | Reserved | 0 | Always read as 0. Writes have no effect. |
| 27-0 | queue_byte_count | | This field indicates how many bytes total are contained in all of the packets which are currently queued on this queue. |

20.1.14.59 Queue Manager Queue N Register C (0x6000 + 16xN + 8)

The queue N register C is used to provide additional information about the packet that is being pushed or popped from the queue. This register provides an option for the packet to be pushed onto either the tail of the queue (default) or the head of the queue (override). This register must be written prior to writing the queue N register D during packet write operations. This register must be read prior to reading queue N register D during pop operations if the packet size information is desired. It does not support byte accesses.

The queue manager queue N register c is shown in [Figure 20-67](#) and described in [Table 20-73](#).

Figure 20-67. Queue Manager Queue N Register C

LEGEND: R/W = Read/Write; R = Read only; Write only; -n = value after reset

Table 20-73. Queue Manager Queue N Register C Field Descriptions

| Bit | Field | Value | Description |
|-------|-------------|-------|--|
| 31 | head_tail | | Head/Tail Push Control. Set to zero in order to push packet onto tail of queue and set to one in order to push packet onto head of queue. |
| 30-14 | Reserved | 0 | Always read as 0. Writes have no effect. |
| 13-0 | packet_size | | This field indicates packet size and is assumed to be zero on each packet add unless the value is explicitly overwritten. This field indicates packet size for packet pop operation. |

20.1.14.60 Queue Manager Queue N Register D (0x6000 + 16xN + C)

The queue N register D is written to add a packet to the queue and read to pop a packets off a queue. The packet is only pushed or popped to/from the queue when the queue register D is written. It does not support byte accesses.

The queue manager queue N register D is shown in [Figure 20-68](#) and described in [Table 20-74](#).

Figure 20-68. Queue Manager Queue N Register D

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 20-74. Queue Manager Queue N Register D Field Descriptions

| Bit | Field | Value | Description |
|------|-----------|-------|---|
| 31-5 | desc_ptr | 0 | Descriptor pointer. It is read as zero if the queue is empty. It indicates a 32-bit aligned address that points to a descriptor when the queue is not empty. |
| 4-0 | desc_size | | Descriptor Size. It is encoded in 4-byte increments with values 0 to 31 representing 24 and so on to 148 bytes. This field returns a 0x0 when an empty queue is read. |

20.1.14.61 Queue Manager Queue N Status Register A (0x6800 + 16xN)

The queue N status register A is an optional register that is only implemented for a queue if the queue supports entry/byte count feature. The entry count feature provides a count of the number of entries that are currently valid in the queue. It does not support byte accesses.

The queue manager queue N status register A is shown in [Figure 20-69](#) and described in [Table 20-75](#).

Figure 20-69. Queue Manager Queue N Status Register A

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 20-75. Queue Manager Queue N Status Register A Field Descriptions

| Bit | Field | Value | Description |

| 31-14 | Reserved | 0 | Always read as 0. Writes have no effect. |
| 13-0 | queue_entry_count | | This field indicates how many packets are currently queued on the queue. |

20.1.14.62 Queue Manager Queue N Status Register B (0x6800 + 16xN + 4)

The queue N status register B is an optional register that is only implemented for a queue if the queue supports a total byte count feature. The total byte count feature provides a count of the total number of bytes in all of the packets that are currently valid in the queue. It does not support byte accesses.

The queue manager queue N status register B is shown in [Figure 20-70](#) and described in [Table 20-76](#).

|-------|------------------|-------|---|
| 31-28 | Reserved | 0 | Always read as 0. Writes have no effect. |
| 27-0 | queue_byte_count | | This field indicates how many bytes total are contained in all of the packets which are currently queued on this queue. |

20.1.14.63 Queue Manager Queue N Status Register C (0x6800 + 16xN + 8)

The queue N status register C specifies the packet size for the head element of a queue. It does not support byte accesses.

The queue manager queue N status requester C is shown in [Figure 20-71](#) and described in [Table 20-77](#).

Figure 20-71. Queue Manager Queue N Status Register C

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 20-77. Queue Manager Queue N Status Register C Field Descriptions

| Bit | Field | Value | Description |
|-------|-------------|-------|--|
| 31-14 | Reserved | 0 | Always read as 0. Writes have no effect. |
| 13-0 | packet_size | | This field indicates packet size of the head element of a queue. |

20.2 High-Speed USB Host Subsystem

Copyright © 2004,2005, 2006, 2007, 2008 Synopsys, Inc. All rights reserved. Used with permission.

20.2.1 High-Speed USB Host Subsystem Overview

The high-speed universal serial bus (USB) host subsystem is composed of the high-speed multiport USB host controller and the USBTLL module.

The USB controller is a high-speed multiport USB2.0 host controller. It contains two independent, 3-port host controllers that operate in parallel:

- The EHCI controller, based on the *Enhanced Host Controller Interface (EHCI) specification for USB Release 1.0*, is in charge of high-speed traffic (480M bit/s), over the ULPI/UTMI interface
- The OHCI controller, based on the *Open Host Controller Interface (OHCI) specification for USB Release 1.0a*, is in charge of full-speed/low-speed traffic (12/1.5M bit/s, respectively), over a serial interface

Each of the three external ports is owned by exactly one of the controllers at any time.

NOTE: If one port is configured as a high-speed ULPI transceiver interface, then all other ports must be likewise configured.

The USBTLL module is a high-speed USB UTMI low-pin interface (ULPI) transceiverless link logic (TLL) adapter. It implements a TLL compatible with a number of USB standard interface protocols. It consists of three channels, defined as independent USB path through the TLL module, which always converts the UTMI+ PHY interface protocol coming from the high-speed USB host controller.

Each USB port (1, 2, and 3) can connect either to an external chip USB transceiver or directly using a transceiverless link to an external integrated circuit (IC) supporting the same TLL protocol.

[Figure 20-72](#) highlights the high-speed USB host subsystem.

Figure 20-72. High-Speed USB Host Subsystem Highlight

usb-007

20.2.1.1 Main Features

The high-speed USB host subsystem includes the following features:

- Multiport high-speed USB host controller:
 - Complies with the USB 2.0 standard for high-speed (480M bit/s) functions
 - USB 2.0 low-speed (1.5M bit/s) and full-speed (12M bit/s) over serial interface
 - High-speed (480M bit/s) operations over ULPI
 - Three downstream ports (3-port root hub)
 - Complies with EHCI (high-speed host controller)
 - Complies with OHCI (low-speed/full-speed host controller)
 - Supports suspend/resume and remote wakeup
 - Interface with ULPI PHYs (transceivers) on two ports
 - 12-pin/8-bit data single data rate (SDR) mode
 - 60-MHZ clock, generated by the host: ULPI "input" clocking mode

CAUTION

The HS USB host subsystem only supports PHYs that can accept a 60 MHz input clock.

The HS USB host subsystem can only support the external charge pump of PHY (no support of internal charge pump for ULPI PHY).

- Hardware-driven save-and-restore of the suspended host hardware context
- Two interrupt lines
- USBTLL module
 - Three channels
 - Three ports (A, C, and D) by channel
 - Port A: PHY-side UTMI+ port. Connects to the local link controller. The UTMI “local” port is used in all configurations, (that is, the entire channel can be seen as a protocol converted from that port to one of the other, “remote” ports).
 - Compliant with UTMI+ (USB 2.0 Transceiver Macrocell Interface) version 1.0
 - 8-data-bit, 60-MHZ UTMI (HS/FS/LS-capable)
 - UTMI+ Level 3 extensions
 - Vcontrol/Vstatus (from UTMI)
 - Serial FS/LS “6-pin” mode
 - Port C: PHY-side ULPI port. Connects to a remote (off-chip) ULPI link controller through I/O pads.
 - SDR and dual data rate (DDR) ULPI capable (8/4-bit data width modes)
 - Supports optional 6-pin/3-pin serial modes
 - Supports optional input clocking mode
 - Port D: Serial multimode port. Connects to either a serial link controller (TLL modes) or a serial PHY (PHY interface modes).
 - Supports 6-pin unidirectional, 4-pin bidirectional, 3-pin bidirectional, 2-pin bidirectional modes
 - All modes are supported for TLL or PHY interface configuration.
 - Supports sideband signals (pullup/down control, speed/suspend enable, etc)
 - An interrupt line
 - OCP target slave interface (L4) for configuration
- USB port signal pins interface supporting:
 - External USB transceivers
 - ULPI interface: 12-pin/8-bit data SDR version supporting "input" clocking mode
 - Serial 6-pin PHY (transceiver) interfaces: 6-pin mode (TX: DAT/SE0 or TX: DP/DM unidirectional mode), 4-pin mode (DP/DM bidirectional mode), and 3-pin mode (DAT/SE0 bidirectional mode)
 - TLL mode
 - ULPI TLL interfaces: 12-pin/8-bit data SDR and 8-pin/4-bit data DDR versions
 - Serial 6-pin TLL interfaces: 6-pin mode (DAT/SE0 and DP/DM unidirectional modes), 4-pin mode, (DP/DM bidirectional mode), 3-pin mode (DAT/SE0 bidirectional mode) and 2-pin mode (DAT/SE0 and DP/DM bidirectional modes)

NOTE: Some features may not be available or supported in your particular device. For more information, see Chapter 1, the *Device Family* section, and your device-specific data manual.

Table 20-78. USB Connectivity Modes

| USB Connectivity Modes | Port 1 | Port 2 | Port 3 |
|-------------------------------------|--------|--------|--------|
| ULPI interface | √ | √ | |
| Serial 6-pin transceiver interfaces | √ | √ | √ |

Table 20-78. USB Connectivity Modes (continued)

| USB Connectivity Modes | Port 1 | Port 2 | Port 3 |
|-----------------------------|--------|--------|--------|
| ULPI TLL interfaces | √ | √ | √ |
| Serial 6-pin TLL interfaces | √ | √ | √ |

NOTE: If either port 1 or port 2 is configured as a ULPI interface, then both ports must be configured as a ULPI interface.

Only FS/LS USB transceivers can be connected to port 3; HS ULPI transceivers are not supported on port 3.

20.2.2 High-Speed USB Host Subsystem Environment

The high-speed USB host controller provides two kinds of interfaces for connection:

- ULPI interfaces for high-speed data transactions (up to 480M bit/s)
- Serial interfaces (with the use of the USBTLL module) for full- and low-speed data transactions (up to 12M bit/s)

The high-speed USB host controller connects to either controllers (TLL modes) and/or transceivers. It supports the following configurations with the serial interfaces and ULPI interfaces:

- External USB transceiver configurations
 - ULPI interface: 12-pin/8-bit data SDR version supporting "input" clocking mode
 - Serial 6-pin PHY (transceiver) interfaces: 6-pin mode (TX: DAT/SE0 or TX: DP/DM unidirectional mode), 4-pin mode (DP/DM bidirectional mode) and 3-pin mode (DAT/SE0 bidirectional mode)
- TLL configurations
 - ULPI TLL interfaces: 12-pin/8-bit data SDR and 8-pin/4-bit data DDR versions
 - Serial 6-pin TLL interfaces: 6-pin mode (DAT/SE0 and DP/DM unidirectional modes), 4-pin mode (DP/DM bidirectional mode), 3-pin mode (DAT/SE0 bidirectional mode), and 2-pin mode (DAT/SE0 and DP/DM bidirectional modes)

20.2.2.1 Standard USB Implementation: Transceiver Connection

From a logical point of view, a point-to-point USB connection is composed of several blocks, organized in protocol layers, and shown in [Figure 20-73](#).

Figure 20-73. USB Connection

The host system (USB master) and the peripheral system (USB slave) connected through the USB cable include a link or controller (link layer) and a PHY or transceiver (physical layer). Each system talks to its own controller, which talks to its own transceiver, which is connected to the opposite side (transceiver) through an assembly of connectors, receptacles, and cable.

20.2.2.2 TLL Connection

The TLL feature enables connection of the high-speed USB host subsystem to an external, onboard USB peripheral controller, without using USB transceivers or associated circuitry. When TLL is used, the following components are removed from the system:

- Both USB transceivers
- The series resistors
- Pullup and pulldown resistors
- VBUS switching components
- USB connectors and cables, typically used between a USB host controller and the downstream USB peripheral controller

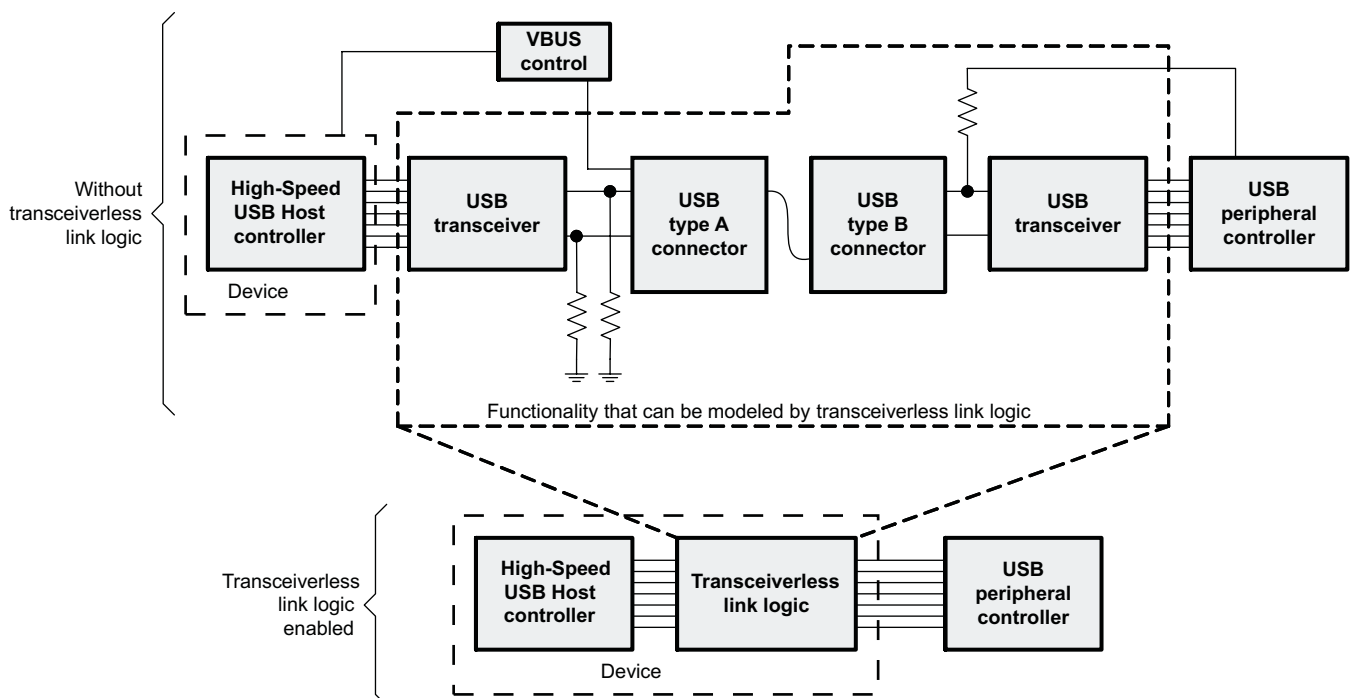

The TLL signaling system is not suitable for use across a cable. It is intended only for use when the device is used with an external USB integrated circuit (IC) that is on the same board.

When using the TLL, signals of the external USB IC pins, which typically connect to a USB transceiver, instead directly connect to the device pins. Signaling on these pins use CMOS levels. TLL logic can be used with external devices that support ULPI TLL interface and serial 6-pin TLL interface connectivity.

The TLL function in the device interprets the transmit control signals from the external USB IC and similar signals from the device USB host controller, and computes the equivalent USB differential-pair state. The computed differential-pair state is interpreted and the appropriate transceiver output signals are provided to the external USB IC and to the device USB host controller.

Figure 20-74 shows the device and how TLL can be compared to a typical USB implementation. The top portion of Figure 20-74 shows the a transceiver-based solution, and the bottom portion shows a transceiverless solution using TLL.

Figure 20-74. High-Speed USB Host Controller Connection—With and Without TLL

usb-009

NOTE: The USB bus lines (D+/D-) no longer appear in subsequent figures: They are emulated by the TLL.

20.2.2.3 ULPI Interfaces

The high-speed USB host subsystem supports the following configurations with the ULPI interfaces:

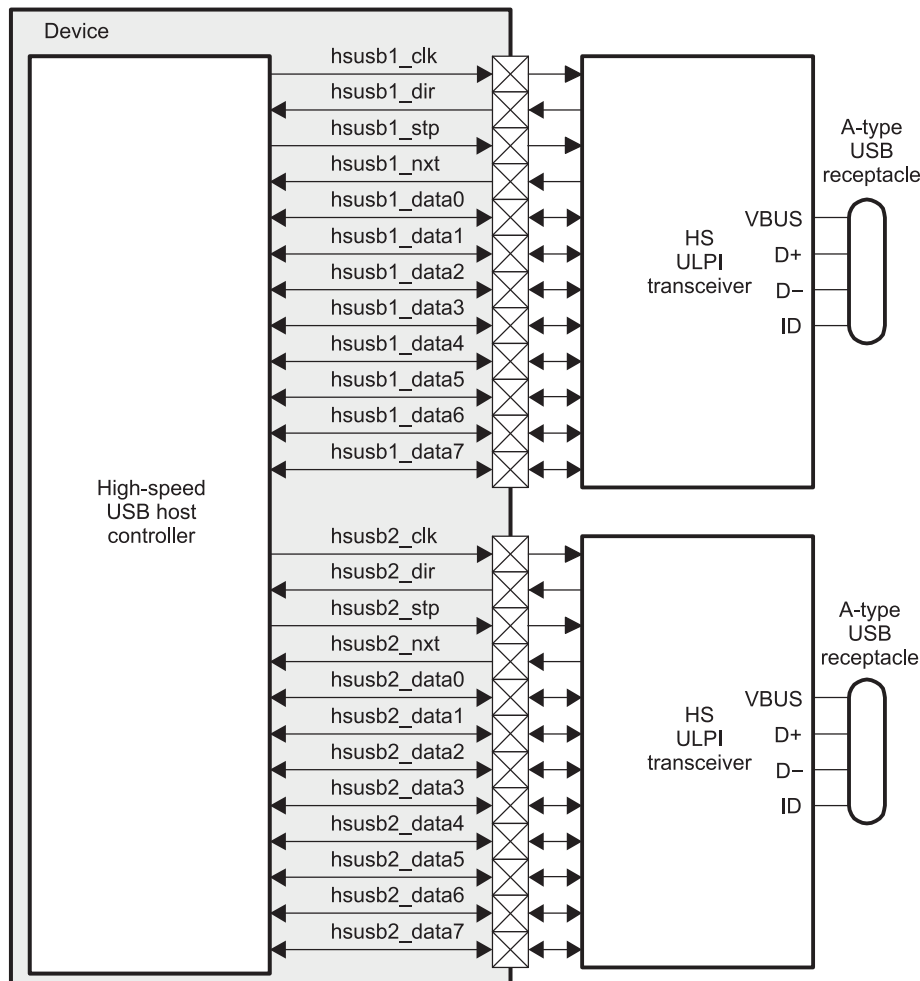

- External USB transceiver
 - ULPI interfaces: 12-pin/8-bit data SDR version supporting "input" clocking mode
- TLL
 - ULPI TLL interfaces: 12-pin/8-bit data SDR and 8-pin/4-bit data DDR versions

Figure 20-75 and Figure 20-76 show typical applications using the high-speed USB host subsystem with the ULPI and with the ULPI TLL, respectively.

The high-speed USB host subsystem supports USB ports, which use the ULPI interface mode to connect to an off-chip high-speed ULPI transceiver (12-pin/8-bit data SDR mode) for high-speed data transactions (up to 480M bit/s). Using the ULPI interfaces in 12-pin/8-bit data version, the device and the transceiver achieve the USB function. An A-type external receptacle allows the connection of an external device.

The device supports TLL logic interfaces on its ports in the ULPI interface mode. TLL modes enable glueless interconnect to another USB device port without a costly transceiver.

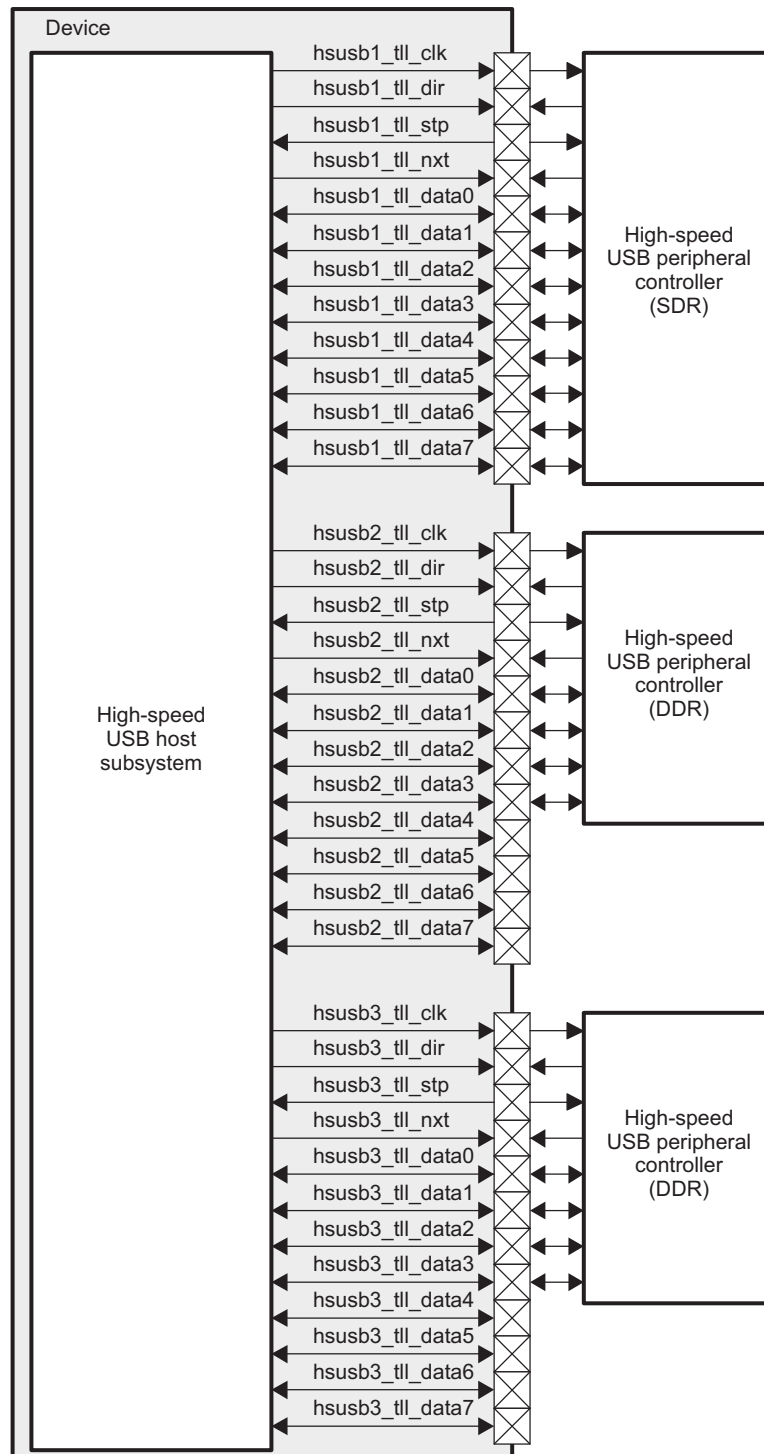

Figure 20-75. High-Speed USB Host Controller Typical Application System – ULPI Interfaces

ULPI Interfaces - USBTLL is bypassed and high-speed USB host controller ports 1 and 2 are connected directly to external transceivers

Figure 20-76. High-Speed USB Host Subsystem Typical Application System - ULPI TLL Interfaces

ULPI TLL Interfaces -The high-speed USB host controller is coupled with the USBTLL module to compose the ULPITLL interface modes usb-032

The current implementation of the ULPI includes a method for manual, software-controlled generation of PHY-side register accesses. This implies support of the following features:

- Access to vendor-specific or optional PHY-side registers
- Access to vendor ID, product ID, and scratch and debug registers

The 12-pin ULPI interface uses an 8-bit data bus with data synchronous to the rising edge of the PHY (transceiver) clock (SDR mode), whereas the 8-pin ULPI uses a 4-bit data bus with data generated on both the rising and falling clock edges (DDR mode).

20.2.2.3.1 Transceiver Interface Configurations

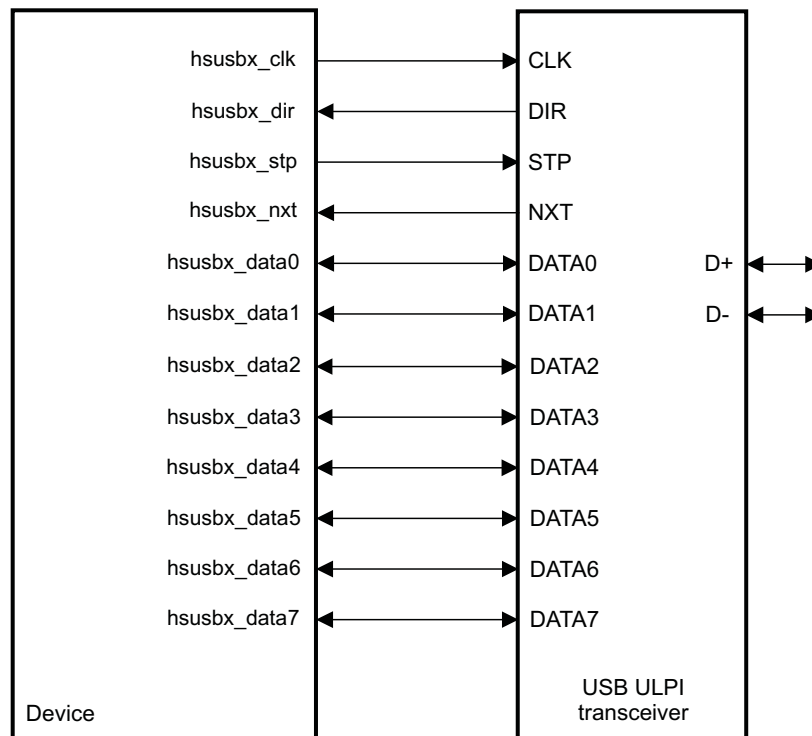

The high-speed USB host subsystem supports only the 12-pin/8-bit data SDR version of the ULPI interface mode.

NOTE: In the device, only the ULPI ports 1 and 2 of the high-speed USB host controller are mapped and can be connected directly to external transceivers.

The ULPI transceiver must support "input" clocking mode, that is, it must accept a 60 MHz input clock.

Figure 20-77 shows USB ports using the 12-pin/8-bit data SDR version of the ULPI interface mode.

Figure 20-77. ULPI Interfaces – 12-Pin/8-Bit Data SDR Version

⁽³⁾ This output signal is also used as re-timing input.

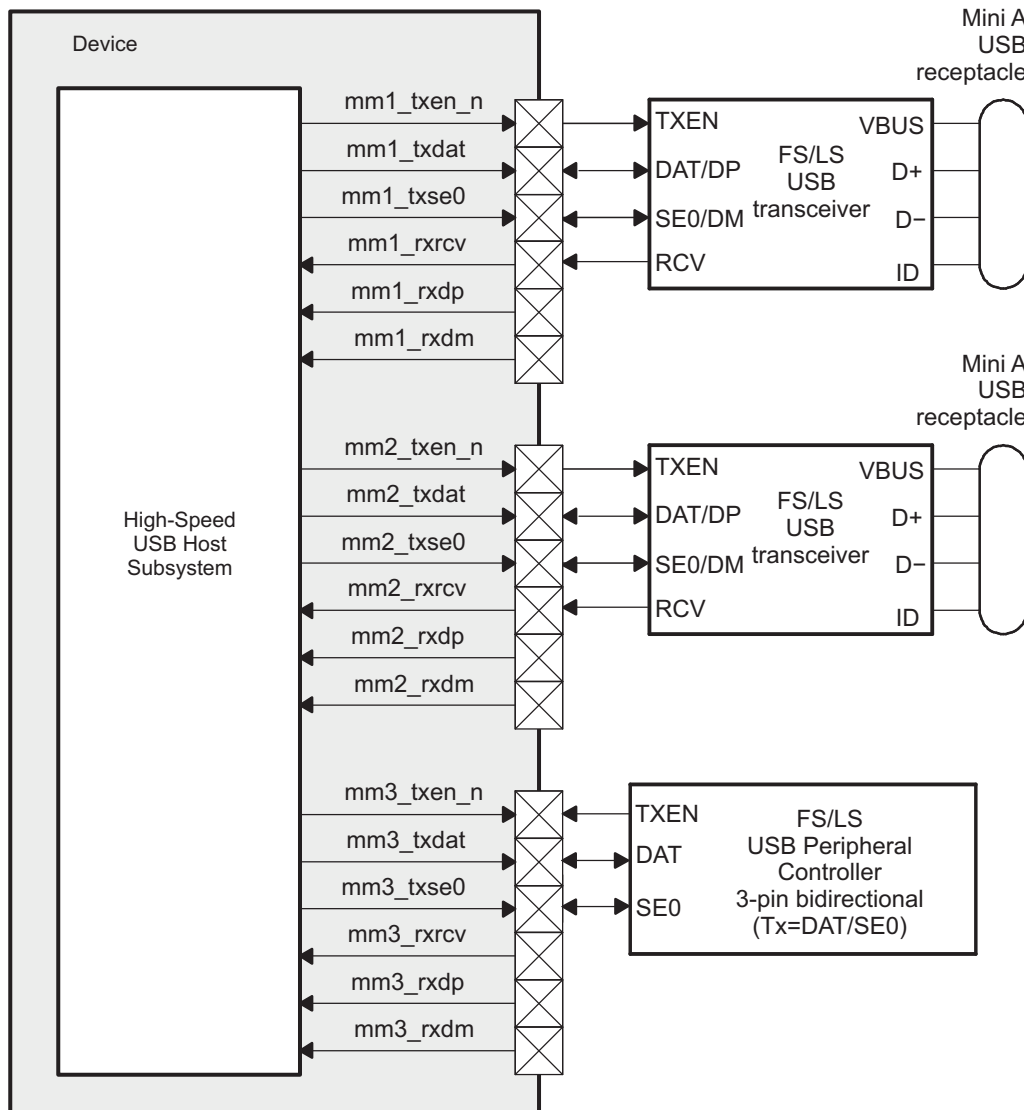

20.2.2.4 Serial Interfaces

The high-speed USB host subsystem supports the following configurations with the serial interfaces:

- External USB transceiver
 - Serial 6-pin PHY (transceiver) interfaces: 6-pin mode (TX: DAT/SE0 or TX: DP/DM unidirectional mode), 4-pin mode (DP/DM bidirectional mode), and 3-pin mode (DAT/SE0 bidirectional mode)
- TLL
 - Serial 6-pin TLL interfaces: 6-pin mode (DAT/SE0 and DP/DM unidirectional modes), 4-pin mode (DP/DM bidirectional mode), 3-pin mode (DAT/SE0 bidirectional mode), and 2-pin mode (DAT/SE0 and DP/DM bidirectional modes)

Figure 20-81 shows a typical application using the high-speed USB host subsystem with the serial interfaces.

Figure 20-81. High-Speed USB Host Subsystem Typical Application System

usb-015

The high-speed USB host controller is coupled with the USBTLL module to compose the serial interface modes. The USBTLL module translates the parallel, synchronous UTMI+ (Level 3) protocol to a serial, asynchronous one. The benefit of the conversion is a simplified interface to the transceiver.

CAUTION

Only full- and low-speed data transactions are possible in serial mode. Transceiver interface is serial (its frequency is that of the actual USB line) and combinatorial (no clock is passed).

Whether in TLL or transceiver configuration, the serial interface follows the same principles. It is limited to full/low speed, and that high speed requires a parallel interface.

20.2.2.4.1 Encoding in Serial Mode

20.2.2.4.1.1 Unidirectional

When a USB transceiver is connected to the device and used in 6-pin unidirectional DAT/SE0 encoding mode, the encoding described in [Table 20-80](#) is used.

Table 20-80. Signaling Between High-Speed USB Host Subsystem and 6-Pin Unidirectional USB Transceiver (DAT/SE0 Signaling)

| Logical Signal Name | Device Pin Direction | Transceiver Pin Direction | Description | | | | |
|---------------------|----------------------|---------------------------|---|----------|-----|----|----|
| TXEN | Output | Input | When low, the USB transceiver drives D+ and D-. | | | | |
| DAT and SE0 | Output | Input | Controls the values output by the USB transceiver on D+ and D- when TXEN is low; ignored when TXEN is high. | | | | |
| | | | TXEN | DAT | SE0 | D+ | D- |
| | | | 0 | 0 | 0 | 0 | 1 |
| | | | | 1 | 0 | 1 | 0 |
| | | | | X | 1 | 0 | 0 |
| 1 | X | X | Undriven | Undriven | | | |
| RCV | Input | Output | Output from transceiver differential receiver | | | | |
| | | | D+ | D- | RCV | | |
| | | | 0 | 0 | X | | |
| | | | 0 | 1 | 0 | | |
| | | | 1 | 0 | 1 | | |
| 1 | 1 | X | | | | | |
| DP | Input | Output | Output from transceiver single-ended D+ signal receiver | | | | |
| | | | D+ | DP | | | |
| | | | 0 | 0 | | | |
| 1 | 1 | | | | | | |
| DM | Input | Output | Output from transceiver single-ended D- signal receiver | | | | |
| | | | D- | DM | | | |
| | | | 0 | 0 | | | |
| 1 | 1 | | | | | | |

When a USB transceiver is connected to the device and used in 6-pin unidirectional DP/DM encoding mode, the encoding described in [Table 20-81](#) is used.

Table 20-81. Signaling Between High-Speed USB Host Subsystem and 6-Pin Unidirectional USB Transceiver (DP/DM Signaling)

| Logical Signal Name | Device Pin Direction | Transceiver Pin Direction | Description | | | | |
|---------------------|----------------------|---------------------------|---|----------|-----|----|----|
| TXEN | Output | Input | When low, the USB transceiver drives D+ and D-. | | | | |
| DAT and SE0 | Output | Input | Controls the values output by the USB transceiver on D+ and D- when TXEN is low; ignored when TXEN is high. | | | | |
| | | | TXEN | DAT | SE0 | D+ | D- |
| | | | 0 | 0 | 0 | 0 | 1 |
| | | | | 1 | 0 | 1 | 0 |
| | | | | X | 1 | 0 | 0 |
| 1 | X | X | Undriven | Undriven | | | |

Table 20-81. Signaling Between High-Speed USB Host Subsystem and 6-Pin Unidirectional USB Transceiver (DP/DM Signaling) (continued)

| Logical Signal Name | Device Pin Direction | Transceiver Pin Direction | Description | | |
|---------------------|----------------------|---------------------------|---|----|-----|
| RCV | Input | Output | Output from transceiver differential receiver | | |
| | | | D+ | D- | RCV |
| | | | 0 | 0 | X |
| | | | 0 | 1 | 0 |
| | | | 1 | 0 | 1 |
| 1 | 1 | X | | | |
| DP | Input | Output | Output from transceiver single-ended D+ signal receiver | | |
| | | | D+ | DP | |
| | | | 0 | 0 | |
| 1 | 1 | | | | |
| DM | Input | Output | Output from transceiver single-ended D- signal receiver | | |
| | | | D- | DM | |
| | | | 0 | 0 | |
| | | | 1 | 1 | |

20.2.2.4.1.2 Bidirectional

When a USB or USB OTG transceiver is connected to the device and is used in 3-pin bidirectional DAT/SE0 encoding mode, the encoding described in [Table 20-82](#) is used.

Table 20-82. Signaling Between High-Speed USB Host Subsystem and 3-Pin Bidirectional USB Transceiver Using DAT/SE0 Signaling

| Logical Signal Name | Device Pin Direction | Transceiver Pin Direction | Description | | | | |
|---------------------|----------------------|---------------------------|--|-----|-----|-----------|-----------|
| TXEN | Output | Input | When low, USB transceiver drives D+ and D-. | | | | |
| DAT and SE0 | Output | Input | When TXEN is low, the device drives DAT and SE0 and the transceiver drives D+ and D- based on the values of DAT and SE0. | | | | |
| | | | TXEN | DAT | SE0 | D+ | D- |
| | | | 0 | 0 | 0 | 0 | 1 |
| | | 1 | 0 | 1 | 0 | | |
| | | X | 1 | 0 | 0 | | |
| | Input | Output | TXEN | D+ | D- | DAT | SE0 |
| | | | 1 | 0 | 0 | 0 | 1 |
| | | | | 0 | 1 | 0 | 0 |
| | | | | 1 | 0 | 1 | 0 |
| | | | 1 | 1 | 1 | Undefined | Undefined |

NOTE: The device does not support 3-wire bidirectional signaling using DP/DM signals.

When a USB or USB OTG transceiver is connected to the device and is used in 4-pin bidirectional DP/DM encoding mode, the encoding described in [Table 20-83](#) is used.

Table 20-83. Signaling Between High-Speed USB Host Subsystem and 4-Pin Bidirectional USB Transceiver Using DP/DM Signaling

| Logical Signal Name | Device Pin Direction | Transceiver Pin Direction | Description | | |
|---------------------|----------------------|---------------------------|---|----|-----|
| TXEN | Output | Input | When low, USB transceiver drives D+ and D-. | | |
| DM | Output | Input | Value driven to or received from D- | | |
| | | | TXEN | DM | D- |
| | | | 0 | 0 | 0 |
| | Input | Output | TXEN | D- | DM |
| | | | 1 | 0 | 0 |
| | | | 1 | 1 | 1 |
| DP | Output | Input | Value driven to or received from D+ | | |
| | | | TXEN | DP | D+ |
| | | | 0 | 0 | 0 |
| | Input | Output | TXEN | D+ | DP |
| | | | 1 | 0 | 0 |
| | | | 1 | 1 | 1 |
| RCV | Input | Output | Output from transceiver single-ended D- signal receiver | | |
| | | | D+ | D- | RCV |
| | | | 0 | 0 | X |
| | | | 0 | 1 | 0 |
| | | | 1 | 0 | 1 |
| | | | 1 | 1 | X |

NOTE: The device does not support 4-pin bidirectional signaling using DAT/SEO signals.

20.2.2.4.2 Sideband Signals for Serial Modes

Serial interfaces only carry the USB data information. Sideband control and status (respectively, to/from the transceiver/TLL or to the bus lines themselves) require additional signals, which are usually implemented in a case-by-case, ad hoc way.

- Sideband control examples: FS/LS (slew rate control), transceiver suspend, connect (D+/D- pullup), pulldown enable, VBUS drive, etc.
- Sideband status example: VBUS level (VBUS valid, session valid, session end), etc.
- Sideband signal implementations: dedicated lines (one per sideband information bit), serial bus + interrupt line with register-mapped control/status (I2C, UART, etc.)

Figure 20-82 and Figure 20-83 show system integration for sideband signals for two logically identical USB connections: one in transceiver configuration, and one in TLL configuration. Although the sideband (purple) arrows are all oriented from controller to transceiver in the two figures, the sideband information flow is bidirectional (that is, it flows from controller to transceiver [control] but also from transceiver to controller [status]).

Figure 20-82 shows the transceiver configuration, where each side connects the sideband signals to its own transceiver. On the device (containing the USBTLL module), the sideband is decoded/re-encoded. The sideband signals available at the device boundary (and the USBTLL module) are decoded from the standard UTMI+ interface.

- Sideband output signals from the USBTLL module (speed, suspend, puen, etc.)
- The software-driven VBUS reporting procedure is described in [Section 20.2.4.2.4.1.1](#).

Figure 20-82. Serial Interface Sideband Integration - Transceiver Configuration

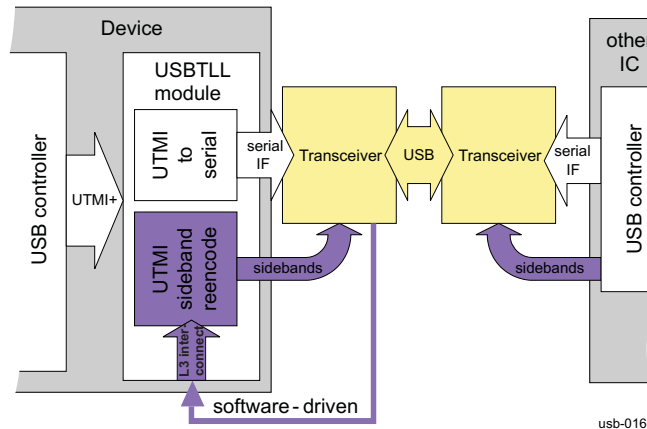

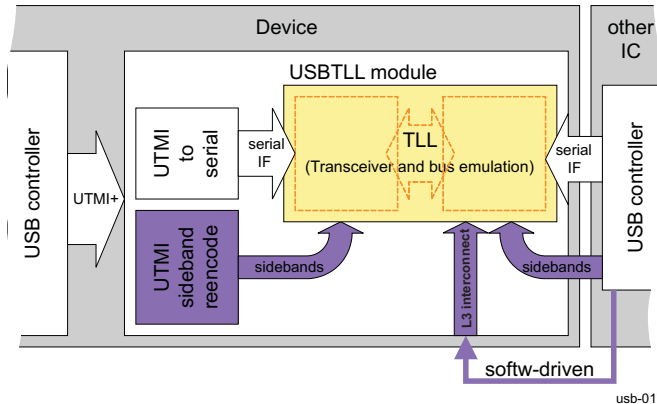

Figure 20-83 shows the TLL configuration, where both transceivers are actually emulated inside the USBTLL module.

- The transceiver of the local controller (left) is working with the sideband information to/from the UTMI+ port. This is internal to the USBTLL module.
- The transceiver of the remote controller (right) must communicate with its controller, located on another IC. This is done in two ways:
 - Sideband input signals at the TLL module boundary (tlmpuen, tlldrvbus, tllvbusvalid, etc.)
 - The software-driven VBUS control procedure is described in [Section 20.2.4.2.4.2.2](#)

Figure 20-83. Serial Interface Sideband Integration - TLL Configuration

20.2.2.4.3 Transceiver Interface Configurations

An external USB transceiver is required for each USB port used in the system. It converts between appropriate signaling for the high-speed USB host subsystem and appropriate signaling for the USB wire.

The serial interface mode of the high-speed USB host subsystem includes support for several types of USB transceivers. It provides signaling to up to three external USB transceivers.

Several types of external transceiver signaling are supported. Signaling between the high-speed USB subsystem in the serial-interface mode and the external USB transceiver for monitoring and controlling the differential USB signal can be done through a 6-, 4-, or 3-wire signaling interface, with two or more control signals provided either by additional signals or through an I²C link.

The following subsections describe the transceiver interface modes supported by the high-speed USB host subsystem in the serial interface mode. In each case, the subsystem is connected to external transceivers, on the other side of which are the actual USB lines (D+/D-).

20.2.2.4.3.1 Unidirectional Transceiver Interface Modes: 6-Pin

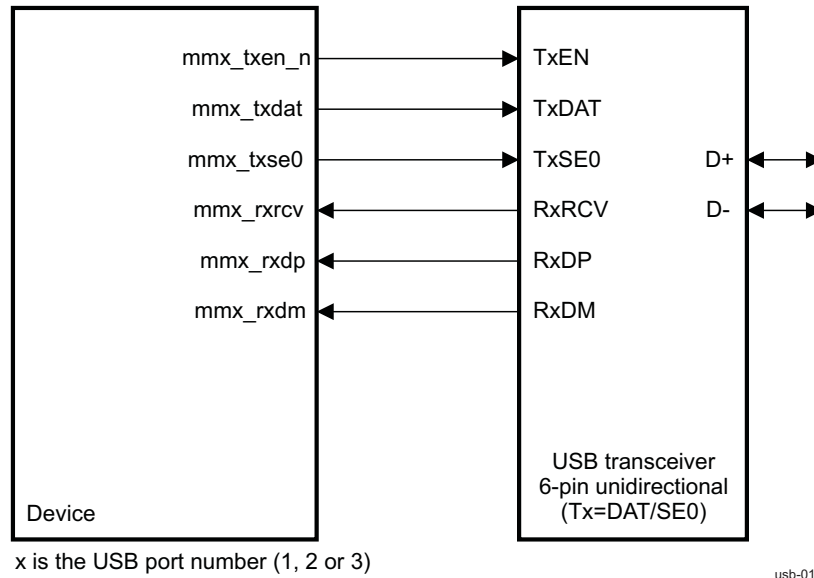

The 6-pin modes are the "natural" transceiver interface modes for the full-speed transceivers in the sense that they mirror the internal makeup of the transceivers.

Two encodings exist for TX: DAT/SE0 or DP/DM.

When a USB is connected to the device and used in 6-pin unidirectional DAT/SE0 signaling mode, the signaling described in Table 20-80 is used.

Figure 20-84 shows a USB port using DAT/SE0 encoding.

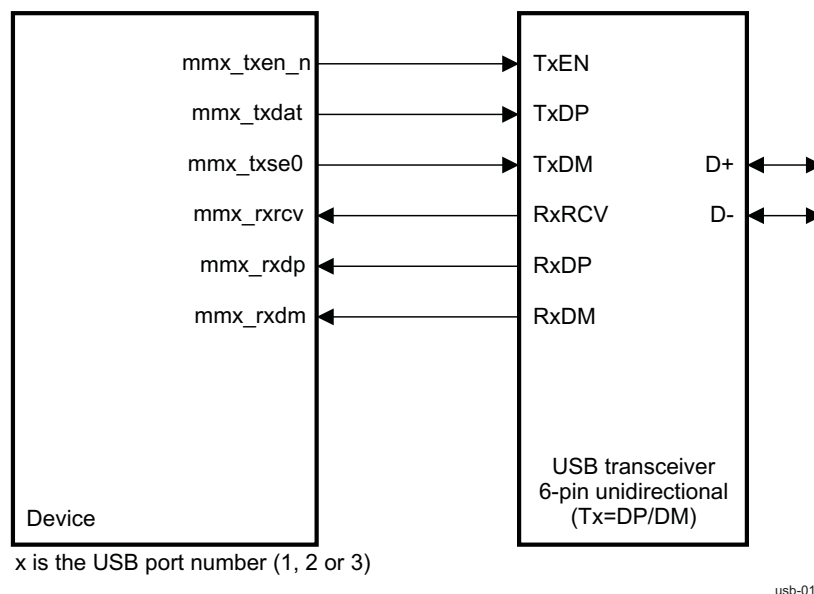

Figure 20-84. 6-Pin Unidirectional Using DAT/SE0 Signaling

When a USB is connected to the device and used in 6-pin unidirectional DP/DM signaling mode, the signaling described in Table 20-81 is used.

Figure 20-85 shows a USB port using DP/DM encoding.

Figure 20-85. 6-Pin Unidirectional Using DP/DM Signaling

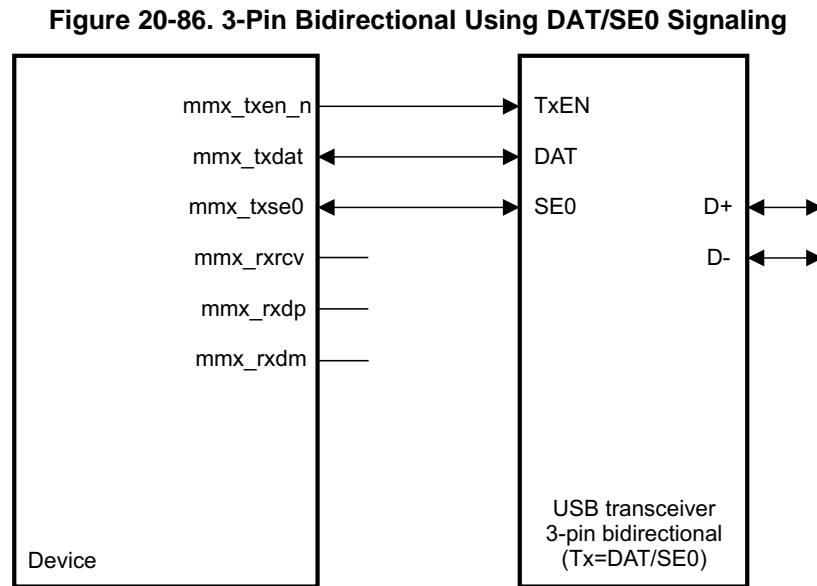

20.2.2.4.3.2 Bidirectional Transceiver Interface Modes: 3-Pin, 4-Pin

The bidirectional transceiver interface modes are pin-count optimizations of the unidirectional modes. They take advantage of the fact that a USB port is either sending or receiving at any given time, but never both. The TX and RX paths of the unidirectional mode can be multiplexed on bidirectional lines. To prevent glitches at TX/RX turnaround, the same encoding is used for both directions (DAT/SE0 or DP/DM).

The signaling listed in [Table 20-82](#) is used when a USB transceiver is connected to the device and is used in 3-pin bidirectional DAT/SE0 signaling mode.

NOTE: The device does not support 3-wire bidirectional signaling using DP/DM signals.

[Figure 20-86](#) shows a USB port using DAT/SE0 encoding.

x is the USB port number (1, 2 or 3)

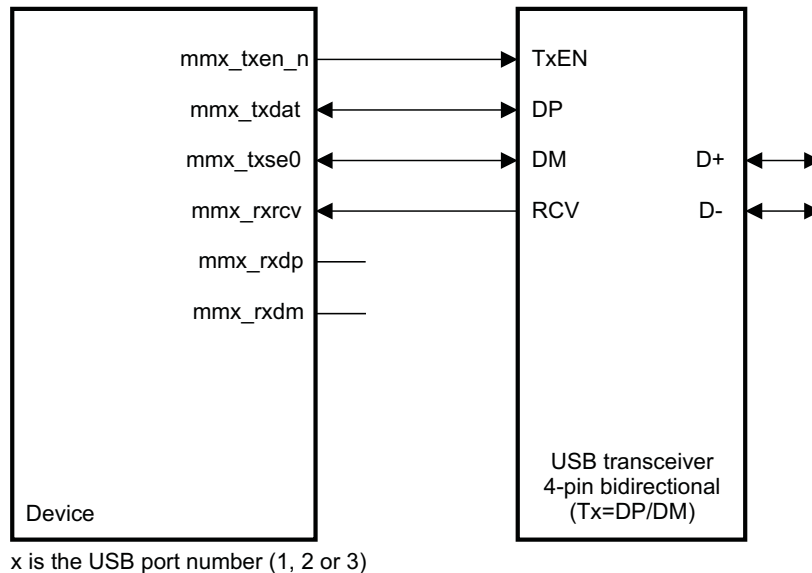

usb-020

The signaling listed in [Table 20-83](#) is used when a USB transceiver is connected to the device and is used in 4-pin bidirectional DP/DM signaling mode.

NOTE: The device does not support 4-pin bidirectional signaling using DAT/SE0 signals.

Figure 20-87 shows a USB port using DP/DM encoding.

Figure 20-87. 4-Pin Bidirectional Using DP/DM Signaling

108-021

20.2.2.4.4 TLL Configurations

The high-speed USB host subsystem supports unidirectional and bidirectional TLL logic interfaces on its ports. The TLL modes enable glueless interconnect to the USB device port of another device without needing a costly transceiver.

Serial interface modes are full- or low-speed only. Transceiver interface is serial (its frequency is that of the actual USB line) and combinatorial (no clock is passed).

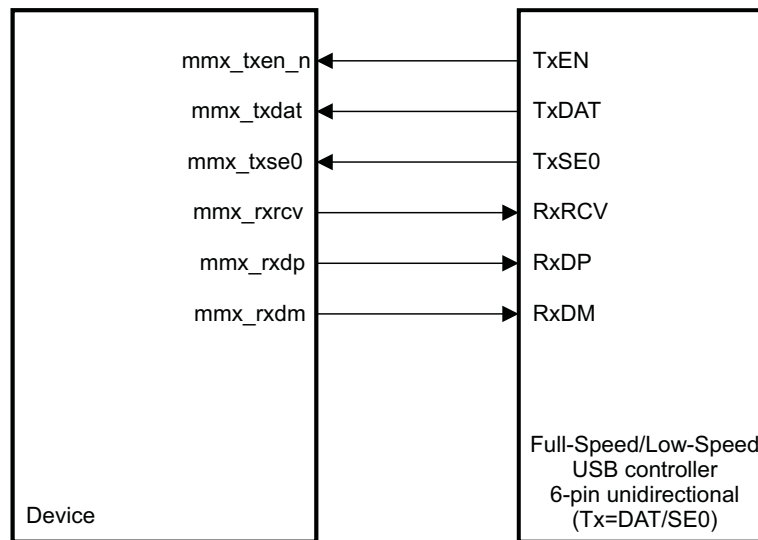

20.2.2.4.4.1 Unidirectional TLL Modes

The 6-pin TLL configurations are mirror images of the 6-pin transceiver configurations presented above. The same signals are mapped on the same physical pins, but in the opposite directions.

Two possible modes exist, depending on the TX data encoding used by the external device.

Figure 20-88 shows an external device using DAT/SE0 encoding.

Figure 20-88. 6-Pin Unidirectional TLL Using DAT/SE0 Signaling

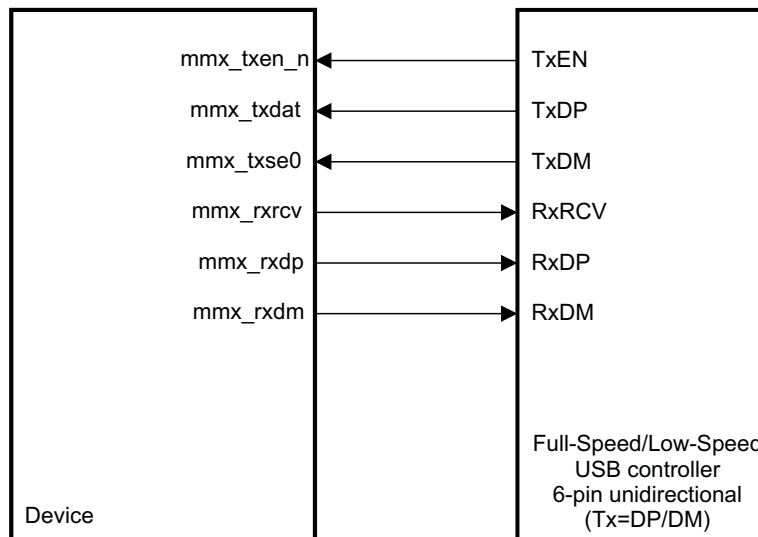

x is the USB port number (1, 2 or 3)

usb-022

Figure 20-89 shows an external device using DP/DM encoding.

Figure 20-89. 6-Pin Unidirectional TLL Using DP/DM Signaling

x is the USB port number (1, 2 or 3)

usb-023

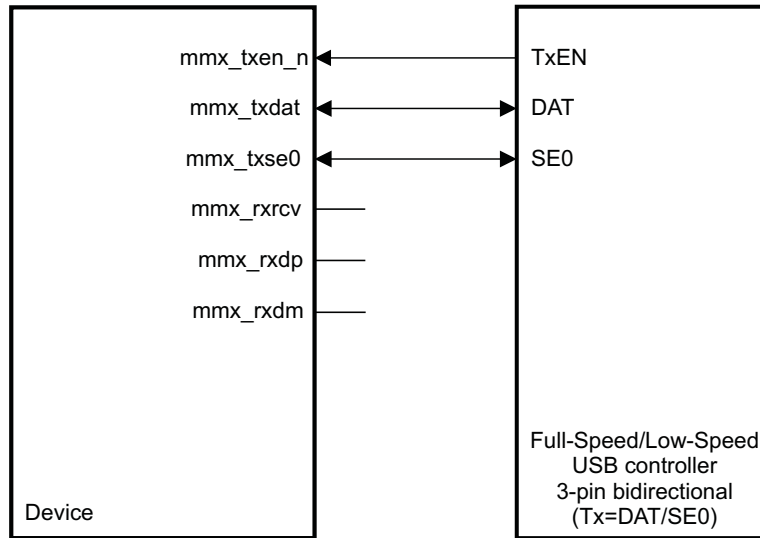

20.2.2.4.4.2 Bidirectional TLL Modes

The 3-pin/4-pin TLL configurations are mirror images of the 3-pin/4-pin transceiver configurations presented above. The same signals are mapped on the same physical pins, but in the opposite directions (bidirectional lines remain bidirectional).

Two possible modes exist, depending on the TX data encoding used by the external device.

Figure 20-90 shows an external device using DAT/SE0 encoding.

Figure 20-90. 3-Pin Bidirectional TLL Using DAT/SE0 Signaling

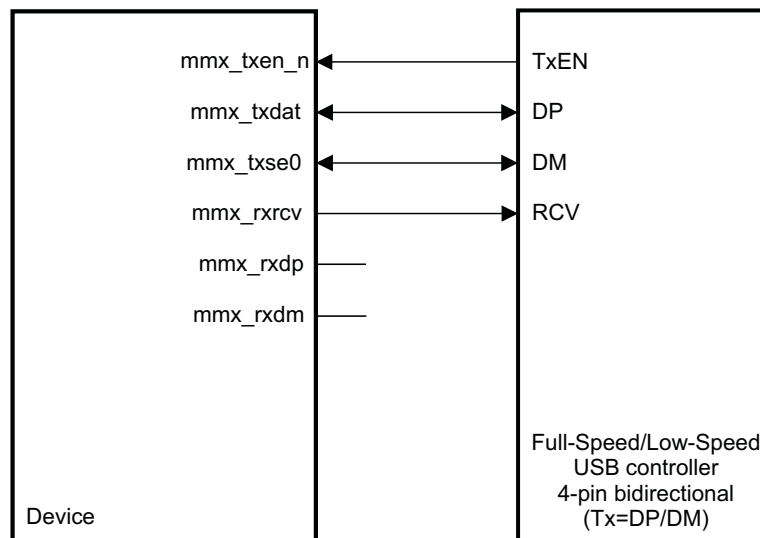

x is the USB port number (1, 2 or 3)

usb-024

Figure 20-91 shows an external device using DP/DM encoding.

Figure 20-91. 4-Pin Bidirectional TLL Using DP/DM Signaling

x is the USB port number (1, 2 or 3)

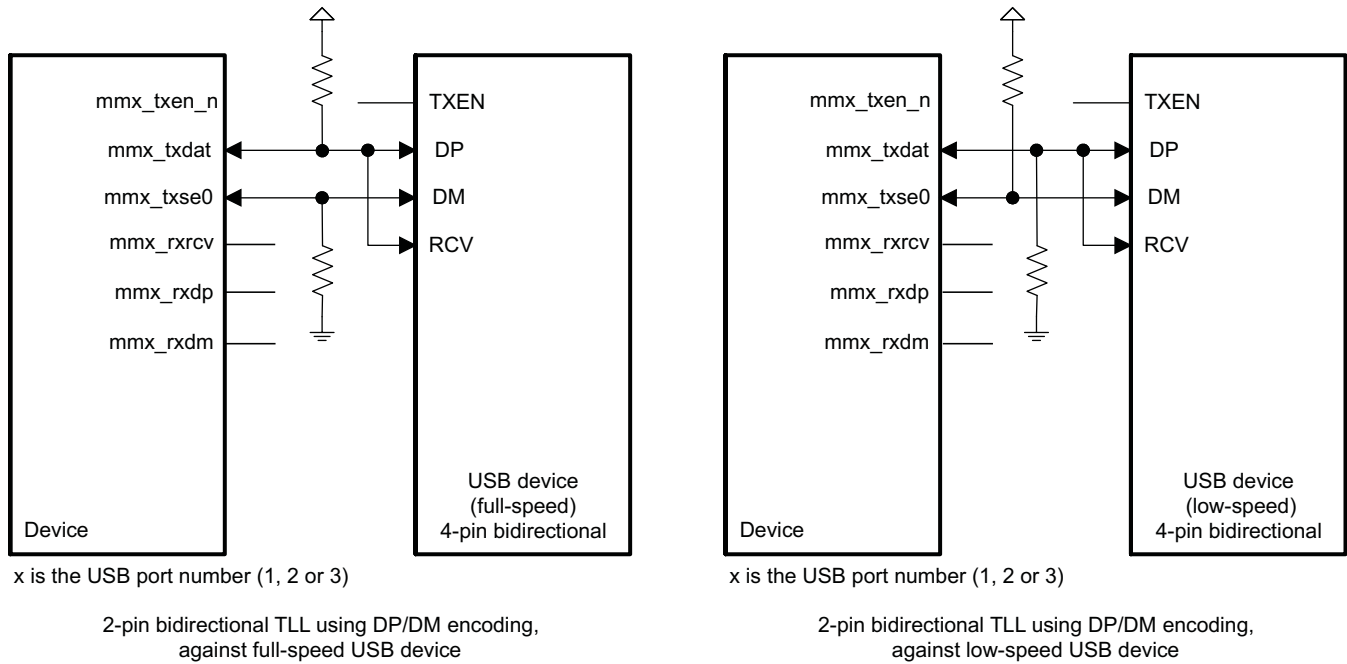

usb-025

The 2-pin TLL configurations have unique specifications:

- They require pullups/pulldowns to operate, because the bidirectional lines are not driven at all times like the other serial transceiver interfaces described above. The connection of pull resistors depends on the speed of the controller.
- The module supports explicit 2-pin TLL modes, with either DAT/SE0 or DP/DM encoding.
- Non-TLL modes (that is, transceiver configuration mode) can be used to implement the 2-pin functionality, using a specific connectivity.

Figure 20-92 shows USB port using DP/DM encoding.

Figure 20-92. 2-Pin Bidirectional TLL Using DP/DM Encoding, With 4-Pin Bidirectional USB Device

usb-026

Table 20-84 shows the pullup/pulldown configuration for DP/DM encoding.

Table 20-84. Pullup/Pulldown Configuration for DP/DM Encoding

| | Nonconnected Device (Any Speed) | Connected Low-Speed Device | Connected Full-Speed Device |
|----|------------------------------------|-------------------------------|--------------------------------|
| DP | Pulldown | Pulldown | Pullup |
| DM | Pulldown | Pullup | Pulldown |

Figure 20-93 shows a USB port using DAT/SE0 encoding.

Figure 20-93. 2-Pin Bidirectional TLL Using DAT/SE0 Encoding, With 3-Pin Bidirectional USB Device

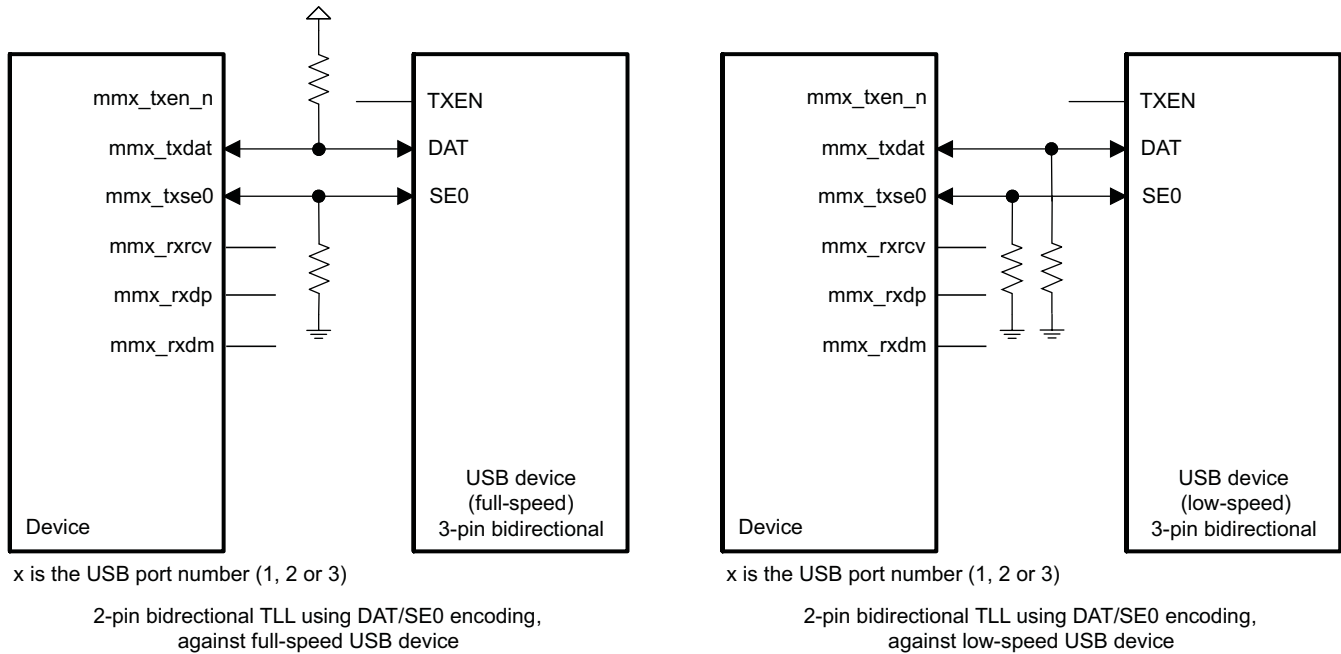

Table 20-85 shows pullup/pulldown configuration for DAT/SE0 encoding.

Table 20-85. Pullup/Pulldown Configuration for DAT/SE0 Encoding

| | Nonconnected Device (Any Speed) | Connected Low-Speed Device | Connected Full-Speed Device |
|-----|------------------------------------|-------------------------------|--------------------------------|
| DAT | Pulldown | Pulldown | Pullup |
| SE0 | Pullup | Pulldown | Pulldown |

20.2.2.4.5 High-Speed USB Host Subsystem Interface Description

Table 20-86 describes the I/O of the high-speed USB host subsystem serial interfaces.

Table 20-86. I/O Description

| Signal Name | I/O ⁽¹⁾ | Description | Value at Reset |
|---|--------------------|--|----------------|
| Multiple-Mode FS/LS Serial Interface: Port 1 | | | |
| mm1_txse0 | I/O | SE0 function in 3-pin bidirectional DAT/SE0 mode | 0 |
| | I/O | DM function in 4-pin bidirectional DP/DM mode | |
| | O | SE0 output in 6-pin unidirectional DAT/SE0 mode | |
| | O | DM output in 6-pin unidirectional DP/DM mode | |
| | I/O | SE0-TLL in 2-/3-pin bidirectional DAT/SE0 TLL mode | |
| | I/O | DM-TLL in 2-/4-pin bidirectional DP/DM TLL mode | |
| | I | SE0-TLL input in 6-pin unidirectional DAT/SE0 TLL mode | |
| | I | DM-TLL input in 6-pin unidirectional DP/DM TLL mode | |

⁽¹⁾ I = Input, O = Output

Table 20-86. I/O Description (continued)

| Signal Name | I/O ⁽¹⁾ | Description | Value at Reset |
|---|--------------------|---|----------------|
| mm1_txdm | I/O | DAT function in 3-pin bidirectional DAT/SE0 mode | Unknown |
| | I/O | DP function in 4-pin bidirectional DP/DM mode | |
| | O | DAT output in 6-pin unidirectional DAT/SE0 mode | |

| | O | Single-ended DM receiver signal output in 6-pin unidirectional TLL modes (not used in the 3-pin bidirectional DAT/SE0 TLL or 4-pin bidirectional DP/DM TLL or 2-pin bidirectional TLL modes) | |

20.2.3 High-Speed USB Host Subsystem Integration

This section describes the integration of the high-speed USB host subsystem.

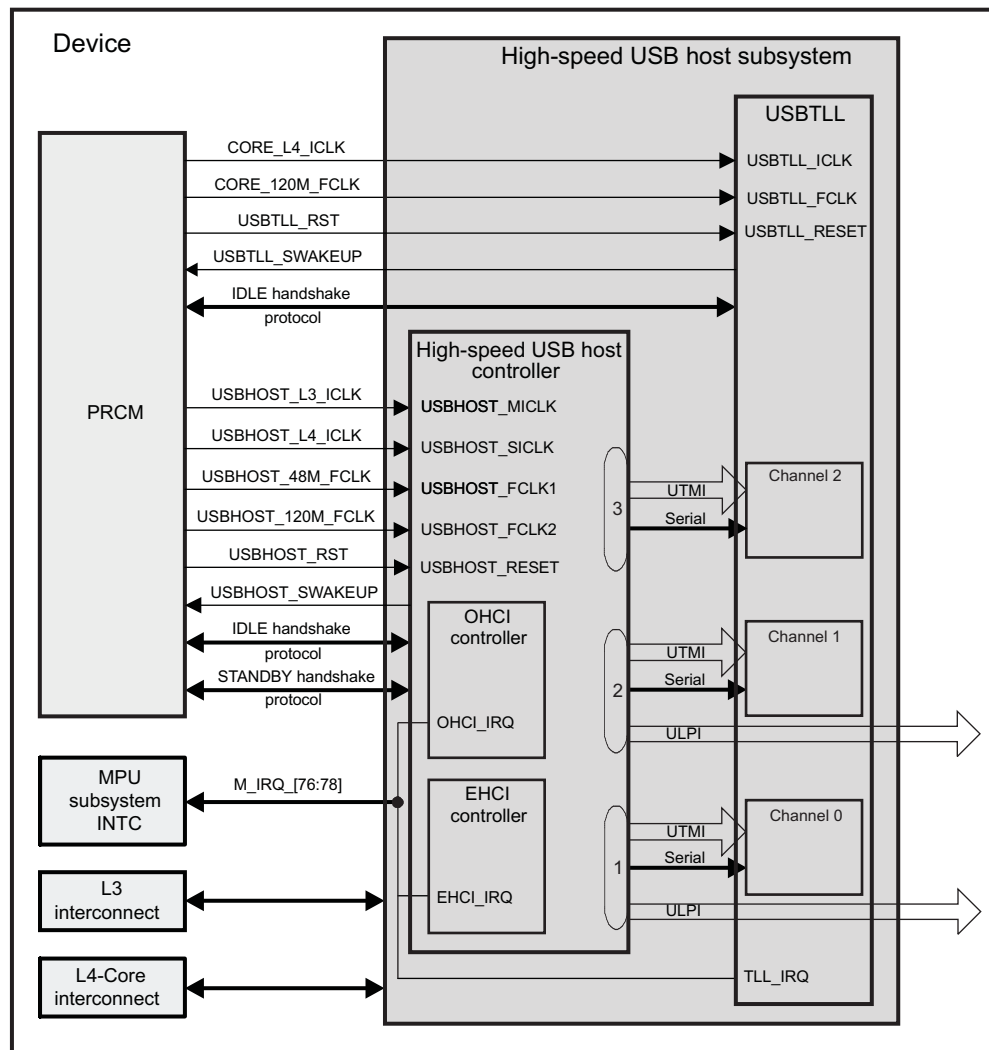

The high-speed USB host controller is connected to the L3 interconnect master (initiator) and L4-Core interconnect slave (target) interfaces. The USBTLL module is connected to the L4-Core interconnect slave (target) interface. The L3 interconnect is used to generate data traffic within the device. The L4-Core interconnect is a configuration port for register setting.

Three interrupts, M_IRQ_[78:76], are connected to the system.

The system control module (SCM) offers complementary settings for USB port connectivity modes.

Figure 20-94 highlights the high-speed USB host subsystem integration in the device.

Figure 20-94. High-Speed USB Subsystem Integration

usb-028

20.2.3.1 Reset, Clocking, and Power-Management Scheme

The high-speed USB host controller belongs to the USBHOST power domain. As part of the USBHOST power domain, it is sensible to the USBHOST_RST reset signal issued by the PRCM and to USBHOST power domain-related transitions. For further details about USBHOST power domain implementation and USBHOST_RST signal, see the *Power, Reset, and Clock Management* chapter.

The USBTLL module belongs to the CORE power domain. As part of the CORE power domain, it is sensible to the asynchronous USBTLL_RST reset signal issued by the PRCM and to CORE power domain-related transitions. For further details about CORE power domain implementation and USBTLL_RST signal, see the *Power, Reset, and Clock Management* chapter.

20.2.3.1.1 High-Speed USB Host Subsystem Resets

Table 20-87 lists and describes all the high-speed USB host subsystem resets:

Table 20-87. High-Speed USB Host Subsystem Reset Description

| Type | Name | Source | Polarity | Description |
|----------|---|--|-------------|---|
| Software | USBHOST.UHH_SYSCONFIG[1] SOFTRESET bit | High-speed USB host controller internal software reset | Active high | Writing 1 to the SOFTRESET bit resets the module. The bit value of 1 remains until the reset is complete. When the software reset is complete, the SOFTRESET bit is automatically reset to 0 and has the same effect as the hardware reset. |
| Software | USBHOST.USBTLL_SYSCONFIG[1] SOFTRESET bit | USBTLL module internal software reset | Active high | Writing 1 to the SOFTRESET bit resets the module. The bit value of 1 remains until the reset is complete. When the software reset is complete, the SOFTRESET bit is automatically reset to 0 and has the same effect as the hardware reset. |
| Hardware | USBHOST_RESET | PRCM USBHOST_RST signal | Active low | The USBHOST_RST signal resets the module. The hardware reset signal has a global reset action on the high-speed USB host controller (see the <i>Power, Reset, and Clock Management</i> chapter). |
| Hardware | USBTLL_RESET | PRCM USBTLL_RST signal | Active low | The USBTLL_RST signal resets asynchronously the module. The hardware reset signal has a global reset action on the USBTLL module (see the <i>Power, Reset, and Clock Management</i> chapter). |

20.2.3.1.1.1 Hardware Resets

The high-speed USB host controller is attached to the USBHOST power domain: the USBHOST_RST signal resets the module. The USBTLL module is attached to the CORE power domain: the USBTLL_RST signal resets asynchronously the module (see the *Power, Reset, and Clock Management* chapter). The hardware reset signal has a global reset action on the modules.

20.2.3.1.1.2 Software Resets

The high-speed USB host controller and the USBTLL module have their own software-reset functionality through the USBHOST.UHH_SYSCONFIG[1] SOFTRESET bit (0: normal mode; 1: module is reset) for the high-speed USB host controller, and through the USBHOST.USBTLL_SYSCONFIG[1] SOFTRESET bit (0: normal mode; 1: module is reset) for the USBTLL module.

Writing 1 to the SOFTRESET bit resets the module. The bit value of 1 remains until the reset is complete. When the software reset is complete, the SOFTRESET bit is automatically reset to 0 and has the same effect as the hardware reset.

20.2.3.1.2 High-Speed USB Host Subsystem Clocks

The high-speed USB host controller operates from four clock domains:

- USBHOST_FCLK1 is a high-speed USB host controller functional clock. It is used to clock the OHCI and EHCI controller internal logic of the high-speed USB host controller. Its source is the PRCM USBHOST_48M_FCLK output clock. USBHOST_FCLK1 is controlled by the PRCM.PRCM.CM_FCLKEN_USBHOST[0] EN_USBHOST1 bit (0: disabled; 1: enabled).
- USBHOST_FCLK2 is a high-speed USB host controller functional clock. It is used to clock EHCI controller internal logic of the high-speed USB host controller. Its source is the PRCM USBHOST_120M_FCLK output clock. USBHOST_FCLK2 is controlled by the PRCM.PRCM.CM_FCLKEN_USBHOST[1] EN_USBHOST2 bit (0: disabled; 1: enabled).
- USBHOST_MICLK is the high-speed USB host controller L3 master interface clock. It is used to synchronize the high-speed USB host controller L3 port to L3 interconnect. All accesses from the interconnect are synchronous to USBHOST_MICLK. Its source is the PRCM USBHOST_L3_ICLK output clock. USBHOST_MICLK is controlled by the PRCM.CM_ICLKEN_USBHOST[0] EN_USBHOST bit (0: disabled; 1: enabled) and the PRCM.CM_AUTOIDLE_USBHOST[0] AUTO_USBHOST bit (enables/disables automatic control of the interface clock).
- USBHOST_SICLK is a high-speed USB host controller L4 slave interface clock. It is used to synchronize the high-speed USB host controller L4 port to L4 interconnect. All accesses from the interconnect are synchronous to USBHOST_SICLK. Its source is the PRCM USBHOST_L4_ICLK output clock.

The USBTLL module operates from two clock domains:

- USBTLL_FCLK is the USBTLL module functional clock. It is used to clock the USBTLL module internal logic. Its source is the PRCM CORE_120M_FCLK output clock. UBTLL_FCLK is controlled by the PRCM.CM_FCLKEN3_CORE[2] EN_USBTLL bit (0: disabled; 1: enabled).
- USBTLL_ICLK is the USBTLL module interface clock. It is used to synchronize USBTLL module L4 port to L4 interconnect. All accesses from the interconnect are synchronous to USBTLL_ICLK. Its source is the PRCM CORE_L4_ICLK output clock. USBTLL_ICLK is controlled by the PRCM.CM_ICLKEN3_CORE[2] EN_USBTLL bit (0: disabled; 1: enabled) and the PRCM.CM_AUTOIDLE3_CORE[2] AUTO_USBTLL bit (enables/disables automatic control of the interface clock).

Table 20-88 summarizes the high-speed USB host subsystem clocks.

Table 20-88. High-Speed USB Host Subsystem Clocks

| Attributes | Frequency | Name | Module | Mapping | Comments |
|---------------------------|-------------------------------------|---------------|--------------------------------|-------------------|-----------------------|
| Functional clock | 48 MHz | USBHOST_FCLK1 | High-speed USB Host controller | USBHOST_48M_FCLK | Source is PRCM module |
| Functional clock | 120 MHz | USBHOST_FCLK2 | High-speed USB Host controller | USBHOST_120M_FCLK | Source is PRCM module |
| L3 master interface clock | Depending on PRCM register settings | USBHOST_MICLK | High-speed USB Host controller | USBHOST_L3_ICLK | Source is PRCM module |
| L4 slave interface clock | Depending on PRCM register settings | USBHOST_SICLK | High-speed USB Host controller | USBHOST_L4_ICLK | Source is PRCM module |
| Functional clock | 120 MHz | USBTLL_FCLK | USBTLL | CORE_120M_FCLK | Source is PRCM module |
| L4 interface clock | Depending on PRCM register settings | USBTLL_ICLK | USBTLL | CORE_L4_ICLK | Source is PRCM module |

20.2.3.1.2.1 L3 Master Interface Clock

The L3 master interface clock (USBHOST_L3_ICLK) is used only by the high-speed USB host controller (USBHOST_MICLK) in the subsystem, and comes from the PRCM module. This clock is controlled by the PRCM register bits PRCM.CM_ICLKEN_USBHOST[0] (0 = disabled, 1 = enabled) and PRCM.CM_AUTOIDLE_USBHOST[0] (enables/disables automatic control of the interface clock)—see [Table 20-89](#).

Table 20-89. High-Speed USB Controller L3 Master Interface Clock

| PRCM.CM_AUTOIDLE_USBHOST[0] | PRCM.CM_ICLKEN_USBHOST[0] | Interface Clock |
|-----------------------------|---------------------------|------------------------------|
| 0 | 0 | Disabled |
| 0 | 1 | Enabled |
| 1 | 0 | Disabled |
| 1 | 1 | Automatic enabling/disabling |

CAUTION

The L3 master interface clock shall not be less than 30 MHz, ULPI clock divided by 2 (this can occur during DPLL3 relocking).

20.2.3.1.2.2 L4 Slave Interface Clock

The L4 slave interface clock (USBHOST_L4_ICLK) is used only by the high-speed USB host controller (USBHOST_SICLK) in the subsystem, and comes from the PRCM module.

20.2.3.1.2.3 L4 Interface Clock

The L4 interface clock (CORE_L4_ICLK) is used only by the USBTLL module (USBTLL_ICLK) in the subsystem, and comes from the PRCM module. This clock is controlled by the PRCM register bits PRCM.CM_ICLKEN3_CORE[2] (0 = disabled, 1 = enabled) and PRCM.CM_AUTOIDLE3_CORE[2] (enables/disables automatic control of the interface clock)—see [Table 20-90](#).

Table 20-90. USBTLL Module Interface Clock

| PRCM.CM_AUTOIDLE3_CORE[2] | PRCM.CM_ICLKEN3_CORE[2] | Interface Clock |
|---------------------------|-------------------------|------------------------------|
| 0 | 0 | Disabled |
| 0 | 1 | Enabled |
| 1 | 0 | Disabled |
| 1 | 1 | Automatic enabling/disabling |

20.2.3.1.2.4 Functional Clocks

Two functional clocks are provided by the PRCM module to the high-speed USB host controller: USBHOST_FLCK1 running at 48 MHz (USBHOST_48M_FCLK) and USBHOST_FLCK2 running at 120 MHz (USBHOST_120M_FCLK).

The USBHOST_FLCK1 functional clock is controlled by the PRCM register bit PRCM.CM_FCLKEN_USBHOST[0] (0 = disabled, 1 = enabled).

The USBHOST_FLCK2 functional clock is controlled by the PRCM register bit PRCM.CM_FCLKEN_USBHOST[1] (0 = disabled, 1 = enabled).

The CORE_120M_FCLK functional clock is used only by the USBTLL module (USBTLL_FCLK) in the subsystem, and comes from the PRCM module. This clock is controlled by the PRCM register bit PRCM.CM_FCLKEN3_CORE[2] (0 = disabled, 1 = enabled).

20.2.3.1.3 Power-Management Scheme

20.2.3.1.3.1 High-Speed USB Host Controller Power-Management Scheme

20.2.3.1.3.1.1 Overview

To save dynamic power consumption, an efficient idle scheme in the device is based on the following:

- An efficient local autoclock gating for each module
- The implementation of control sideband signals between the PRCM module and each module

This enhanced idle control allows clocks to be activated/deactivated safely without complex software intervention. In both cases, the high-speed USB host controller power management is applied only to the interface clock domain.

The high-speed USB host controller has both master (initiator) and slave (target) interfaces.

- As an initiator, the high-speed USB host controller implements the standby handshake protocol to inform the PRCM module when it enters standby mode and does not generate traffic on the interconnect.
- As a target, the high-speed USB host controller implements the IDLE handshake protocol to allow the PRCM module requiring it to enter idle mode.

Table 20-91 details the high-speed USB host controller module PRCM clock control bits.

Table 20-91. High-Speed USB Host Controller PRCM Clock Control Bits

| Module Clock | Associated PRCM Clock Output | Enabled Bit | Autoidle Bit |
|---------------|------------------------------|--|---|
| USBHOST_FCLK1 | USBHOST_48M_FCLK | PRCM.CM_FCLKEN_USBHOST[0] EN_USBHOST1 bit | N/A |
| USBHOST_FCLK2 | USBHOST_120M_FCLK | PRCM.CM_FCLKEN_USBHOST[1] EN_USBHOST2 bit | N/A |
| USBHOST_MICLK | USBHOST_L3_ICLK | PRCM.CM_ICLKEN_USBHOST[0] EN_USBHOST bit | PRCM.CM_AUTOIDLE_USBHOST[0] AUTO_USBHOST bit |

NOTE:

- The PRCM USBHOST_48M_FCLK output is cut at PRCM level assuming all the modules that share it have been disabled in the corresponding register. Disabling the high-speed USB host controller is a necessary but not sufficient condition.
- The PRCM USBHOST_120M_FCLK output is cut at PRCM level assuming all the modules that share it have been disabled in the corresponding register. Disabling the high-speed USB host controller is a necessary but not sufficient condition.
- The PRCM USBHOST_L3_ICLK output is cut at PRCM level assuming all the modules that share it have been disabled in the corresponding register. Disabling the high-speed USB host controller is a necessary but not sufficient condition.
- The PRCM.CM_AUTOIDLE_USBHOST[0] AUTO_USBHOST bit is used to link/unlink the high-speed USB host controller from USBHOST_L3_ICLK-related clock domain transitions.
- For further details about source clocks gating and domain transitions, see the *Power, Reset, and Clock Management* chapter.

20.2.3.1.3.1.2 L3 Master Interface Power Management

The high-speed USB host controller can go to standby mode, in which case it stops generating transactions on the interconnect. The module standby leads the PRCM to disable the USB clocks to save power.

The high-speed USB host controller has a MSTANDBY/WAIT handshake mechanism with the PRCM module (see [Figure 20-94](#)).

The module is ready to enter standby mode (indicated by the MSTANDBY signal to the PRCM asserted) when there is no USB activity and the module is idle. It means the following:

- The module is committed not to start any new transaction on its master interface.
- The whole module is idle and, therefore, the power manager can start the procedure to turn off the interface clock, if needed. This procedure must be implemented using the slave power-management protocol.

The handshake mechanism lets the module go to standby mode based on the USBHOST.UHH_SYSCONFIG[13:12] MIDDLEMODE field.

Table 20-92. High-Speed USB Host Controller MIDDLEMODE Settings

| MIDDLEMODE Value | Selected Mode | Description |
|------------------|---------------|--|
| 0x0 | Force-standby | The high-speed USB host controller enters standby mode unconditionally (MSTANDBY is asserted unconditionally). |
| 0x1 | No-standby | The high-speed USB host controller never enters standby mode (MSTANDBY is never asserted). |
| 0x2 | Smart-standby | The high-speed USB host controller is ready to enter standby mode (MSTANDBY is asserted) when there is no more activity on the USB master interface of the interconnect. MSTANDBY is asserted when the module is idle and deasserted when the module is activated by either an external USB event or an appropriate register access. The module then waits for MWAIT deassertion before a DMA transfer is started. |

20.2.3.1.3.1.3 L4 Slave Interface Power Management

At PRCM level, when all the conditions to shut off the high-speed USB host controller output clocks are met (see the *Power, Reset, and Clock Management* chapter for details), the PRCM module automatically launches a hardware handshake protocol to ensure the high-speed USB host controller is ready to have its clocks switched off. Namely, the PRCM asserts an IDLE request to the high-speed USB host controller. Although this handshake is completely hardware and out of any software control, the way in which the high-speed USB host controller acknowledges the PRCM IDLE request is configurable through the USBHOST.UHH_SYSCONFIG[4:3] SIDLEMODE bit field. [Table 20-93](#) details SIDLEMODE settings and the related acknowledgment modes.

Table 20-93. High-Speed USB Host Controller SIDLEMODE Settings

| SIDLEMODE Value | Selected Mode | Description |
|-----------------|---------------|---|
| 0x0 | Force-idle | The high-speed USB host controller acknowledges unconditionally the IDLE request from the PRCM, regardless of its internal operations. Because such a mode does not prevent any loss of data when the clock is switched off, the mode must be used carefully. |
| 0x1 | No-idle | The high-speed USB host controller never acknowledges any IDLE request from the PRCM. This mode is secure from a module point of view as it ensures the clocks remain active; however, it is not efficient from a power-saving perspective because it does not allow the PRCM output clock to be shut off and thus the power domain to be set to a lower power state. |
| 0x2 | Smart-idle | The high-speed USB host controller acknowledges the IDLE request basing its decision on its internal activity. Namely, the acknowledge signal is asserted only when all pending transactions, IRQs or DMA requests are treated. This is the best approach for an efficient system power management. |

When configured in smart-idle mode, the high-speed USB host controller also offers an additional granularity on its interface clock gating. The USBHOST.UHH_SYSCONFIG[9:8] CLOCKACTIVITY bit is used to control the interface clock internal gating while module is idle. [Table 20-94](#) details the CLOCKACTIVITY settings.

Table 20-94. High-Speed USB Host Controller CLOCKACTIVITY Settings

| CLOCKACTIVITY Value | Interface Clock Effect | Description |
|---------------------|------------------------|---|
| 0 | OFF | Interface clock is considered for generating the acknowledgment. This setting also means the interface clock is shut down upon PRCM IDLE request. |
| 1 | ON | Interface clock is not shut down upon PRCM IDLE request. The high-speed USB host controller can potentially acknowledge the IDLE request without checking the internal functionalities linked to its clock. |

CAUTION

The PRCM does not have any hardware means to read CLOCKACTIVITY settings. Software ensures a consistent programming between the high-speed USB host controller CLOCKACTIVITY and PRCM interface clock control bit. Indeed, if the USBTLL module is disabled in the PRCM.CM_ICLKEN_USBHOST register while CLOCKACTIVITY is set to 1, nothing prevents the PRCM module from asserting its IDLE request, which is acknowledged regardless of the features associated to the USBTLL module interface clock. This may lead to unpredictable behaviors.

20.2.3.1.3.2 USBTLL Module Device Power-Management Scheme

From a global system power-management perspective, when one or both of the USBTLL module clocks are no longer required, the USBTLL module can be deactivated at PRCM level in the corresponding registers.

Table 20-95 details the USBTLL module PRCM clock control bits.

Table 20-95. USBTLL Module PRCM Clock Control Bits

| Module Clock | Associated PRCM Clock Output | Enabled Bit | Autoidle Bit |
|--------------|------------------------------|---------------------------------------|--|
| USBTLL_FCLK | CORE_120M_FCLK | PRCM.CM_FCLKEN3_CORE[2] EN_USBTLL bit | N/A |
| USBTLL_ICLK | CORE_L4_ICLK | PRCM.CM_ICLKEN3_CORE[2] EN_USBTLL bit | PRCM.CM_AUTOIDLE3_CORE [2] AUTO_USBTLL bit |

NOTE:

- The PRCM CORE_120M_CLK output is cut at PRCM level assuming all the modules that share it have been disabled in the corresponding register. Disabling the USBTLL module is a necessary but not sufficient condition.
- The PRCM CORE_L4_ICLK output is cut at PRCM level assuming all the modules that share it have been disabled in the corresponding register. Disabling the USBTLL module is a necessary but not sufficient condition.
- The PRCM.CM_AUTOIDLE3_CORE[2] AUTO_USBTLL bit is used to link/unlink the USBTLL module from CORE_L4_ICLK-related clock domain transitions.
- For further details about source clocks gating and domain transitions, see the *Power, Reset, and Clock Management* chapter.

At PRCM level, when all the conditions to shut off the USBTLL_FCLK or USBTLL_ICLK output clocks are met (see the *Power, Reset, and Clock Management* chapter for details), the PRCM module automatically launches a hardware handshake protocol to ensure the USBTLL module is ready to have its clocks switched off. Namely, the PRCM asserts an IDLE request to the USBTLL module. Although this handshake is completely hardware and out of any software control, the way in which the USBTLL module acknowledges the PRCM IDLE request is configurable through the USBHOST.USBTLL_SYSCONFIG[4:3] SIDLEMODE bit field. Table 20-96 details SIDLEMODE settings and the related acknowledgment modes.

Table 20-96. USBTLL Module SIDLEMODE Settings

| SIDLEMODE Value | Selected Mode | Description |
|-----------------|---------------|--|
| 0x0 | Force-idle | The USBTLL module acknowledges unconditionally the IDLE request from the PRCM, regardless of its internal operations. Because such a mode does not prevent any loss of data when the clock is switched off, the mode must be used carefully. |
| 0x1 | No-idle | The USBTLL module never acknowledges any IDLE request from the PRCM. This mode is secure from a module point of view as it ensures the clocks remain active; however, it is not efficient from a power-saving perspective because it does not allow the PRCM output clock to be shut off and thus the power domain to be set to a lower power state. |
| 0x2 | Smart-idle | The USBTLL module acknowledges the IDLE request basing its decision on its internal activity. Namely, the acknowledge signal is asserted only when all pending transactions, IRQs or DMA requests are treated. This is the best approach for an efficient system power management. |

When configured in smart-idle mode, the USBTLL module also offers an additional granularity on USBTLL_ICLK gating. The USBHOST.USBTLL_SYSCONFIG[9:8] CLOCKACTIVITY bit is used to control the USBTLL_ICLK clock internal gating while the module is idle. [Table 20-97](#) details the CLOCKACTIVITY settings.

Table 20-97. USBTLL Module CLOCKACTIVITY Settings

| CLOCKACTIVITY Value | USBTLL_ICLK Effect | Description |
|---------------------|--------------------|--|
| 0 | OFF | USBTLL_ICLK is considered for generating the acknowledgment. This setting also means USBTLL_ICLK is shut down upon PRCM IDLE request. |
| 1 | ON | USBTLL_ICLK is not shut down upon PRCM IDLE request. The USBTLL module can potentially acknowledge the IDLE request without checking the internal functionalities linked to its clock. |

CAUTION

The PRCM does not have any hardware means to read CLOCKACTIVITY settings. Software ensures a consistent programming between the USBTLL module CLOCKACTIVITY and PRCM USBTLL_ICLK control bit. Indeed, if the USBTLL module is disabled in the PRCM.CM_ICLKEN3_CORE register while CLOCKACTIVITY is set to 1, nothing prevents the PRCM module from asserting its IDLE request, which is acknowledged regardless of the features associated to the USBTLL module interface clock. This may lead to unpredictable behaviors.

20.2.3.2 Hardware Requests

20.2.3.2.1 Interrupt Requests

Table 20-98 lists the interrupt lines that are driven out from the high-speed USB host controller to the microprocessor unit (MPU) subsystem interrupt controller (INTC).

Table 20-98. High-Speed USB Host Subsystem Interrupts

| Name | Mapping | Comments |
|--|----------|---|
| HS USB OHCI Host Controller Interrupt | | |
| OHCI_IRQ | M_IRQ_76 | Destination is MPU subsystem interrupt controller |
| HS USB EHCI Host Controller Interrupt | | |
| EHCI_IRQ | M_IRQ_77 | Destination is MPU subsystem interrupt controller |
| USBTLL Module Interrupt | | |
| TLL_IRQ | M_IRQ_78 | Destination is MPU subsystem interrupt controller |

20.2.3.2.2 IDLE Handshake Protocol

The PRCM handles an IDLE handshake protocol for the high-speed USB host controller and the USBTLL module. The IDLE handshake protocol allows the PRCM requiring the high-speed USB host controller to enter idle mode. The module acknowledges when it is ready.

20.2.3.2.3 MSTANDBY Handshake Protocol

The PRCM module handles an MSTANDBY handshake protocol for the high-speed USB host controller, which initiates the MSTANDBY handshake to inform the PRCM module when it enters standby mode and does not generate traffic on interconnect.

20.2.3.2.4 Wake-Up Request

Wake-up request signal USBHOST_SWAKEUP is generated by the high-speed USB host controller to the PRCM module. Wake-up request signal USBTLL_SWAKEUP is generated by the USBTLL module to the PRCM module.

20.2.4 High-Speed USB Host Subsystem Functional Description

This section describes the functionality of the high-speed USB host subsystem by describing the high-speed USB host controller and the USBTLL module.

20.2.4.1 High-Speed USB Host Controller Functionality

The full details of the standard OHCI and EHCI host controller APIs (implemented by the current module) are not repeated here. For more information, see the following specifications:

- *Open Host Controller Interface (OHCI) specification for USB Release 1.0a*
- *Enhanced Host Controller Interface (EHCI) specification for USB Release 1.0*

20.2.4.1.1 High-Speed USB Host Controller Architecture

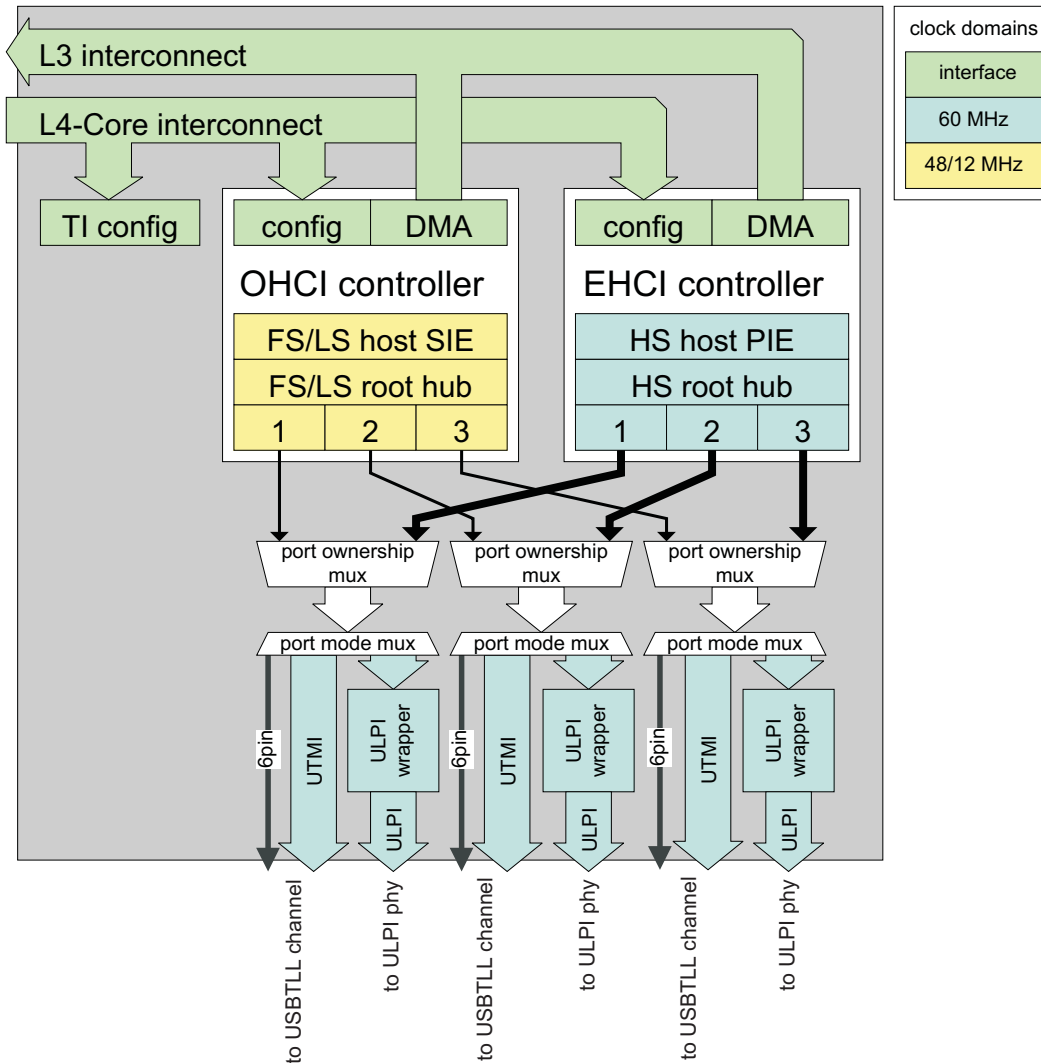

Figure 20-95 shows an overview of the high-speed USB host controller internal architecture: it contains two independent, 3-port host controllers that operate in parallel: EHCI and OHCI. Each of the three external ports is owned by exactly one of the controllers at any point in time. Each port can work in several modes:

- When the port is owned by the OHCI (full-speed) host controller, the serial 6-pin interface mode is used.
- When the port is owned by the EHCI (high-speed) host controller, either the ULPI or the UTMI modes are used.

NOTE: If one port is connected to a high-speed ULPI transceiver, all other ports must be connected to high-speed ULPI transceivers or not used.

The L4-Core interconnect is used to configure the two controllers, as well as a general, TI-specific register bank. The L3 interconnect merges and arbitrates between the transactions generated by the controller respective DMA engines.

Figure 20-95. High-Speed USB Host Controller Architecture

usb-029

20.2.4.1.2 OHCI Implementation Specifications

Some features of the OHCI API are optional and/or implementation-specific. The choices made in the current implementation, the high-speed USB host controller, are described below, and are reflected in the register descriptions (see [Section 20.2.6.6, OHCI Registers](#)). For all standard features, see the *Open Host Controller Interface (OHCI) specification for USB Release 1.0a*.

- USBHOST.HCFMINTERVAL[30:16] FSMPs field (FullSpeedMaxPacketSize) = 0x0000: Host will stop scheduling new packets 0 bit times before the end of the frame (that is, there is no scheduling overrun protection by default). To be updated by the software driver.
- USBHOST.HCRHDESCRIPTORA[7:0] NDP field (NumberDownstreamPorts) = 0x03 = 3 ports.
- USBHOST.HCRHDESCRIPTORA[9] NPS bit (NoPowerSwitching) = 0: Ports are power-switched by default.

- USBHOST.HCRHDESCRIPTORA[8] PSM bit (PowerSwitchingMode) = 1: Per-port power switching is supported, although PPCM default setup has all ports controlled globally.
- USBHOST.HCRHDESCRIPTORA[31:24] POTPG field (PowerOnToPowerGood) = 0x0A = 10: Power rampup time is 10 x 2 ms = 20 ms.
- USBHOST.HCRHDESCRIPTORB[15:0] DR field (DeviceRemovable) = 0x0000: By default, no nonremovable devices (that is, devices attached to any of the ports) are removable.
- USBHOST.HCRHDESCRIPTORB[31:16] PPCM field (PortPowerControlMask) = 0x0000: By default, all ports are affected only by global power control.

20.2.4.1.3 UTMI Ports

The high-speed USB host controller supports N “downstream” ports, numbered from 1 through N. (In USB terminology, port 0 is necessarily an “upstream” port, and because the host is on “top” of the USB topological tree it has none). In the current implementation N = 3 (that is, available ports are 1, 2, 3).

The high-speed USB host controller is configured to be either in UTMI or in ULPI mode (see the USBHOST.UHH_HOSTCONFIG[0] ULPI_BYPASS bit).

In UTMI mode (see *USB 2.0 Transceiver Macrocell Interface specification Release 1.05*, and *UTMI+ specification Release 1.0*), all ports are in UTMI mode (that is, each port has its UTMI signal set broadcast the “outgoing” packets — from the host to the peripherals) and gather the “incoming” ones (that is, from the addressed peripheral to the host). ULPI signal sets are undefined/don’t care on all ports.

In the device, the UTMI ports connect to the USBTLL module. The UTMI ports between the high-speed USB host controller and the USBTLL module are on-chip and remain invisible.

20.2.4.1.4 ULPI Ports

The high-speed USB host controller supports N “downstream” ports, numbered from 1 through N. (In USB terminology, port 0 is necessarily an “upstream” port, and because the host is on “top” of the USB topological tree it has none). In the current implementation N = 3 (that is, available ports are 1, 2, 3).

The high-speed USB host controller is configured to be either in UTMI or in ULPI mode (see the USBHOST.UHH_HOSTCONFIG[0] ULPI_BYPASS bit).

In ULPI mode (see *UTMI Low-Pin Interface (ULPI) specification Release 1.1*), all ports are in ULPI mode (that is, each port has its ULPI signal set broadcast the “outgoing” packets — from the host to the peripherals) and gather the “incoming” ones (that is, from the addressed peripheral to the host). UTMI signal sets are undefined/don’t care on all ports.

When in ULPI mode, the high-speed USB host controller is in charge of generating the (nominally 60-MHZ) clock to the transceiver on the ULPI interface. This is called ULPI “input” clocking mode, because the ULPI protocol is transceiver-centric. The opposite mode, “output mode” (that is, the host receives the ULPI clock from the transceiver), is not supported and there is consequently no ULPI clock input.

In the device, the ULPI ports (only port 1 and port 2 are mapped) can only be connected directly to external transceivers. The USBTLL module is bypassed. USB traffic can be monitored directly on the USB lines.

20.2.4.1.5 Port Status

The USB port status is given through the USBHOST.UHH_HOSTCONFIG[10:8] bit field. The default value of the following bits is 1:

- USBHOST.UHH_HOSTCONFIG[8] P1_CONNECT_STATUS
- USBHOST.UHH_HOSTCONFIG[9] P2_CONNECT_STATUS
- USBHOST.UHH_HOSTCONFIG[10] P3_CONNECT_STATUS

CAUTION

These bits show the port status as connected after power on even though no USB device is connected. The USB host controller has operational status registers (for example, USBHOST.HCRHPORTSTATUS_1 for OHCI port 1) that indicate the correct port connect status. The USB driver software must read these status bits and check whether or not a port is connected. If the port is not connected, the USB driver software must reprogram the USBHOST.UHH_HOSTCONFIG bits to indicate the correct port connect status.

20.2.4.1.6 Save and Restore

The save-and-restore (SAR) mechanism can extract the hardware context of the high-speed USB host controller (after all USB activity has been suspended) before switching off (=save), save it to an external always-on memory, and reinject it later after the module has been switched on again and reset (=restore) seamlessly for the USB. Part of that context is composed of the register fields described in the current chapter. The rest of the context is composed of the “buried” flip-flops and memories (not accessible by software) like finite state-machine (FSM) states, buffer contents, and miscellaneous random logic bits.

The PRCM.PM_PWSTCTRL_USBHOSTE[4] SAVEANDRESTORE bit enables the SAR mechanism for the high-speed USB host controller (see the *Power, Reset, and Clock Management* chapter). When set, the PRCM module initiates the save and/or the restore sequences at the appropriate time. When not set, the USB host is treated as a standard module, and the save/restore sequences do not occur.

20.2.4.1.7 Burst Control

To avoid buffer underflow bursts shall be enabled by writing 0x7 in USBHOST.UHH_HOSTCONFIG[4:2] and 0x0 in USBHOST.UHH_HOSTCONFIG[5] ENA_INCR_ALIGN.

20.2.4.2 USBTLL Module Functionality

The USBTLL module implements a TLL compatible with a number of USB standard interface protocols. Once the interface protocol has been selected during an initial configuration phase, USB operation should take place seamlessly (that is, as if actual transceivers were present). To ensure maximum compatibility, as many features as possible have been included, as described in the rest of this document. The basic principle is that all the software “handles” should be available and behave in a proper way, even if there is no actual functionality underneath.

The USBTLL module is integrated with the high-speed USB host controller in the device. The transceiver interfaces (UTMI ports) between the high-speed USB host controller and the USBTLL module are on-chip and remain invisible. The other transceiver interfaces go off-chip, where they can be connected to the other controllers (for example, peripherals) on another IC.

20.2.4.2.1 Channels and Ports

Following the same convention than UTMI and ULPI, the current specification is consistently PHY-centric (that is, directions are always given with respect to the transceiver emulated here by the TLL), and not with respect to the link controller: An “input” goes from the link controller to the TLL (transceiver emulator) (that is, it is an input for the USBTLL module. Reciprocally, an “output” goes from TLL (transceiver) to the link controller (that is, it is an output for the USBTLL module).

By convention, the local link controller is the controller integrated on the same IC as the USBTLL module: This is the high-speed USB host controller in the device. The remote link controller is the other controller, located off-chip (that is, on another IC). One controller is always the USB host, the other the USB peripheral, and they communicate through the USBTLL module.

A channel is defined as a independent USB path through the USBTLL module, which always converts the UTMI+ transceiver interface protocol coming from the local link controller (the high-speed USB host controller in the device). The number of channels of the USBTLL module is three in the device.

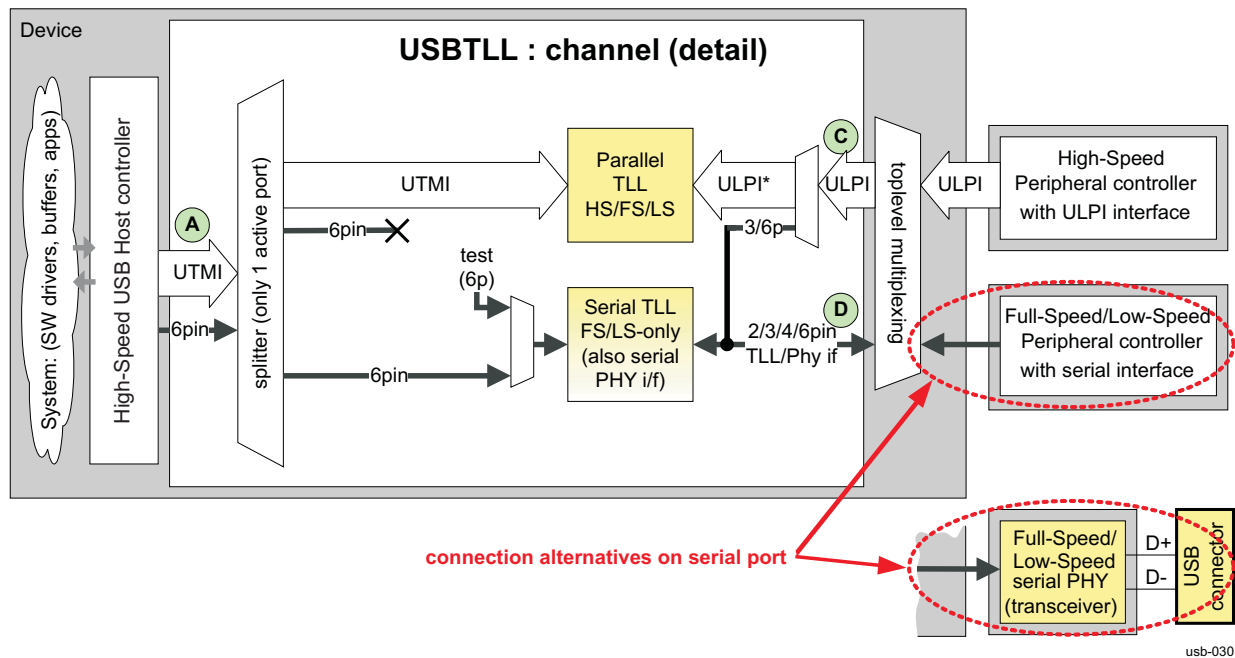

A USB port is a set of I/O signals that carry the data and control information from/to a USB line. Several port formats exist, with different capabilities. A channel has three ports. If the channel is active, two ports are active at a time, depending on the channel configuration. The mode remains static throughout USB operation. Table 20-99 summarizes the ports features.

20.2.4.2.2 Channel Architecture

Figure 20-96 shows the architecture of a single channel (of three) of the USBTLL module, and its integration in a USB system. The ports are indicated by the circled letters (A, C, and D). See the following descriptions:

- Full arrows represent parallel, synchronous, high-speed-capable interfaces.
- Line arrows represent serial, combinatorial, full-speed/low-speed-only interfaces.
- Arrows always point toward the PHY layer (actual transceiver or TLL, in yellow), away from the link controller.
- The arrow marked ULPI* represents the entire ULPI protocol (synchronous or not) except the 3-/6-pin serial TLL modes which are reoriented toward the serial TLL block.
- The USBTLL module cannot interface with a ULPI transceiver. This functionality is provided by the high-speed USB host controller.
- Top-level multiplexing is shown only for information. It is static and does not add functionality. The figure shows ULPI and serial ports implemented on different I/O pads for clarity, but a real implementation would typically reuse the same pads, because the interfaces cannot be active simultaneously

Figure 20-96. USBTLL Channel

usb-030

Table 20-99 summarizes the properties of each port.

Table 20-99. USBTLL Channel USB Ports

| USBTLL Port | Port Description | Connect to Controller | Connect to Transceiver | Serial (Full-Speed/ Low-Speed only) | Parallel (High-Speed/ Full-Speed/Low-Speed) |
|-------------|------------------|-----------------------|------------------------|-------------------------------------|---|
| A | PHY-side UTMI+ | UTMI+ (L3) | No | 6-pin | 60-MHZ UTMI |
| C | PHY-side ULPI | ULPI TLL | No | 6-pin | 60-MHZ UTMI |
| D | Multimode Serial | 6-/4-/3-/2-pin TLL | 6-/4-/3-/2-pin | 6-/4-/3-/2-pin TLL | No |

20.2.4.2.2.1 Port A: PHY-side UTMI+ Port

Connects to the high-speed USB host controller in the device. The UTMI “local” port is used in all configurations (that is, the entire channel can be seen as a protocol converted from that port to one of the remote ports C or D).

- Compliant with UTMI+ version 1.0
- 8-data-bit, 60 MHz UTMI (HS/FS/LS-capable)
- UTMI+ Level 3 extensions
- Vcontrol/Vstatus (from UTMI)
- Serial FS/LS “6-pin” mode

20.2.4.2.2.2 Port C: PHY-Side ULPI Port

Connects to a remote (off-chip) ULPI controller through I/O pads.

- Compliant with ULPI version 1.1
- SDR and DDR ULPI capable (respectively, 8-bit/4-bit data width modes)
- Supports optional 6-pin/3-pin serial modes
- Supports optional input clocking mode

20.2.4.2.2.3 Port D: Serial Multimode Port

Connects to either a serial controller (TLL modes) or a serial transceiver (transceiver interface modes).

- Supports 6-pin (TX: DAT/SE0 or TX: DP/DM) unidirectional, 4-pin bidirectional, 3-pin bidirectional, 2-pin bidirectional modes
- All modes are supported for TLL or transceiver interface configuration.
- Supports sideband signals (pullup/down control, speed/suspend enable, etc.)

20.2.4.2.3 Channel Configuration

A channel configuration is a set of software settings that specifies the connection of two of the channel ports through the USBTLL module. USB data and control injected on one side (or port) comes out on the other side (or port) after a certain amount of processing, depending on the mode. [Table 20-100](#), lists the modes.

All configurations connect the PHY UTMI port (attached to the high-speed USB host controller) to one of the other two ports (attached to a variety of transceivers or controllers on the pads side).

[Table 20-100](#) describes the available modes and the software settings required for each. Channel I has the following settings:

- CHANMODE: USBHOST.TLL_CHANNEL_CONF_i[2:1] CHANMODE field
- FLSMODE: USBHOST.TLL_CHANNEL_CONF_i[27:24] FLSMODE field
- FLS SERIALMODE_3PIN/6PIN: Either the ULPI PHY-side USBHOST.ULPI_INTERFACE_CTRL[1] FLS SERIALMODE_3PIN bit or the USBHOST.ULPI_INTERFACE_CTRL[0] FLS SERIALMODE_6PIN bit (only one can be set to 1 at a time)

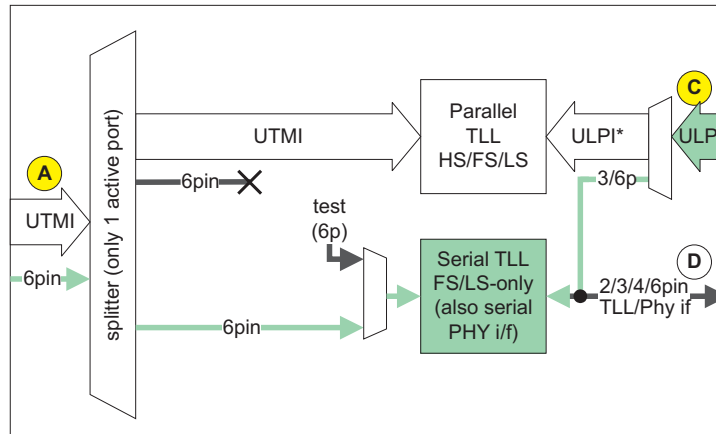

Table 20-100. USBTLL Channel Configuration

| Configuration | Mode | CHAN MODE | FLSMODE | Other Settings | Ports | Speed | Remote Port Connection |
|---------------|--------------------------------|-----------|---------------------------|------------------------------|-------|-------|--|
| 2 | ULPI synchronous TLL | 0 | N/A | FLS SERIALMODE_3PIN/6PIN = 0 | A-C | HFL | ULPI link (peripheral controller) |
| 4 | Serial UTMI to serial ULPI TLL | 0 | N/A | FLS SERIALMODE_3PIN/6PIN = 1 | A-C | FL | ULPI link (peripheral controller) supporting 3-/6-pin mode |
| 6 | Serial UTMI to serial TLL | 1 | 0x4 to 0x7; 0xA to 0xB | - | A-D | FL | Serial link (2-/3-/4-/6-pin) |
| 6 | Serial UTMI to serial PHY | 1 | 0x0 to 0x3 | - | A-D | FL | Serial transceiver (2-/3-/4-/6-pin) |

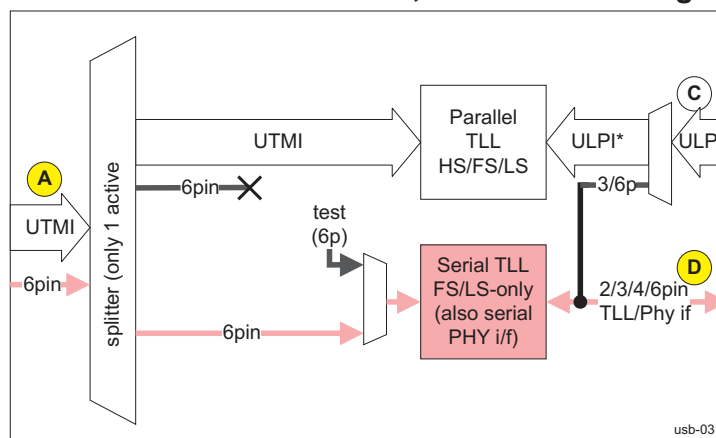

Figure 20-97. Per-Configuration Datapath Through USBTLL
2: Sync UTMI to sync ULPI TLL config (HS/FS/LS)

4: Serial UTMI to serial ULPI TLL config (FS/LS)

6: Serial UTMI to serial ULPI, TLL or PHY config

usb-031

20.2.4.2.4 VBUS Management and Emulations

In transceiver configurations, an actual USB cable is present, including an actual 5 V VBUS supply line. On the other hand, in TLL configurations, the physical USB lines are emulated and have no physical existence. This is especially true for the VBUS line, which distributes the 5-V power provided by the default host (or A-device) to the entire bus. VBUS is also used for signaling purposes, and those features must be emulated:

- A peripheral detects the presence of a host by detecting the presence of VBUS.
- USB OTG defines an elaborate voltage-sensing scheme to dynamically switch on and off VBUS (start and stop sessions). In the context of TLL, this brings no power saving compared to simple suspend.
- In particular, USB OTG uses VBUS as a wake-up source (VBUS-pulsing SRP) for the default peripheral (or B-device).

For more information on how sideband controls are integrated, see [Figure 20-82](#) and [Figure 20-83](#) and the related explanations.

20.2.4.2.4.1 VBUS Control and Status for Transceiver (Non-TLL) Configurations

In non-TLL modes, VBUS exists, and the problem is to propagate control and status to/from the actual VBUS manager IC (typically the transceiver itself).

Only serial transceiver configurations are concerned in the case of the high-speed USB host subsystem in the device.

20.2.4.2.4.1.1 VBUS Management in Serial Transceiver Configurations

VBUS management is not standardized in transceiver configurations. The chosen implementation is described below. See also [Figure 20-82](#).

- VBUS control required for host and OTG operation (VBUS drive, VBUS pullup “charge”, VBUS pulldown “discharge”) is assumed to be taken care of separately from the USBTLL module (that is, by software and straight to the power IC, which can be the transceiver itself, especially in OTG cases).
- VBUS status must be sampled by the appropriate hardware (again, most of the time the transceiver itself) and reported by software to the USBTLL module, using the USBHOST.TLL_CHANNEL_CONF_i DRVVBUS and CHRGVBUS bits, as indicated in [Table 20-101](#).

[Table 20-101](#) lists the values to write to the USBHOST.TLL_CHANNEL_CONF_i register depending on the VBUS status observed by the transceiver on the actual VBUS line. The same register fields are also used in TLL configuration, and have been named according to that second configuration. In transceiver configurations the fields' actual signification is:

- DRVVBUS: set to 1 to report a VBUS level greater than *VBUS valid*.
- CHRGVBUS: set to 1 to report a VBUS level greater than *Session valid*

Table 20-101. VBUS Level Software Reporting for Serial Transceiver Configuration

| VBUS Status | USBHOST.TLL_CHANNEL_CONF_i[16] DRVVBUS Bit | USBHOST.TLL_CHANNEL_CONF_i[15] CHRGVBUS Bit |
|---------------------|---|--|
| VBUS valid | 1 | 1 |
| Session valid (A/B) | 0 | 1 |
| Session not valid | 0 | 0 |
| Session end | 0 | 0 |

20.2.4.2.4.2 VBUS Emulation for TLL Configurations

The TLL VBUS emulation sums up all actions on the VBUS line, obtains a voltage level, reported in the VBUS status bits following the protocol. The level depends on the immediate VBUS actions and has no memory of previous levels, whereas a real VBUS line behaves like an RC circuit and takes time to charge and discharge. This causes the following differences:

- The TLL level always jumps abruptly from session valid to session end (and back) with no transient time in between (where session is neither valid nor ended) as in real life.
- The Charge feature is used for VBUS-pulsing SRP, and is enabled long enough to go over the Session valid threshold, but without reaching VBUS valid. In the TLL the transition to Session valid is immediate, and VBUS valid is never reached even if the Charge is intentionally kept active.
- The Discharge feature is used in real life to accelerate the voltage drop of an undriven VBUS towards the session-end level. For TLL, this is therefore useless (although the UTMI input/ULPI register bit do exist, for compatibility), and always a “don’t care”

20.2.4.2.4.2.1 VBUS Emulation in ULPI TLL Modes

Table 20-102 summarizes the VBUS emulation in ULPI TLL modes. VBUS controls are writable, static PHY-side registers on the ULPI side, and input signals on the ULPI ports (port A). VBUS status bits are read-only, volatile PHY-side registers on the ULPI, and output signals on the ULPI ports (port A).

Table 20-102. Emulation of VBUS Levels for UTMI-to-ULPI TLL Mode

| USBHOST.ULPI_OTG_CTRL[5] DRVVBUS Bit | VBUS Controls (Actions) | | VBUS Level | VBUS Status | | |
|--------------------------------------|---------------------------------------|--|-------------|--|--|---|
| | USBHOST.ULPI_OTG_CTRL[4] CHRGVBUS Bit | USBHOST.ULPI_OTG_CTRL[3] DISCHRGVBUS Bit | | USBHOST.ULPI_USB_INT_STATUS[1] VBUSVALID Bit | USBHOST.ULPI_USB_INT_STATUS[2] SESSVALID Bit | USBHOST.ULPI_USB_INT_STATUS[3] SESSSEND Bit |
| 1 | X | X | VBUS valid | 1 | 1 | 0 |
| 0 | 1 | X | VBUS valid | 0 | 1 | 0 |
| 0 | 0 | X | Session end | 0 | 0 | 1 |

20.2.4.2.4.2.2 VBUS Emulation in Serial TLL Modes

In serial TLL modes, VBUS status and control is implemented with ad-hoc sideband signals. See Figure 20-83.

VBUS control can be done in software, by writing to the following fields of the USBHOST.TLL_CHANNEL_CONF_i register:

- DRVVBUS: set to 1 to drive VBUS to 5 V (for A-device or host)
- CHRGVBUS: set to 1 to pullup VBUS (for SRP)
- There is no pulldown (discharge) control, because the emulated VBUS has no latency and VBUS level goes to the session end level as soon as it is neither driven nor pulled up.

Alternatively, VBUS drive can also be hardware-controlled through a dedicated input. (DRVVBUS register bit and input signal are actually ORed internally.)

VBUS status is available on dedicated output signals. If those outputs are not available at top level, a software alternative is to use the voltage status reported on the local controller (the high-speed USB host controller in the device) interface (through the standard UTMI+ sideband signals) and to pass it to the remote controller (a peripheral controller), by means of an ad hoc software-controller interface other than the USB itself. This is based on the fact that the level of VBUS is the same on both extremities of the bus (that is, it does not matter which side does the measurement).

20.2.4.2.5 Multimode Serial Port

The multimode serial port requires six bidirectional I/O pads to support all eight defined modes (selected in the USBHOST.TLL_CHANNEL_CONF_i[27:24] FLSMODE field when field CHANMODE = 0x1 = UTMI-to-serial). Those modes are full-speed/low-speed only (that is, high-speed is not supported over a serial interface).

The pads are named TXEN, TXDAT, TXSE0, RXRCV, and RXDM after their functionality in standard 6-pin mode (mode 0). Each pad has an input, output, and output enable signal associated to it on the USBTLL entity.

Table 20-103 shows the functionality of each pad in each mode. USBTLL outputs are shown in yellow, inputs in blue, and bidirectional pads in green.

Table 20-103. Serial Mode Description, Signal Functionality

| Usual Name | 6-Pin Mode | 6-Pin Mode (Alt) | 3-Pin Mode | 4-Pin Mode | 6-Pin TLL Mode | 6-Pin TLL (Alt) Mode | 3-Pin TLL Mode | 4-Pin TLL Mode | 2-Pin TLL Mode | 2-Pin TLL (Alt) Mode |
|---|------------------|------------------|-----------------|---------------------|-----------------------|-----------------------|-----------------|-----------------------|-----------------|----------------------|
| USBHOST.TLL_CHANNEL_CONF_i[27:24] FLSMODE field | 0x0 | 0x1 | 0x2 | 0x3 | 0x4 | 0x5 | 0x6 | 0x7 | 0xA | 0xB |
| TX encoding | DAT/SE0 | DP/DM | DAT/SE0 | DP/DM | DAT/SE0 | DP/DM | DAT/SE0 | DP/DM | DAT/SE0 | DP/DM |
| RX encoding | DP/DM/RCV | DP/DM/RCV | DAT/SE0 | DP/DM/RCV | DP/DM/RCV | DP/DM/RCV | DAT/SE0 | DP/DM/RCV | DAT/SE0 | DP/DM |
| Pin usage | Unidirect | Unidirect | Bidirect | Bidirect | Unidirect | Unidirect | Bidirect | Bidirect | Bidirect | Bidirect |
| Pin count | 6 | 6 | 3 | 4 | 6 or 5 ⁽¹⁾ | 6 or 5 ⁽¹⁾ | 3 | 4 or 3 ⁽²⁾ | 2 | 2 |
| I/O Pad Function Per Mode | | | | | | | | | | |
| TXEN | TX Enable | TX Enable | TX Enable | TX Enable | TX Enable | TX Enable | TX Enable | TX Enable | N/C | N/C |
| TXDAT | TX Diff Data | TX SE Plus Data | TX/RX Diff Data | TX/RX SE Plus Data | TX Diff Data | TX SE Plus Data | TX/RX Diff Data | TX/RX Diff Data | TX/RX Diff Data | TX/RX SE Plus Data |
| TXSE0 | TX force SE0 | TX SE Minus Data | TX/RX force SE0 | TX/RX SE Minus Data | TX force SE0 | TX SE Minus Data | TX/RX force SE0 | TX/RX force SE0 | TX/RX force SE0 | TX/RX SE Minus Data |
| RXRCV | RX Diff Data | RX Diff Data | N/C | RX Diff Data | RX Diff Data | RX Diff Data | N/C | RX Diff Data | N/C | N/C |
| RXDM | RX SE Plus Data | RX SE Plus Data | N/C | N/C | RX SE Plus Data | RX SE Plus Data | N/C | N/C | N/C | N/C |
| RXDM | RX SE Minus Data | RX SE Minus Data | N/C | N/C | RX SE Minus Data | RX SE Minus Data | N/C | N/C | N/C | N/C |

⁽¹⁾ RXRCV and RXDM carry the same info: RXDM can drive both inputs of the remote controller and RXRCV kept unused

⁽²⁾ Same remark on TXDAT (for outputs) and RXRCV: TXDAT only is enough

20.2.4.2.6 Attach/Connect Emulation for Serial TLL Modes

This section applies to all serial TLL modes:

- In UTMI-to-serial mode (USBHOST.TLL_CHANNEL_CONF_i[2:1] CHANMODE field = 0x1) for all TLL values of USBHOST.TLL_CHANNEL_CONF_i[27:24] FLSMODE field (0x4 to 0x7; 0xA to 0xB)
- In UTMI-to-ULPI TLL mode (USBHOST.TLL_CHANNEL_CONF_i[2:1] CHANMODE field = 0x0) when the ULPI bus is switched to 6-pin serial or 3-pin serial modes

In those modes, the USB bus lines are emulated by USBTLL internal logic, and are never available on the outside. The pullup/pulldown actions described in the USB specification cannot be applied directly, and the USB cable cannot be physically attached.

Because serial modes do not specify a standard format for those sideband settings, a custom software-controlled one was implemented:

- USBHOST.TLL_CHANNEL_CONF_i[4] TLLATTACH bit emulates the physical attachment of the two controllers through a TLL cable.
 - When this bit is cleared, the local controller RX path only shows the local controller (the high-speed USB host controller) actions on the bus: TX driving, pullups, pulldowns (see below). The same thing applies for the remote controller RX path (except that test override is not available).
 - As soon as the bit is set, the actions of both sides are applied to the same bus and are resolved, similar to a real bus. The RX path for both sides shows the same bus state.
- USBHOST.TLL_CHANNEL_CONF_i[5] TLLCONNECT bit emulates the USB electrical connect (that is, the pullup by the USB peripheral of one of the two USB lines [by a 1.5kOhm resistor]), which causes the linestate to transition from SE0 to J, which is detected by the USB host. The register bit is ORed with a USBTLL module input signal — the connect control can be software (L4-Core interconnect write access) or hardware (input level). The speed of the connection is determined by the TLLFULLSPEED bit below.
- USBHOST.TLL_CHANNEL_CONF_i[6] TLLFULLSPEED bit determines the speed (full or low) of the USB connect to be emulated. The connect enable (controlled as defined above) results in the pulling-up of either D+ (1 = full speed) or D- (0 = low speed): see [Table 20-104](#).
- The 15kOhm pulldowns are implicit: because they are supposed to be turned on at least on the host side of the bus, they do not require an additional control.

NOTE: Sideband control and status actions like pullups are included in parallel (that is, nonserial) standards (UTMI, ULPI), and do not require any custom additions.

Table 20-104. Pullup Enable Emulation in Serial TLL Modes

| USBHOST.TLL_CHANNEL_CONF_i Fields | | Input Signal | Resulting TLL Pullup Emulation | |
|-----------------------------------|------------|------------------------|--------------------------------|-----------|
| TLLFULLSPEED | TLLCONNECT | USB State | D+ Pullup | D- Pullup |
| 1 | 0 | Full-speed unconnected | Off | Off |
| 1 | 1 | Full-speed connected | On | Off |
| 0 | 0 | Low-speed unconnected | Off | Off |
| 0 | 1 | Low-speed connected | Off | On |

20.2.4.2.7 Save and Restore

The SAR mechanism can extract the hardware context of the USBTLL module (after all USB activity has been suspended) before switching off (=save), save it to an external always-on memory, and reinject it later after the module has been switched on again and reset (=restore) seamlessly for the USB. Part of that context is composed of the register fields described in the current chapter. The rest of the context is composed of the buried flip-flops and memories (not accessible by software) like FSM states, buffer contents, and miscellaneous random logic bits.

The PRCM.PM_PWSTCTRL_CORE[4] SAVEANDRESTORE bit enables the SAR mechanism for the USBTLL module (see the *Power, Reset, and Clock Management* chapter). When set, the PRCM module initiates the save and/or the restore sequences at the appropriate time. When not set, the USB host is treated as a standard module, and the save/restore sequences do not occur.

Table 20-105 lists the USBTLL registers impacted by the SAR context.

NOTE: Because all addresses give access to the same physical register (that is, to the same piece of context), the ULPI registers with multiple accesses (write, set, clear) are listed only once in the table.

Table 20-105. USBTLL Registers Impacted by the SAR Context

| Register Name | Comments on SAR Policy |
|--------------------------|---------------------------------------|
| USBTLL_SYSCONFIG | Except the SOFTRESET bit (write-only) |
| USBTLL_IRQENABLE | - |
| TLL_SHARED_CONF | Except the FCLK_REQ bit |
| TLL_CHANNEL_CONF_i | Except the FSLSLINESTATE field |
| ULPI_FUNCTION_CTRL_i | - |
| ULPI_INTERFACE_CTRL_i | - |
| ULPI_OTG_CTRL_i | - |
| ULPI_USB_INT_EN_RISE_i | - |
| ULPI_USB_INT_EN_FALL_i | - |
| ULPI_USB_INT_STATUS_i | - |
| ULPI_VENDOR_INT_EN_i | - |
| ULPI_VENDOR_INT_STATUS_i | - |

20.2.5 High-Speed USB Host Subsystem Basic Programming Model

20.2.5.1 Selecting and Configuring USB Connectivity

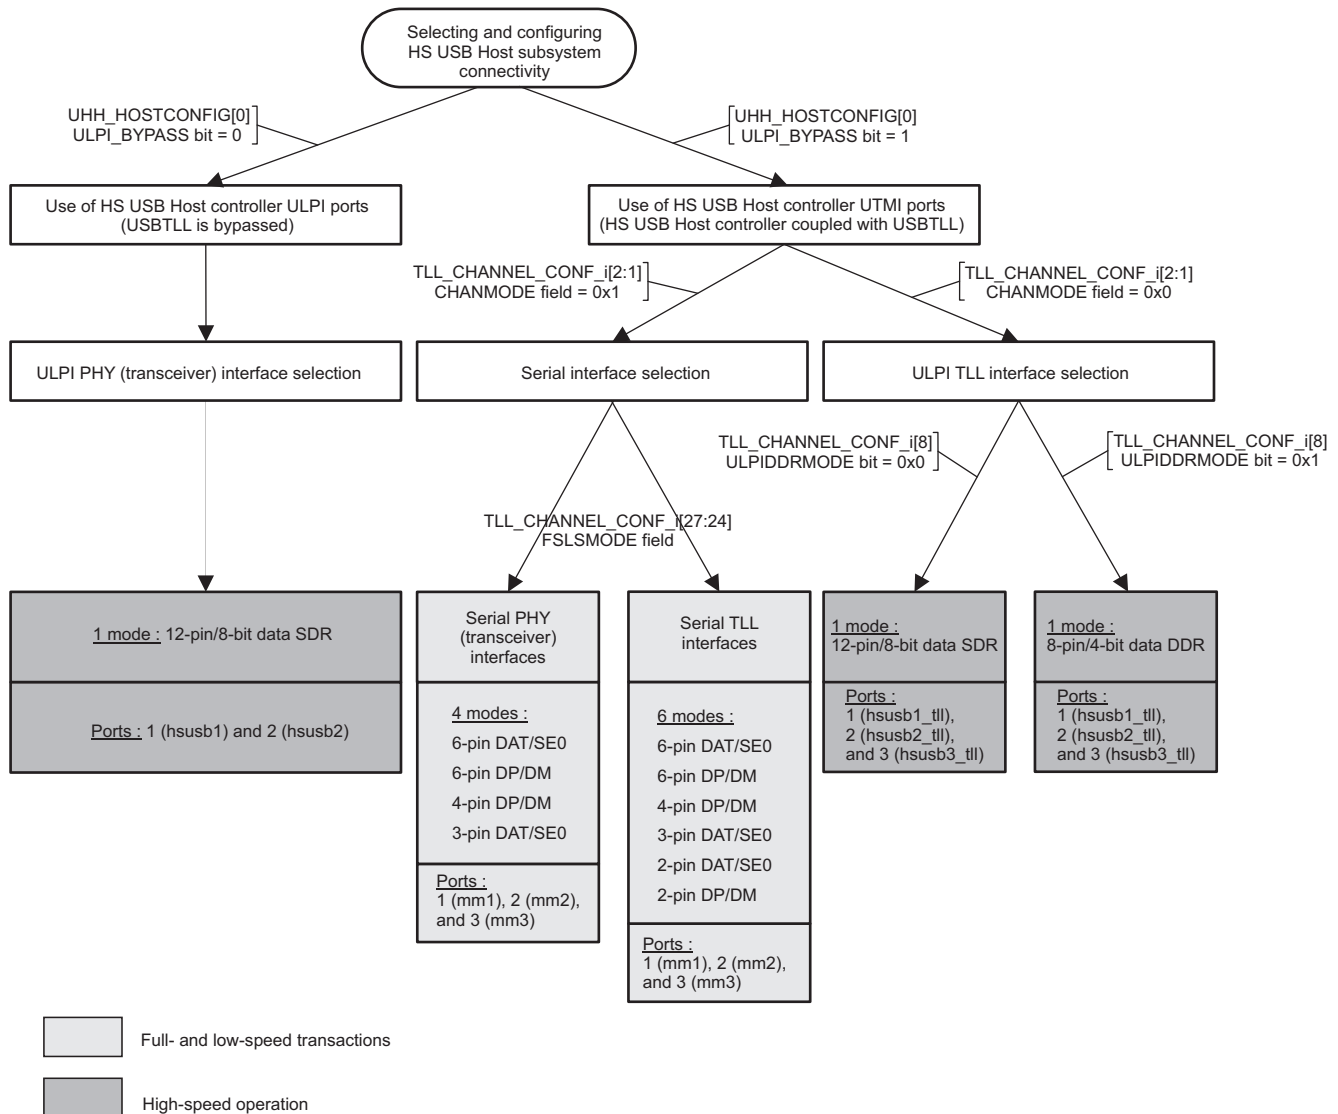

Perform the following steps to select the desired USB connectivity and configure the device accordingly.

The high-speed USB host subsystem provides three kinds of interfaces for connection:

- ULPI PHY interfaces for high-speed data transactions (up to 480 Mbps)
- Serial interfaces for full- and low-speed data transactions (up to 12 Mbps)
- ULPI TLL interfaces for high-speed data transactions (up to 480 Mbps)

Figure 20-98 shows how to select and configure the high-speed USB host subsystem connectivity.

Figure 20-98. Selecting and Configuring High-Speed USB Host Subsystem Connectivity

046 G25-033

NOTE: When the USBHOST.UHH_HOSTCONFIG[0] ULPI_BYPASS bit is 0 (ULPI transceiver interface selection), only the ULPI ports 1 and 2 of the high-speed USB host controller can be used. Only the 12-pin/8-bit data SDR version of the ULPI interface mode is supported.

When the USBHOST.UHH_HOSTCONFIG[0] ULPI_BYPASS bit is 1 (ULPI TLL interface selection and serial interface selection), there is no restriction and the three ports can be configured in any ULPI TLL or serial mode.

20.2.5.1.1 ULPI Interface Selection

The high-speed USB host subsystem supports the following modes with the ULPI interfaces:

- External USB transceiver
 - ULPI interfaces: 12-pin/8-bit data version supporting "input" clocking mode
- TLL
 - ULPI TLL interfaces: 12-pin/8-bit data version or 8-pin/4-bit data version

20.2.5.1.1.1 Transceiver Interfaces

The USBTLL module is bypassed and the high-speed USB host controller ports 1 and 2 are connected directly to external transceivers.

The high-speed USB host subsystem supports only the 12-pin/8-bit data SDR version of the ULPI interface mode. The high-speed USB host controller uses its ULPI ports (UTMI ports cannot be used), the USBHOST.UHH_HOSTCONFIG[0] ULPI_BYPASS bit must be cleared to 0. In ULPI mode, all ports are in ULPI mode.

20.2.5.1.1.2 TLL

The high-speed USB host controller is coupled with the USBTLL module to compose the ULPI TLL interface modes.

The high-speed USB host controller uses its UTMI ports (bypassing the ULPI ports), the USBHOST.UHH_HOSTCONFIG[0] ULPI_BYPASS bit must be set to 1. In UTMI mode, all ports of the high-speed USB host controller are in UTMI mode.

At the USBTLL module level, a channel configuration for ULPI TLL interfaces must be set (see [Section 20.2.4.2.3](#)), *Channel Configurations*.

Two configurations are supported for ULPI TLL interfaces in the device:

- Configuration 2: ULPI synchronous TLL mode
- Configuration 4: Serial UTMI to serial ULPI TLL mode

In both configurations, the USBHOST.TLL_CHANNEL_CONF_i[2:1] CHANMODE field must be cleared to 0x0 (UTMI-to-ULPI TLL mode).

The selection of the ULPI TLL interface version, 12-pin/8-bit data version (SDR mode) or 8-pin/4-bit data version (DDR mode) is done through the USBHOST.TLL_CHANNEL_CONF_i[8] ULPIDDRMODE bit (0: SDR mode; 1: DDR mode).

20.2.5.1.2 Serial Interface Selection

The high-speed USB host subsystem supports the following modes with the serial interfaces:

- External USB transceiver configurations
 - Serial 6-pin PHY (transceiver) interfaces: 6-pin unidirectional (TX: DAT/SE0 or TX: DP/DM), 4-pin bidirectional and 3-pin bidirectional modes
- TLL configurations
 - Serial 6-pin TLL interfaces: 6-pin unidirectional (TX: DAT/SE0 or TX: DP/DM), 4-pin bidirectional, 3-pin bidirectional, and 2-pin bidirectional modes

The high-speed USB host controller is coupled with the USBTLL module to compose the serial interface modes.

The high-speed USB host controller uses its UTMI ports (bypassing the ULPI ports), and the USBHOST.UHH_HOSTCONFIG[0] ULPI_BYPASS bit must be set to 1. In UTMI mode, all ports of the high-speed USB host controller are in UTMI mode.

At the USBTLL module level, a channel configuration for serial interfaces must be set (see [Section 20.2.4.2.3](#), *Channel Configurations*).

One configuration is supported for serial interfaces in the device, the Configuration 6 including two modes:

- Serial UTMI to serial TLL
- Serial UTMI to serial PHY

The multimode-mode serial interface mode selection is done through the USBHOST.TLL_CHANNEL_CONF_i[27:24] FLSMODE field only when the main channel mode is serial (USBHOST.TLL_CHANNEL_CONF_i[2:1] CHANMODE field = 0x1 = UTMI-to-serial mode).

Table 20-106. USB Connectivity Mode Description

| Usual Name | 6-Pin Mode | 6-Pin Mode (Alt) | 3-Pin Mode | 4-Pin Mode | 6-Pin TLL Mode | 6-Pin TLL Mode (Alt) | 3-Pin TLL Mode | 4-Pin TLL Mode | 2-Pin TLL Mode | 2-Pin TLL (Alt) Mode |
|---|------------|------------------|------------|------------|-----------------------|-----------------------|----------------|-----------------------|----------------|----------------------|
| USBHOST.TLL_CHANNEL_CONF_i[27:24] FLSMODE field | 0x0 | 0x1 | 0x2 | 0x3 | 0x4 | 0x5 | 0x6 | 0x7 | 0xA | 0xB |
| TX encoding | DAT/SE0 | DP/DM | DAT/SE0 | DP/DM | DAT/SE0 | DP/DM | DAT/SE0 | DP/DM | DAT/SE0 | DP/DM |
| RX encoding | DP/DM/RCV | DP/DM/RCV | DAT/SE0 | DP/DM/RCV | DP/DM/RCV | DP/DM/RCV | DAT/SE0 | DP/DM/RCV | DAT/SE0 | DP/DM |
| Pin usage | Unidirect | Unidirect | Bidirect | Bidirect | Unidirect | Unidirect | Bidirect | Bidirect | Bidirect | Bidirect |
| Pin count | 6 | 6 | 3 | 4 | 6 or 5 ⁽¹⁾ | 6 or 5 ⁽¹⁾ | 3 | 4 or 3 ⁽²⁾ | 2 | 2 |

⁽¹⁾ RxRCV and RxDP carry the same info: RxDP can drive both inputs of the remote controller and RxRCV kept unused

⁽²⁾ Same remark on TXDAT (for outputs) and RxRCV: TXDAT only is enough

20.2.5.2 USBTLL Registers

The USBTLL module contains two types of software-programmable registers.

20.2.5.2.1 TLL Control and Status Registers

Those 32-bit registers configure the various channels. Those registers are accessed by the MPU through the L4-Core interconnect. They are used mostly before the actual USB activity starts. Those registers are:

- OCP-standard registers for revision number, IRQ, clocking management, etc.
- TLL-specific registers

20.2.5.2.2 ULPI PHY-Side Registers

Each TLL channel emulates a ULPI transceiver and accordingly contains this set of 8-bit PHY-side registers, per ULPI specification. Those registers are:

- All ULPI-mandatory standard registers and fields
- A selection of ULPI-optional standard registers and fields, when relevant to the TLL context
- Vendor-specific registers, mapped at the addresses specified for that purpose in ULPI specification

Those registers are accessed by the external (that is, off-chip) link controller over the ULPI port of each channel, in the 0x100-byte ULPI address space, using the ULPI register access protocol.

Those registers are accessible by the L4-Core interconnect: The ULPI register sets of all channels are mapped side by side in the upper part of the L4-Core interconnect address space, where they can be accessed through byte accesses. In case of conflict between the two access modes, the access over ULPI will have priority, but both accesses will eventually complete correctly. For normal USB activity, all register accesses are expected to go over ULPI, and register changes caused by L4-Core interconnect accesses could compromise proper USB operation. The L4-Core interconnect access port is intended for:

- Miscellaneous test and debug
- Nonintrusive observation of ongoing USB operations (test)
- Context restore: During USB suspend periods, the USBTLL module can be switched off to save power. Upon resume, the ULPI register contents have been lost and can be restored over L4-Core interconnect before USB operations restarts, provided they have been saved elsewhere beforehand.

CAUTION

The INSNREG04[5] bit must be set to 1 for proper behavior.

20.2.6 High-Speed USB Host Subsystem Registers

20.2.6.1 USBTLL ULPI PHY-Side Register Space

Each ULPI port emulates a separate ULPI transceiver and as such gives access to a single set of ULPI PHY-side registers, mapped in a separate ULPI register space as specified in the ULPI specification. The ULPI protocol defines two register access methods: immediate and extended.

- The immediate space maps ULPI PHY-side registers in a 0x40- (64-) byte space (address is 6 bits wide). All ULPI PHY-side registers implemented in the USBTLL implementation are in the immediate space.
- The extended register space maps all ULPI PHY-side registers in a 0x100- (256-) byte space (address is 8 bits wide). The immediate space is remapped at the bottom of the extended space (that is, the extended access method can be used to access any ULPI register).

An access is recognized as extended by first pointing to a reserved dummy address 0x2F (EXTENDED_SET_ACCESS in [Table 20-107](#)). Immediate-mode accesses to this address over the ULPI interface are forbidden by the protocol and the USBTLL behavior is then undefined. Extended accesses to this address have no effect.

Some physical registers are accessible at more than one address, where write accesses perform different actions on the register value: (over-)write, set, clear. A read to any of the addresses returns the register value. The names of the set and clear registers are the write name postfixed with respectively `_SET` and `_CLR`. The register fields are described only once, at the write address (see [Section 20.2.6.7, EHCI Register Descriptions](#)).

NOTE: Some ULPI registers are cleared upon read.

Table 20-107. ULPI Register Mapping Summary (For a Single ULPI Port)

| Register Name | Type | Read Action | Write Action | Address Offset |
|---------------------|------|-------------|--------------|----------------|
| VENDOR_ID_LO | R | - | - | 0x0000 0000 |

20.2.6.2 L4-Core Interconnect Register Space

[Table 20-108](#) lists the base address and address space for the high-speed USB host subsystem.

Table 20-108. Instance Summary

| Module Name | Base Address (hex) | Size |
|-------------|--------------------|------------|
| USBTLL | 0x4806 2000 | 4096 bytes |
| UHH_CONFIG | 0x4806 4000 | 1024 bytes |
| OHCI | 0x4806 4400 | 1024 bytes |
| EHCI | 0x4806 4800 | 1024 bytes |

20.2.6.3 High-Speed USB Host Subsystem Register Mapping Summary

The USBTLL single L4-Core interconnect gives access to both the TLL control and status registers, and the ULPI PHY-side registers.

[Table 20-109](#) lists all the USBTLL registers mapped by the L4-Core interconnect, for the maximum 8-channel configuration.

[Table 20-110](#), [Table 20-111](#), and [Table 20-112](#) list the high-speed USB host controller registers.

CAUTION

On ULPI PHY-side register access over L4-Core interconnect:

ULPI registers are byte-sized, and can only be accessed in this size. Attempts to access them over L4-Core interconnect using any other data size (16- or 32-bit) will complete without error (or any other warning), but will result in undefined behaviors.

The following cases can cause problems:

- If the ULPI register contents are defined as static (nonvolatile) by the software, a cache update may result in a burst of 32-bit access, with unwanted consequences.
- Some registers have adjacent overwrite, set, and clear addresses. An oversized write access could clear and set the same bit, which can have several results.
- Some registers are cleared on read: oversized read accesses to adjacent memory locations could cause unwanted clears.

Table 20-109. USBTLL Register Mapping Summary (L4-Core Interconnect Register Space)

| Register Name | Type | Register Width (Bits) | Address Offset | Physical Address | Section |

| Bits | Field Name | Description | Type | Reset |
|------|-----------------|--|------|------------|
| 31:3 | RESERVED | | R | 0x00000000 |
| 2 | ACCESS_ERROR_EN | Enable IRQ generation upon access error to ULPI register over OCP 0x0: IRQ event is masked 0x1: IRQ event is enabled | RW | 0x0 |
| 1 | FCLK_END_EN | 0x0: IRQ event is masked 0x1: IRQ event is enabled | RW | 0x0 |
| 0 | FCLK_START_EN | 0x0: IRQ event is masked 0x1: IRQ event is enabled | RW | 0x0 |

20.2.6.4.6 TLL_SHARED_CONF

Table 20-118. TLL_SHARED_CONF

| | | | |
|-------------------------|--|-----------------|--------|
| Address Offset | 0x0000 0030 | | |
| Physical Address | 0x4806 2030 | Instance | USBTLL |
| Description | Common control register for all TLL channels | | |
| Type | RW | | |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----------------|----|-----------------|----|--------------|----|----------|---|------------|---|---|---|---|---|---|---|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| RESERVED | | | | | | | | | | | | | | | | USB_90D_DDR_EN | | USB_180D_SDR_EN | | USB_DIVRATIO | | FCLK_REQ | | FCLK_IS_ON | | | | | | | |

| Bits | Field Name | Description | Type | Reset |
|------|-----------------|--|------|------------|
| 31:7 | RESERVED | | R | 0x00000000 |
| 6 | USB_90D_DDR_EN | Software enable/disable of the 90-degree phase shift scheme on output DDR data, when implemented. Read-only, always-0 when HDL generic ULPI_90DEG4DDR = 0. 0x0: ULPI DDR output DATA aligned with CLK 0x1: ULPI DDR output DATA delayed by 90 degree wrt CLK | RW | 0x1 |
| 5 | USB_180D_SDR_EN | Software enable/disable of the 180-degree phase shift scheme on output SDR data, when implemented. Read-only, always-0 when HDL generic ULPI_180DEG4SDR = 0 0x0: ULPI SDR output DATA aligned with CLK 0x1: ULPI SDR output DATA delayed by 180 degree wrt CLK | RW | 0x1 |
| 4:2 | USB_DIVRATIO | (Log2 of) division ratio from functional clock to USB (UTMI/ULPI) clock 0x0: div ratio is 2**0 = 1 : bypass 0x1: div ratio is 2**1 = 2 0x2: div ratio is 2**2 = 4 0x3: div ratio is 2**3 = 8 0x4: div ratio is 2**4 = 16 0x5: div ratio is 2**5 = 32 0x6: div ratio is 2**6 = 64 0x7: div ratio is 2**7 = 128 | RW | 0x0 |
| 1 | FCLK_REQ | Functional clock request, ORed from all channels depending on their respective USB bus state. Combined with the Fclk_is_on status to generate fclk_start/end IRQs. 0x0: Func clock input is not requested by TLL 0x1: Func clock input is requested by TLL | R | 0x0 |
| 0 | FCLK_IS_ON | Status of the functional clock input, provided by the system to the TLL module. The TLL module will only use that clock if the current status indicated that it is ready. Combined with the Fclk_request to generate fclk_start/end IRQs. 0x0: Functional clock input is not guaranteed ON (can actually be ON, OFF, or unstable) 0x1: Functional clock input is guaranteed ON and stable | RW | 0x0 |

20.2.6.4.7 TLL_CHANNEL_CONF_i
Table 20-119. TLL_CHANNEL_CONF_i

| | | | |
|-------------------------|--|-----------------|------------|
| Address Offset | 0x0000 0040 + (0x04 x I) | Index | I = 0 to 2 |
| Physical Address | 0x4806 2040 + (0x04 x I) | Instance | USBTLL |
| Description | Control and Status register for channel I. | | |
| Type | RW | | |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |

| Bits | Field Name | Description | Type | Reset |
|-------|---------------|--|------|-------|
| 31:30 | RESERVED | | R | 0x0 |
| 29:28 | FSLSLINESTATE | Line state for Full/Low speed serial modes Bit1 = D- / Bit0 = D+ 0x0: Single-ended 0 0x1: Full-Speed J = differential 1 0x2: Full-Speed K = differential 0 0x3: Single-ended 1 (illegal in USB) | R | 0x0 |
| 27:24 | FSLSMODE | Multiple-mode serial interface's mode select. Only when main channel mode is serial. No effect in other main modes. 0x0: "6pin" unidirectional PHY I/f mode. TX encoding is Dat/Se0 (default) 0x1: "6-pin" unidirectional PHY I/f mode. TX encoding is Dp/Dm 0x2: "3-pin" bidirectional PHY I/f mode. 0x3: "4-pin" bidirectional PHY I/f mode. 0x4: "6pin" unidirectional TLL mode. TX encoding is Dat/Se0 0x5: "6pin" unidirectional TLL mode. TX encoding is Dp/Dm 0x6: "3-pin" bidirectional TLL mode. 0x7: "4-pin" bidirectional TLL mode. 0xA: "2-pin" bidirectional TLL mode. Encoding is Dat/Se0 0xB: "2-pin" bidirectional TLL mode. Encoding is Dp/Dm | RW | 0x0 |
| 23:21 | RESERVED | | R | 0x0 |
| 20 | TESTTXSE0 | Force-Se0 transmit override value for serial mode test Don't care if TestEn = 0 (functional mode) or = TestTxen = 1 (tx = hiz) 0x0: drive differential value on TX according to TestTXDat 0x1: drive SE0 on TX | RW | 0x0 |
| 19 | TESTTXDAT | Differential data transmit override value for serial mode test Don't care if TestEn = 0 (functional mode) or = TestTxen = 1 (tx = hiz) or TestSe0 = 1 (tx = se0) 0x0: Drive full-speed K = differential 0 0x1: Drive full-speed J = differential 1 | RW | 0x0 |
| 18 | TESTTXEN | Differential data transmit override value for serial mode test Don't care if TestEn = 0 (functional mode) 0x0: Drive TX according to TestTXDat/Se0 0x1: Drive TX Hiz (no drive: pullups determine line state) | RW | 0x0 |

| Bits | Field Name | Description | Type | Reset |
|-------|----------------|--|------|-------|
| 17 | TESTEN | Enable manual test override for serial mode TX path (from local controller's UTMI port) 0x0: No override. TX is from local link controller 0x1: Override enabled | RW | 0x0 |
| 16 | DRVVBUS | VBUS-drive for ChanMode = serial * In TLL config, write 1 to emulate serial-side VBUS drive * In PHY config, write 1 to report "VBUS valid" status (of actual VBUS) to UTMI controller 0x0: VBUS not driven 0x1: VBUS driven to 5V | RW | 0x0 |
| 15 | CHRGVBUS | VBUS-drive for ChanMode = serial * In TLL config, write 1 to emulate serial-side VBUS charge / pullup (OTG) * In PHY config, write 1 to reports "session valid" status (of actual VBUS) to UTMI controller 0x0: VBUS not charged, session not valid 0x1: VBUS charged, session valid | RW | 0x0 |
| 14:12 | RESERVED | | R | 0x0 |
| 11 | ULPINOBITSTUFF | Disable bitstuff emulation in ULPI TLL for ULPI ChanMode 0x0: Bitstuff enabled, following USB standard 0x1: No bitstuff or associated delays (non-standard) | RW | 0x0 |
| 10 | ULPIAUTOIDLE | For ChanMode = ULPI TLL only. Allow the ULPI output clock to be stopped when ULPI goes into asynchronous mode (low-power, 3-pin serial, 6-pin serial). No effect in ULPI input clock mode. 0x0: ULPI output clock always-on 0x1: ULPI output clock stops during asynchronous ULPI modes | RW | 0x1 |
| 9 | UTMIAUTOIDLE | For ChanMode = ULPI TLL only. Allow the UTMI clock (output) to be stopped when UTMI goes to suspended mode (suspendm = 0) 0x0: UTMI clock output always on 0x1: UTMI clock output gated upon suspend | RW | 0x1 |
| 8 | ULPIDDRMODE | Select single/double data rate (SDR/DDR) mode for ULPI TLL Reset value depends on hardware generics ULPI_SDR/DDR_MODE. 0x0: SDR mode (8 data bit / 12 pin) 0x1: DDR mode (4 data bit / 8 pin) | RW | 0x0 |
| 7 | ULPIOUTCLKMODE | ULPI clocking mode select for ULPI TLL ChanMode 0x0: ULPI clock provided by LINK (that is, off-chip). ULPI clock is input 0x1: ULPI clock provided by PHY side (that is, TLL, from functional clock). ULPI clock is output | RW | 0x1 |
| 6 | TLLFULLSPEED | Sets PHY speed emulation in TLL (full/slow), which determines the line to pull up upon connect. The two connect source controls are: input m(N)_tlpuen, register field TIConnect. 0x0: Connect is Low-speed: D- pullup 0x1: Connect is Full-Speed: D+ pullup | RW | 0x1 |
| 5 | TLLCONNECT | Emulation of Full/Low-Speed connect (that is, D+ resp D- pullup) for serial TLL modes. Speed is determined by field TllSpeed. 0x0: Unconnected 0x1: Connected | RW | 0x0 |
| 4 | TLLATTACH | Emulates cable attach/detach for all serial TLL modes: * ChanMode = serial, in TLL mode (FsLsMode) * ChanMode = ULPI, in serial mode (6pin/3pin TLL) 0x0: cable detach emulated on serial TLL 0x1: cable attach emulated on serial TLL | RW | 0x1 |

| Bits | Field Name | Description | Type | Reset |
|-------------|-------------------|--|-------------|--------------|
| 3 | UTMIISADEV | Select the cable end "seen" by UTMI side of TLL, that is, the emulated USB cable's orientation. Note that host must always be on A side, Peripheral on B side. Reset value depends on generic DEFUTMIISHOST. 0x0: UTMI side is peripheral, ULPI side is host 0x1: UTMI side is host, ULPI side is peripheral | RW | 0x1 |
| 2:1 | CHANMODE | Main channel mode selection 0x0: UTMI-to-ULPI TLL mode (HS capable): to ULPI controller 0x1: UTMI-to-serial (FS/LS) mode: to serial controller (TLL) or serial PHY 0x2: Transparent UTMI mode: to UTMI PHY 0x3: No mode selected | RW | 0x0 |
| 0 | CHANEN | Active-high channel enable. A disabled channel is unlocked and kept under reset. 0x0: Channel #N disabled 0x1: Channel #N enabled | RW | 0x0 |

20.2.6.4.8 ULPI_VENDOR_ID_LO_i

| 31:20 | RESERVED | Reserved | R | 0x000 |
| 19:17 | RESERVED | Reserved | R | 0x0 |
| 16 | P_INDICATOR | Port indicator support indication This bit indicates whether the ports support port indicator control. 0x1: The port status and control registers include a read/write field for controlling the state of the port indicator. | R | 0 |
| 15:12 | N_CC | Number of Companion Controllers This field indicates the number of companion controllers associated with this USB 2.0 host controller. 0x0: There are no companion host controllers. Port-ownership hand-off is not supported. Only high-speed devices are supported on the host controller root ports. Others: there are companion USB 1.1 host controller(s). Port-ownership hand-off is supported. High-, full-, and low-speed devices are supported on the host controller root ports. | R | 0x1 |
| 11:8 | N_PCC | Number of Ports per Companion Controller This field indicates the number of ports supported per companion host controller. It is used to indicate the port routing configuration to system software. For example, if N_PORTS has a value of 6 and N_CC has a value of 2, then N_PCC can have a value of 3. The convention is that the first N_PCC ports are assumed to be routed to companion controller 1, the next N_PCC ports to companion controller 2, etc. The number in this field must be consistent with N_PORTS and N_CC. | R | 0x3 |
| 7 | PRR | Port Routing Rules The first N_PCC ports are routed to the lowest-numbered function companion host controller, the next N_PCC ports are routed to the next lowest-function companion controller, and so on. | R | 0 |
| 6:5 | RESERVED | Reserved | R | 0x0 |
| 4 | PPC | Port Power control This field indicates whether the host controller implementation includes port power control. 0x0: The ports do not have port power switches. 0x1: The ports have port power switches. | R | 1 |
| 3:0 | N_PORTS | Number of downstream ports This field specifies the number of physical downstream ports implemented on this host controller. | R | 0x3 |

| Bits | Field Name | Description | Type | Reset |
|-------|------------|---|------|--------|
| 31:16 | RESERVED | Reserved | R | 0x0000 |
| 15 | ASS | Asynchronous Schedule Status The bit reports the current real status of the asynchronous schedule. 0x0: The status of the asynchronous schedule is disabled. 0x1: The status of the asynchronous schedule is enabled. | R | 0 |
| 14 | PSS | Periodic Schedule Status The bit reports the current real status of the periodic schedule. 0x0: The status of the periodic schedule is disabled. 0x1: The status of the periodic schedule is enabled. | R | 0 |
| 13 | REC | Reclamation It is used to detect an empty asynchronous schedule. | R | 0 |
| 12 | HCH | Host Controller Halted This bit is a 0 whenever the USBHOST.USBCMD[0] RS bit is a 1. The host controller sets this bit to 1 after it has stopped executing as a result of the RS bit being set to 0, either by software or by the host controller hardware. | R | 1 |
| 11:6 | RESERVED | Reserved | R | 0x00 |
| 5 | IAA | Interrupt on Async Advance System software can force the host controller to issue an interrupt the next time the host controller advances the asynchronous schedule by writing a 1 in the USBHOST.USBCMD[6] IAA bit. This status bit indicates the assertion of that interrupt source. | RW | 0 |
| 4 | HSE | Host System Error The host controller sets this bit to 1 when a serious error occurs during a host system access involving the host controller module. | RW | 0 |
| 3 | FLR | Frame List Rollover The host controller sets this bit to 1 when the USBHOST.FRINDEX rolls over from its maximum value to 0. The exact value at which the rollover occurs depends on the frame list size. | RW | 0 |
| 2 | PCD | Port Change Detect The host controller sets this bit to 1 when any port for which the USBHOST.PORTSC_ <i>i</i> [13] PO bit is set to 0 has a change bit transition from a 0 to a 1 or a USBHOST.PORTSC_ <i>i</i> [6] FPR bit transition from a 0 to a 1. This bit is also set as a result of the USBHOST.PORTSC_ <i>i</i> [1] CSC bit being set to 1 after system software has relinquished ownership of a connected port by writing a 1 to a USBHOST.PORTSC_ <i>i</i> [13] PO bit. | RW | 0 |
| 1 | USBEI | USB Error Interrupt The host controller sets this bit to 1 when completion of a USB transaction results in an error condition. | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|-------------|-------------------|--|-------------|--------------|
| 0 | USBI | <p>USB Interrupt</p> <p>The host controller sets this bit to 1 on completion of a USB transaction, which results in the retirement of a transfer descriptor that had its IOC bit set.</p> <p>The host controller also sets this bit to 1 when a short packet is detected (actual number of bytes received was less than the expected number of bytes).</p> | RW | 0 |

General-Purpose Interface

This chapter describes the general-purpose interface.

NOTE: Some features may not be available or supported in your particular device. For more information, see Chapter 1, the Device Family section, and your device-specific data manual.

| Topic | Page |

| 21.6 General-Purpose Interface Register Manual | 2466 |

21.1 General-Purpose Interface Overview

The general-purpose interface combines six general-purpose input/output (GPIO) banks.

Each GPIO module provides 32 dedicated general-purpose pins with input and output capabilities; thus, the general-purpose interface supports up to 192 (6 x 32) pins.

These pins can be configured for the following applications:

- Data input (capture)/output (drive)
- Keyboard interface with a debounce cell
- Interrupt generation in active mode upon the detection of external events. Detected events are processed by two parallel independent interrupt-generation submodules to support biprocessor operations.
- Wake-up request generation in idle mode upon the detection of external events

These modules do not include pad control (pull up/down control, open-drain feature). For more information, see [Chapter 6, System Control Module](#).

21.1.1 Global Features

The GPIO modules include the following global features:

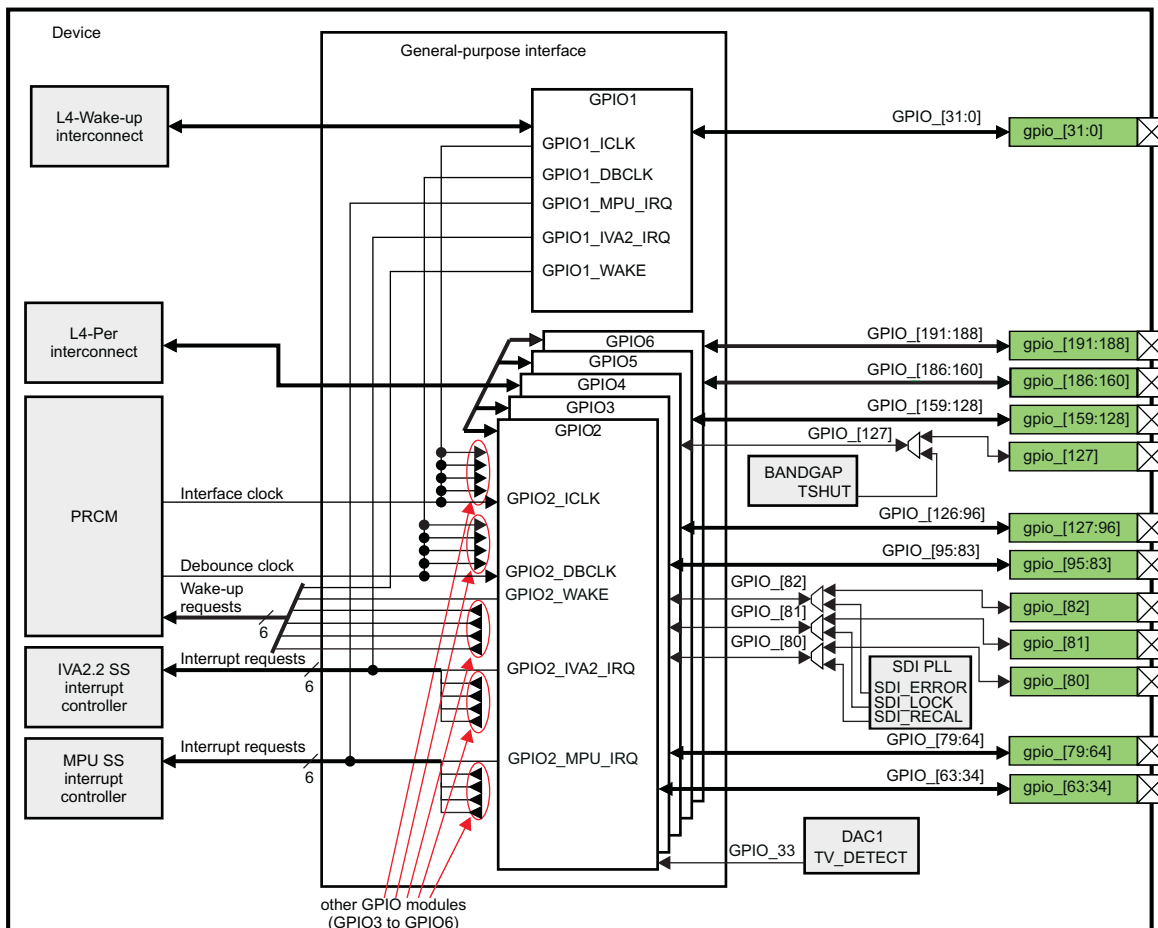

- Synchronous interrupt requests in active mode from each channel are processed by two identical interrupt generation submodules used independently by the imaging video and audio accelerator (IVA2.2) and the microprocessor unit (MPU) subsystems. One of these interrupts is mapped on the IVA2.2 subsystem interrupt controller and the other on the MPU subsystem interrupt controller.
- Asynchronous wake-up requests in idle mode from input channels are merged together to issue one wake-up signal per GPIO module.
- Data input (capture)/output (drive)
- Power management support

The general-purpose interface has 12 interrupt lines (two interrupt lines per GPIO module instance).

Each GPIO module produces a wake-up request signal to the power, reset, and clock management (PRCM) module.

[Figure 21-1](#) shows an overview of the general-purpose interface.

Figure 21-1. General-Purpose Interface Overview

108-001

Each channel in the GPIO modules has the following features:

- The GPIOi.GPIO_OE register controls the output capability for each pin.
- The output line level reflects the value written in the GPIOi.GPIO_DATAOUT register through the L4 interconnect.
- The input line can be fed to the GPIO module through an optional and configurable debounce cell. (The debouncing time value is global for all ports of one GPIO module, so up to five different debouncing time values are possible.)
- The input line value is sampled into the GPIOi.GPIO_DATAIN register and can be read through the L4 interconnect.
- In active mode, the input line can be used through level and edge detectors to trigger synchronous interrupts. The edge (rising, falling, or both) or the level (logical 0, logical 1, or both) used can be configured.
- In idle mode, the input line can be used to activate the asynchronous wake-up request (on edge detection: rising edge, falling edge, or both).

The module provides an alternative to the atomic test and set operations for the following registers:

- GPIOi.GPIO_DATAOUT
- GPIOi.GPIO_IRQENABLE1
- GPIOi.GPIO_IRQENABLE2
- GPIOi.GPIO_WAKEUPENABLE

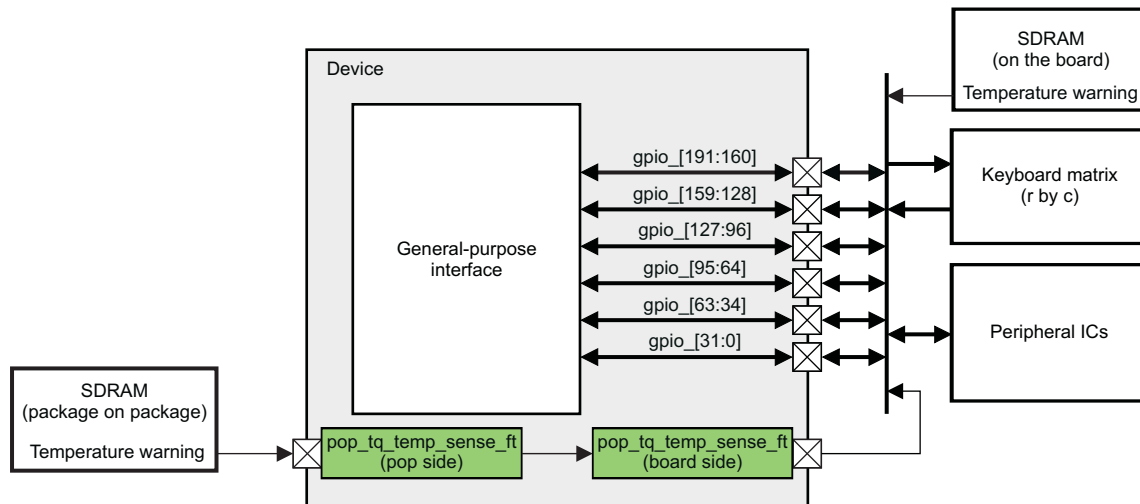

For these registers, the modules implement the set-and-clear protocol register update (see Section 21.5.2, *Set-and-Clear Instructions*).

21.2 General-Purpose Interface Environment

The general-purpose interface combines six GPIO modules for a flexible, user-programmable, general-purpose input/output (I/O) controller. The general-purpose interface implements functions that are not implemented with the dedicated controllers in the device and require simple input and/or output software-controlled signals. The general-purpose interface allows a variety of custom connections and expands the I/O capabilities of the system to the real world.

Figure 21-2 shows a typical application using the general-purpose interface.

Figure 21-2. General-Purpose Interface Typical Application System Overview

NOTE: Temperature Sensing

Most memories provide a temperature sensor to control the auto-refresh duty cycle. The device monitors the temperature of the external memory using the pop_tq_temp_sense_ft ball and a GPIO input. To do this, pop_tq_temp_sense_ft is connected to a GPIO through the customer board. This feature is application-dependent.

CAUTION

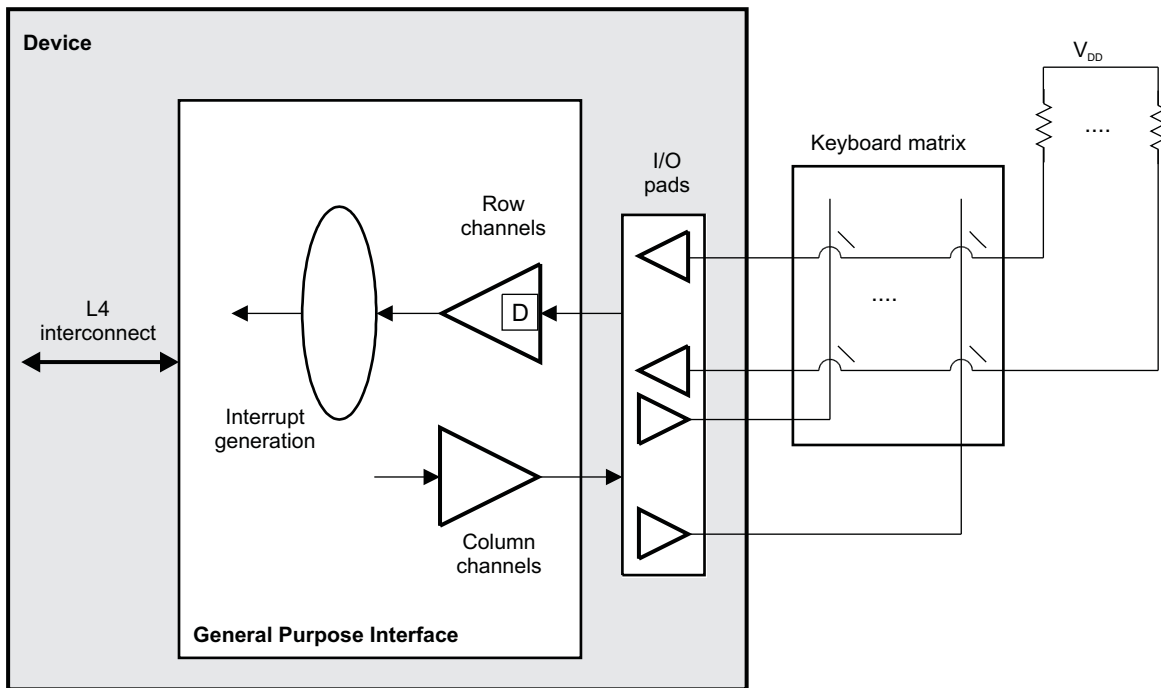

Due to buffer strength, an external serial resistor must be connected to the balls where gpio_120 through gpio_129 are muxed with MMC signals.

The general-purpose interface can physically connect the device to a keyboard matrix and peripheral integrated circuits (ICs).

21.2.1 GPIO as a Keyboard Interface

The general-purpose interface can be used as a keyboard interface. You can dedicate channels based on the keyboard matrix (r * c). Figure 21-3 shows row channels configured as inputs with the input debounce feature enabled. The row channels are driven high with an external pullup. Column channels are configured as outputs and drive a low level.

Figure 21-3. General-Purpose Interface Used as a Keyboard Interface

108-003

When a keyboard matrix key is pressed, the corresponding row and column lines are shorted together and a low level is driven on the corresponding row channel. This generates an interrupt based on the proper configuration (see [Section 21.5.3, Interrupt and Wakeup](#)).

When the keyboard interrupt is received, the processor (MPU and/or IVA2.2 subsystem) can disable the keyboard interrupt and scan the column channels for the key coordinates.

- The scanning sequence has as many states as column channels: For each step in the sequence, the processor drives one column channel low and the others high.
- The processor reads the values of the row channels and thus detects which keys in the column are pressed.

At the end of the scanning sequence, the processor establishes which keys are pressed. The keyboard interface can then be reconfigured in the interrupt waiting state.

21.2.2 General-Purpose Interface Functional Interfaces

21.2.2.1 Basic General-Purpose Interface Pins

Table 21-1 lists the interface pins of the general-purpose interface.

Table 21-1. General-Purpose Interface Functional Pins Description

| Signal Name | I/O ⁽¹⁾ | Description ⁽²⁾ | Module Reset Value |
|----------------|--------------------|-------------------------------|------------------------------------|
| gpio_[31:0] | I/O | GPIO in configuration mode 4. | Input until software configuration |
| gpio_[186:34] | I/O | GPIO in configuration mode 4. | Input until software configuration |
| gpio_[191:188] | I/O | GPIO in configuration mode 4. | Input until software configuration |

⁽¹⁾ I = Input, O = Output

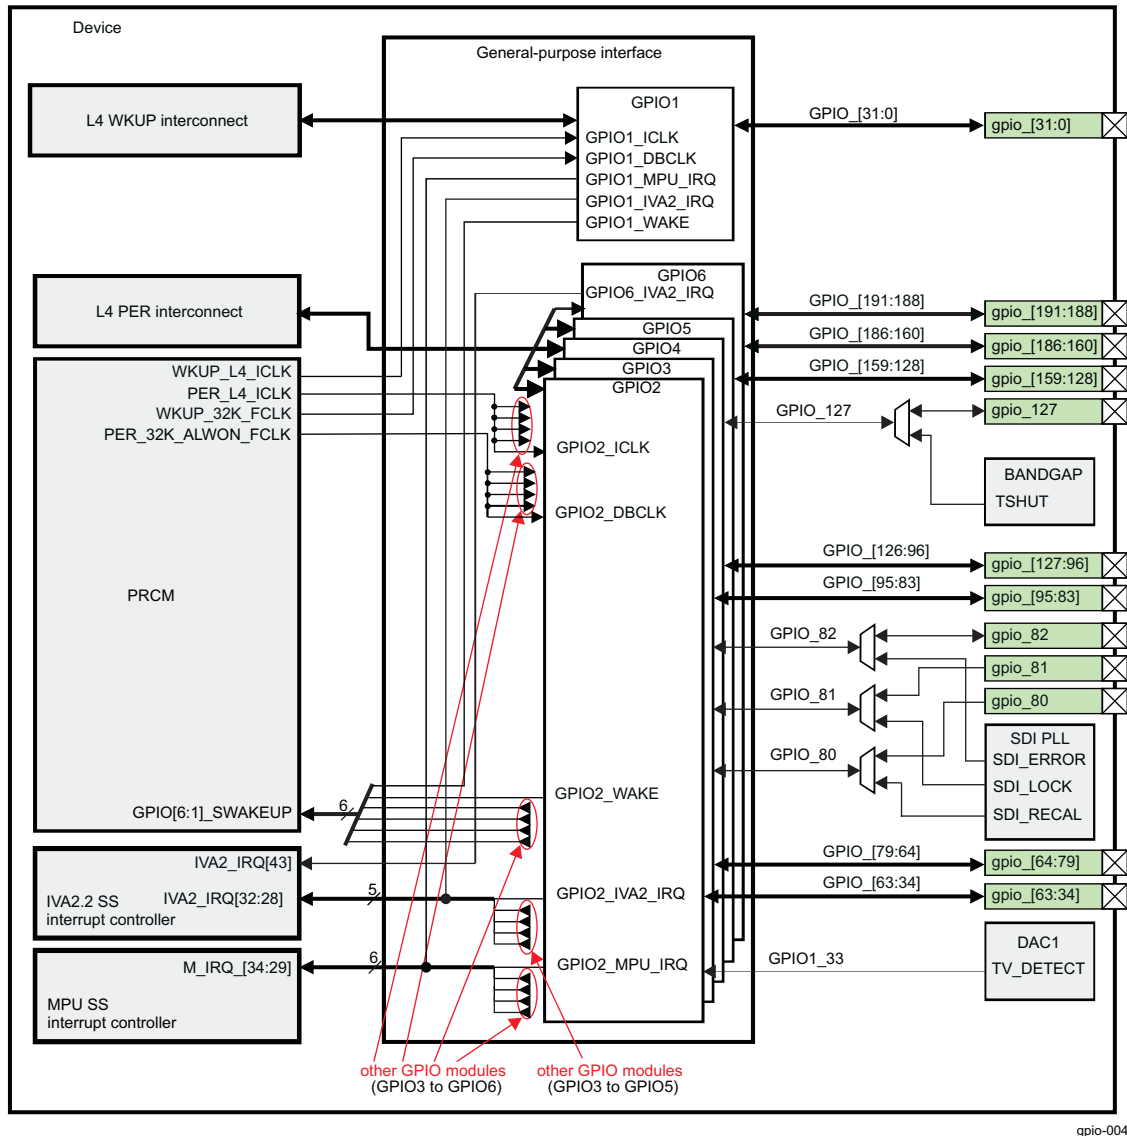

⁽²⁾ See [Chapter 6, System Control Module](#), for more information about pin configuration modes.

21.3 General-Purpose Interface Integration

21.3.1 Description

Figure 21-4 highlights the general-purpose interface integration in the device.

Figure 21-4. General-Purpose Interface Integration Overview

gpio-004

21.3.1.1 Clocking, Reset, and Power-Management Scheme

21.3.1.1.1 Clocking

Each GPIO module uses two clocks:

- Debounce clock: The 32-KHz debounce clock, GPIOi_DBCLK, (where i = 1, 2, 3, 4, 5, and 6, with one debounce clock per module), comes from the PRCM module and is used for the debounce cell logic (without the corresponding configuration registers). This cell can sample the input line and filters the input level using a programmed delay.

For GPIO2 to GPIO6, this clock is controlled by the EN_GPIOi (where i = 2 to 6) bit PRCM.CM_FCLKEN_PER (0: disabled, 1: enabled the clock). For GPIO1, this clock is controlled by EN_GPIO1 bit PRCM.CM_FCLKEN_WKUP[3] (0: disabled, 1: enabled the clock) for GPIO1.

- Interface clock: The interface clock, GPIOi_ICLK (where i = 1, 2, 3, 4, 5, and 6), comes from the PRCM module and is used throughout the GPIO module (except within the debounce cell logic). The interface clock clocks the data exchanges between the L4 interconnect and the internal logic. The clock-gating features allow module power consumption to be adapted to the activity. For GPIO1, this clock is controlled by the EN_GPIO1 bit PRCM.CM_ICLKEN_WKUP[3] (0: disabled, 1:enabled the clock) and AUTO_GPIO1 bit PRCM.CM_AUTOIDLE_WKUP[3] (enables/disables automatic control of the interface clock). For GPIO2 to GPIO6, this clock is controlled by the EN_GPIOi (where i = 2 to 6) bit PRCM.CM_ICLKEN_PER (0: disabled, 1: enabled the clock) and AUTO_GPIOi (where i = 2 to 6) bit PRCM.CM_AUTOIDLE_PER (enables/disables automatic control of the interface clock). Table 25-2 describes the GPIO module clocks.

Table 21-2. Clocks

| Attribute | Frequency | Name | Mapping | Comments |
|-----------------|------------------------------------|-------------------------------|------------------------|------------------------|
| Debounce clock | 32 KHz | GPIOi_DBCLK, where i = 2 to 6 | PER_32K_ALWON_F CLK | Source is PRCM module. |
| | | GPIO1_DBCLK | WKUP_32K_CLK | |
| Interface clock | Depends on PRCM registers settings | GPIOi_ICLK, where i = 2 to 6 | PER_L4_ICLK | |
| | | GPIO1_ICLK | WKUP_L4_ICLK | |

21.3.1.1.2 Reset

The general-purpose interface can be reset by using the domain reset (hardware reset) or by setting a dedicated configuration bit (software reset) in each GPIO module.

- Hardware reset: The GPIO2 to GPIO6 modules are attached to the PER_RST reset domain. The GPIO1 module is attached to the WKUP_RST reset domain. The hardware reset has a global reset action on the GPIO modules of the general-purpose interface. All configuration registers and internal logic are reset when it is active (low level). In each GPIO module, the RESETDONE bit GPIOi.GPIO_SYSTATUS[0] monitors the internal reset status; it is set when the reset completes. For more information, see , *Power, Reset, and Clock Management*.
- Software reset: Each GPIO module has its own software reset using the GPIOi.GPIO_SYSCONFIG[1] SOFTRESET bit (where i = 1, 2, 3, 4, 5, or 6). The software reset has the same effect as the hardware reset signal, but this reset can be applied on one module or more. Writing 1 to SOFTRESET bit GPIOi.GPIO_SYSCONFIG[1](where i = 1, 2, 3, 4, 5, or 6) resets the module. Bit value 1 remains until the reset is complete. When the software reset is complete, the GPIOi.GPIO_SYSCONFIG[1] SOFTRESET bit is automatically reset to 0 and has the same effect as the hardware reset. The GPIOi.GPIO_SYSTATUS[0] RESETDONE is cleared during a software reset. This bit is set to 1 when the software reset is complete.

21.3.1.1.3 Power Domain

The GPIO1 module is attached to the WKUP power domain (see , *Power, Reset, and Clock Management*). This domain is composed of the logic permanently supplied to manage domain power state transitions and detect wake-up events. The WKUP power domain is continuously active. The GPIO2 to GPIO6 modules are attached to the PER power domain (see , *Power, Reset, and Clock Management*). The PER power domain is not active continuously.

21.3.1.1.4 Power Management

21.3.1.1.4.1 Idle Scheme

To save dynamic consumption, an efficient idle scheme is based on the following:

- An efficient local autoclock gating for each module
- The implementation of control sideband signals between the PRCM module and each module

This enhanced idle control allows clocks to be activated and deactivated safely without requiring a complex software management.

The idle mode request, idle acknowledge, and wake-up request (GPIOi_SWAKEUP, where i = 1, 2, 3, 4, 5, and 6) are sideband signals between the PRCM module and the general-purpose interface (see [Section 21.3.1.2, Hardware Requests](#)).

21.3.1.1.4.2 Operating Modes

The following four operating modes are defined for the modules:

- Active mode: The module runs synchronously on the interface clock; interrupts can be generated based on the configuration and external signals.
- Idle mode: Power-saving mode with the module in a waiting state. The interface clock can be stopped, an interrupt cannot be generated, and a wake-up signal can be generated based on the configuration and external signals.

If the debounce clock provided by the PRCM module is active, the debounce cell can sample and filter the input to generate a wake-up event. If the debounce clock is inactive, the debounce cell gates all input signals and thus cannot be used.

- Inactive mode: The module has no activity. The interface clock can be stopped, an interrupt cannot be generated, and the wake-up feature is inhibited.
- Disabled mode: The module is not used. The internal clock paths are gated, and an interrupt or wake-up request cannot be generated.

The idle and inactive modes are configured within the module and activated on request by the PRCM module (see [Power, Reset, and Clock Management](#)) through sideband signals (see [Section 21.3.1.1.4.3, System Power Management and Wake-up](#)).

The disabled mode is set by software through a dedicated configuration bit, the GPIOi.GPIO_CTRL[0] DISABLEMODULE bit (0: the module is enabled and clocks are not gated; 1: the module is disabled and clocks are gated). It unconditionally gates the internal clock paths that are not used for the L4 interconnect.

21.3.1.1.4.3 System Power Management and Wake-Up

The PRCM module can require the GPIO modules to be idled for power saving purposes.

The general-purpose interface has six identical idle mode request/acknowledge (handshake) mechanisms with the PRCM module (see [Figure 21-4](#) and [Section 21.3.1.2, Hardware Requests](#)): one per GPIO module. The general-purpose interface allows the GPIO modules to enter idle mode based on the GPIOi.GPIO_SYSCONFIG[4:3] IDLEMODE field.

The idle acknowledge depends on the configuration and activity of each GPIO module:

- Smart-idle mode (recommended)

When the GPIO module is configured in smart-idle mode (GPIOi.GPIO_SYSCONFIG[4:3] IDLEMODE field [10]) and receives an idle request from the PRCM module (for GPIO2 to GPIO6: the corresponding bits in the PRCM.CM_FCLKEN_PER and PRCM.CM_ICLKEN_PER registers cleared to 0 or the corresponding bit in the PRCM.CM_AUTOIDLE_PER bit set to 1 and L4 interface clock idle transitions; for GPIO1: PRCM.CM_FCLKEN_WKUP[3] EN_GPIO1 bit cleared to 0, PRCM.CM_ICLKEN_WKUP[3] EN_GPIO1 bit cleared to 0, or PRCM.CM_AUTOIDLE_WKUP[3] AUTO_GPIO1 bit set to 1 and L4 interface clock idle transitions), the GPIO module checks for more activity (capture of the input GPIO pins in the GPIOi.GPIO_DATAIN register is complete with no pending interrupt; all interrupt status bits are cleared) ; and there is no access to GPIO.GPIO_DEBOUNCINGTIME register pending to be synchronized.

Idle acknowledge is then asserted and the module enters in idle-mode. It waits for active system clock gating by the PRCM module (when all peripherals supplied by the same L4 interface clock domain are also ready for idle).

Idle mode (that is, when the PRCM module gates the interface clock), no interrupt occurs and the module is ready to issue a wake-up request.

When the expected transition occurs on an enabled GPIO input pin, the GPIO module exits from idle mode, if the GPIOi.GPIO_SYSCONFIG[2] ENAWAKEUP bit is set to 1 (wake-up capability enabled),

and the corresponding bit in the PRCM.PM_WKEN_PER register is also set to 1 for the GPIO2 to GPIO6 modules, and/or the PRCM.PM_WKEN_WKUP[3] EN_GPIO1 bit is also set to 1 for GPIO1.

- Force-idle mode

When the GPIO module is configured in force-idle mode (GPIOi.GPIO_SYSCONFIG[4:3] IDLEMODE field [00]) and receives an idle request from the PRCM module (for the GPIO2 to GPIO6: the corresponding bits in the PRCM.CM_FCLKEN_PER and PRCM.CM_ICLKEN_PER registers cleared to 0 or the corresponding bit in the PRCM.CM_AUTOIDLE_PER bit set to 1 and L4 interface clock idle transitions; for the GPIO1: PRCM.CM_FCLKEN_WKUP[3] EN_GPIO1 bit cleared to 0, PRCM.CM_ICLKEN_WKUP[3] EN_GPIO1 bit cleared to 0, or PRCM.CM_AUTOIDLE_WKUP[3] AUTO_GPIO1 bit set to 1 and L4 interface clock idle transitions), the GPIO module waits unconditionally for active system clock gating by the PRCM module. (This occurs only when all peripherals supplied by the same L4 interface clock domain are also ready for idle.)

When in idle mode (that is, when the PRCM module gates the interface clock), the module (in inactive mode) has no activity, the interface clock paths are gated, an interrupt cannot be generated, and the wake-up feature is totally inhibited.

- No-idle mode

When the GPIO module is configured in no-idle mode (GPIOi.GPIO_SYSCONFIG[4:3] IDLEMODE field [01]) and receives an idle request from the PRCM module (for the GPIO2 to GPIO6: the corresponding bits in the PRCM.CM_FCLKEN_PER and PRCM.CM_ICLKEN_PER registers cleared to 0 or the corresponding bit in the PRCM.CM_AUTOIDLE_PER bit set to 1 and L4 interface clock idle transitions; for the GPIO1: PRCM.CM_FCLKEN_WKUP[3] EN_GPIO1 bit cleared to 0, PRCM.CM_ICLKEN_WKUP[3] EN_GPIO1 bit cleared to 0 or PRCM.CM_AUTOIDLE_WKUP[3] AUTO_GPIO1 bit set to 1 and L4 interface clock idle transitions), the GPIO module does not go to the idle mode and the idle acknowledge is never sent.

NOTE: The GPIO2 to GPIO6 idle state can be checked by reading the corresponding status bits in the PRCM.CM_IDLEST_PER register (0: active, 1: idle) and is idle only when the GPIO2 to GPIO6 modules are configured in smart-idle mode and have asserted their idle acknowledge.

The GPIO1 idle state can be checked by the PRCM.CM_IDLEST_WKUP[3] ST_GPIO1 bit (0: idle, 1: active) and is idle only when the GPIO1 module is configured in smart-idle mode and has asserted its idle acknowledge.

The GPIO2 to GPIO6 wake-up status can be checked by accessing the corresponding bits in the PRCM.PM_WKST_PER register (read 0: no wakeup occurred; read 1: wakeup occurred; write 1: status bit reset).

The GPIO1 wake-up status can also be checked by the PRCM.PM_WKST_WKUP[3] ST_GPIO1 bit (read 0: no wakeup occurred; read 1: wakeup occurred; write 1: status bit reset).

21.3.1.1.4.4 Module Power Saving

The GPIO module has local power management by internal clock-gating features:

- Internal interface clock gating: The clock for the L4 interconnect logic can be gated when the module is not accessed, if the GPIOi.GPIO_SYSCONFIG[0] AUTOIDLE bit is set. Otherwise, this logic is free-running on the interface clock.
- Clock gating for the input data sample logic: Clock for the input data sample logic can be gated when the data in register is not accessed.
- Clock gating for the event detection logic: Each GPIO module implements four clock groups used for the logic in the synchronous events detection. Each group of eight input GPIO pins has a separate enable signal depending on the edge/level detection register setting. If a group requires no detection, the corresponding clock is gated off (see [Section 21.5.1, Power Saving by Grouping the Edge/Level Detection](#)). All channels are also gated using a one-out-of-N scheme. N is the GATINGRATIO field GPIOi.GPIO_CTRL[2:1] and can take the values 1 (b00), 2 (0b01), 4 (b10), or 8 (0b11). The interface clock is enabled for this logic one cycle every N cycles. When N is equal to 1, there is no gating and this logic is free-running on the interface clock. When N is 2, 4, or 8, this logic is running at the equivalent frequency of interface clock frequency divided by N.

- Inactive mode: In inactive mode, all internal clock paths are gated.
- Disabled mode: All internal clock paths not used for the L4 interconnect are gated. The GPIOi.GPIO_CTRL[0] DISABLEMODULE bit controls a clock-gating feature at the module level. When set to 1, this bit forces clock gating for all internal clock paths. Module internal activity is suspended. The L4 interconnect is not affected by this bit.

The interface clock gating is controlled with the GPIOi.GPIO_SYSCONFIG[0] AUTOIDLE bit, which is used to save power when the module is not used because of the multiplexing configuration selected at the chip level. This bit has precedence over all other internal configuration bits.

21.3.1.2 Hardware Requests

21.3.1.2.1 Interrupt Requests

All interrupt sources (the 32 input GPIO channels) are merged to issue two synchronous interrupt requests in each GPIO module. Thus, the general-purpose interface has 12 interrupt lines (two interrupt lines per GPIO module instance).

Synchronous interrupt request lines 1 and 2 are active depending on their respective interrupt enable 1 and 2 registers (GPIOi.GPIO_IRQENABLE1 and GPIOi.GPIO_IRQENABLE2).

- Synchronous interrupt request line 1 is mapped on the MPU interrupt controller.
- Synchronous interrupt request line 2 is mapped on the IVA2.2 interrupt controller.

Table 21-3 lists the interrupt lines that are driven out from the general-purpose interface to the MPU subsystem and IVA2.2 subsystem interrupt controller.

Table 21-3. Interrupts

| Name | Mapping | Comments |
|---------------------|--------------|---|
| GPIO1 Module | | |
| GPIO1_MPU_IRQ | M_IRQ_29 | Destination is the MPU subsystem interrupt controller. |
| GPIO1_IVA2_IRQ | IVA2_IRQ[28] | Destination is the IVA2.2 subsystem interrupt controller. |
| GPIO2 Module | | |
| GPIO2_MPU_IRQ | M_IRQ_30 | Destination is the MPU subsystem interrupt controller. |
| GPIO2_IVA2_IRQ | IVA2_IRQ[29] | Destination is the IVA2.2 subsystem interrupt controller. |
| GPIO3 Module | | |
| GPIO3_MPU_IRQ | M_IRQ_31 | Destination is the MPU subsystem interrupt controller. |
| GPIO3_IVA2_IRQ | IVA2_IRQ[30] | Destination is the IVA2.2 subsystem interrupt controller. |
| GPIO4 Module | | |
| GPIO4_MPU_IRQ | M_IRQ_32 | Destination is the MPU subsystem interrupt controller. |
| GPIO4_IVA2_IRQ | IVA2_IRQ[31] | Destination is the IVA2.2 subsystem interrupt controller. |
| GPIO5 Module | | |
| GPIO5_MPU_IRQ | M_IRQ_33 | Destination is the MPU subsystem interrupt controller. |
| GPIO5_IVA2_IRQ | IVA2_IRQ[32] | Destination is the IVA2.2 subsystem interrupt controller. |
| GPIO6 Module | | |
| GPIO6_MPU_IRQ | M_IRQ_34 | Destination is the MPU subsystem interrupt controller. |
| GPIO6_IVA2_IRQ | IVA2_IRQ[43] | Destination is the IVA2.2 subsystem interrupt controller. |

21.3.1.2.1.1 Wake-Up Generation

The GPIO1 module of the general-purpose interface is attached to the WKUP power domain (see , *Power, Reset, and Clock Management*) and can wake up the system.

NOTE: The GPIO2 to GPIO6 modules belong to the PER power domain and thus have wake-up system capability only when the PER power domain is active.

All wake-up sources (the 32 input GPIO channels) are merged together to issue a single asynchronous wake-up request in each GPIO module following the expected transition(s) (based on register programming). Each GPIO module generates a wake-up signal to the PRCM module.

NOTE: Only gpio_1, gpio_9, gpio_10, gpio_11, gpio_30, and gpio_31 can be used to generate a direct wake-up event. The other GPIO1 pins cannot be used to generate a direct wake-up event because they are connected to the device I/O pad logic in the CORE power domain (VDD2). When the CORE power domain is off, the I/O pins of the GPIO1 module, which are supplied by VDD2, cannot generate a wake-up event.

The asynchronous wake-up request line is active based on the GPIOi.GPIO_WAKEUPENABLE register (where i = 1, 2, 3, 4, 5, and 6).

CAUTION

The wake-up capabilities of the GPIO2 to GPIO6 modules are operational only when the PER power domain is active.

Table 21-4 shows the wake-up signals mapping.

Table 21-4. Wake-Up Signals

| Name | Mapping | Comments |
|------------|---------------|---|
| GPIOi_WAKE | GPIOi_SWAKEUP | Where i = 1, 2, 3, 4, 5, and 6. Destination is the PRCM module. |

Table 21-5 describes the GPIO channels.

Table 21-5. GPIO Channel Description

| Channel Number | Type ⁽¹⁾ | Mapping | Wake-Up Feature | Comments |
|---------------------|---------------------|--------------|--------------------|--|
| GPIO1 Module | | | | |
| [31:0] | I/O | gpio_[31:0] | Yes | GPIO |
| GPIO2 Module | | | | |
| [0] | I | - | No | Not available on external balls. Read value is always 0. |
| [1] | I | TV_DETECT | Yes | Internal TV detection signal from the 10-bit composite/luma video DAC1 |
| [31:2] | I/O | gpio_[63:34] | Yes ⁽²⁾ | GPIO ⁽³⁾ |
| GPIO3 Module | | | | |
| [15:0] | I/O | gpio_[79:64] | Yes ⁽²⁾ | GPIO ⁽³⁾ |
| [16] | I/O | gpio_80 | Yes ⁽²⁾ | GPIO ⁽³⁾ |
| | I | SDI_RECAL | Yes ⁽²⁾ | Internal SDI_RECAL signal from the SDI PLL module ⁽⁴⁾ |
| [17] | I/O | gpio_81 | Yes ⁽²⁾ | GPIO ⁽³⁾ |
| | I | SDI_LOCK | Yes ⁽²⁾ | Internal SDI_LOCK signal from the SDI PLL module ⁽⁴⁾ |
| [18] | I/O | gpio_82 | Yes ⁽²⁾ | GPIO ⁽³⁾ |
| | I | SDI_ERROR | Yes ⁽²⁾ | Internal SDI_ERROR signal from the SDI PLL module ⁽⁴⁾ |
| [31:19] | I/O | gpio_[95:83] | Yes ⁽²⁾ | GPIO ⁽³⁾ |
| GPIO4 Module | | | | |

⁽¹⁾ I = Input, O = Output

⁽²⁾ Only when the PER power domain is active

⁽³⁾ Configuration mode 4. See Chapter 6, System Control Module.

⁽⁴⁾ All configuration modes except configuration mode 4. See Chapter 6, System Control Module.

Table 21-5. GPIO Channel Description (continued)

| Channel Number | Type ⁽¹⁾ | Mapping | Wake-Up Feature | Comments |
|---------------------|---------------------|------------------------------|--------------------|---|
| [30:0] | I/O | gpio_[126:96] ⁽⁵⁾ | Yes ⁽²⁾ | GPIO ⁽³⁾ |
| [31] | I/O | gpio_127 | Yes ⁽²⁾ | GPIO ⁽³⁾ |
| | I | TSHUT | Yes ⁽²⁾ | Internal TSHUT signal from the BANDGAP module for the SRAMs LDOs ⁽⁴⁾ |
| GPIO5 Module | | | | |
| [31:0] | I/O | gpio_[159:128] | Yes ⁽²⁾ | GPIO ⁽³⁾ |
| GPIO6 Module | | | | |
| [26:0] | I/O | gpio_[186:160] | Yes ⁽²⁾ | GPIO ⁽³⁾ |
| [27] | I | - | No | Not available on external balls. Read value is always 0. |
| [31:28] | I/O | gpio_[191:188] | Yes ⁽²⁾ | GPIO ⁽³⁾ |

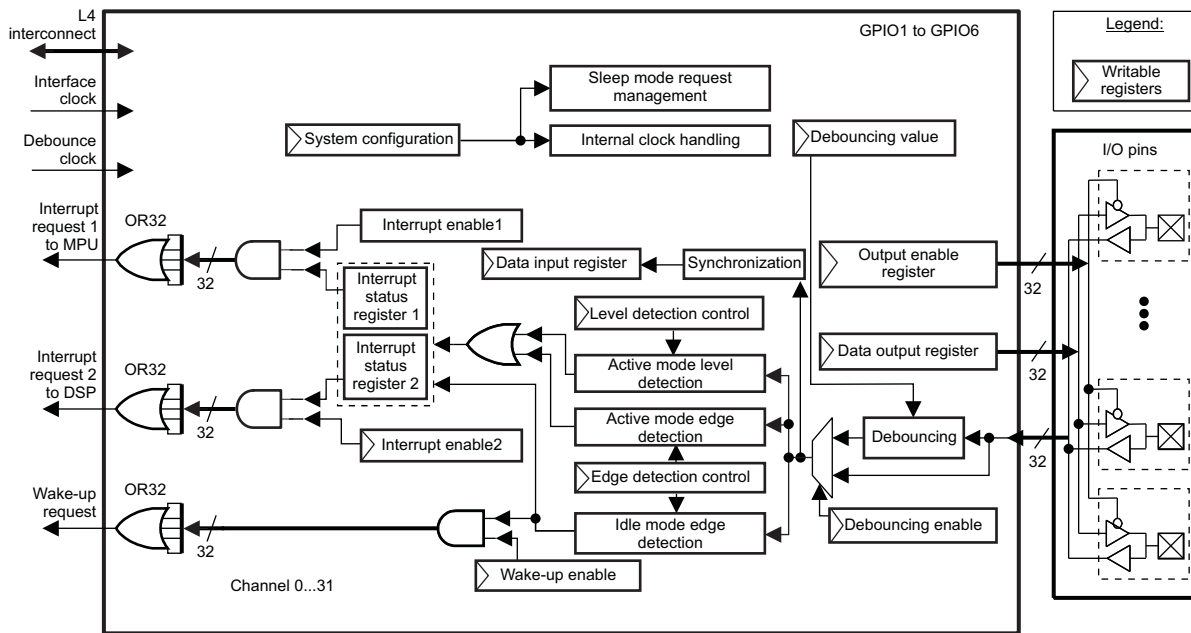

⁽⁵⁾ All signals are I/O type, except gpio_99, gpio_100, gpio_112, gpio_113, gpio_114, and gpio_115, which are input-only signals.

NOTE: The thermal shutdown comparator output signal (TSHUT) is an output from the BANDGAP module. This signal is low during normal operation and goes high during a thermal shutdown event. When channel 31 of the GPIO4 is not connected to a ball of the device (the corresponding pin is configured in a mode different from the configuration mode 4; see [Chapter 6, System Control Module](#), for more information about pin configuration), TSHUT is connected to channel 31 of the GPIO4, and an interrupt can be generated when a low-to-high transition occurs on TSHUT whether or not the interrupt generation for channel 31 of the GPIO4 is correctly configured.

21.4 General-Purpose Interface Functional Description

Figure 21-5 shows the general-purpose interface description.

Figure 21-5. General-Purpose Interface Description

108-005

Figure 21-5 details the GPIO modules in the general-purpose interface block diagram with their configuration registers and their main functional paths:

- The synchronous path (for active mode operation) used to generate a synchronous interrupt request on expected event detection on any input GPIO; the synchronous interrupt request lines 1 and 2 are active based on their respective interrupt enable 1 and 2 registers (GPIOi.GPIO_IRQENABLE1 and GPIOi.GPIO_IRQENABLE2). See Figure 21-6.

Figure 21-6. Synchronous Path

108-006

- The asynchronous path (for idle mode operation) used to generate an asynchronous wake-up request on the expected edge detection on any input GPIO; the asynchronous wake-up request line is active based on the wake-up enable register. See Figure 21-7.

Figure 21-7. Asynchronous Path

- The blocks handling the internal clock (clock gating) and managing the sleep mode request/acknowledge protocol (enabling the synchronous path in active mode and the asynchronous path in idle mode).

21.4.1 Interrupt and Wake-Up Features

21.4.1.1 Synchronous Path: Interrupt Request Generation

The general-purpose interface has 12 interrupt lines (two interrupt lines per GPIO module instance). The 12 interrupt signals are GPIOi_MPU_IRQ (used by the MPU subsystem) and GPIOi_IVA2_IRQ (used by the IVA2.2 subsystem), where $i = 1, 2, 3, 4, 5,$ and 6 .

Synchronous interrupt requests from each channel are processed by two identical interrupt generation submodules used independently by the IVA2.2 subsystem and the MPU subsystem. Each submodule controls its own synchronous interrupt request line and has its own interrupt enable (GPIOi.GPIO_IRQENABLE1 or GPIOi.GPIO_IRQENABLE2) and interrupt status (GPIOi.GPIO_IRQSTATUS1 or GPIOi.GPIO_IRQSTATUS2) registers. The interrupt enable register selects the channel(s) considered for the interrupt request generation, and the interrupt status register determines which channel(s) activate the interrupt request. Event detection on GPIO channels is reflected in the interrupt status registers independent of the content of the interrupt enable registers.

In active mode, when the GPIO configuration registers are set to enable the interrupt generation (see Section 21.5.3, *Interrupt and Wakeup*), a synchronous path samples the transitions and levels on the input GPIO with the internally gated interface clock (see Section 21.3.1.1.4.4, *Module Power Saving*). When an event matches the programmed settings (see Section 21.5.3, *Interrupt and Wakeup*), the corresponding bit in the interrupt status register is set to 1 and, on the following interface clock cycle, the interrupt lines 1 and/or 2 are activated (depending on the interrupt enable registers).

Because of the sampling operation, the minimum pulse width on the input GPIO to trigger a synchronous interrupt request is two times the internally gated interface clock period (the internally gated interface clock period equals N times the interface clock period; see Section 21.3.1.1.4.4, *Module Power Saving*). This minimum pulse width must be met before and after any expected level transition detection. Level detection requires the selected level to be stable for at least two times the internally gated interface clock period to trigger a synchronous interrupt.

Because the module is synchronous, latency is minimal between the expected event occurrence and the activation of the interrupt line(s). This latency must not exceed four internally gated interface clock cycles + one interface clock cycle when the debounce feature is not used.

When the debounce feature is active, the latency depends on the debouncing time register (GPIOi.GPIO_DEBOUNCINGTIME) value (see Section 21.5.5, *Debouncing Time*) and is less than three internally gated interface clock cycles + two interface clock cycle + GPIOi.GPIO_DEBOUNCINGTIME register value debounce clock cycles + three debounce clock cycles.

Synchronous interrupt request line 1 is mapped on the MPU interrupt controller.

Synchronous interrupt request line 2 is mapped on the IVA2.2 interrupt controller.

Figure 21-8 shows an overview of the interrupt request generation.

Figure 21-8. Interrupt Request Generation

108-008

21.4.1.2 Asynchronous Path: Wake-Up Request Generation

The general-purpose interface has six wake-up lines (one wake-up line per GPIO module instance) connected to the PRCM module.

Asynchronous wake-up requests from input channels are merged to issue one wake-up signal to the system per GPIO module. The wake-up enable register (`GPIOi.GPIO_WAKEUPENABLE`) selects the channel(s) considered for the wake-up request generation. The asynchronous wake-up request is reflected into the synchronous interrupt status registers (`GPIOi.GPIO_IRQSTATUS1` and `GPIOi.GPIO_IRQSTATUS2`).

In idle mode (the interface clock is shut down and the GPIO configuration registers are programmed; see [Section 21.5.3, *Interrupt and Wakeup*](#)), an asynchronous path detects the expected transition(s) on a GPIO input (based on register programming) and activates an asynchronous wake-up request by the sideband signal (`GPIOi_SWAKEUP`, where $i = 1, 2, 3, 4, 5,$ and 6), if the wake-up enable register is set.

When the system is awakened, the interface clock is restarted and synchronously set to 1 based on the input GPIO pin triggering the wake-up request and the corresponding bit in the interrupt status registers (`GPIOi.GPIO_IRQSTATUS1` and `GPIOi.GPIO_IRQSTATUS2`). On the following internal clock cycle, the interrupt lines 1 and/or 2 are active (active low) when the corresponding bits are set in the interrupt enable registers (`GPIOi.GPIO_IRQENABLE1` and `GPIOi.GPIO_IRQENABLE2`).

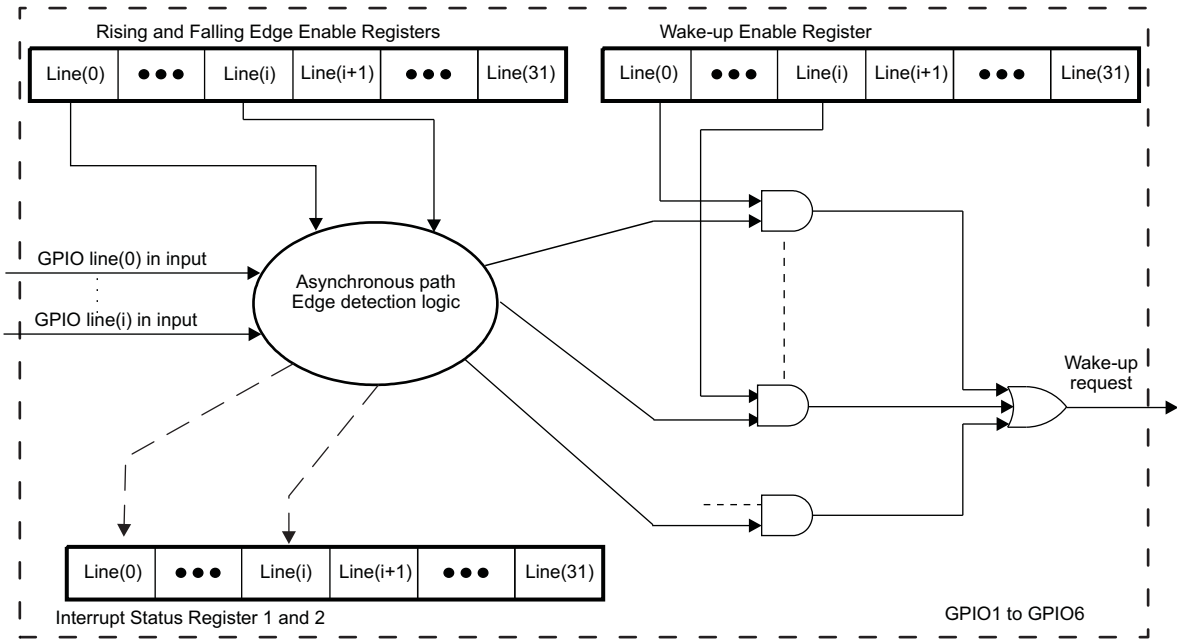

NOTE: When debouncing is not enabled, a minimum input pulse width does not trigger the wake-up request because there is no sampling operation.

When debouncing is enabled, the minimum pulse width is set by the specified debouncing time.

The `GPIOi.GPIO_SYSCONFIG[2]` `ENAWAKEUP` bit enables or disables the GPIO wake-up feature globally. If the bit is 0, the wake-up enable register (`GPIOi.GPIO_WAKEUPENABLE`) has no effect.

Figure 21-9 shows an overview of the wake-up request generation.

Figure 21-9. Wake-Up Request Generation

108-009

21.4.1.3 Interrupt (or Wake-Up) Line Release

When the host processor (the MPU and/or IVA2.2 subsystem in the device) receives an interrupt request issued by the GPIO module, it reads the corresponding interrupt status register (GPIOi.GPIO_IRQSTATUS1 or GPIOi.GPIO_IRQSTATUS2) to determine which GPIO input triggered the interrupt (or the wake-up request).

After servicing the interrupt (or acknowledging the wake-up request), the processor resets the status bit and releases the interrupt line by writing 1 in the corresponding bit of the interrupt status register. If there is still a pending interrupt request to serve (all bits in the interrupt status register that are not masked by the interrupt enable register are not cleared), the interrupt line is reasserted.

NOTE: The status bit must be reset to re-enter idle mode.

21.5 General-Purpose Interface Basic Programming Model

21.5.1 Power Saving by Grouping the Edge/Level Detection

Each GPIO module implements four gated clocks used by the edge/level detection logic to save power. Each group of eight input GPIO pins generates a separate enable signal depending on the edge/level detection register setting (because the input is 32 bits, four groups of eight inputs are defined for each GPIO module). If a group requires no edge/level detection, then the corresponding clock is gated (cut off). Grouping the edge/level enable can save the power consumption of the module as described in the following example.

If any of the registers:

GPIOi.GPIO_LEVELDETECT0
 GPIOi.GPIO_LEVELDETECT1
 GPIOi.GPIO_RISINGDETECT
 GPIOi.GPIO_FALLINGDETECT

are set to 0x01 01 01 01, then all clocks are active (power consumption is high).

are set to 0x00 00 00 FF, then a single clock is active (power saving).

NOTE: When the clocks are enabled by writing to the GPIOi.GPIO_LEVELDETECT0, GPIOi.GPIO_LEVELDETECT1, GPIOi.GPIO_RISINGDETECT, and GPIOi.GPIO_FALLINGDETECT registers, the detection starts after five clock cycles. This period is required to clean the synchronization edge/level detection pipeline.

The mechanism is independent of each clock group. If the clock has been started before and a new setting is performed, the following is recommended: First, set the new detection required; second, disable the previous setting (if necessary). In this way, the corresponding clock is not gated and the detection starts immediately.

21.5.2 Set-and-Clear Instructions

21.5.2.1 Description

The GPIO module implements the set-and-clear protocol register update for the GPIOi.GPIO_DATAOUT, GPIOi.GPIO_IRQENABLE1, GPIOi.GPIO_IRQENABLE2, and GPIOi.GPIO_WAKEUPENABLE registers. This protocol is an alternative to the atomic test and set operations and consists of writing operations at dedicated addresses (one address for setting bit[s] and one address for clearing bit[s]). The data to write is 1 at bit position(s) to clear (or to set) and 0 at unaffected bit(s). Registers can be accessed in two ways:

- Standard: Full register read and write operations at the primary register address
- Set and clear (recommended): Separate addresses are provided to set (and clear) bits in registers. Writing 1 at these addresses sets (or clears) the corresponding bit into the equivalent register; writing a 0 has no effect.

Therefore, for these registers, three addresses are defined for one unique physical register. Reading these addresses has the same effect and returns the register value.

21.5.2.2 Clear Instruction

21.5.2.2.1 Clear Registers Addresses

Clear interrupt enable registers (GPIOi.GPIO_CLEARIRQENABLE1 and GPIOi.GPIO_CLEARIRQENABLE2).

A write operation in the clear interrupt enable1 (or enable2) register clears the corresponding bit in the interrupt enable1 (or enable2) register when the written bit is 1; a written bit at 0 has no effect.

A read of the clear interrupt enable1 (or enable2) register returns the value of the interrupt enable1 (or enable2) register

Clear wake-up enable register (GPIOi.GPIO_CLEARWКУENA).

A write operation in the clear wake-up enable register clears the corresponding bit in the wake-up enable register when the written bit is 1; a written bit at 0 has no effect.

A read of the clear wake-up enable register returns the value of the wake-up enable register.

Clear data output register (GPIOi.GPIO_CLEARDATAOUT).

A write operation in the clear data output register clears the corresponding bit in the data output register when the written bit is 1; a written bit at 0 has no effect.

A read of the clear data output register returns the value of the data output register.

21.5.2.2.2 Clear Instruction Example

Assume the data output register (or one of the interrupt/wake-up enable register) contains the binary value, 0b0000 0001 0000 0001, and you want to clear the bit 0.

With the clear instruction feature, write 0b0000 0000 0000 0001 at the address of the clear data output register (or at the address of the clear interrupt/wake-up enable register). After this write operation, a reading of the data output register (or the interrupt/wake-up enable register) returns 0b0000 0001 0000 0000; the bit 0 is cleared.

NOTE: Although the general-purpose interface registers are 32 bits wide, only the less-significant 16 bits are represented in this example.

Figure 21-10 shows an example of a clear instruction.

108-010

21.5.2.3 Set Instruction

21.5.2.3.1 Set Registers Addresses

Set interrupt enable registers (GPIOi.GPIO_SETIRQENABLE1 and GPIOi.GPIO_SETIRQENABLE2).

A write operation in the set interrupt enable1 (or enable2) register sets the corresponding bit in the interrupt enable1 (or enable2) register when the written bit is 1; a written bit at 0 has no effect.

A read of the set interrupt enable1 (or enable2) register returns the value of the interrupt enable1 (or enable2) register.

Set wake-up enable register (GPIOi.GPIO_SETWKUENA).

A write operation in the set wake-up enable register sets the corresponding bit in the wake-up enable register when the written bit is 1; a written bit at 0 has no effect.

A read of the set wake-up enable register returns the value of the wake-up enable register.

Set data output register (GPIOi.GPIO_SETDATAOUT).

A write operation in the set data output register sets the corresponding bit in the data output register when the written bit is 1; a written bit at 0 has no effect.

A read of the set data output register returns the value of the data output register.

21.5.2.3.2 Set Instruction Example

Assume the interrupt enable1 (or enable2) register (or the data output register) contains the binary value, 0b0000 0001 0000 0000, and you want to set the bits 15, 3, 2, and 1.

With the set instruction feature, write 0b1000 0000 0000 1110 at the address of the set interrupt enable1 (or enable2) register (or at the address of the set data output register). After this write operation, a reading of the interrupt enable1 (or enable2) register (or the data output register) returns 0b1000 0001 0000 1110; the bits 15, 3, 2, and 1 are set.

NOTE: Although the general-purpose interface registers are 32 bits wide, only the less-significant 16 bits are represented in this example.

Figure 21-11 shows an example of a set instruction.

Figure 21-11. Write @GPIO_SETIRQENABLEx Register Example

108-011

The set wake-up enable register offers the same feature with the wake-up enable register.

21.5.3 Interrupt and Wakeup

21.5.3.1 Involved Configuration Registers

- Interrupt enable registers (GPIOi.GPIO_IRQENABLE1 and GPIOi.GPIO_IRQENABLE2)
The interrupt enable1 (or interrupt enable2) register allows masking of the expected transition on input GPIO to prevent the generation of an interrupt request on line1 (or line2). The interrupt enable registers are programmed synchronously with the interface clock.
These registers can be accessed with direct read/write operations or using the alternate set and clear protocol register update feature. This feature enables to set or clear specific bits of these registers with a single write access to the corresponding set interrupt enable1 (or interrupt enable2) registers (or to the clear interrupt enable1 [or interrupt enable2] registers) address (see Section 21.5.2, *Set-and-Clear Instructions*).
- Wake-up enable register (GPIOi.GPIO_WAKEUPENABLE)
The wake-up enable register allows masking of the expected transition on input GPIO to prevent the generation of a wake-up request. The wake-up enable register is programmed synchronously with the interface clock before any idle mode request coming from the host processor.
This register can be accessed with direct read/write operations or by using the alternate set and clear protocol register update feature. This feature allows setting or clearing specific bits of this register with a single write access to the set wake-up enable register (or to the clear wake-up enable register) address (see Section 21.5.2, *Set-and-Clear Instructions*).

NOTE: It must be a correlation between Wake-up enable and interrupt enable registers. If a GPIO pin has a Wake-up configured on it, it should also have the corresponding interrupt enabled (on one of the 2 interrupt lines). Otherwise, it is possible to have a Wake-up event, but after exiting the Idle state, no interrupt will be generated, thus the corresponding bit from the interrupt status register will not be cleared, and the module will not acknowledge a future Idle Request.

- Interrupt status registers (GPIOi.GPIO_IRQSTATUS1 and GPIOi.GPIO_IRQSTATUS2)
The interrupt status1 (or interrupt status2) register determines which of the input GPIO pins triggered the interrupt line1 (or interrupt line2) request (or the wake-up line).
When a bit in this register is set to 1, it indicates that the corresponding GPIO pin is requesting the interrupt (or the wake-up). To reset a bit in this register, write 1 to the appropriate bit. However, an interrupt cannot be generated by writing 1 to the interrupt status1 (or interrupt status2) register.
If 0 is written to a bit in this register, the value remains unchanged. The interrupt status1 (or interrupt

status2) register is synchronous with the interface clock. In idle mode, the event is detected via an asynchronous path, and the corresponding bit in the interrupt status1 and interrupt status2 registers are set when the GPIO module is awake.

NOTE: The wake-up capabilities of the GPIO2 to GPIO6 modules are operational only when the PER power domain is active.

21.5.3.2 Description

To generate interrupt request to a host processor (the MPU and/or DSP subsystem in the device) at a defined event (level or edge logic transition) occurring on a GPIO pin (interrupt source), the GPIO configuration registers must be programmed as follows:

1. The GPIO channel must be configured as input by the output enable register (write 1 to the corresponding bit of the GPIOi.GPIO_OE register).
2. The expected event(s) on the GPIO input to trigger the interrupt request must be selected in the low-level interrupt enable register (write 1 or 0 to the corresponding bit of GPIOi.GPIO_LEVELDETECT0), and/or high-level interrupt enable register (write 1 or 0 to the corresponding bit of GPIOi.GPIO_LEVELDETECT1), and/or rising-edge interrupt/wake-up enable register (write 1 or 0 to the corresponding bit of GPIOi.GPIO_RISINGDETECT), and/or falling edge interrupt/wake-up enable register (write 1 or 0 to the corresponding bit of GPIOi.GPIO_FALLINGDETECT).

NOTE: Interrupt generation on both edges on one input is configured by setting the corresponding bit to 1 in the rising detect enabling register (GPIOi.GPIO_RISINGDETECT) and falling detect enabling register (GPIOi.GPIO_FALLINGDETECT) along with the interrupt enable by setting the corresponding bit to 1 in on one or both interrupt enable registers (GPIOi.GPIO_IRQENABLE1 and GPIOi.GPIO_IRQENABLE2).

Enabling at the same time high level detection and low level detection for one given pin makes a constant interrupt generator.

3. Interrupts from the GPIO channel must be enabled in the interrupt 1 enable register (write 1 to the corresponding bit of GPIOi.GPIO_IRQENABLE1 register) and/or the interrupt 2 enable register (write 1 to the corresponding bit of GPIOi.GPIO_IRQENABLE2 register).

To configure a GPIO module to sent a wake-up request to the PRCM at a defined event (logic transition) occurring on a GPIO pin (wake-up source), the GPIO configuration registers must be programmed as follows:

1. The GPIO pin must be configured as input by the output enable register (write 1 to the corresponding bit of the GPIOi.GPIO_OE register).
2. The expected event(s) on the GPIO input to trigger the wake-up request must be selected in the rising-edge interrupt/wake-up enable register (write 1 or 0 to the corresponding bit of GPIOi.GPIO_RISINGDETECT) and/or falling-edge interrupt/wake-up enable register (write 1 or 0 to the corresponding bit of GPIOi.GPIO_FALLINGDETECT). The wake-up request can only be generated on edge transitions.
3. The GPIO channel must be enabled in the wake-up enable register (write 1 to the corresponding bit of the GPIOi.GPIO_WAKEUPENABLE).
4. The wake-up request generation on the expected transition occurring on the GPIO input pins must enable for the module (write 1 to the corresponding bit of the GPIOi.GPIO_SYSCONFIG[2] ENAWAKEUP) .

CAUTION

For each GPIO channel used, do not forget to configure the corresponding pad configuration registers in [Chapter 6](#), *System Control Module*.

After servicing the interrupt, the status bit in the interrupt status register (GPIOi.GPIO_IRQSTATUS1 or GPIOi.GPIO_IRQSTATUS2) must be reset and the interrupt line released (by writing 1 in the corresponding bit of the interrupt status register) before enabling an interrupt for the GPIO channel in the interrupt enable register (GPIOi.GPIO_IRQENABLE1 or GPIOi.GPIO_IRQENABLE2) to prevent the occurrence of unexpected interrupts when enabling an interrupt for the GPIO channel.

21.5.4 Data Input (Capture)/Output (Drive)

The output enable register (GPIOi.GPIO_OE) controls the output/input capability for each pin. At reset, all the GPIO-related pins are configured as input and output capabilities are disabled. This register is not used within the module. Its only function is to carry the pads configuration.

When configured as an output (the desired bit reset in the GPIOi.GPIO_OE register), the value of the corresponding bit in the GPIOi.GPIO_DATAOUT register is driven on the corresponding GPIO pin. Data is written to the data output register synchronously with the interface clock. This register can be accessed with read/write operations or by using the alternate set and clear protocol register update feature. This feature lets you set or clear specific bits of this register with a single write access to the set output data register (GPIOi.GPIO_SETDATAOUT) or to the clear output data register (GPIOi.GPIO_CLEARDATAOUT) address (see [Section 21.5.2](#), *Set-and-Clear Instructions*). If the application uses a pin as an output and does not want interrupt/wake-up generation from this pin, the application must properly configure the wake-up enable (GPIOi.GPIO_WAKEUPENABLE) and the interrupt enable (GPIOi.GPIO_IRQENABLE1 and GPIOi.GPIO_IRQENABLE2) registers.

When configured as an input (the desired bit set to 1 in the GPIOi.GPIO_OE register), the state of the input can be read from the corresponding bit in the GPIOi.GPIO_DATAIN register. The input data is sampled synchronously with the interface clock and then captured in the data input register synchronously with the interface clock (see [Section 21.5.2](#), *Set-and-Clear Instructions*). When the GPIO pin levels change, they are captured into this register after two interface clock cycles (the required cycles to synchronize and to write data). If the application uses a pin as an input, the application must properly configure the wake-up enable (GPIOi.GPIO_WAKEUPENABLE) and the interrupt enable (GPIOi.GPIO_IRQENABLE1 and GPIOi.GPIO_IRQENABLE2) registers to the interrupt and wake-up feature as needed.

21.5.5 Debouncing Time

To enable the debounce feature for a pin, the GPIO configuration registers must be programmed as follows:

1. The GPIO pin must be configured as input in the output enable register (write 1 to the corresponding bit of the GPIOi.GPIO_OE register)
2. The debouncing time must be set in the debouncing time register (GPIOi.GPIO_DEBOUNCINGTIME)
The debouncing value register (GPIOi.GPIO_DEBOUNCINGTIME) is used to set the debouncing time for all input lines in the GPIO module. The value is global for all the ports of one GPIO module, so up to six different debouncing values are possible. The debounce cell is running with the debounce clock (32 kHz). This register represents the number of the clock cycle(s) (one cycle is 31 microseconds long) to be used.

The following formula describes the required input stable time to be propagated to the debounced output:

Required input line stable = (GPIOi.GPIO_DEBOUNCINGTIME[7:0] DEBOUNCVAL field value + 1) x 31 μs.

where GPIOi.GPIO_DEBOUNCINGTIME[7:0] field DEBOUNCVAL value is from 0 to 255.

3. The debouncing feature must be enabled in the debouncing enable register (write 1 to the corresponding bit of the GPIOi.GPIO_DEBOUNCENABLE register)

21.6 General-Purpose Interface Register Manual

This section summarizes the hardware interface for the GPIO product. Each module instance within the design is shown, together with the module register map and bit definitions for each bit field.

Table 21-6 shows the base address and address space for the GPIO module instances.

Table 21-6. Instance Summary

| Module Name | Base Address | Size |
|-------------|--------------|----------|
| GPIO1 | 0x4831 0000 | 4K bytes |
| GPIO2 | 0x4905 0000 | 4K bytes |
| GPIO3 | 0x4905 2000 | 4K bytes |
| GPIO4 | 0x4905 4000 | 4K bytes |
| GPIO5 | 0x4905 6000 | 4K bytes |
| GPIO6 | 0x4905 8000 | 4K bytes |

21.6.1 General-Purpose Interface Register Mapping Summary

All module registers are 8-, 16-, or 32-bit accessible through the L4 interconnect (little endian encoding). Access to registers is direct; no shadow registers are implemented.

Table 21-7 through Table 21-8 describe the GPIO register offset addresses.

Table 21-7. GPIO1 to GPIO3 Register Summary

| Register Name | Type | Register Width (Bits) | Address Offset | Physical Address (GPIO1) | Physical Address (GPIO2) | Physical Address (GPIO3) |
|----------------------|------|-----------------------|----------------|--------------------------|--------------------------|--------------------------|

The write latency for all the R/W registers is immediate (with respect to the interface clock)

NOTE: When two write accesses in the GPIOi.GPIO_DEBOUNCINGTIME register are performed in less than two debounce clock cycles (32 kHz) + four interface clock cycles, the first write access latency is immediate, but the second write access is acknowledged only after this interval ends.

In the register descriptions in this section, when one single register carries an individual configuration or setting for all the channels of the module, one bit in the register is dedicated to each channel. The bit and the corresponding channel are identified with the same number: bit 0 refers to channel 0, bit 1 refers to channel 1, and so on, up to 31.

21.6.2 Register Descriptions

Table 21-9 through Table 21-59 describe the register bits.

Ethernet Media Access Controller (EMAC)/Management Data Input/Output (MDIO) Module

22.1 Introduction

This document provides a functional description of the Ethernet Media Access Controller (EMAC) and physical layer (PHY) device Management Data Input/Output (MDIO) module integrated in the device. Included are the features of the EMAC and MDIO modules, a discussion of their architecture and operation, how these modules connect to the outside world, and a description of the registers for each module.

The EMAC controls the flow of packet data from the system to the PHY. The MDIO module controls PHY configuration and status monitoring.

Both the EMAC and the MDIO modules interface to the system core through a custom interface that allows efficient data transmission and reception. This custom interface is referred to as the EMAC subsystem module and is considered integral to the EMAC/MDIO peripheral.

22.1.1 Purpose of the Peripheral

The EMAC module is used to move data between the device and another host connected to the same network, in compliance with the Ethernet protocol.

22.1.2 Features

The EMAC/MDIO has the following features:

- Synchronous 10/100 Mbit operation.
- CBA3.1 compliant DMA controllers with VBUSP data transfers.
- Selectable RMI Interface.
- Hardware Error handling including CRC.
- Little and Big Endian Support.
- Eight receive channels with VLAN tag discrimination for receive hardware QOS support.
- Eight transmit channels with round-robin or fixed priority for hardware QOS support.
- CPPI 3.0 compliant.
- EtherStats and 802.3Stats RMON statistics gathering.
- Transmit CRC generation selectable on a per channel basis.
- Broadcast frames selectable for reception on a single channel.
- Multicast frames selectable for reception on a single channel.
- Promiscuous receive mode selectable for reception on a single channel (all frames, all good frames, short frames, error frames).
- TI Adaptive Performance Optimization for improved half duplex performance.
- Configurable receive address matching/filtering.
- Emulation Support.
- EMAC Loopback Mode.
- 8K (2048 x 32) internal CPPI buffer descriptor memory.
- MDIO module for PHY Management.
- Programmable interrupt control with selected interrupt pacing.

22.1.3 Functional Block Diagram

After reset, initialization, configuration, and auto-negotiation the host may initiate transmit and receive operations. Transmit operations are initiated by host writes to the appropriate transmit channel head descriptor pointer contained in the EMAC STATERAM block. The EMAC transmit DMA controller then fetches the first packet in the packet chain from memory in accordance with the CPPI 3.0 protocol.

The EMAC receive DMA controller then writes packets to external memory in accordance with the CPPI 3.0 protocol. The EMAC is in configuration 2 (CFIG2). Configuration 2 is the 10/100 configuration with configurable address matching.

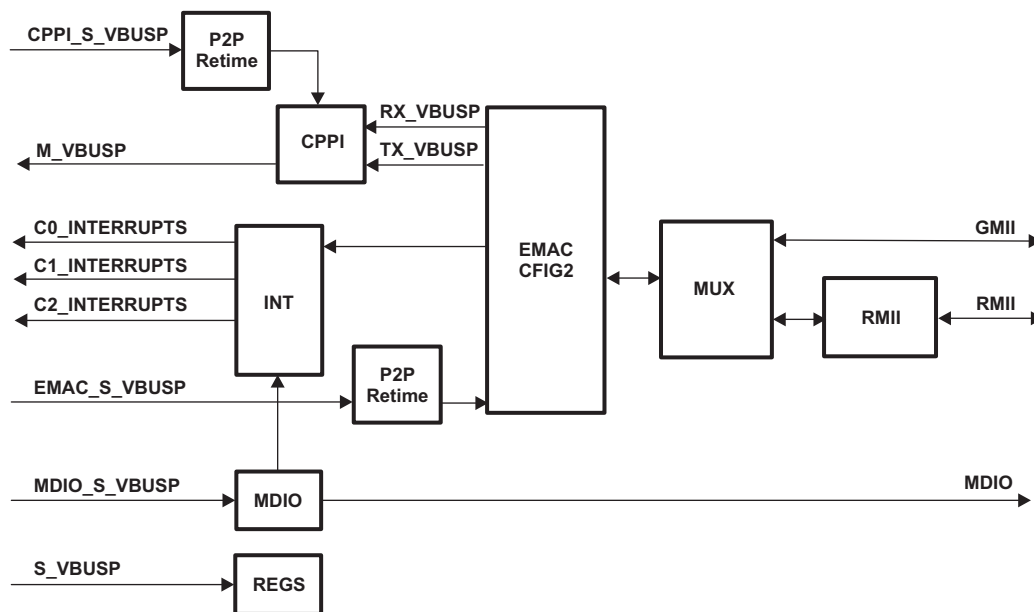

The CPPI block contains a 2048 by 32-bit memory (8K bytes) to be used for transmit and receive buffer descriptors. The CPPI block also contains a CBA 3.1 SCR (Switch Central Resource) to combine the EMAC transmit and receive VBUSP interfaces onto a single master VBUSP interface.

The host configures and initializes the device through the five module slave VBUSP interfaces. The CPPI, REGS, MDIO, and EMAC, modules have slave interfaces. The CPPI and EMAC slave interfaces are input directly to a VBUSP to VBUSP retiming bridge before being input to the switched central resource (SCR) inside the respective modules. The retiming bridges help to minimize long paths.

The SCR handles decode between multiple master/slaves inside the respective modules. The interrupt control block is used to select the interrupts from the EMAC and the MDIO for output to the three CPU's.

The signals required to support gigabit mode are included in the module. However gigabit transfer rates are not supported due to the small 3-cell transmit and receive FIFO's. The upper nibble of the GMII transmit and receive busses can be unused for MII pinout. Also, the RFTCLK input can be tied low for 10/100 operation.

Figure 22-1. EMAC and MDIO Block Diagram

22.1.4 Industry Standard(s) Compliance Statement

The EMAC peripheral conforms to the IEEE 802.3 standard, describing the Carrier Sense Multiple Access with Collision Detection (CSMA/CD) Access Method and Physical Layer specifications. The IEEE 802.3 standard has also been adopted by ISO/IEC and re-designated as ISO/IEC 8802-3:2000(E).

However, the EMAC deviates from the standard in the way it handles transmit underflow errors. The EMAC MII interface does not use the Transmit Coding Error signal MTXER. Instead of driving the error pin when an underflow condition occurs on a transmitted frame, the EMAC intentionally generates an incorrect checksum by inverting the frame CRC, so that the transmitted frame is detected as an error by the network.

22.2 Architecture

This section discusses the architecture and basic function of the EMAC peripheral.

22.2.1 Clock Control

All internal EMAC logic is clocked synchronously on one clock domain.

The MDIO clock is based on a divide-down of the peripheral clock and is specified to run up to 2.5 MHz (although typical operation would be 1.0 MHz). Because the peripheral clock frequency is variable, the application software or driver must control the divide-down value. Interface clock is running at 166MHz and the VBUSP clock is running at 166MHz.

The clock sources are provided by the external PHY to the RMI reference clock pin. Data is transmitted and received with respect to the reference clocks of the interface pins.

The RMI interface frequency for the transmit and receive clocks are fixed at 50 MHz for both 10 Mbps and 100 Mbps.

22.2.2 Memory Map

The EMAC peripheral includes internal memory that is used to hold buffer descriptions of the Ethernet packets to be received and transmitted. This internal RAM is 2K x 32 bits in size. Data can be written to and read from the EMAC internal memory by either the EMAC or the CPU. It is used to store buffer descriptors that are 4-words (16-bytes) deep. This 8K local memory holds enough information to transfer up to 512 Ethernet packets without CPU intervention. This EMAC RAM is also referred to as the CPPI buffer descriptor memory because it complies with the Communications Port Programming Interface (CPPI) v3.0 standard.

The packet buffer descriptors can also be placed in other on- and off-chip memories. There are some tradeoffs in terms of cache performance and throughput when descriptors are placed in the system memory, versus when they are placed in the EMAC's internal memory. In general, the EMAC throughput is better when the descriptors are placed in the local EMAC CPPI RAM.

22.2.2.1 CPPI Descriptors

The base address of CPPI descriptors is 5C02 0000h.

The 8K bytes of CPPI memory begin at address 01E2 0000h from the EMAC perspective.

22.2.2.2 EMAC Subsystem Module

The base address of EMAC subsystem is 5C00 0000h.

22.2.2.3 EMAC Module

The base address of EMAC module is 5C01 0000h.

22.2.2.4 MDIO Module

The base address of MDIO module is 5C03 0000h.

22.2.3 Signal Descriptions

22.2.3.1 RMII Receive (RX)

The CPRMII receive (RX) interface converts the input data from the external RMII PHY (or switch) into the required MII (EMAC) signals. The carrier sense and collision signals are determined from the RMII input data stream and transmit inputs as defined in the RMII specification.

An asserted RMII_RXER on any di-bit in the received packet will cause an MII_RXER assertion to the EMAC during the packet. In 10Mbps mode, the error is not required to be duplicated on 10 successive clocks. Any di-bit which has an asserted RMII_RXER during any of the 10 replications of the data will cause the error to be propagated.

Any received packet that ends with an improper nibble boundary aligned RMII_CRS_DV toggle will issue an MII_RXER during the packet to the EMAC. Also, a change in speed or duplex mode during packet operations will cause packet corruption.

The CPRMII can accept receive packets with shortened preambles, but 0x55 followed by a 0x5d is the shortest preamble that will be recognized (1 preamble byte with the start of frame byte). At least one byte of preamble with the start of frame indicator is required to begin a packet. An asserted RMII_CRS_DV without at least a single correct preamble byte followed by the start of frame indicator will be ignored.

22.2.3.2 RMII Transmit (TX)

The CPRMII transmit (TX) interface converts the EMAC MII input data into the RMII transmit format. The data is then output to the external RMII PHY.

The EMAC does not source the transmit error (MII_TXERR) signal. Any transmit frame from the EMAC with an error (i.e. underrun) will be indicated as an error by an error CRC. Transmit error is assumed to be deasserted at all times and is not an input into the CPRMII module. Zeroes are output on RMII_TXD[1:0] for each clock that RMII_TXEN is deasserted.

22.2.3.3 Reduced Media Independent Interface (RMII) Connections

Figure 22-2 shows a device with integrated EMAC and MDIO interfaced via a RMII connection in a typical system.

The individual EMAC and MDIO signals for the RMII interface are summarized in Table 22-1. For more information, refer to either the IEEE 802.3 standard or ISO/IEC 8802-3:2000(E).

Figure 22-2. Ethernet Configuration—RMII Connections

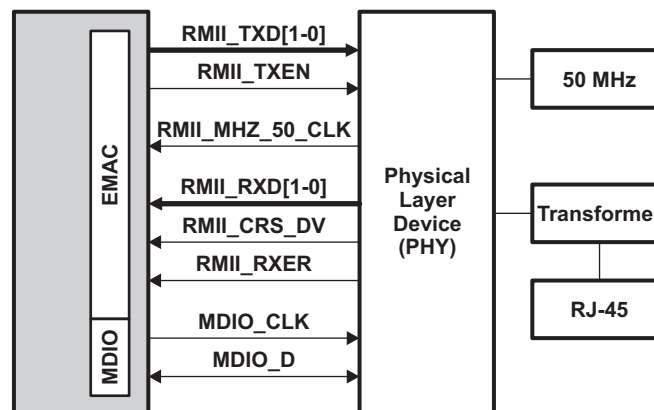

Table 22-1. EMAC and MDIO Signals for RMII Interface

| Signal | Type | Description |
|---------------|------|--|
| RMII_TXD[1-0] | O | Transmit data (RMII_TXD). The transmit data pins are a collection of 2 bits of data. RMTDX0 is the least-significant bit (LSB). The signals are synchronized by RMII_MHZ_50_CLK and valid only when RMII_TXEN is asserted. |

Table 22-1. EMAC and MDIO Signals for RMI Interface (continued)

| Signal | Type | Description |
|-----------------|------|---|
| RMII_TXEN | O | Transmit enable (RMII_TXEN). The transmit enable signal indicates that the RMII_TXD pins are generating data for use by the PHY. RMII_TXEN is synchronous to RMII_MHZ_50_CLK. |
| RMII_MHZ_50_CLK | I | RMII reference clock (RMII_MHZ_50_CLK). The reference clock is used to synchronize all RMII signals. RMII_MHZ_50_CLK must be continuous and fixed at 50 MHz. |
| RMII_RXD[1-0] | I | Receive data (RMII_RXD). The receive data pins are a collection of 2 bits of data. RMRDX0 is the least-significant bit (LSB). The signals are synchronized by RMII_MHZ_50_CLK and valid only when RMII_CRS_DV is asserted and RMII_RXER is deasserted. |
| RMII_CRS_DV | I | Carrier sense/receive data valid (RMII_CRS_DV). Multiplexed signal between carrier sense and receive data valid. |
| RMII_RXER | I | Receive error (RMII_RXER). The receive error signal is asserted to indicate that an error was detected in the received frame. |
| MDIO_CLK | O | Management data clock (MDIO_CLK). The MDIO data clock is sourced by the MDIO module on the system. It is used to synchronize MDIO data access operations done on the MDIO pin. The frequency of this clock is controlled by the CLKDIV bits in the MDIO control register (CONTROL). |
| MDIO_D | I/O | Management data input output (MDIO_D). The MDIO data pin drives PHY management data into and out of the PHY by way of an access frame consisting of start of frame, read/write indication, PHY address, register address, and data bit cycles. The MDIO_D pin acts as an output for all but the data bit cycles at which time it is an input for read operations. |

22.2.4 Ethernet Protocol Overview

A brief overview of the Ethernet protocol is given in the following subsections. See the IEEE 802.3 standard document for in-depth information on the Carrier Sense Multiple Access with Collision Detection (CSMA/CD) Access Method.

22.2.4.1 Ethernet Frame Format

All the Ethernet technologies use the same frame structure. The format of an Ethernet frame is shown in Figure 22-3 and described in Table 22-2. The Ethernet packet, which is the collection of bytes representing the data portion of a single Ethernet frame on the wire, is shown outlined in bold. The Ethernet frames are of variable lengths, with no frame smaller than 64 bytes or larger than RXMAXLEN bytes (header, data, and CRC).

Figure 22-3. Ethernet Frame Format

Legend: SFD=Start Frame Delimiter; FCS=Frame Check Sequence (CRC)

Table 22-2. Ethernet Frame Description

| Field | Bytes | Description |
|-------------|-------|---|
| Preamble | 7 | Preamble. These 7 bytes have a fixed value of 55h and serve to wake up the receiving EMAC ports and to synchronize their clocks to that of the sender's clock. |
| SFD | 1 | Start of Frame Delimiter. This field with a value of 5Dh immediately follows the preamble pattern and indicates the start of important data. |
| Destination | 6 | Destination address. This field contains the Ethernet MAC address of the EMAC port for which the frame is intended. It may be an individual or multicast (including broadcast) address. When the destination EMAC port receives an Ethernet frame with a destination address that does not match any of its MAC physical addresses, and no promiscuous, multicast or broadcast channel is enabled, it discards the frame. |
| Source | 6 | Source address. This field contains the MAC address of the Ethernet port that transmits the frame to the Local Area Network. |

Table 22-2. Ethernet Frame Description (continued)

| Field | Bytes | Description |
|-------|--------------------------|--|
| Len | 2 | Length/Type field. The length field indicates the number of EMAC client data bytes contained in the subsequent data field of the frame. This field can also be used to identify the type of data the frame is carrying. |
| Data | 46 to (RXMAXLEN - 18) | Data field. This field carries the datagram containing the upper layer protocol frame, that is, IP layer datagram. The maximum transfer unit (MTU) of Ethernet is (RXMAXLEN - 18) bytes. This means that if the upper layer protocol datagram exceeds (RXMAXLEN - 18) bytes, then the host has to fragment the datagram and send it in multiple Ethernet packets. The minimum size of the data field is 46 bytes. This means that if the upper layer datagram is less than 46 bytes, the data field has to be extended to 46 bytes by appending extra bits after the data field, but prior to calculating and appending the FCS. |
| FCS | 4 | Frame Check Sequence. A cyclic redundancy check (CRC) is used by the transmit and receive algorithms to generate a CRC value for the FCS field. The frame check sequence covers the 60 to 1514 bytes of the packet data. Note that this 4-byte field may or may not be included as part of the packet data, depending on how the EMAC is configured. |

22.2.4.2 Ethernet's Multiple Access Protocol

Nodes in an Ethernet Local Area Network are interconnected by a broadcast channel -- when an EMAC port transmits a frame, all the adapters on the local network receive the frame. Carrier Sense Multiple Access with Collision Detection (CSMA/CD) algorithms are used when the EMAC operates in half-duplex mode. When operating in full-duplex mode, there is no contention for use of a shared medium because there are exactly two ports on the local network.

Each port runs the CSMA/CD protocol without explicit coordination with the other ports on the Ethernet network. Within a specific port, the CSMA/CD protocol works as follows:

1. The port obtains data from upper layer protocols at its node, prepares an Ethernet frame, and puts the frame in a buffer.
2. If the port senses that the medium is idle, it starts to transmit the frame. If the port senses that the transmission medium is busy, it waits until it no longer senses energy (plus an Inter-Packet Gap time) and then starts to transmit the frame.
3. While transmitting, the port monitors for the presence of signal energy coming from other ports. If the port transmits the entire frame without detecting signal energy from other Ethernet devices, the port is done with the frame.
4. If the port detects signal energy from other ports while transmitting, it stops transmitting its frame and instead transmits a 48-bit jam signal.
5. After transmitting the jam signal, the port enters an exponential backoff phase. If a data frame encounters back-to-back collisions, the port chooses a random value that is dependent on the number of collisions. The port then waits an amount of time that is a multiple of this random value and returns to step 2.

22.2.5 Programming Interface of Packet Descriptors

22.2.5.1 CPPI Packet Buffer Descriptors

The buffer descriptor is a central part of the EMAC module and is how the application software describes Ethernet packets to be sent and empty buffers to be filled with incoming packet data. The basic descriptor format is shown in [Figure 22-4](#) and described in [Table 22-3](#).

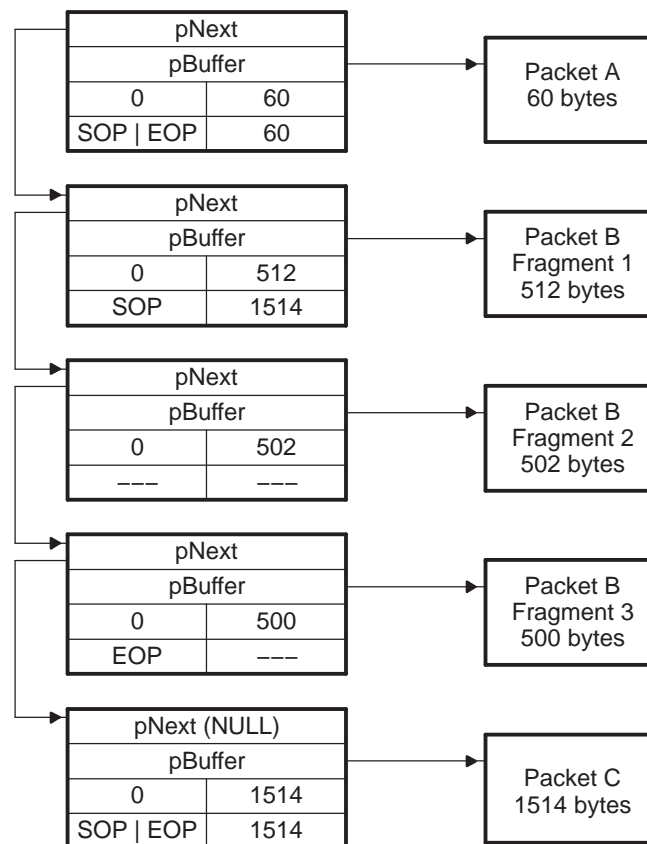

For example, consider three packets to be transmitted: Packet A is a single fragment (60 bytes), Packet B is fragmented over three buffers (1514 bytes total), and Packet C is a single fragment (1514 bytes). The linked list of descriptors to describe these three packets is shown in [Figure 22-5](#).

Figure 22-4. Basic Descriptor Format

| Word Offset | Bit Fields | | 0 |
|----------------|-------------------------|---------|---------------|
| | 31 | 16 15 | |
| 0 | Next Descriptor Pointer | | |
| 1 | Buffer Pointer | | |
| 2 | Buffer Offset | | Buffer Length |
| 3 | Flags | | Packet Length |

Table 22-3. Basic Descriptor Description

| Word Offset | Field | Field Description |
|-------------|-------------------------|--|
| 0 | Next Descriptor Pointer | The next descriptor pointer is used to create a single linked list of descriptors. Each descriptor describes a packet or a packet fragment. When a descriptor points to a single buffer packet or the first fragment of a packet, the start of packet (SOP) flag is set in the flags field. When a descriptor points to a single buffer packet or the last fragment of a packet, the end of packet (EOP) flag is set. When a packet is fragmented, each fragment must have its own descriptor and appear sequentially in the descriptor linked list. |
| 1 | Buffer Pointer | The buffer pointer refers to the actual memory buffer that contains packet data during transmit operations, or is an empty buffer ready to receive packet data during receive operations. |
| 2 | Buffer Offset | The buffer offset is the offset from the start of the packet buffer to the first byte of valid data. This field only has meaning when the buffer descriptor points to a buffer that actually contains data. |
| | Buffer Length | The buffer length is the actual number of valid packet data bytes stored in the buffer. If the buffer is empty and waiting to receive data, this field represents the size of the empty buffer. |
| 3 | Flags | The flags field contains more information about the buffer, such as, is it the first fragment in a packet (SOP), the last fragment in a packet (EOP), or contains an entire contiguous Ethernet packet (both SOP and EOP). The flags are described in Section 22.2.5.4 and Section 22.2.5.5 . |
| | Packet Length | The packet length only has meaning for buffers that both contain data and are the start of a new packet (SOP). In the case of SOP descriptors, the packet length field contains the length of the entire Ethernet packet, regardless if it is contained in a single buffer or fragmented over several buffers. |

Figure 22-5. Typical Descriptor Linked List

22.2.5.2 Transmit and Receive Descriptor Queues

The EMAC module processes descriptors in linked lists as discussed in [Section 22.2.5.1](#). The lists used by the EMAC are maintained by the application software through the use of the head descriptor pointer registers (HDP). Since the EMAC supports eight channels for transmit and receive, there are eight head descriptor pointer registers for both transmit and receive. They are:

- TX n HDP - Transmit Channel n DMA Head Descriptor Pointer Register
- RX n HDP - Receive Channel n DMA Head Descriptor Pointer Register

After an EMAC reset and before enabling the EMAC for send and receive, all 16 head descriptor pointer registers must be initialized to 0.

The EMAC uses a simple system to determine if a descriptor is currently owned by the EMAC or by the application software. There is a flag in the buffer descriptor flags called OWNER. When this flag is set, the packet that is referenced by the descriptor is considered to be owned by the EMAC. Note that ownership is done on a packet based granularity, not on descriptor granularity, so only SOP descriptors make use of the OWNER flag. As packets are processed, the EMAC patches the SOP descriptor of the corresponding packet and clears the OWNER flag. This is an indication that the EMAC has finished processing all descriptors up to and including the first with the EOP flag set, indicating the end of the packet (note this may only be one descriptor with both the SOP and EOP flags set).

To add a descriptor or a linked list of descriptors to an EMAC descriptor queue for the first time, the software application simply writes the pointer to the descriptor or first descriptor of a list to the corresponding HDP register. Note that the last descriptor in the list must have its “next” pointer cleared to 0. This is the only way the EMAC has of detecting the end of the list. Therefore, in the case where only a single descriptor is added, its “next descriptor” pointer must be initialized to 0.

The HDP must never be written to while a list is active. To add additional descriptors to a descriptor list already owned by the EMAC, the NULL “next” pointer of the last descriptor of the previous list is patched with a pointer to the first descriptor of the new list. The list of new descriptors to be appended to the existing list must itself be NULL terminated before the pointer patch is performed.

There is a potential race condition where the EMAC may read the “next” pointer of a descriptor as NULL in the instant before an application appends additional descriptors to the list by patching the pointer. This case is handled by the software application always examining the buffer descriptor flags of all EOP packets, looking for a special flag called end of queue (EOQ). The EOQ flag is set by the EMAC on the last descriptor of a packet when the descriptor’s “next” pointer is NULL. This is the way the EMAC indicates to the software application that it believes it has reached the end of the list. When the software application sees the EOQ flag set, the application may at that time submit the new list, or the portion of the appended list that was missed by writing the new list pointer to the same HDP that started the process.

This process applies when adding packets to a transmit list, and empty buffers to a receive list.

22.2.5.3 Transmit and Receive EMAC Interrupts

The EMAC processes descriptors in linked list chains as discussed in [Section 22.2.5.1](#), using the linked list queue mechanism discussed in [Section 22.2.5.2](#).

The EMAC synchronizes descriptor list processing through the use of interrupts to the software application. The interrupts are controlled by the application using the interrupt masks, global interrupt enable, and the completion pointer register (CP). The CP is also called the interrupt acknowledge register.

As the EMAC supports eight channels for both transmit and receive, there are eight completion pointer registers for both. They are:

- TX n CP - Transmit Channel n Completion Pointer (Interrupt Acknowledge) Register
- RX n CP - Receive Channel n Completion Pointer (Interrupt Acknowledge) Register

These registers serve two purposes. When read, they return the pointer to the last descriptor that the EMAC has processed. When written by the software application, the value represents the last descriptor processed by the software application. When these two values do not match, the interrupt is active.

Interrupts in the interrupt control module of EMAC subsystem are routed to three independent interrupt cores which are then mapped to CPU interrupt controllers. The system configuration determines whether or not an active interrupt actually interrupts the CPU. In general the following settings are required for basic EMAC transmit and receive interrupts:

1. EMAC transmit and receive interrupts are enabled by setting the mask registers RXINTMASKSET and TXINTMASKSET
2. Global interrupts for the appropriate interrupt core registers are set in the EMAC interrupt control module: C n RXEN and C n TXEN on core n
3. The CPU interrupt controller is configured to accept C n _RX_PULSE and C n _TX_PULSE interrupts from the interrupt control module of EMAC subsystem

Whether or not the interrupt is enabled, the current state of the receive or transmit channel interrupt can be examined directly by the software application reading the EMAC receive interrupt status (unmasked) register (RXINTSTATRAW) and transmit interrupt status (unmasked) register (TXINTSTATRAW).

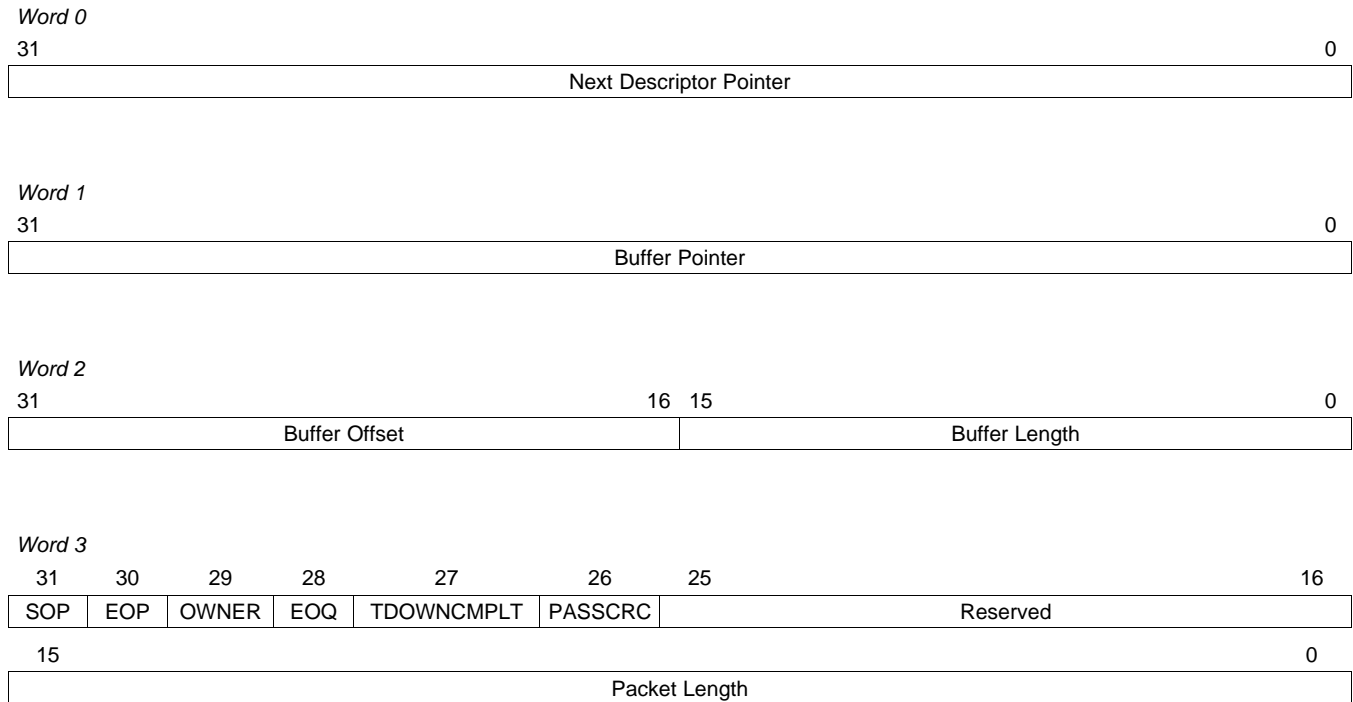

After servicing transmit or receive interrupts, the application software must acknowledge both the EMAC and EMAC subsystem interrupts.

EMAC interrupts are acknowledged when the application software updates the value of TX n CP or RX n CP with a value that matches the internal value kept by the EMAC. This mechanism ensures that the application software never misses an EMAC interrupt because the interrupt acknowledgment is tied directly to the buffer descriptor processing.

EMAC module interrupts are acknowledged when the application software writes the appropriate C n TX or C n RX key to the EMAC End-Of-Interrupt Vector register (MACEOIVECTOR). The MACEOIVECTOR behaves as an interrupt pulse interlock -- once the EMAC interrupt control module has issued an interrupt pulse to the CPU, it will not generate further pulses of the same type until the original pulse has been acknowledged.

22.2.5.4 CPPI Transmit Buffer Descriptor Format

Transmit buffer descriptors contain a minimum of 16 bytes (4 words) and are 32-bit aligned structures located in host memory. Tx buffer descriptors provide information about the descriptor data buffer and channel queue. Four words are required, but protocol specific control information may be added by using as many extra words as necessary. Transmit buffer descriptors may be linked together to form packets. Buffer descriptor SOP and EOP bits are used to delimit packets. Packets in turn may be linked together to form transmit queues. Each queue consists of a chain of buffer descriptors linked together by Next Descriptor Pointers. The last buffer descriptor in a queue has a zero Next Descriptor Pointer. Each descriptor points to a data buffer yielding a queue of buffers. Each transmit buffer descriptor contains at least four 32-bit words.

Figure 22-6. Transmit Buffer Descriptor Format**Example 22-1. Transmit Buffer Descriptor in C Structure Format**

```

/*
// EMAC Descriptor
//
// The following is the format of a single buffer descriptor
// on the EMAC.
*/
typedef struct _EMAC_Desc {
    struct _EMAC_Desc *pNext; /* Pointer to next descriptor in chain */
    Uint8 *pBuffer; /* Pointer to data buffer */
    Uint32 BufOffLen; /* Buffer Offset(MSW) and Length(LSW) */
    Uint32 PktFlgLen; /* Packet Flags(MSW) and Length(LSW) */
} EMAC_Desc;
/* Packet Flags */
#define EMAC_DSC_FLAG_SOP 0x80000000u
#define EMAC_DSC_FLAG_EOP 0x40000000u
#define EMAC_DSC_FLAG_OWNER 0x20000000u
#define EMAC_DSC_FLAG_EOQ 0x10000000u
#define EMAC_DSC_FLAG_TDOWNCMLPT 0x08000000u
#define EMAC_DSC_FLAG_PASSCRC 0x04000000u

```

22.2.5.4.1 Next Descriptor Pointer

The next descriptor pointer points to the 32-bit word aligned memory address of the next buffer descriptor in the transmit queue. This pointer is used to create a linked list of buffer descriptors. If the value of this pointer is zero, then the current buffer is the last buffer in the queue. The software application must set this value prior to adding the descriptor to the active transmit list. This pointer is not altered by the EMAC.

The value of pNext should never be altered once the descriptor is in an active transmit queue, unless its current value is NULL. If the pNext pointer is initially NULL, and more packets need to be queued for

transmit, the software application may alter this pointer to point to a newly appended descriptor. The EMAC will use the new pointer value and proceed to the next descriptor unless the pNext value has already been read. In this latter case, the transmitter will halt on the transmit channel in question, and the software application may restart it at that time. The software can detect this case by checking for an end of queue (EOQ) condition flag on the updated packet descriptor when it is returned by the EMAC.

22.2.5.4.2 Buffer Pointer

The buffer pointer is the byte-aligned memory address of the memory buffer associated with the buffer descriptor. The software application must set this value prior to adding the descriptor to the active transmit list. This pointer is not altered by the EMAC.

22.2.5.4.3 Buffer Offset

This 16-bit field indicates how many unused bytes are at the start of the buffer. For example, a value of 0000h indicates that no unused bytes are at the start of the buffer and that valid data begins on the first byte of the buffer, while a value of 000Fh indicates that the first 15 bytes of the buffer are to be ignored by the EMAC and that valid buffer data starts on byte 16 of the buffer. The software application must set this value prior to adding the descriptor to the active transmit list. This field is not altered by the EMAC.

Note that this value is only checked on the first descriptor of a given packet (where the start of packet (SOP) flag is set). It can not be used to specify the offset of subsequent packet fragments. Also, since the buffer pointer may point to any byte-aligned address, this field may be entirely superfluous, depending on the device driver architecture.

The range of legal values for this field is 0 to (Buffer Length – 1).

22.2.5.4.4 Buffer Length

This 16-bit field indicates how many valid data bytes are in the buffer. On single fragment packets, this value is also the total length of the packet data to be transmitted. If the buffer offset field is used, the offset bytes are not counted as part of this length. This length counts only valid data bytes. The software application must set this value prior to adding the descriptor to the active transmit list. This field is not altered by the EMAC.

22.2.5.4.5 Packet Length

This 16-bit field specifies the number of data bytes in the entire packet. Any leading buffer offset bytes are not included. The sum of the buffer length fields of each of the packet's fragments (if more than one) must be equal to the packet length. The software application must set this value prior to adding the descriptor to the active transmit list. This field is not altered by the EMAC. This value is only checked on the first descriptor of a given packet (where the start of packet (SOP) flag is set).

22.2.5.4.6 Start of Packet (SOP) Flag

When set, this flag indicates that the descriptor points to a packet buffer that is the start of a new packet. In the case of a single fragment packet, both the SOP and end of packet (EOP) flags are set. Otherwise, the descriptor pointing to the last packet buffer for the packet sets the EOP flag. This bit is set by the software application and is not altered by the EMAC.

22.2.5.4.7 End of Packet (EOP) Flag

When set, this flag indicates that the descriptor points to a packet buffer that is last for a given packet. In the case of a single fragment packet, both the start of packet (SOP) and EOP flags are set. Otherwise, the descriptor pointing to the last packet buffer for the packet sets the EOP flag. This bit is set by the software application and is not altered by the EMAC.

22.2.5.4.8 Ownership (OWNER) Flag

When set, this flag indicates that all the descriptors for the given packet (from SOP to EOP) are currently owned by the EMAC. This flag is set by the software application on the SOP packet descriptor before adding the descriptor to the transmit descriptor queue. For a single fragment packet, the SOP, EOP, and OWNER flags are all set. The OWNER flag is cleared by the EMAC once it is finished with all the descriptors for the given packet. Note that this flag is valid on SOP descriptors only.

22.2.5.4.9 End of Queue (EOQ) Flag

When set, this flag indicates that the descriptor in question was the last descriptor in the transmit queue for a given transmit channel, and that the transmitter has halted. This flag is initially cleared by the software application prior to adding the descriptor to the transmit queue. This bit is set by the EMAC when the EMAC identifies that a descriptor is the last for a given packet (the EOP flag is set), and there are no more descriptors in the transmit list (next descriptor pointer is NULL).

The software application can use this bit to detect when the EMAC transmitter for the corresponding channel has halted. This is useful when the application appends additional packet descriptors to a transmit queue list that is already owned by the EMAC. Note that this flag is valid on EOP descriptors only.

22.2.5.4.10 Teardown Complete (TDOWNCMPLT) Flag

This flag is used when a transmit queue is being torn down, or aborted, instead of allowing it to be transmitted. This would happen under device driver reset or shutdown conditions. The EMAC sets this bit in the SOP descriptor of each packet as it is aborted from transmission.

Note that this flag is valid on SOP descriptors only. Also note that only the first packet in an unsent list has the TDOWNCMPLT flag set. Subsequent descriptors are not processed by the EMAC.

22.2.5.4.11 Pass CRC (PASSCRC) Flag

This flag is set by the software application in the SOP packet descriptor before it adds the descriptor to the transmit queue. Setting this bit indicates to the EMAC that the 4 byte Ethernet CRC is already present in the packet data, and that the EMAC should not generate its own version of the CRC.

When the CRC flag is cleared, the EMAC generates and appends the 4-byte CRC. The buffer length and packet length fields do not include the CRC bytes. When the CRC flag is set, the 4-byte CRC is supplied by the software application and is already appended to the end of the packet data. The buffer length and packet length fields include the CRC bytes, as they are part of the valid packet data. Note that this flag is valid on SOP descriptors only.

Table 22-4. Tx Buffer Descriptor Word 0

| Bits | Name | Description |
|------|------------------------|--|
| 31:0 | Next DescriptorPointer | Next Descriptor Pointer: The 32-bit word aligned memory address of the next buffer descriptor in the Tx queue. This is the mechanism used to reference the next buffer descriptor from the current buffer descriptor. If the value of this pointer is zero then the current buffer is the last buffer in the queue. The host sets the Next Descriptor Pointer. |

Table 22-5. Tx Buffer Descriptor Word 1

| Bits | Name | Description |
|------|----------------|--|
| 31:0 | Buffer Pointer | Buffer Pointer: The Buffer Pointer is the byte aligned memory address of the buffer associated with the buffer desc. The host sets the Buffer Pointer. |

Table 22-6. Tx Buffer Descriptor Word 2

| Bits | Name | Description |
|-------|---------------|---|
| 31:16 | Buffer Offset | Buffer Offset: The Buffer Offset indicates how many unused bytes are at the start of the buffer (SOP buffers only). A value of zero indicates that there are no unused bytes at the start of the buffer and that valid data begins on the first byte of the buffer. A value of 000fh (decimal 15) indicates that the first 15 bytes of the buffer are to be ignored by the port and that valid buffer data starts on byte 16 of the buffer. The Buffer Offset is valid only on Start Of Packet buffer descriptors and must be zero otherwise. The host sets the Buffer Offset. The Buffer Offset must be less than the Buffer Length. |
| 15:0 | Buffer Length | Buffer Length: The Buffer Length field indicates how many valid data bytes are in the buffer. Unused or protocol specific bytes at the beginning of the buffer are not counted in the Buffer Length field. The host sets the Buffer Length. |

Table 22-7. Tx Buffer Descriptor Word 3

| Bits | Name | Description |
|-------|-------------------|--|
| 31 | SOP | Start of Packet: SOP Indicates that the descriptor buffer is the first buffer in the packet. The host sets the SOP bit. 0 = Not start of packet buffer 1 = Start of packet buffer |
| 30 | EOP | End of Packet: EOP Indicates that the descriptor buffer is the last buffer in the packet. The host sets the EOP bit. 0 = Not end of packet buffer. 1 = End of packet buffer. |
| 29 | Ownership | Ownership: The Ownership bit indicates ownership of the packet and is valid only on SOP. This bit is set by the host and cleared by the port when the packet has been transmitted. The host uses this bit to reclaim buffers. 0 = The packet is owned by the host 1 = The packet is owned by the port |
| 28 | EOQ | End Of Queue: The End of Queue bit is set by the port to indicate that all packets in the queue have been transmitted and the Tx queue is empty. This bit is valid only on EOP. 0 = The Tx queue has more packets to transfer. 1 = The port took this descriptor buffer as the last buffer descriptor in the last packet in the queue. |
| 27:16 | Protocol Specific | |
| 15:0 | Packet Length | Packet Length: The length of the packet in bytes. This field is valid only on SOP and is written by the host. If the Packet Length is less than the sum of the buffer lengths, then the packet data will be truncated. A Packet Length greater than the sum of the buffers is a host error. |

22.2.5.5 CPPI Receive Buffer Descriptor Format

Receive buffer descriptors contain a minimum of 16 bytes (4 words) and are 32-bit aligned structures located in host memory. Rx buffer descriptors provide information about the associated data buffer and Rx queue. Four words are required, but protocol specific control information may be added using as many extra words as necessary. The protocol specific control information is valid only on SOP buffers.

Receive buffer descriptors contain a minimum of 16 bytes (4 words) and are 32-bit aligned structures located in host memory. Rx buffer descriptors provide information about the associated data buffer and Rx queue. Four words are required, but protocol specific control information may be added using as many extra words as necessary. The protocol specific control information is valid only on SOP buffers. Receive buffer descriptors may be linked together to form packets. Buffer descriptor SOP and EOP bits are used to delimit packets. Packets in turn are linked together to form receive queues (although an Rx queue may consist of just one packet). Each queue consists of a chain of buffer descriptors linked together by Next Descriptor Pointers. The last buffer descriptor in a queue has a zero Next Descriptor Pointer. Each descriptor points to a data buffer yielding a queue of buffers. Each receive buffer descriptor contains at least four 32-bit words, as described below:

Table 22-8. Rx Buffer Descriptor Word 0

| Bits | Name | Description |
|------|------------------------|--|
| 31:0 | Next DescriptorPointer | Next Descriptor Pointer: The 32-bit word aligned memory address of the next buffer descriptor in the Rx queue. This is the mechanism used to reference the next buffer descriptor from the current buffer descriptor. The current buffer is the last buffer in the queue if the value of this pointer is zero. The host sets the Next Descriptor Pointer |

Table 22-9. Rx Buffer Descriptor Word 1

| Bits | Name | Description |
|------|----------------|--|
| 31:0 | Buffer Pointer | Buffer Pointer: The Buffer Pointer is the byte aligned memory address of the buffer associated with the buffer descriptor. The host sets the Buffer Pointer. |

Table 22-10. Rx Buffer Descriptor Word 2

| Bits | Name | Description |
|-------|---------------|---|
| 31:16 | Buffer Offset | Buffer Offset: The Buffer Offset indicates how many unused bytes are at the beginning of the SOP buffer. A value of 0x0000 indicates that there are no unused bytes at the beginning of the buffer and that valid data begins on the first byte of the buffer. A value of 0x000f (decimal 15) indicates that the first 15 bytes of the buffer are to be ignored by the port and that valid buffer data starts on byte 16 of the buffer. The host sets the buffer offset to zero on buffer initialization and the port overwrites the zero value on SOP packets with the Rx DMA State buffer offset value. |
| 15:0 | Buffer Length | Buffer Length: The Buffer Length field indicates how many valid data bytes are in the buffer. Unused or protocol specific bytes at the beginning of the buffer are not counted in the Buffer Length field. The host sets the buffer length on buffer initialization. The port will overwrite the host initialized value on an EOP buffer when the number of received data bytes is less than the host initiated value. The port will overwrite the host initialized value on SOP when the Buffer Offset is greater than zero, or the Packet Length is less than the buffer length. |

Table 22-11. Rx Buffer Descriptor Word 3

| Bits | Name | Description |
|-------|-------------------|--|
| 31 | SOP | Start of Packet: SOP Indicates that the descriptor buffer is the first buffer in the packet. The host sets the SOP bit. 0 = Not start of packet buffer 1 = Start of packet buffer |
| 30 | EOP | End of Packet: EOP Indicates that the descriptor buffer is the last buffer in the packet. The host sets the EOP bit. 0 = Not end of packet buffer. 1 = End of packet buffer. |
| 29 | Ownership | Ownership: The Ownership bit indicates ownership of the packet and is valid only on SOP. This bit is set by the host and cleared by the port when the packet has been received. 0 = The packet is owned by the host. 1 = The packet is owned by the port. |
| 28 | EOQ | End Of Queue: The End of Queue bit is set by the port to indicate that the queue empty condition exists. This bit is valid only on EOP. 0 = The Rx queue has more buffers available for reception. 1 = The Descriptor buffer is the last buffer in the last packet in the queue. |
| 27:16 | Protocol Specific | |
| 15:0 | Packet Length | Packet Length: The length of the packet in bytes. This field is valid only on SOP and is written by the port at the end of the packet reception. |

22.2.5.5.1 Next Descriptor Pointer

This pointer points to the 32-bit word aligned memory address of the next buffer descriptor in the receive queue. This pointer is used to create a linked list of buffer descriptors. If the value of this pointer is zero, then the current buffer is the last buffer in the queue. The software application must set this value prior to adding the descriptor to the active receive list. This pointer is not altered by the EMAC.

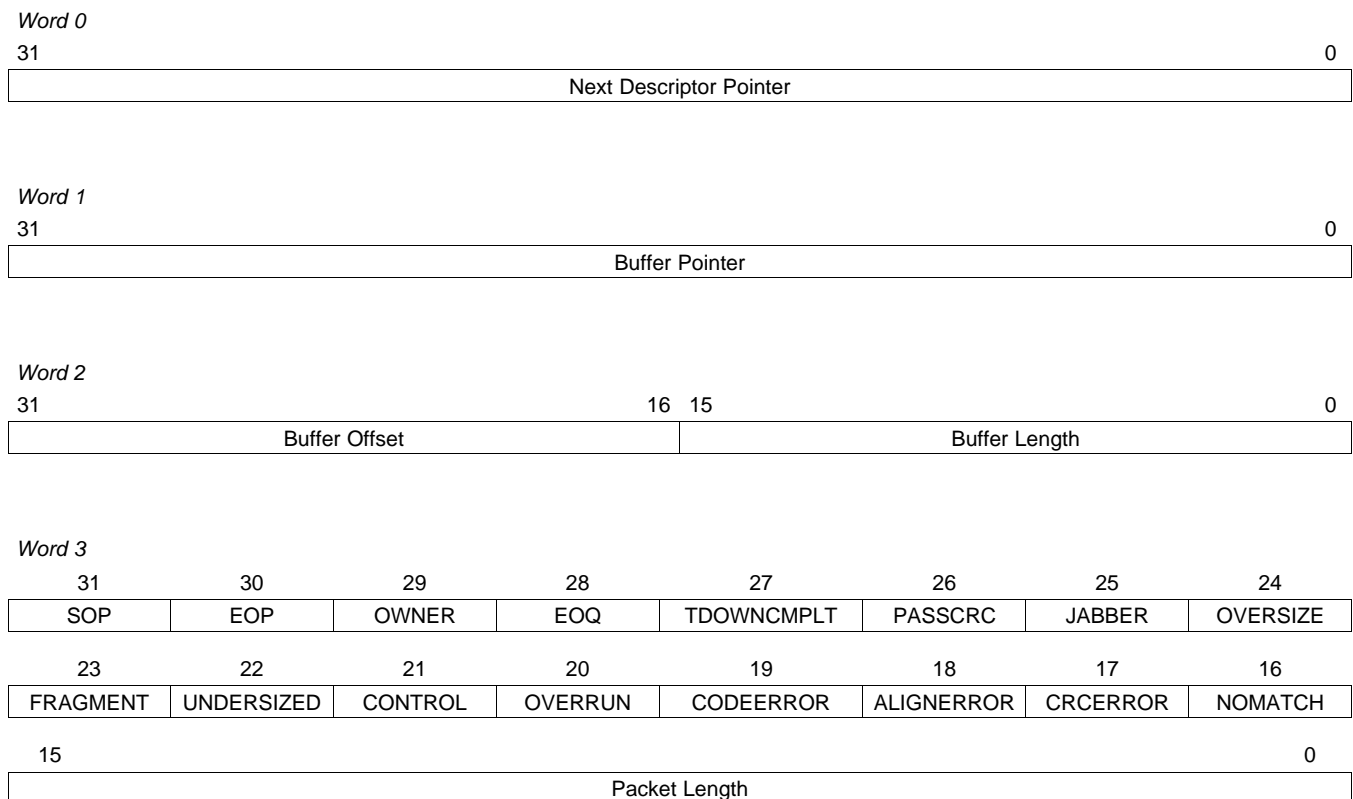

The value of pNext should never be altered once the descriptor is in an active receive queue, unless its

current value is NULL. If the pNext pointer is initially NULL, and more empty buffers can be added to the pool, the software application may alter this pointer to point to a newly appended descriptor. The EMAC will use the new pointer value and proceed to the next descriptor unless the pNext value has already been read. In this latter case, the receiver will halt the receive channel in question, and the software application may restart it at that time. The software can detect this case by checking for an end of queue (EOQ) condition flag on the updated packet descriptor when it is returned by the EMAC.

22.2.5.5.2 Buffer Pointer

The buffer pointer is the byte-aligned memory address of the memory buffer associated with the buffer descriptor. The software application must set this value prior to adding the descriptor to the active receive list. This pointer is not altered by the EMAC.

Figure 22-7. Receive Buffer Descriptor Format

Example 22-2. Receive Buffer Descriptor in C Structure Format

```

/*
// EMAC Descriptor
//
// The following is the format of a single buffer descriptor
// on the EMAC.
*/
typedef struct _EMAC_Desc {
    struct _EMAC_Desc *pNext; /* Pointer to next descriptor in chain */
    struct _EMAC_Desc *pNext; /* Pointer to next descriptor in chain */
    UInt32      BufOffLen; /* Buffer Offset(MSW) and Length(LSW) */
    UInt32
    PktFlgLen; /* Packet Flags(MSW) and Length(LSW) */
} EMAC_Desc;

/* Packet Flags */

```

22.2.5.5.3 Buffer Offset

This 16-bit field must be initialized to zero by the software application before adding the descriptor to a receive queue.

Whether or not this field is updated depends on the setting of the RXBUFFEROFFSET register. When the offset register is set to a non-zero value, the received packet is written to the packet buffer at an offset given by the value of the register, and this value is also written to the buffer offset field of the descriptor.

When a packet is fragmented over multiple buffers because it does not fit in the first buffer supplied, the buffer offset only applies to the first buffer in the list, which is where the start of packet (SOP) flag is set in the corresponding buffer descriptor. In other words, the buffer offset field is only updated by the EMAC on SOP descriptors.

The range of legal values for the BUFFEROFFSET register is 0 to (Buffer Length – 1) for the smallest value of buffer length for all descriptors in the list.

22.2.5.5.4 Buffer Length

This 16-bit field is used for two purposes:

- Before the descriptor is first placed on the receive queue by the application software, the buffer length field is first initialized by the software to have the physical size of the empty data buffer pointed to by the buffer pointer field.
- After the empty buffer has been processed by the EMAC and filled with received data bytes, the buffer length field is updated by the EMAC to reflect the actual number of valid data bytes written to the buffer.

22.2.5.5.5 Packet Length

This 16-bit field specifies the number of data bytes in the entire packet. This value is initialized to zero by the software application for empty packet buffers. The value is filled in by the EMAC on the first buffer used for a given packet. This is signified by the EMAC setting a start of packet (SOP) flag. The packet length is set by the EMAC on all SOP buffer descriptors.

22.2.5.5.6 Start of Packet (SOP) Flag

When set, this flag indicates that the descriptor points to a packet buffer that is the start of a new packet. In the case of a single fragment packet, both the SOP and end of packet (EOP) flags are set. Otherwise, the descriptor pointing to the last packet buffer for the packet has the EOP flag set. This flag is initially cleared by the software application before adding the descriptor to the receive queue. This bit is set by the EMAC on SOP descriptors.

22.2.5.5.7 End of Packet (EOP) Flag

When set, this flag indicates that the descriptor points to a packet buffer that is last for a given packet. In the case of a single fragment packet, both the start of packet (SOP) and EOP flags are set. Otherwise, the descriptor pointing to the last packet buffer for the packet has the EOP flag set. This flag is initially cleared by the software application before adding the descriptor to the receive queue. This bit is set by the EMAC on EOP descriptors.

22.2.5.5.8 Ownership (OWNER) Flag

When set, this flag indicates that the descriptor is currently owned by the EMAC. This flag is set by the software application before adding the descriptor to the receive descriptor queue. This flag is cleared by the EMAC once it is finished with a given set of descriptors, associated with a received packet. The flag is updated by the EMAC on SOP descriptor only. So when the application identifies that the OWNER flag is cleared on an SOP descriptor, it may assume that all descriptors up to and including the first with the EOP flag set have been released by the EMAC. (Note that in the case of single buffer packets, the same descriptor will have both the SOP and EOP flags set.)

22.2.5.5.9 End of Queue (EOQ) Flag

When set, this flag indicates that the descriptor in question was the last descriptor in the receive queue for a given receive channel, and that the corresponding receiver channel has halted. This flag is initially cleared by the software application prior to adding the descriptor to the receive queue. This bit is set by the EMAC when the EMAC identifies that a descriptor is the last for a given packet received (also sets the EOP flag), and there are no more descriptors in the receive list (next descriptor pointer is NULL).

The software application can use this bit to detect when the EMAC receiver for the corresponding channel has halted. This is useful when the application appends additional free buffer descriptors to an active receive queue. Note that this flag is valid on EOP descriptors only.

22.2.5.5.10 Teardown Complete (TDOWNCMPLT) Flag

This flag is used when a receive queue is being torn down, or aborted, instead of being filled with received data. This would happen under device driver reset or shutdown conditions. The EMAC sets this bit in the descriptor of the first free buffer when the tear down occurs. No additional queue processing is performed.

22.2.5.5.11 Pass CRC (PASSCRC) Flag

This flag is set by the EMAC in the SOP buffer descriptor if the received packet includes the 4-byte CRC. This flag should be cleared by the software application before submitting the descriptor to the receive queue.

22.2.5.5.12 Jabber Flag

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet is a jabber frame and was not discarded because the RXCEFEN bit was set in the RXMBPENABLE. Jabber frames are frames that exceed the RXMAXLEN in length, and have CRC, code, or alignment errors.

22.2.5.5.13 Oversize Flag

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet is an oversized frame and was not discarded because the RXCEFEN bit was set in the RXMBPENABLE.

22.2.5.5.14 Fragment Flag

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet is only a packet fragment and was not discarded because the RXCEFEN bit was set in the RXMBPENABLE.

22.2.5.5.15 Undersized Flag

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet is undersized and was not discarded because the RXCSFEN bit was set in the RXMBPENABLE.

22.2.5.5.16 Control Flag

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet is an EMAC control frame and was not discarded because the RXCMFEN bit was set in the RXMBPENABLE.

22.2.5.5.17 Overrun Flag

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet was aborted due to a receive overrun.

22.2.5.5.18 Code Error (CODEERROR) Flag

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet contained a code error and was not discarded because the RXCEFEN bit was set in the RXMBPENABLE.

22.2.5.5.19 Alignment Error (ALIGNERROR) Flag

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet contained an alignment error and was not discarded because the RXCEFEN bit was set in the RXMBPENABLE.

22.2.5.5.20 CRC Error (CRCERROR) Flag

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet contained a CRC error and was not discarded because the RXCEFEN bit was set in the RXMBPENABLE.

22.2.5.5.21 No Match (NOMATCH) Flag

This flag is set by the EMAC in the SOP buffer descriptor, if the received packet did not pass any of the EMAC's address match criteria and was not discarded because the RXCAFEN bit was set in the RXMBPENABLE. Although the packet is a valid Ethernet data packet, it was only received because the EMAC is in promiscuous mode.

22.2.6 MDIO Module

The MDIO module is used to manage up to 32 physical layer (PHY) devices connected to the Ethernet Media Access Controller (EMAC). The device supports a single PHY being connected to the EMAC at any given time. The MDIO module is designed to allow almost transparent operation of the MDIO interface with little maintenance from the CPU.

The MDIO module continuously polls 32 MDIO addresses in order to enumerate all PHY devices in the system. Once a PHY device has been detected, the MDIO module reads the MDIO PHY link status register (LINK) to monitor the PHY link state. Link change events are stored in the MDIO module, which can interrupt the CPU. This storing of the events allows the CPU to poll the link status of the PHY device without continuously performing MDIO module accesses. However, when the CPU must access the MDIO module for configuration and negotiation, the MDIO module performs the MDIO read or write operation independent of the CPU. This independent operation allows the processor to poll for completion or interrupt the CPU once the operation has completed.

22.2.6.1 MDIO Module Components

The VBUS MII management interface module consists of the following blocks:

- MDIO Regs
- Control and Schedule
- MDIO Interface

Figure 22-8. VBUS MII Management Interface Module

22.2.6.1.1 MDIO Regs

The MDIO regs block provides a VBUSP 2.0 compliant slave interface to the MII Management Interface module. Host interaction with this module is facilitated through the registers in this block.

22.2.6.1.2 Control and Schedule

The control and register logic in the MII Management Interface module contain the state machine and scheduling logic which control the wire side operation.

22.2.6.1.3 MDIO Interface

The MDIO interface block provides the serial interface to the MDIO interface.

22.2.6.2 MDIO Module Operational Overview

The MDIO module implements the 802.3 serial management interface to interrogate and control an Ethernet PHY, using a shared two-wired bus. It separately performs autodetection and records the current link status of up to 32 PHYs, polling all 32 MDIO addresses.

Application software uses the MDIO module to configure the autonegotiation parameters of the PHY attached to the EMAC, retrieve the negotiation results, and configure required parameters in the EMAC.

In this device, the Ethernet PHY attached to the system can be directly controlled and queried. The Media Independent Interface (MII) address of this PHY device is specified in one of the PHYADRMON bits in the MDIO user PHY select register (USERPHYSEL n). The MDIO module can be programmed to trigger a CPU interrupt on a PHY link change event, by setting the LINKINTENB bit in USERPHYSEL n . Reads and writes to registers in this PHY device are performed using the MDIO user access register (USERACCESS n).

The MDIO module powers-up in an idle state until specifically enabled by setting the ENABLE bit in the MDIO control register (CONTROL). At this time, the MDIO clock divider and preamble mode selection are also configured. The MDIO preamble is enabled by default, but can be disabled when the connected PHY does not require it. Once the MDIO module is enabled, the MDIO interface state machine continuously polls the PHY link status (by reading the generic status register) of all possible 32 PHY addresses and records the results in the MDIO PHY alive status register (ALIVE) and MDIO PHY link status register (LINK). The corresponding bit for the connected PHY (0-31) is set in ALIVE, if the PHY responded to the read request. The corresponding bit is set in LINK, if the PHY responded and also is currently linked. In addition, any PHY register read transactions initiated by the application software using USERACCESS n causes ALIVE to be updated.

The USERPHYSEL n is used to track the link status of the connected PHY address. A change in the link status of the PHY being monitored sets the appropriate bit in the MDIO link status change interrupt registers (LINKINTRAW and LINKINTMASKED), if enabled by the LINKINTENB bit in USERPHYSEL n .

While the MDIO module is enabled, the host issues a read or write transaction over the MII management interface using the DATA, PHYADR, REGADR, and WRITE bits in USERACCESS n . When the application sets the GO bit in USERACCESS n , the MDIO module begins the transaction without any further intervention from the CPU. Upon completion, the MDIO module clears the GO bit and sets the corresponding USERINTRAW bit (0 or 1) in the MDIO user command complete interrupt register (USERINTRAW) corresponding to USERACCESS n used. The corresponding USERINTMASKED bit (0 or 1) in the MDIO user command complete interrupt register (USERINTMASKED) may also be set, depending on the mask setting configured in the MDIO user command complete interrupt mask set register (USERINTMASKSET) and the MDIO user interrupt mask clear register (USERINTMASKCLEAR).

A round-robin arbitration scheme is used to schedule transactions that may be queued using both USERACCESS0 and USERACCESS1. The application software must check the status of the GO bit in USERACCESS n before initiating a new transaction, to ensure that the previous transaction has completed. The application software can use the ACK bit in USERACCESS n to determine the status of a read transaction.

22.2.6.2.1 Initializing the MDIO Module

The following steps are performed by the application software or device driver to initialize the MDIO device:

1. Configure the PREAMBLE and CLKDIV bits in the MDIO control register (CONTROL).
2. Enable the MDIO module by setting the ENABLE bit in CONTROL.
3. The MDIO PHY alive status register (ALIVE) can be read in polling fashion until a PHY connected to the system responded, and the MDIO PHY link status register (LINK) can determine whether this PHY already has a link.
4. Setup the appropriate PHY addresses in the MDIO user PHY select register (USERPHYSEL n), and set the LINKINTENB bit to enable a link change event interrupt if desirable.
5. If an interrupt on general MDIO register access is desired, set the corresponding bit in the MDIO user command complete interrupt mask set register (USERINTMASKSET) to use the MDIO user access register (USERACCESS n). Since only one PHY is used in this device, the application software can use one USERACCESS n to trigger a completion interrupt; the other USERACCESS n is not setup.

22.2.6.2.2 Writing Data To a PHY Register

The MDIO module includes a user access register (USERACCESS n) to directly access a specified PHY device. To write a PHY register, perform the following:

1. Check to ensure that the GO bit in the MDIO user access register (USERACCESS n) is cleared.
2. Write to the GO, WRITE, REGADR, PHYADR, and DATA bits in USERACCESS n corresponding to the PHY and PHY register you want to write.
3. The write operation to the PHY is scheduled and completed by the MDIO module. Completion of the write operation can be determined by polling the GO bit in USERACCESS n for a 0.
4. Completion of the operation sets the corresponding USERINTRAW bit (0 or 1) in the MDIO user command complete interrupt register (USERINTRAW) corresponding to USERACCESS n used. If interrupts have been enabled on this bit using the MDIO user command complete interrupt mask set register (USERINTMASKSET), then the bit is also set in the MDIO user command complete interrupt register (USERINTMASKED) and an interrupt is triggered on the CPU.

22.2.6.2.3 Reading Data From a PHY Register

The MDIO module includes a user access register (USERACCESS n) to directly access a specified PHY device. To read a PHY register, perform the following:

1. Check to ensure that the GO bit in the MDIO user access register (USERACCESS n) is cleared.
2. Write to the GO, REGADR, and PHYADR bits in USERACCESS n corresponding to the PHY and PHY register you want to read.
3. The read data value is available in the DATA bits in USERACCESS n after the module completes the read operation on the serial bus. Completion of the read operation can be determined by polling the GO and ACK bits in USERACCESS n . Once the GO bit has cleared, the ACK bit is set on a successful read.
4. Completion of the operation sets the corresponding USERINTRAW bit (0 or 1) in the MDIO user command complete interrupt register (USERINTRAW) corresponding to USERACCESS n used. If interrupts have been enabled on this bit using the MDIO user command complete interrupt mask set register (USERINTMASKSET), then the bit is also set in the MDIO user command complete interrupt register (USERINTMASKED) and an interrupt is triggered on the CPU.

22.2.6.2.4 Example of MDIO Register Access Code

The MDIO module uses the MDIO user access register (USERACCESS n) to access the PHY control registers. Software functions that implement the access process may simply be the following four macros:

- PHYREG_read(regadr, phyadr) Start the process of reading a PHY register
- PHYREG_write(regadr, phyadr, data) Start the process of writing a PHY register
- PHYREG_wait() Synchronize operation (make sure read/write is idle)
- PHYREG_waitResults(results) Wait for read to complete and return data read

Note that it is not necessary to wait after a write operation, as long as the status is checked before every operation to make sure the MDIO hardware is idle. An alternative approach is to call PHYREG_wait() after every write, and PHYREG_waitResults() after every read, then the hardware can be assumed to be idle when starting a new operation.

The implementation of these macros using the chip support library (CSL) is shown in [Example 22-3](#) (USERACCESS0 is assumed).

Note that this implementation does not check the ACK bit in USERACCESS n on PHY register reads (does not follow the procedure outlined in [Section 22.2.6.2.3](#)). Since the MDIO PHY alive status register (ALIVE) is used to initially select a PHY, it is assumed that the PHY is acknowledging read operations. It is possible that a PHY could become inactive at a future point in time. An example of this would be a PHY that can have its MDIO addresses changed while the system is running. It is not very likely, but this condition can be tested by periodically checking the PHY state in ALIVE.

Example 22-3. MDIO Register Access Macros

```
#define PHYREG_read(regadr, phyadr)
MDIO_REGS->USERACCESS0 =
    CSL_FMK(MDIO_USERACCESS0_GO,1u)           |           /
    CSL_FMK(MDIO_USERACCESS0_REGADR,regadr)    |           /
    CSL_FMK(MDIO_USERACCESS0_PHYADR,phyadr)    |           /

#define PHYREG_write(regadr, phyadr, data)
MDIO_REGS->USERACCESS0 =
    CSL_FMK(MDIO_USERACCESS0_GO,1u)           |           /
    CSL_FMK(MDIO_USERACCESS0_WRITE,1)         |           /
    CSL_FMK(MDIO_USERACCESS0_REGADR,regadr)    |           /
    CSL_FMK(MDIO_USERACCESS0_PHYADR,phyadr)    |           /
    CSL_FMK(MDIO_USERACCESS0_DATA, data)      |           /

#define PHYREG_wait()
while( CSL_FEXT(MDIO_REGS->USERACCESS0,MDIO_USERACCESS0_GO) )

#define PHYREG_waitResults( results ) {
while( CSL_FEXT(MDIO_REGS->USERACCESS0,MDIO_USERACCESS0_GO) );
results = CSL_FEXT(MDIO_REGS->USERACCESS0, MDIO_USERACCESS0_DATA); }
```

22.2.7 EMAC Module

This section discusses the architecture and basic function of the EMAC module.

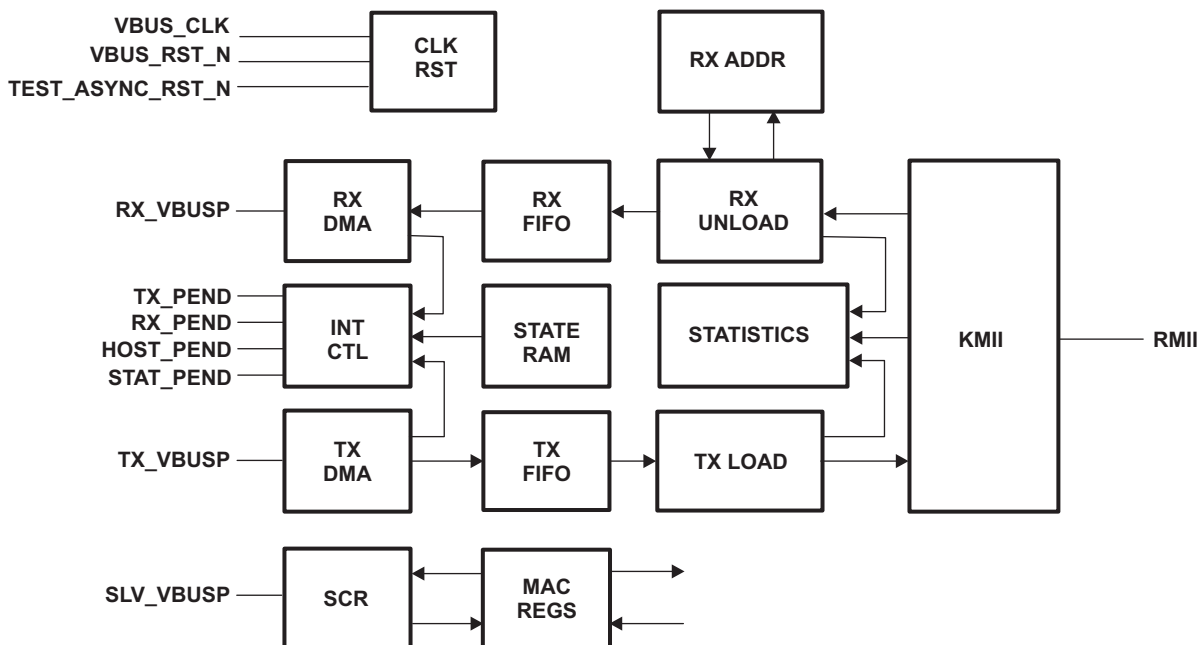

22.2.7.1 EMAC Module Components

The EMAC module (Figure 22-9) interfaces to the outside world Reduced Media Independent Interface (RMII). After reset, initialization, and configuration the host may initiate transmit operations. Transmit operations are initiated by host writes to the appropriate transmit channel head descriptor pointer contained in the STATERAM block. The transmit DMA controller then fetches the first packet in the packet chain from memory in accordance with CPPI 3.0 protocol. The DMA controller writes the packet into the transmit FIFO in 64-byte cells. When the threshold number of cells (configurable) have been written to the transmit FIFO, or a complete packet whichever is smaller, the transmit load block then initiates the packet transmission. The KMII block transmits the packet over the RMII in accordance with the 802.3 protocol. Transmit statistics are counted by the statistics submodule.

Receive operations are initiated by host writes to the appropriate receive channel head descriptor pointer after host initialization and configuration. The KMII submodule receives packets and strips off the Ethernet related protocol. The packet data is input to the receive unload submodule which checks for address match (in conjunction with the receive address submodule) and processes errors. Accepted packets are then written to the receive FIFO in 64-byte cells. The receive DMA controller then writes the packet data to memory in accordance with CPPI 3.0 protocol. Receive statistics are counted by the statistics block.

The host configures and initializes the device through the five module slave VBUSP interfaces. The CPPI, REGS, MDIO, and EMAC, modules have slave interfaces. The CPPI and EMAC slave interfaces are input directly to a VBUSP to VBUSP retiming bridge before being input to the switched central resource (SCR) inside the respective modules. The retiming bridges help to minimize long paths. The SCR handles decode between multiple master/slaves inside the respective modules. The interrupt control block is used to select the interrupts from the EMAC and the MDIO for output to the three CPU's. The signals required to support gigabit mode are included in the module. However gigabit transfer rates are not supported due to the small 3-cell transmit and receive FIFO's. Also, the RFTCLK input can be tied low for 10/100 operation.

Figure 22-9. EMAC Module Block Diagram

22.2.7.2 EMAC Module Operational Overview

After reset, initialization, and configuration, the host may initiate transmit operations. Transmit operations are initiated by host writes to the appropriate transmit channel head descriptor pointer contained in the

state RAM block. The transmit DMA controller then fetches the first packet in the packet chain from memory. The DMA controller writes the packet into the transmit FIFO in bursts of 64-byte cells. When the threshold number of cells, configurable using the TXCELLTHRESH bit in the FIFO control register (FIFOCONTROL), have been written to the transmit FIFO, or a complete packet, whichever is smaller, the MAC transmitter then initiates the packet transmission. The SYNC block transmits the packet over the MII or RMII interfaces in accordance with the 802.3 protocol. Transmit statistics are counted by the statistics block.

Receive operations are initiated by host writes to the appropriate receive channel head descriptor pointer after host initialization and configuration. The SYNC submodule receives packets and strips off the Ethernet related protocol. The packet data is input to the MAC receiver, which checks for address match and processes errors. Accepted packets are then written to the receive FIFO in bursts of 64-byte cells. The receive DMA controller then writes the packet data to memory. Receive statistics are counted by the statistics block.

The EMAC module operates independently of the CPU. It is configured and controlled by its register set mapped into device memory. Information about data packets is communicated by use of 16-byte descriptors that are placed in an 8K-byte block of RAM in the EMAC subsystem (CPPI buffer descriptor memory).

For transmit operations, each 16-byte descriptor describes a packet or packet fragment in the system's internal or external memory. For receive operations, each 16-byte descriptor represents a free packet buffer or buffer fragment. On both transmit and receive, an Ethernet packet is allowed to span one or more memory fragments, represented by one 16-byte descriptor per fragment. In typical operation, there is only one descriptor per receive buffer, but transmit packets may be fragmented, depending on the software architecture.

An interrupt is issued to the CPU whenever a transmit or receive operation has completed. However, it is not necessary for the CPU to service the interrupt while there are additional resources available. In other words, the EMAC continues to receive Ethernet packets until its receive descriptor list has been exhausted. On transmit operations, the transmit descriptors need only be serviced to recover their associated memory buffer. Thus, it is possible to delay servicing of the EMAC interrupt if there are real-time tasks to perform.

Eight channels are supplied for both transmit and receive operations. On transmit, the eight channels represent eight independent transmit queues. The EMAC can be configured to treat these channels as an equal priority "round-robin" queue or as a set of eight fixed-priority queues. On receive, the eight channels represent eight independent receive queues with packet classification. Packets are classified based on the destination MAC address. Each of the eight channels is assigned its own MAC address, enabling the EMAC module to act like eight virtual MAC adapters. Also, specific types of frames can be sent to specific channels. For example, multicast, broadcast, or other (promiscuous, error, etc.), can each be received on a specific receive channel queue.

The EMAC keeps track of 36 different statistics, plus keeps the status of each individual packet in its corresponding packet descriptor.

22.2.8 MAC Interface

The following sections discuss the operation of the Media Independent Interface (MII) and Reduced Media Independent Interface (RMII) in 10 Mbps and 100 Mbps mode. An IEEE 802.3 compliant Ethernet MAC controls the interface.

22.2.8.1 Data Reception

22.2.8.1.1 Receive Control

Data received from the PHY is interpreted and output to the EMAC receive FIFO. Interpretation involves detection and removal of the preamble and start-of-frame delimiter, extraction of the address and frame length, data handling, error checking and reporting, cyclic redundancy checking (CRC), and statistics control signal generation. Address detection and frame filtering is performed outside the MAC interface.

22.2.8.1.2 Receive Inter-Frame Interval

The 802.3 standard requires an interpacket gap (IPG), which is 96 bit times. However, the EMAC can tolerate a reduced IPG of 8 bit times with a correct preamble and start frame delimiter. This interval between frames must comprise (in the following order):

1. An Interpacket Gap (IPG).
2. A 7-byte preamble (all bytes 55h).
3. A 1-byte start of frame delimiter (5Dh).

22.2.8.1.3 Receive Flow Control

When enabled and triggered, receive flow control is initiated to limit the EMAC from further frame reception. Two forms of receive buffer flow control are available:

- Collision-based flow control for half-duplex mode
- IEEE 802.3x pause frames flow control for full-duplex mode

In either case, receive flow control prevents frame reception by issuing the flow control appropriate for the current mode of operation. Receive flow control prevents reception of frames on the EMAC until all of the triggering conditions clear, at which time frames may again be received by the EMAC.

Receive flow control is enabled by the RXBUFFERFLOWEN bit in the MAC control register (MACCONTROL). The EMAC is configured for collision or IEEE 802.3X flow control using the FULLDUPLEX bit in MACCONTROL. Receive flow control is triggered when the number of free buffers in any enabled receive channel free buffer count register (RXnFREEBUFFER) is less than or equal to the receive channel flow control threshold register (RXnFLOWTHRESH) value. Receive flow control is independent of receive QOS, except that both use the free buffer values.

22.2.8.1.3.1 Collision-Based Receive Buffer Flow Control

Collision-based receive buffer flow control provides a means of preventing frame reception when the EMAC is operating in half-duplex mode (the FULLDUPLEX bit is cleared in MACCONTROL). When receive flow control is enabled and triggered, the EMAC generates collisions for received frames. The jam sequence transmitted is the 12-byte sequence C3.C3.C3.C3.C3.C3.C3.C3.C3.C3.C3h. The jam sequence begins no later than approximately as the source address starts to be received. Note that these forced collisions are not limited to a maximum of 16 consecutive collisions, and are independent of the normal back-off algorithm.

Receive flow control does not depend on the value of the incoming frame destination address. A collision is generated for any incoming packet, regardless of the destination address, if any EMAC enabled channel's free buffer register value is less than or equal to the channel's flow threshold value.

22.2.8.1.3.2 IEEE 802.3x-Based Receive Buffer Flow Control

IEEE 802.3x-based receive buffer flow control provides a means of preventing frame reception when the EMAC is operating in full-duplex mode (the FULLDUPLEX bit is set in MACCONTROL). When receive flow control is enabled and triggered, the EMAC transmits a pause frame to request that the sending station stop transmitting for the period indicated within the transmitted pause frame.

The EMAC transmits a pause frame to the reserved multicast address at the first available opportunity (immediately if currently idle or following the completion of the frame currently being transmitted). The pause frame contains the maximum possible value for the pause time (FFFFh). The EMAC counts the receive pause frame time (decrements FF00h to 0) and retransmits an outgoing pause frame, if the count reaches 0. When the flow control request is removed, the EMAC transmits a pause frame with a zero pause time to cancel the pause request.

Note that transmitted pause frames are only a request to the other end station to stop transmitting. Frames that are received during the pause interval are received normally (provided the receive FIFO is not full).

Pause frames are transmitted if enabled and triggered, regardless of whether or not the EMAC is observing the pause time period from an incoming pause frame.

The EMAC transmits pause frames as described below:

- The 48-bit reserved multicast destination address 01.80.C2.00.00.01h.
- The 48-bit source address (set using the MACSRCADDRLO and MACSRCADDRHI registers).
- The 16-bit length/type field containing the value 88.08h.
- The 16-bit pause opcode equal to 00.01h.
- The 16-bit pause time value of FF.FFh. A pause-quantum is 512 bit-times. Pause frames sent to cancel a pause request have a pause time value of 00.00h.
- Zero padding to 64-byte data length (EMAC transmits only 64-byte pause frames).
- The 32-bit frame-check sequence (CRC word).

All quantities are hexadecimal and are transmitted most-significant byte first. The least-significant bit (LSB) is transferred first in each byte.

If the RXBUFFERFLOWEN bit in MACCONTROL is cleared to 0 while the pause time is nonzero, then the pause time is cleared to 0 and a zero count pause frame is sent.

22.2.8.2 Data Transmission

The EMAC passes data to the PHY from the transmit FIFO (when enabled). Data is synchronized to the transmit clock rate. Transmission begins when there are TXCELLTHRESH cells of 64 bytes each, or a complete packet, in the FIFO.

22.2.8.2.1 Transmit Control

A jam sequence is output if a collision is detected on a transmit packet. If the collision was late (after the first 64 bytes have been transmitted), the collision is ignored. If the collision is not late, the controller will back off before retrying the frame transmission. When operating in full-duplex mode, the carrier sense (MII_CRFS) and collision-sensing (MII_COL) modes are disabled.

22.2.8.2.2 CRC Insertion

If the SOP buffer descriptor PASSCRC flag is cleared, the EMAC generates and appends a 32-bit Ethernet CRC onto the transmitted data. For the EMAC-generated CRC case, a CRC (or placeholder) at the end of the data is allowed but not required. The buffer byte count value should not include the CRC bytes, if they are present.

If the SOP buffer descriptor PASSCRC flag is set, then the last four bytes of the transmit data are transmitted as the frame CRC. The four CRC data bytes should be the last four bytes of the frame and should be included in the buffer byte count value. The MAC performs no error checking on the outgoing CRC.

22.2.8.2.3 Adaptive Performance Optimization (APO)

The EMAC incorporates adaptive performance optimization (APO) logic that may be enabled by setting the TXPACE bit in the MAC control register (MACCONTROL). Transmission pacing to enhance performance is enabled when the TXPACE bit is set. Adaptive performance pacing introduces delays into the normal transmission of frames, delaying transmission attempts between stations, reducing the probability of collisions occurring during heavy traffic (as indicated by frame deferrals and collisions), thereby, increasing the chance of successful transmission.

When a frame is deferred, suffers a single collision, multiple collisions, or excessive collisions, the pacing counter is loaded with an initial value of 31. When a frame is transmitted successfully (without experiencing a deferral, single collision, multiple collision, or excessive collision), the pacing counter is decremented by 1, down to 0.

With pacing enabled, a new frame is permitted to immediately (after one interpacket gap) attempt transmission only if the pacing counter is 0. If the pacing counter is nonzero, the frame is delayed by the pacing delay of approximately four interpacket gap (IPG) delays. APO only affects the IPG preceding the first attempt at transmitting a frame; APO does not affect the back-off algorithm for retransmitted frames.

22.2.8.2.4 Interpacket-Gap (IPG) Enforcement

The measurement reference for the IPG of 96 bit times is changed depending on frame traffic conditions. If a frame is successfully transmitted without collision and MII_CRD is deasserted within approximately 48 bit times of MII_TXEN being deasserted, then 96 bit times is measured from MII_TXEN. If the frame suffered a collision or MII_CRD is not deasserted until more than approximately 48 bit times after MII_TXEN is deasserted, then 96 bit times (approximately, but not less) is measured from MII_CRD.

22.2.8.2.5 Back Off

The EMAC implements the 802.3 binary exponential back-off algorithm.

22.2.8.2.6 Transmit Flow Control

Incoming pause frames are acted upon, when enabled, to prevent the EMAC from transmitting any further frames. Incoming pause frames are only acted upon when the FULLDUPLEX and TXFLOWEN bits in the MAC control register (MACCONTROL) are set. Pause frames are not acted upon in half-duplex mode. Pause frame action is taken if enabled, but normally the frame is filtered and not transferred to memory. MAC control frames are transferred to memory, if the RXCMFEN bit in the receive multicast/broadcast/promiscuous channel enable register (RXMBPENABLE) is set. The TXFLOWEN and FULLDUPLEX bits affect whether or not MAC control frames are acted upon, but they have no affect upon whether or not MAC control frames are transferred to memory or filtered.

Pause frames are a subset of MAC control frames with an opcode field of 0001h. Incoming pause frames are only acted upon by the EMAC if:

- TXFLOWEN bit is set in MACCONTROL
- The frame's length is 64 to RXMAXLEN bytes inclusive
- The frame contains no CRC error or align/code errors

The pause time value from valid frames is extracted from the two bytes following the opcode. The pause time is loaded into the EMAC transmit pause timer and the transmit pause time period begins. If a valid pause frame is received during the transmit pause time period of a previous transmit pause frame then:

- If the destination address is not equal to the reserved multicast address or any enabled or disabled unicast address, then the transmit pause timer immediately expires, or
- If the new pause time value is 0, then the transmit pause timer immediately expires, else
- The EMAC transmit pause timer immediately is set to the new pause frame pause time value. (Any remaining pause time from the previous pause frame is discarded).

If the TXFLOWEN bit in MACCONTROL is cleared, then the pause timer immediately expires.

The EMAC does not start the transmission of a new data frame any sooner than 512 bit-times after a pause frame with a nonzero pause time has finished being received (MII_RXDV going inactive). No transmission begins until the pause timer has expired (the EMAC may transmit pause frames in order to initiate outgoing flow control). Any frame already in transmission when a pause frame is received is completed and unaffected.

Incoming pause frames consist of:

- A 48-bit destination address equal to one of the following:
 - The reserved multicast destination address 01.80.C2.00.00.01h
 - Any EMAC 48-bit unicast address. Pause frames are accepted, regardless of whether the channel is enabled or not.
- The 16-bit length/type field containing the value 88.08h.
- The 48-bit source address of the transmitting device.
- The 16-bit pause opcode equal to 00.01h.
- The 16-bit pause time. A pause-quantum is 512 bit-times.
- Padding to 64-byte data length.
- The 32-bit frame-check sequence (CRC word).

All quantities are hexadecimal and are transmitted most-significant byte first. The least-significant bit (LSB) is transferred first in each byte.

The padding is required to make up the frame to a minimum of 64 bytes. The standard allows pause frames longer than 64 bytes to be discarded or interpreted as valid pause frames. The EMAC recognizes any pause frame between 64 bytes and RXMAXLEN bytes in length.

22.2.8.2.7 Speed, Duplex, and Pause Frame Support

The MAC operates at 10 Mbps or 100 Mbps, in half-duplex or full-duplex mode, and with or without pause frame support as configured by the host.

22.2.9 Packet Receive Operation

22.2.9.1 Receive DMA Host Configuration

To configure the receive DMA for operation the host must:

- Initialize the receive addresses.
- Initialize the receive channel n DMA head descriptor pointer registers (RX n HDP) to 0.
- Write the MAC address hash n registers (MACHASH1 and MACHASH2), if multicast addressing is desired.
- If flow control is to be enabled, initialize:
 - the receive channel n free buffer count registers (RX n FREEBUFFER)
 - the receive channel n flow control threshold register (RX n FLOWTHRESH)
 - the receive filter low priority frame threshold register (RXFILTERLOWTHRESH)
- Enable the desired receive interrupts using the receive interrupt mask set register (RXINTMASKSET in EMAC module).
- Enable the receive interrupts of the desired channels in the *Interrupt Core Receive Interrupt Enable Registers* (EMAC subsystem).
- Set the appropriate configuration bits in the MAC control register (MACCONTROL).
- Write the receive buffer offset register (RXBUFFEROFFSET) value (typically zero).
- Setup the receive channel(s) buffer descriptors in host memory as required by CPPI 3.0 and initialize RX n HDP.
- Enable the RX DMA controller by setting the RXEN bit in the RXCONTROL register.
- Configure and enable the receive operation, as desired, in the receive multicast/broadcast/promiscuous channel enable register (RXMBPENABLE) and by using the receive unicast set register (RXUNICASTSET) and the receive unicast clear register (RXUNICASTCLEAR).

22.2.9.2 Receive Channel Enabling

Each of the eight receive channels has an enable bit (RXCH n EN) in the receive unicast set register (RXUNICASTSET) that is controlled using RXUNICASTSET and the receive unicast clear register (RXUNICASTCLEAR). The RXCH n EN bits determine whether the given channel is enabled (when set to 1) to receive frames with a matching unicast or multicast destination address.

The RXBROADEN bit in the receive multicast/broadcast/promiscuous channel enable register (RXMBPENABLE) determines if broadcast frames are enabled or filtered. If broadcast frames are enabled (when set to 1), then they are copied to only a single channel selected by the RXBROADCH bit in RXMBPENABLE.

The RXMULTEN bit in RXMBPENABLE determines if hash matching multicast frames are enabled or filtered. Incoming multicast addresses (group addresses) are hashed into an index in the hash table. If the indexed bit is set then the frame hash matches and will be transferred to the channel selected by the RXMULTCH bit in RXMBPENABLE when multicast frames are enabled. The multicast hash bits are set in the MAC address hash n registers (MACHASH1 and MACHASH2).

The RXPROMCH bit in RXMBPENABLE selects the promiscuous channel to receive frames selected by the RXCMFEN, RXCSFEN, RXCEFEN, and RXCAFEN bits. These four bits allow reception of MAC control frames, short frames, error frames, and all frames (promiscuous), respectively.

22.2.9.3 Receive Address Matching

All eight MAC addresses corresponding to the eight receive channels share the upper 40 bits. Only the lower byte is unique for each address. All eight receive addresses should be initialized, because pause frames are acted upon regardless of whether a channel is enabled or not.

A MAC address is written by first writing the address number (channel) to be written into the MAC index register (MACINDEX). The upper 32 bits of address are then written to the MAC address high bytes register (MACADDRHI), which is followed by writing the lower 16 bits of address to the MAC address low bytes register (MACADDRLO). Since all eight MAC addresses share the upper 40 bits of address, MACADDRHI needs to be written only the first time (for the first channel configured).

22.2.9.4 VBUSP Latency

The transmit (and receive) FIFOs each contain a configurable number of 64-byte cells. The EMAC begins transmission of a packet on the wire after `tx_cell_thresh` cells, or a complete packet, are available in the FIFO. Transmit underrun cannot occur for packet sizes of `tx_cell_thresh` times 64 bytes (or less) because the entire packet is contained in the FIFO before the packet transmission is started. For larger packet sizes, transmit underrun can occur if the memory latency is greater than the time required to transmit a 64-byte cell on the wire (5.12 μ s in 100 Mbit mode). The latency time includes all buffer descriptor reads for the entire cell data.

Receive overrun will be prevented if the receive memory cell latency is less than the time required to transmit a 64-byte cell on the wire (5.12 μ s in 100 Mbit mode). The latency time includes any required buffer descriptor reads for the cell data.

22.2.9.5 Hardware Receive QOS Support

Hardware receive quality of service (QOS) is supported, when enabled, by the Tag Protocol Identifier format and the associated Tag Control Information (TCI) format priority field. When the incoming frame length/type value is equal to 81.00h, the EMAC recognizes the frame as an Ethernet Encoded Tag Protocol Type. The two octets immediately following the protocol type contain the 16-bit TCI field. Bits 15-13 of the TCI field contain the received frames priority (0 to 7). The received frame is a low-priority frame, if the priority value is 0 to 3; the received frame is a high-priority frame, if the priority value is 4 to 7. All frames that have a length/type field value not equal to 81.00h are low-priority frames. Received frames that contain priority information are determined by the EMAC as:

- A 48-bit (6 bytes) destination address equal to:
 - The destination station's individual unicast address.
 - The destination station's multicast address (MACHASH1 and MACHASH2).
 - The broadcast address of all ones.
- A 48-byte (6 bytes) source address.
- The 16-bit (2 bytes) length/type field containing the value 81.00h.
- The 16-bit (2 bytes) TCI field with the priority field in the upper 3 bits.
- Data bytes
- The 4 bytes CRC.

The receive filter low priority frame threshold register (`RXFILTERLOWTHRESH`) and the receive channel *n* free buffer count registers (`RXnFREEBUFFER`) are used in conjunction with the priority information to implement receive hardware QOS. Low-priority frames are filtered if the number of free buffers (`RXnFREEBUFFER`) for the frame channel is less than or equal to the filter low threshold (`RXFILTERLOWTHRESH`) value. Hardware QOS is enabled by the `RXQOSEN` bit in the receive multicast/broadcast/promiscuous channel enable register (`RXMBPENABLE`).

22.2.9.6 Host Free Buffer Tracking

The host must track free buffers for each enabled channel (including unicast, multicast, broadcast, and promiscuous), if receive QOS or receive flow control is used. Disabled channel free buffer values are do not cares. During initialization, the host should write the number of free buffers for each enabled channel to the appropriate receive channel *n* free buffer count registers (`RXnFREEBUFFER`). The EMAC decrements the appropriate channel's free buffer value for each buffer used. When the host reclaims the frame buffers, the host should write the channel free buffer register with the number of reclaimed buffers (write to increment). There are a maximum of 65,535 free buffers available. `RXnFREEBUFFER` only needs to be updated by the host if receive QOS or flow control is used.

22.2.9.7 Receive Channel Teardown

The host commands a receive channel teardown by writing the channel number to the receive teardown register (`RXTEARDOWN`). When a teardown command is issued to an enabled receive channel, the following occurs:

- Any current frame in reception completes normally.
- The `TDOWNCMPLT` flag is set in the next buffer descriptor in the chain, if there is one.

- The channel head descriptor pointer is cleared to 0.
- A receive interrupt for the channel is issued to the host.
- The corresponding receive channel n completion pointer register (RX n CP) contains the value FFFF FFFCh.

Channel teardown may be commanded on any channel at any time. The host is informed of the teardown completion by the set teardown complete (TDOWNCMPLT) buffer descriptor bit. The EMAC does not clear any channel enables due to a teardown command. A teardown command to an inactive channel issues an interrupt that software should acknowledge with an FFFF FFFCh acknowledge value to RX n CP (note that there is no buffer descriptor in this case). Software may read RX n CP to determine if the interrupt was due to a commanded teardown. The read value is FFFF FFFCh, if the interrupt was due to a teardown command.

22.2.9.8 Receive Frame Classification

Received frames are proper (good) frames, if they are between 64 bytes and the value in the receive maximum length register (RXMAXLEN) bytes in length (inclusive) and contain no code, align, or CRC errors.

Received frames are long frames, if their frame count exceeds the value in RXMAXLEN. The RXMAXLEN reset (default) value is 5EEh (1518 in decimal). Long received frames are either oversized or jabber frames. Long frames with no errors are oversized frames; long frames with CRC, code, or alignment errors are jabber frames.

Received frames are short frames, if their frame count is less than 64 bytes. Short frames that address match and contain no errors are undersized frames; short frames with CRC, code, or alignment errors are fragment frames. If the frame length is less than or equal to 20, then the frame CRC is passed, regardless of whether the RXPASSCRC bit is set or cleared in the receive multicast/broadcast/promiscuous channel enable register (RXMBPENABLE).

A received long packet always contains RXMAXLEN number of bytes transferred to memory (if the RXCEFEN bit is set in RXMBPENABLE), regardless of the value of the RXPASSCRC bit. Following is an example with RXMAXLEN set to 1518:

- If the frame length is 1518, then the packet is not a long packet and there are 1514 or 1518 bytes transferred to memory depending on the value of the RXPASSCRC bit.
- If the frame length is 1519, there are 1518 bytes transferred to memory regardless of the RXPASSCRC bit value. The last three bytes are the first three CRC bytes.
- If the frame length is 1520, there are 1518 bytes transferred to memory regardless of the RXPASSCRC bit value. The last two bytes are the first two CRC bytes.
- If the frame length is 1521, there are 1518 bytes transferred to memory regardless of the RXPASSCRC bit value. The last byte is the first CRC byte.
- If the frame length is 1522, there are 1518 bytes transferred to memory. The last byte is the last data byte.

22.2.9.9 Promiscuous Receive Mode

When the promiscuous receive mode is enabled by setting the RXCAFEN bit in the receive multicast/broadcast/promiscuous channel enable register (RXMBPENABLE), nonaddress matching frames that would normally be filtered are transferred to the promiscuous channel. Address matching frames that would normally be filtered due to errors are transferred to the address match channel when the RXCAFEN and RXCEFEN bits in RXMBPENABLE are set. A frame is considered to be an address matching frame only if it is enabled to be received on a unicast, multicast, or broadcast channel. Frames received to disabled unicast, multicast, or broadcast channels are considered nonaddress matching.

MAC control frames address match only if the RXCMFEN bit in RXMBPENABLE is set. The RXCEFEN and RXCSFEN bits in RXMBPENABLE determine whether error frames are transferred to memory or not, but they do not determine whether error frames are address matching or not. Short frames are a special type of error frames.

A single channel is selected as the promiscuous channel by the RXPROMCH bit in RXMBPENABLE. The promiscuous receive mode is enabled by the RXCMFEN, RXCEFEN, RXCSFEN, and RXCAFEN bits in RXMBPENABLE. Table 22-12 shows the effects of the promiscuous enable bits. Proper frames are frames that are between 64 bytes and the value in the receive maximum length register (RXMAXLEN) bytes in length inclusive and contain no code, align, or CRC errors.

Table 22-12. Receive Frame Treatment Summary

| Address Match | RXCAFEN | RXCEFEN | RXCMFEN | RXCSFEN | Receive Frame Treatment |
|---------------|---------|---------|---------|---------|--|
| 0 | 0 | X | X | X | No frames transferred. |
| 0 | 1 | 0 | 0 | 0 | Proper frames transferred to promiscuous channel. |
| 0 | 1 | 0 | 0 | 1 | Proper/undersized data frames transferred to promiscuous channel. |
| 0 | 1 | 0 | 1 | 0 | Proper data and control frames transferred to promiscuous channel. |
| 0 | 1 | 0 | 1 | 1 | Proper/undersized data and control frames transferred to promiscuous channel. |
| 0 | 1 | 1 | 0 | 0 | Proper/oversize/jabber/code/align/CRC data frames transferred to promiscuous channel. No control or undersized/fragment frames are transferred. |
| 0 | 1 | 1 | 0 | 1 | Proper/undersized/fragment/oversize/jabber/code/align/CRC data frames transferred to promiscuous channel. No control frames are transferred. |
| 0 | 1 | 1 | 1 | 0 | Proper/oversize/jabber/code/align/CRC data and control frames transferred to promiscuous channel. No undersized frames are transferred. |
| 0 | 1 | 1 | 1 | 1 | All nonaddress matching frames with and without errors transferred to promiscuous channel. |
| 1 | X | 0 | 0 | 0 | Proper data frames transferred to address match channel. |
| 1 | X | 0 | 0 | 1 | Proper/undersized data frames transferred to address match channel. |
| 1 | X | 0 | 1 | 0 | Proper data and control frames transferred to address match channel. |
| 1 | X | 0 | 1 | 1 | Proper/undersized data and control frames transferred to address match channel. |
| 1 | X | 1 | 0 | 0 | Proper/oversize/jabber/code/align/CRC data frames transferred to address match channel. No control or undersized frames are transferred. |
| 1 | X | 1 | 0 | 1 | Proper/oversize/jabber/fragment/undersized/code/align/CRC data frames transferred to address match channel. No control frames are transferred. |
| 1 | X | 1 | 1 | 0 | Proper/oversize/jabber/code/align/CRC data and control frames transferred to address match channel. No undersized/fragment frames are transferred. |
| 1 | X | 1 | 1 | 1 | All address matching frames with and without errors transferred to the address match channel |

22.2.9.10 Big Endian Mode

When the BIG_ENDIAN input is asserted, the EMAC assumes that packet data is contained in memory in big endian format. When the BIG_ENDIAN input is deasserted, the EMAC assumes that packet data is contained in memory in little endian format. The BIG_ENDIAN input causes big endian packet data to go out on the wire in the same order that little endian packet data goes out on the wire when the input is not asserted (byte 0 first). The BIG_ENDIAN input has no effect on buffer descriptor data reads or writes because buffer descriptor data is a 32-bit quantity (unlike packet data which is an 8-bit quantity).

Table 22-13. Little Endian

| High Add | | | Low Add |
|----------|---------|--------|---------|
| Byte 3 | Byte 2 | Byte 1 | Byte 0 |
| Byte 7 | Byte 6 | Byte 5 | Byte 4 |
| Byte 11 | Byte 10 | Byte 9 | Byte 8 |

Table 22-14. Big Endian

| High Add | | | Low Add |
|----------|--------|---------|---------|
| Byte 0 | Byte 1 | Byte 2 | Byte 3 |
| Byte 4 | Byte 5 | Byte 6 | Byte 7 |
| Byte 8 | Byte 9 | Byte 10 | Byte 11 |

22.2.9.11 Receive Overrun

The types of receive overrun are:

- FIFO start of frame overrun (FIFO_SOF)
- FIFO middle of frame overrun (FIFO_MOF)
- DMA start of frame overrun (DMA_SOF)
- DMA middle of frame overrun (DMA_MOF)

The statistics counters used to track these types of receive overrun are:

- Receive start of frame overruns register (RXSOFOVERRUNS)
- Receive middle of frame overruns register (RXMOFOVERRUNS)
- Receive DMA overruns register (RXDMAOVERRUNS)

Start of frame overruns happen when there are no resources available when frame reception begins. Start of frame overruns increment the appropriate overrun statistic(s) and the frame is filtered.

Middle of frame overruns happen when there are some resources to start the frame reception, but the resources run out during frame reception. In normal operation, a frame that overruns after starting the frame reception is filtered and the appropriate statistic(s) are incremented; however, the RXCEFEN bit in the receive multicast/broadcast/promiscuous channel enable register (RXMBPENABLE) affects overrun frame treatment. [Table 22-15](#) shows how the overrun condition is handled for the middle of frame overrun.

Table 22-15. Middle of Frame Overrun Treatment

| Address Match | RXCAFEN | RXCEFEN | Middle of Frame Overrun Treatment |
|---------------|---------|---------|---|
| 0 | 0 | X | Overrun frame filtered. |
| 0 | 1 | 0 | Overrun frame filtered. |
| 0 | 1 | 1 | As much frame data as possible is transferred to the promiscuous channel until overrun. The appropriate overrun statistic(s) is incremented and the OVERRUN and NOMATCH flags are set in the SOP buffer descriptor. Note that the RXMAXLEN number of bytes cannot be reached for an overrun to occur (it would be truncated and be a jabber or oversize). |
| 1 | X | 0 | Overrun frame filtered with the appropriate overrun statistic(s) incremented. |
| 1 | X | 1 | As much frame data as possible is transferred to the address match channel until overrun. The appropriate overrun statistic(s) is incremented and the OVERRUN flag is set in the SOP buffer descriptor. Note that the RXMAXLEN number of bytes cannot be reached for an overrun to occur (it would be truncated). |

22.2.10 Packet Transmit Operation

The transmit DMA is an eight channel interface. Priority between the eight queues may be either fixed or round-robin as selected by the TXPTYPE bit in the MAC control register (MACCONTROL). If the priority type is fixed, then channel 7 has the highest priority and channel 0 has the lowest priority. Round-robin priority proceeds from channel 0 to channel 7.

22.2.10.1 Transmit DMA Host Configuration

To configure the transmit DMA for operation the host must perform:

- Write the MAC source address low bytes register (MACSRCADDRLO) and the MAC source address high bytes register (MACSRCADDRHI) (used for pause frames on transmit).
- Initialize the transmit channel n DMA head descriptor pointer registers (TX n HDP) to 0.
- Enable the desired transmit interrupts using the transmit interrupt mask set register (TXINTMASKSET in EMAC module).
- Enable the transmit interrupts of the desired channels in the *Interrupt Core Transmit Interrupt Enable Registers* (EMAC subsystem).
- Set the appropriate configuration bits in the MAC control register (MACCONTROL).
- Setup the transmit channel(s) buffer descriptors in host memory.
- Enable the transmit DMA controller by setting the TXEN bit in the transmit control register (TXCONTROL).
- Write the appropriate TX n HDP with the pointer to the first descriptor to start transmit operations.

22.2.10.2 Transmit Channel Teardown

The host commands a transmit channel teardown by writing the channel number to the transmit teardown register (TXTEARDOWN). When a teardown command is issued to an enabled transmit channel, the following occurs:

- Any frame currently in transmission completes normally.
- The TDOWNCMPLT flag is set in the next SOP buffer descriptor in the chain, if there is one.
- The channel head descriptor pointer is cleared to 0.
- A transmit interrupt is issued to inform the host of the channel teardown.
- The corresponding transmit channel n completion pointer register (TX n CP) contains the value FFFF FFFCh.
- The host should acknowledge a teardown interrupt with an FFFF FFFCh acknowledge value.

Channel teardown may be commanded on any channel at any time. The host is informed of the teardown completion by the set teardown complete (TDOWNCMPLT) buffer descriptor bit. The EMAC does not clear any channel enables due to a teardown command. A teardown command to an inactive channel issues an interrupt that software should acknowledge with an FFFF FFFCh acknowledge value to TX n CP (note that there is no buffer descriptor in this case). Software may read the interrupt acknowledge location (TX n CP) to determine if the interrupt was due to a commanded teardown. The read value is FFFF FFFCh, if the interrupt was due to a teardown command.

22.2.11 Receive and Transmit Latency

The transmit and receive FIFOs each contain three 64-byte cells. The EMAC begins transmission of a packet on the wire after TXCELLTHRESH (configurable through the FIFO control register) cells, or a complete packet, are available in the FIFO.

Transmit underrun cannot occur for packet sizes of TXCELLTHRESH times 64 bytes (or less). For larger packet sizes, transmit underrun occurs if the memory latency is greater than the time required to transmit a 64-byte cell on the wire; this is 5.12 μ s in 100 Mbps mode and 51.2 μ s in 10 Mbps mode. The memory latency time includes all buffer descriptor reads for the entire cell data.

Receive overrun is prevented if the receive memory cell latency is less than the time required to transmit a 64-byte cell on the wire: 5.12 μ s in 100 Mbps mode, or 51.2 μ s in 10 Mbps mode. The latency time includes any required buffer descriptor reads for the cell data.

Latency to system's internal and external RAM can be controlled through the use of the transfer node priority allocation register available at the device level. Latency to descriptor RAM is low because RAM is local to the EMAC, as it is part of the EMAC subsystem.

22.2.12 Transfer Node Priority

The device contains a chip-level master priority register that is used to set the priority of the transfer node used in issuing memory transfer requests to system memory.

Although the EMAC has internal FIFOs to help alleviate memory transfer arbitration problems, the average transfer rate of data read and written by the EMAC to internal or external processor memory must be at least that of the Ethernet wire rate. In addition, the internal FIFO system can not withstand a single memory latency event greater than the time it takes to fill or empty a TXCELLTHRESH number of internal 64 byte FIFO cells.

For 100 Mbps operation, these restrictions translate into the following rules:

- The short-term average, each 64-byte memory read/write request from the EMAC must be serviced in no more than 5.12 μ s.
- Any single latency event in request servicing can be no longer than (5.12 \times TXCELLTHRESH) μ s.

22.2.13 Clock Stop

The clock stop interface allows the EMAC to be gracefully commanded to enter into a stopped clock state. When the (CLKSTOP_REQ) input is asserted, the EMAC suspend state is entered and the EMAC will stop processing receive and transmit frames at the next frame boundary. Any frame currently in reception or transmission will be completed normally without suspension. For transmission, any complete or partial frame in the TX cell FIFO will be transmitted. For receive, frames that are detected by the EMAC after the suspend state is entered are ignored. No statistics will be kept for ignored frames. The (CLKSTOP_ACK) output will be asserted when the EMAC_F enters the IDLE state indicating that the clock (VBUSP_CLK) may be stopped. (For details on programming the clock stop, see the *System Control Module* chapter.)

22.2.14 Software Reset

The EMAC subsystem software reset register (REGS) and the EMAC submodule software reset register enable the EMAC subsystem to be reset by software. For the EMAC, the reset state is entered at packet boundaries, at which time the EMAC reset occurs. EMAC reset status is determined by reading or polling the EMAC soft reset bit. If the EMAC reset bit is read as a one, then the reset process has not yet completed. The EMAC soft reset process could take up to 2ms. The reset has completed if the EMAC reset bit is read as a zero. After the EMAC soft reset is complete, the EMAC subsystem software reset register bits may be written to complete the software reset operation.

22.2.14.1 Soft Reset of EMAC Submodule

The EMAC software reset register enables the EMAC to be reset by software. Soft reset will occur at frame boundaries. Soft reset occurs when both receive and transmit DMA controllers are not using their respective VBUS interfaces so that there is no VBUS lockup. The soft reset process could take up to 2ms. The reset has completed if the soft reset bit is read as a zero.

22.2.15 Initialization

22.2.15.1 Enabling the EMAC/MDIO Peripheral

When the device is powered on, the EMAC peripheral may be in a disabled state. Before any EMAC specific initialization can take place, the EMAC needs to be enabled; otherwise, its registers cannot be written and the reads will all return a value of zero.

When first enabled, the EMAC peripheral registers are set to their default values. After enabling the peripheral, you may proceed with the module specific initialization.

22.2.15.2 EMAC Subsystem Module Initialization

The EMAC subsystem module is used for global interrupt enables and to pace interrupts using 1ms time windows. There is also an 8K block of CPPI RAM local to the EMAC that is used to hold packet buffer descriptors.

The initialization of the EMAC subsystem module consists of three parts:

1. Configuration of the interrupt to the CPU.
2. Initialization of the EMAC subsystem module:
 - Setting the interrupt pace counts using the EMAC control module registers INTCONTROL, *CnRXIMAX*, and *CnTXIMAX*
 - Initializing the EMAC and MDIO modules
 - Enabling interrupts in the EMAC subsystem module using the EMAC control module interrupt control registers *CnRXTHRESHEN*, *CnRXEN*, *CnTXEN*, and *CnMISCEN*.

The process of mapping the EMAC interrupts to the CPU is done through the CPU interrupt controller. Once the interrupt is mapped to a CPU interrupt, general masking and unmasking of interrupts (to control reentrancy) should be done at the chip level by manipulating the interrupt core enable mask registers.

22.2.15.3 MDIO Module Initialization

The MDIO module is used to initially configure and monitor one or more external PHY devices. Other than initializing the software state machine (details on this state machine can be found in the IEEE 802.3 standard), all that needs to be done for the MDIO module is to enable the MDIO engine and to configure the clock divider. To set the clock divider, supply an MDIO clock of 1 MHz. For example, if the peripheral clock is 50 MHz, the divider can be set to 50.

Both the state machine enable and the MDIO clock divider are controlled through the MDIO control register (CONTROL). If none of the potentially connected PHYs require the access preamble, the PREAMBLE bit in CONTROL can also be set to speed up PHY register access.

If the MDIO module is to operate on an interrupt basis, the interrupts can be enabled at this time using the MDIO user command complete interrupt mask set register (USERINTMASKSET) for register access and the MDIO user PHY select register (USERPHYSEL n) if a target PHY is already known.

Once the MDIO state machine has been initialized and enabled, it starts polling all 32 PHY addresses on the MDIO bus, looking for an active PHY. Since it can take up to 50 μ s to read one register, it can be some time before the MDIO module provides an accurate representation of whether a PHY is available. Also, a PHY can take up to 3 seconds to negotiate a link. Thus, it is advisable to run the MDIO software off a time-based event rather than polling.

For more information on PHY control registers, see your PHY device documentation.

22.2.15.4 EMAC Module Initialization

The EMAC module is used to send and receive data packets over the network. This is done by maintaining up to eight transmit and receive descriptor queues. The EMAC module configuration must also be kept up-to-date based on PHY negotiation results returned from the MDIO module. Most of the work in developing an application or device driver for Ethernet is programming this module.

The following is the initialization procedure a device driver would follow to get the EMAC to the state where it is ready to receive and send Ethernet packets. Some of these steps are not necessary when performed immediately after device reset.

1. If enabled, clear the device interrupt enable bits in the EMAC subsystem module interrupt control registers $CnRXTHRESHEN$, $CnRXEN$, $CnTXEN$, and $CnMISCEN$.
2. Clear the MAC control register (MACCONTROL), receive control register (RXCONTROL), and transmit control register (TXCONTROL) (not necessary immediately after reset).
3. Initialize all 16 header descriptor pointer registers ($RXnHDP$ and $TXnHDP$) to 0.
4. Clear all 36 statistics registers by writing 0 (not necessary immediately after reset).
5. Setup the local Ethernet MAC address by programming the MAC index register (MACINDEX), MAC address high bytes register (MACADDRHI), and MAC address low bytes register (MACADDRLO). Be sure to program all eight MAC address registers - whether the receive channel is to be enabled or not. Duplicate the same MAC address across all unused channels. When using more than one receive channel, start with channel 0 and progress upwards.
6. If buffer flow control is to be enabled, initialize the receive channel n free buffer count registers ($RXnFREEBUFFER$), receive channel n flow control threshold register ($RXnFLOWTHRESH$), and receive filter low priority frame threshold register ($RXFILTERLOWTHRESH$).
7. Most device drivers open with no multicast addresses, so clear the MAC address hash registers ($MACHASH1$ and $MACHASH2$) to 0.
8. Write the receive buffer offset register ($RXBUFFEROFFSET$) value (typically zero).
9. Initially clear all unicast channels by writing FFh to the receive unicast clear register ($RXUNICASTCLEAR$). If unicast is desired, it can be enabled now by writing the receive unicast set register ($RXUNICASTSET$). Some drivers will default to unicast on device open while others will not.
10. Setup the receive multicast/broadcast/promiscuous channel enable register ($RXMBPENABLE$) with an initial configuration. The configuration is based on the current receive filter settings of the device driver. Some drivers may enable things like broadcast and multicast packets immediately, while others may not.
11. Set the appropriate configuration bits in MACCONTROL (do not set the GMIEN bit yet).
12. Clear all unused channel interrupt bits by writing the receive interrupt mask clear register ($RXINTMASKCLEAR$) and the transmit interrupt mask clear register ($TXINTMASKCLEAR$).
13. Enable the receive and transmit channel interrupt bits in the receive interrupt mask set register ($RXINTMASKSET$) and the transmit interrupt mask set register ($TXINTMASKSET$) for the channels to be used, and enable the HOSTMASK and STATMASK bits using the MAC interrupt mask set register ($MACINTMASKSET$).
14. Initialize the receive and transmit descriptor list queues.
15. Prepare receive by writing a pointer to the head of the receive buffer descriptor list to $RXnHDP$.
16. Enable the receive and transmit DMA controllers by setting the RXEN bit in RXCONTROL and the TXEN bit in TXCONTROL. Then set the GMIEN bit in MACCONTROL.
17. Enable the device interrupt in EMAC subsystem module registers $CnRXTHRESHEN$, $CnRXEN$, $CnTXEN$, and $CnMISCEN$.

22.2.16 Interrupt Support

22.2.16.1 EMAC Module Interrupt Events and Requests

The EMAC module generates 26 interrupt events:

- TXPEND n : Transmit packet completion interrupt for transmit channels 0 through 7
- RXPEND n : Receive packet completion interrupt for receive channels 0 through 7
- RXTRESHPEND n : Receive packet completion interrupt for receive channels 0 through 7 when flow control is enabled and the number of free buffers is below the threshold
- STATPEND: Statistics interrupt
- HOSTPEND: Host error interrupt

22.2.16.1.1 Transmit Packet Completion Interrupts

The transmit DMA engine has eight channels, with each channel having a corresponding interrupt (TXPEND n). The transmit interrupts are level interrupts that remain asserted until cleared by the CPU.

Each of the eight transmit channel interrupts may be individually enabled by setting the appropriate bit in the transmit interrupt mask set register (TXINTMASKSET) to 1. Each of the eight transmit channel interrupts may be individually disabled by clearing the appropriate bit by writing a 1 to the transmit interrupt mask clear register (TXINTMASKCLEAR). The raw and masked transmit interrupt status may be read by reading the transmit interrupt status (unmasked) register (TXINTSTATRAW) and the transmit interrupt status (masked) register (TXINTSTATMASKED), respectively.

When the EMAC completes the transmission of a packet, the EMAC issues an interrupt to the CPU (via the EMAC subsystem) when it writes the packet's last buffer descriptor address to the appropriate channel queue's transmit completion pointer located in the state RAM block. The interrupt is generated by the write when enabled by the interrupt mask, regardless of the value written.

Upon interrupt reception, the CPU processes one or more packets from the buffer chain and then acknowledges an interrupt by writing the address of the last buffer descriptor processed to the queue's associated transmit completion pointer in the transmit DMA state RAM.

The data written by the host (buffer descriptor address of the last processed buffer) is compared to the data in the register written by the EMAC port (address of last buffer descriptor used by the EMAC). If the two values are not equal (which means that the EMAC has transmitted more packets than the CPU has processed interrupts for), the transmit packet completion interrupt signal remains asserted. If the two values are equal (which means that the host has processed all packets that the EMAC has transferred), the pending interrupt is cleared. The value that the EMAC is expecting is found by reading the transmit channel n completion pointer register (TX n CP).

The EMAC write to the completion pointer actually stores the value in the state RAM. The CPU written value does not actually change the register value. The host written value is compared to the register content (which was written by the EMAC) and if the two values are equal then the interrupt is removed; otherwise, the interrupt remains asserted. The host may process multiple packets prior to acknowledging an interrupt, or the host may acknowledge interrupts for every packet.

The application software must acknowledge the EMAC subsystem module after processing packets by writing the appropriate C n RX key to the EMAC End-Of-Interrupt Vector register (MACEOIVECTOR). See [Section 22.5.12](#) for the acknowledge key values.

22.2.16.1.2 Receive Packet Completion Interrupts

The receive DMA engine has eight channels, which each channel having a corresponding interrupt (RXPEND n). The receive interrupts are level interrupts that remain asserted until cleared by the CPU.

Each of the eight receive channel interrupts may be individually enabled by setting the appropriate bit in the receive interrupt mask set register (RXINTMASKSET) to 1. Each of the eight receive channel interrupts may be individually disabled by clearing the appropriate bit by writing a 1 in the receive interrupt mask clear register (RXINTMASKCLEAR). The raw and masked receive interrupt status may be read by reading the receive interrupt status (unmasked) register (RXINTSTATRAW) and the receive interrupt status (masked) register (RXINTSTATMASKED), respectively.

When the EMAC completes a packet reception, the EMAC issues an interrupt to the CPU by writing the packet's last buffer descriptor address to the appropriate channel queue's receive completion pointer located in the state RAM block. The interrupt is generated by the write when enabled by the interrupt mask, regardless of the value written.

Upon interrupt reception, the CPU processes one or more packets from the buffer chain and then acknowledges one or more interrupt(s) by writing the address of the last buffer descriptor processed to the queue's associated receive completion pointer in the receive DMA state RAM.

The data written by the host (buffer descriptor address of the last processed buffer) is compared to the data in the register written by the EMAC (address of last buffer descriptor used by the EMAC). If the two values are not equal (which means that the EMAC has received more packets than the CPU has processed interrupts for), the receive packet completion interrupt signal remains asserted. If the two values are equal (which means that the host has processed all packets that the EMAC has received), the pending interrupt is de-asserted. The value that the EMAC is expecting is found by reading the receive channel n completion pointer register (RX n CP).

The EMAC write to the completion pointer actually stores the value in the state RAM. The CPU written value does not actually change the register value. The host written value is compared to the register content (which was written by the EMAC) and if the two values are equal then the interrupt is removed; otherwise, the interrupt remains asserted. The host may process multiple packets prior to acknowledging an interrupt, or the host may acknowledge interrupts for every packet.

The application software must acknowledge the EMAC subsystem module after processing packets by writing the appropriate C n TX key to the EMAC End-Of-Interrupt Vector register (MACEOIVECTOR). See [Section 22.5.12](#) for the acknowledge key values.

22.2.16.1.3 Statistics Interrupt

The statistics level interrupt (STATPEND) is issued when any statistics value is greater than or equal to 8000 0000h, if enabled by setting the STATMASK bit in the MAC interrupt mask set register (MACINTMASKSET) to 1. The statistics interrupt is removed by writing to decrement any statistics value greater than 8000 0000h. As long as the most-significant bit of any statistics value is set, the interrupt remains asserted.

The application software must acknowledge the EMAC subsystem module after receiving statistics interrupts by writing the appropriate C n MISC key to the EMAC End-Of-Interrupt Vector register (MACEOIVECTOR). See [Section 22.5.12](#) for the acknowledge key values.

22.2.16.1.4 Host Error Interrupt

The host error interrupt (HOSTPEND) is issued, if enabled, under error conditions dealing with the handling of buffer descriptors, detected during transmit or receive DMA transactions. The failure of the software application to supply properly formatted buffer descriptors results in this error. The error bit can only be cleared by resetting the EMAC module in hardware.

The host error interrupt is enabled by setting the HOSTMASK bit in the MAC interrupt mask set register (MACINTMASKSET) to 1. The host error interrupt is disabled by clearing the appropriate bit by writing a 1 in the MAC interrupt mask clear register (MACINTMASKCLEAR). The raw and masked host error interrupt status may be read by reading the MAC interrupt status (unmasked) register (MACINTSTATRAW) and the MAC interrupt status (masked) register (MACINTSTATMASKED), respectively.

The transmit host error conditions are:

- SOP error
- Ownership bit not set in SOP buffer
- Zero next buffer descriptor pointer with EOP
- Zero buffer pointer
- Zero buffer length
- Packet length error

The receive host error conditions are:

- Ownership bit not set in input buffer
- Zero buffer pointer

The application software must acknowledge the EMAC subsystem module after receiving host error interrupts by writing the appropriate $CnMISC$ key to the EMAC End-Of-Interrupt Vector (MACEOIVECTOR). See [Section 22.5.12](#) for the acknowledge key values.

22.2.16.1.5 Receive Threshold Interrupts

Each of the eight receive channels have a corresponding receive threshold interrupt ($RXnTHRESHPEND$). The receive threshold interrupts are level interrupts that remain asserted until the triggering condition is cleared by the host. Each of the eight threshold interrupts may be individually enabled by setting to 1 the appropriate bit in the $RXINTMASKSET$ register. Each of the eight channel interrupts may be individually disabled by clearing to zero the appropriate bit by writing a 1 in the receive interrupt mask clear register ($RXINTMASKCLEAR$). The raw and masked interrupt receive interrupt status may be read by reading the receive interrupt status (unmasked) register ($RXINTSTATRAW$) and the receive interrupt status (masked) register ($RXINTSTATMASKED$), respectively.

An $RXnTHRESHPEND$ interrupt bit is asserted when enabled and when the channel's associated free buffer count ($RXnFREEBUFFER$) is less than or equal to the channel's associated flow control threshold register ($RXnFLOWTHRESH$). The receive threshold interrupts use the same free buffer count and threshold logic as does flow control, but the interrupts are independently enabled from flow control. The threshold interrupts are intended to give the host an indication that resources are running low for a particular channel(s).

The applications software must acknowledge the EMAC subsystem module after receiving threshold interrupts by writing the appropriate $CnRXTHRESH$ key to the EMAC End-Of-Interrupt Vector (MACEOIVECTOR). See [Section 22.5.12](#) for the acknowledge key values.

22.2.16.1.6 Pulse Interrupts

EMAC generates both $TX_PULSE[7:0]$ and $RX_PULSE[7:0]$ pulse interrupts.

- **$TX_PULSE[7:0]$** - Transmit packet completion interrupts for transmit channels 7 to 0.
- **$RX_PULSE[7:0]$** - Receive packet completion interrupts for receive channels 7 to 0.

22.2.16.1.6.1 Pulse Interrupt Description

The following sections describe the pulse interrupts.

22.2.16.1.6.1.1 Transmit Packet Completion Interrupts

The transmit DMA controller has eight channels with each channel having a corresponding pulse interrupt ($TX_PULSE[7:0]$). Each of the eight channel pulse interrupts may be individually enabled by setting to one the appropriate bit in the $Tx_IntMask_Set$ register. Each of the eight channel interrupts may be individually disabled by clearing to zero the appropriate bit in the $Tx_IntMask_Clear$ register. When each CPPI packet DMA transmission is complete (not the complete packet transmission on the wire), the EMAC issues a single $VBUSP_CLK$ wide interrupt pulse. No acknowledgment from the host is required.

22.2.16.1.6.1.2 Receive Packet Completion Interrupts

The receive DMA controller has eight channels with each channel having a corresponding pulse interrupt ($RX_PULSE[7:0]$). Each of the eight channel interrupts may be individually enabled by setting to one the appropriate bit in the $Rx_IntMask_Set$ register. Each of the eight channel interrupts may be individually disabled by clearing to zero the appropriate bit in the $Rx_IntMask_Clear$ register. When a packet DMA reception is complete, the EMAC issues a single $VBUSP_CLK$ wide pulse interrupt. No acknowledgment from the host is required.

22.2.16.2 Proper Interrupt Processing

All the interrupts signaled from the EMAC and MDIO modules are level driven, so if they remain active, their level remains constant; the CPU core may require edge- or pulse-triggered interrupts. In order to properly convert the level-driven interrupt signal to an edge- or pulse-triggered signal, the application software must make use of the interrupt control logic contained in the EMAC subsystem module.

For safe interrupt processing, upon entry to the ISR, the software application should disable interrupts using the EMAC subsystem module registers *CnRXTHRESHEN*, *CnRXEN*, *CnTXEN*, *CnMISCEN*, and then reenables them upon leaving the ISR. If any interrupt signals are active at that time, this creates another rising edge on the interrupt signal going to the CPU interrupt controller, thus triggering another interrupt. The EMAC subsystem module also uses the EMAC subsystem module registers *INTCONTROL*, *CnTXIMAX*, and *CnRXIMAX* to implement interrupt pacing. The application software must acknowledge the EMAC subsystem module by writing the appropriate key to the EMAC End-Of-Interrupt Vector (*MACEOIVECTOR*). See [Section 22.5.12](#) for the acknowledge key values.

EMAC modules do not support level interrupt outputs. External logic has been implemented to convert pulse interrupts into level interrupt. Once the MPU writes corresponding bits in this register, this logic registers the pulse interrupt generated by IP and clears the interrupt.

22.2.16.3 Interrupt Multiplexing

The EMAC subsystem module combines different interrupt signals from both the EMAC and MDIO modules into four interrupt signals (*CnRXTHRESHPULSE*, *CnRXPULSE*, *CnTXPULSE*, *CnMISCPULSE*) that are routed to three independent interrupt cores in the subsystem module. Each interrupt core is capable of relaying all four interrupt signals out of the subsystem module. Some devices may have an individual interrupt core dedicated to a specific CPU or interrupt controller. This configuration gives users of devices greater flexibility when allocating system resources for EMAC management.

When an interrupt is generated, the reason for the interrupt can be read from the MAC input vector register (*MACINVECTOR*) located in the EMAC memory map. *MACINVECTOR* combines the status of the following 28 interrupt signals: *TXPEND_n*, *RXPEND_n*, *RXTHRESHPEND_n*, *STATPEND*, *HOSTPEND*, *LINKINT0*, and *USERINT0*.

22.2.16.4 Pulse Interrupts in EMAC SubSystem

The following subsections describe the pulse interrupts that are generated by the EMAC subsystem.

22.2.16.4.1 C(0/1/2) RXTHRESHPULSE Interrupt Description

The C(0/1/2) *RXTHRESHPULSE* interrupts are each an immediate (non-paced) pulse interrupt selected from the EMAC *RXTHRESHPEND[7:0]* interrupts. The receive threshold pending interrupt(s) is selected by setting one or more bits in the C(0/1/2) *RxThreshEn[7:0]* register. The masked interrupt status can be read in the C(0/1/2) *RxThreshStat[7:0]* address location. Upon reception of an interrupt, software should perform the following:

- Read the C(0/1/2) *RxThreshStat[7:0]* address location to determine which channel(s) caused the interrupt.
- Process received packets in order to add more buffers to any channel that is below the threshold value.
- Write the EMAC completion pointer(s).
- Write the appropriate value (0x0, 0x4, or 0x8) to the *MACEOIVector* register in the emac slave address space.
- Write 1 to the bit 2 of *LVL_INTR_CLEAR* register (0x4800 2594) to clear the interrupt.

22.2.16.4.2 2 C(0/1/2) RXPULSE Interrupt Description

The C(0/1/2) *RXPULSE* interrupts are each a paced pulse interrupt selected from the EMAC *RXPEND[7:0]* interrupts. The receive pending interrupt(s) is selected by setting one or more bits in the C(0/1/2) *RxEn[7:0]* register. The masked interrupt status can be read in the C(0/1/2) *RxStat[7:0]* address location. Upon reception of an interrupt, software should perform the following:

- Read the C(0/1/2) *RxStat[7:0]* address location to determine which channel(s) caused the interrupt.

- Process received packets for the interrupting channel(s).
- Write the EMAC completion pointer(s).
- Write the appropriate value (0x1, 0x5, or 0x9) to the MACEOIVector register in the EMAC slave address space.
- Write 1 to the bit 1 in LVL_INTR_CLEAR register (0x4800 2594) to clear the interrupt.

22.2.16.4.3 C(0/1/2) TXPULSE Interrupt Description

The C(0/1/2) TXPULSE interrupts are each a paced pulse interrupt selected from the EMAC TXPEND[7:0] interrupts. The transmit pending interrupt(s) is selected by setting one or more bits in the C(0/1/2) TxEn[7:0] register. The masked interrupt status can be read in the C(0/1/2) TxStat[7:0] address location. Upon reception of an interrupt, software should perform the following:

- Read the C(0/1/2) TxStat[7:0] address location to determine which channel(s) caused the interrupt.
- Process received packets for the interrupting channel(s).
- Write the EMAC completion pointer(s).
- Write the appropriate value (0x2, 0x6, or 0xa) to the MACEOIVector register in the EMAC slave address space.
- Write 1 to the bit 3 in LVL_INTR_CLEAR register (0x4800 2594) to clear the interrupt.

22.2.16.4.4 C(0/1/2) MISCPULSE Interrupt Description

The C(0/1/2) MISCPULSE interrupts are each an immediate (non-paced) pulse interrupt selected from the miscellaneous interrupts (STATPEND, HOSTPEND, MDIOLINKINT[0], MDIOUSERINT[0]). The miscellaneous interrupt(s) is selected by setting one or more bits in the C(0/1/2) MiscEn[3:0] register. The masked interrupt status can be read in the C(0/1/2) MiscStat[3:0] address location. Upon reception of an interrupt, software should perform the following:

- Read the C(0/1/2) MiscStat[3:0] address location to determine which channel(s) caused the interrupt.
- Process the interrupt.
- Write the appropriate value (0x3, 0x7, or 0xb) to the MACEOIVector register in the emac slave address space.
- Write 1 to the bit 0 in LVL_INTR_CLEAR register(0x48002594) to clear the interrupt.

NOTE: MDIOLINKINT[1] and MDIOUSERINT[1] are not connected.

The following 4 pulse interrupts are only connected from the EMAC module to ARM CPU.

- C0MISCPULSE – Core 0 Miscellaneous Interrupt
- C0RXPULSE – Core 0 Receive Interrupt
- C0RXTHRESHPULSE – Core 0 Receive Threshold Interrupt
- C0TXPULSE – Core 0 Transmit Interrupt.

C1 and C2 interrupts are not connected from EMAC Module to ARM CPU.

22.2.16.5 Interrupt Pacing

The receive and transmit pulse interrupts can be paced. The receive threshold and miscellaneous interrupts are not paced. The Interrupt pacing feature limits the number of interrupts that occur during a given period of time. For heavily loaded systems in which interrupts can occur at a very high rate (e.g. 148,800 packets per second for Ethernet), the performance benefit is significant due to minimizing the overhead associated with servicing each interrupt. Interrupt pacing increases the CPU cache hit ratio by minimizing the number of times that large interrupt service routines are moved to and from the CPU instruction cache. Each CPU receive and transmit pulse interrupt contains an interrupt pacing sub-block (six total). Each sub-block is disabled by default allowing the selected interrupt inputs to pass through unaffected. The interrupt pacing module counts the number of interrupts that occur over a 1ms interval of time. At the end of each 1ms interval, the current number of interrupts is compared with a target number of interrupts (specified by the associated maximum number of interrupts register). Based on the results of the comparison, the length of time during which interrupts are blocked is dynamically adjusted.

The 1ms interval is derived from a 4 μ s pulse that is created from a prescale counter whose value is set in the INTPRESCALE value in the Interrupt Control register of EMAC subsystem. The INTPRESCALE value should be written with the number of VBUSP_CLK periods in 4 μ s. The pacing timer determines the interval during which interrupts are blocked and decrements every 4 μ s. It is reloaded each time a zero count is reached.

The value loaded into the pacing timer is calculated by hardware every 1ms according to the following algorithm:

```

if (intr_count > 2*intr_max)
    pace_timer = 255;

else if (intr_count > 1.5*intr_max)
    pace_timer = last_pace_timer*2 + 1;

else if (intr_count > 1.0*intr_max)
    pace_timer = last_pace_timer + 1;

else if (intr_count > 0.5*intr_max)
    pace_timer = last_pace_timer - 1;

else if (intr_count != 0)
    pace_timer = last_pace_timer/2;

else
    pace_timer = 0;

```

If the rate of interrupt inputs is much less than the target interrupt rate specified in the associated maximum interrupts register, then the interrupt is not blocked. If the interrupt rate is greater than the target rate, the interrupt will be "paced" at the rate specified in the interrupt maximum register. The interrupt maximum register should be written with a value between 2 and 63 inclusive indicating the target number of interrupts per milli-second.

22.2.16.6 MDIO Module Interrupt Events and Requests

The MDIO module generates two interrupt events:

- LINKINT0: Serial interface link change interrupt. Indicates a change in the state of the PHY link selected by the USERPHYSEL0 register
- USERINT0: Serial interface user command event complete interrupt selected by the USERACCESS0 register

22.2.16.6.1 Link Change Interrupt

The MDIO module asserts a link change interrupt (LINKINT0) if there is a change in the link state of the PHY corresponding to the address in the PHYADRMON bit in the MDIO register USERPHYSEL0, and if the LINKINTENB bit is also set in USERPHYSEL0. This interrupt event is also captured in the LINKINTRAW bit in the MDIO link status change interrupt register (LINKINTRAW). LINKINTRAW bits 0 and 1 correspond to USERPHYSEL0 and USERPHYSEL1, respectively.

When the interrupt is enabled and generated, the corresponding LINKINTMASKED bit is also set in the MDIO link status change interrupt register (LINKINTMASKED). The interrupt is cleared by writing back the same bit to LINKINTMASKED (write to clear).

The application software must acknowledge the EMAC subsystem after receiving MDIO interrupts by writing the appropriate CnMISC key to the EMAC End-Of-Interrupt Vector (MACEOIVECTOR). See [Section 22.5.12](#) for the acknowledge key values.

22.2.16.6.2 User Access Completion Interrupt

When the GO bit in one of the MDIO register USERACCESS0 transitions from 1 to 0 (indicating completion of a user access) and the corresponding USERINTMASKSET bit in the MDIO user command complete interrupt mask set register (USERINTMASKSET) corresponding to USERACCESS0 is set, a user access completion interrupt (USERINT) is asserted. This interrupt event is also captured in the USERINTRAW bit in the MDIO user command complete interrupt register (USERINTRAW). USERINTRAW bits 0 and bit 1 correspond to USERACCESS0 and USERACCESS1, respectively.

When the interrupt is enabled and generated, the corresponding USERINTMASKED bit is also set in the MDIO user command complete interrupt register (USERINTMASKED). The interrupt is cleared by writing back the same bit to USERINTMASKED (write to clear).

The application software must acknowledge the EMAC subsystem module after receiving MDIO interrupts by writing the appropriate CnMISC key to the EMAC End-Of-Interrupt Vector (MACEOIVECTOR). See [Section 22.5.12](#) for the acknowledge key values.

22.2.17 Power Management

The clock stop interface allows the EMAC to be gracefully commanded to enter into a stopped clock state. When the (CLKSTOP_REQ) input is asserted, the EMAC suspend state is entered and the EMAC will stop processing receive and transmit frames at the next frame boundary. Any frame currently in reception or transmission will be completed normally without suspension. For transmission, any complete or partial frame in the TX cell FIFO will be transmitted. For receive, frames that are detected by the EMAC after the suspend state is entered are ignored. No statistics will be kept for ignored frames. The (CLKSTOP_ACK) output will be asserted when the EMAC_F enters the IDLE state indicating that the clock (VBUSP_CLK) may be stopped.

22.2.18 Emulation Considerations

22.2.18.1 EMAC Subsystem

The emulation control input (TBEMUSUSP) and EMAC submodule emulation control register allows EMAC subsystem operation to be completely or partially suspended. There is one EMAC subsystem submodule that contains an emulation control register (EMAC). The EMAC submodule emulation control register must be accessed to facilitate EMAC subsystem emulation control. The EMAC subsystem module enters the emulation suspend state if the EMAC submodule is configured for emulation suspend and the emulation suspend input is asserted. EMAC Emulation suspend occurs at packet boundaries. The emulation control feature is implemented for compatibility with other peripherals.

[Table 22-16](#) shows the operation of the emulation control input and register bits.

Table 22-16. Emulation Control

| EMUSUSP | SOFT | FREE | Description |
|---------|------|------|-------------------|
| 0 | X | X | Normal operation |
| 1 | 0 | 0 | Normal operation |
| 1 | 1 | 0 | Emulation suspend |
| 1 | X | 1 | Normal operation |

22.2.18.2 EMAC Submodule

The emulation control input (TBEMUSUP) and register bits (SOFT and FREE in the EMCONTROL register) allow EMAC operation to be suspended. When the emulation suspend state is entered, the EMAC will stop processing receive and transmit frames at the next frame boundary. Any frame currently in reception or transmission will be completed normally without suspension. For transmission, any complete or partial frame in the TX cell FIFO will be transmitted. For receive, frames that are detected by the EMAC after the suspend state is entered are ignored. No statistics will be kept for ignored frames. Emulation control is implemented for compatibility with other peripherals.

[Table 22-17](#) shows the operation of the emulation control input and register bits:

Table 22-17. Emulation Control

| TBEMUSU SP | SOFT | FREE | Description |
|---------------|------|------|------------------|
| 0 | X | X | Normal operation |
| 1 | 0 | 0 | Normal operation |

Table 22-17. Emulation Control (continued)

| | | | |
|---|---|---|-------------------|
| 1 | 1 | 0 | Emulation suspend |
| 1 | X | 1 | Normal operation |

22.3 EMAC Subsystem Registers

Table 22-18 lists the memory-mapped registers for EMAC subsystem.

The base address of these registers is 0x5c00 0000.

Table 22-18. EMAC Subsystem Registers

| Offset | Acronym | Register Description | Section |
|--------|----------------|---|---------------------------------|

22.3.1 Revision ID Register (REVID)

The Revision ID Register (REVID) is shown in [Figure 22-10](#) and described in [Table 22-19](#).

Figure 22-10. Revision ID Register (REVID)

LEGEND: R = Read only; -n = value after reset

Table 22-19. Revision ID Register (REVID) Field Descriptions

| Bit | Field | Value | Description |
|------|-------|------------|--|
| 31-0 | REV | 4EC8 0100h | Identifies the revision ID. Current revision of the EMAC subsystem. |

22.3.2 Software Reset Register (SOFTRESET)

The Software Reset Register (SOFTRESET) is shown in [Figure 22-11](#) and described in [Table 22-20](#).

Figure 22-11. Software Reset Register (SOFTRESET)

LEGEND: R = Read only; R/W = Read/Write; -n = value after reset

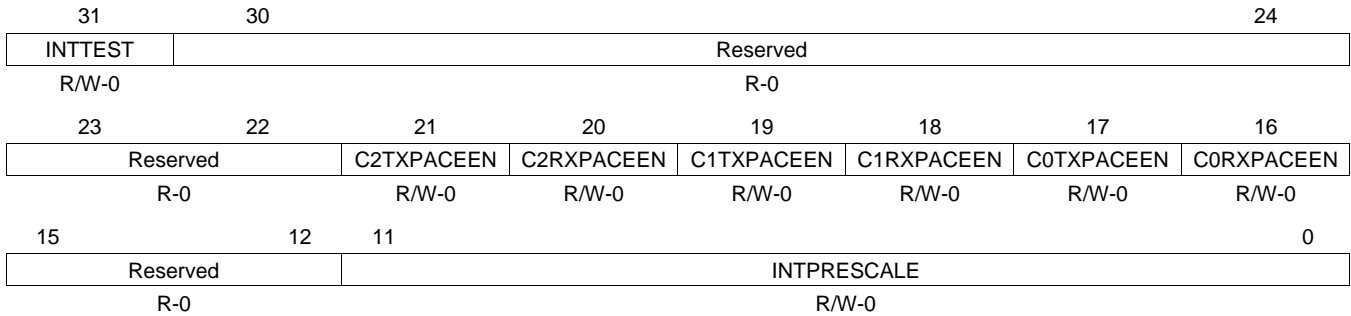

Table 22-20. Software Reset Register (SOFTRESET)

| Bit | Field | Value | Description |
|------|----------|-------|---------------------------|
| 31-1 | Reserved | 0 | Reserved |
| 0 | RESET | 0 | No software reset. |
| | | 1 | Perform a software reset. |

22.3.3 Interrupt Control Register (INTCONTROL)

The Interrupt Control Register (INTCONTROL) is shown in [Figure 22-12](#) and described in [Table 22-21](#)

Figure 22-12. Interrupt Control Register (INTCONTROL)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

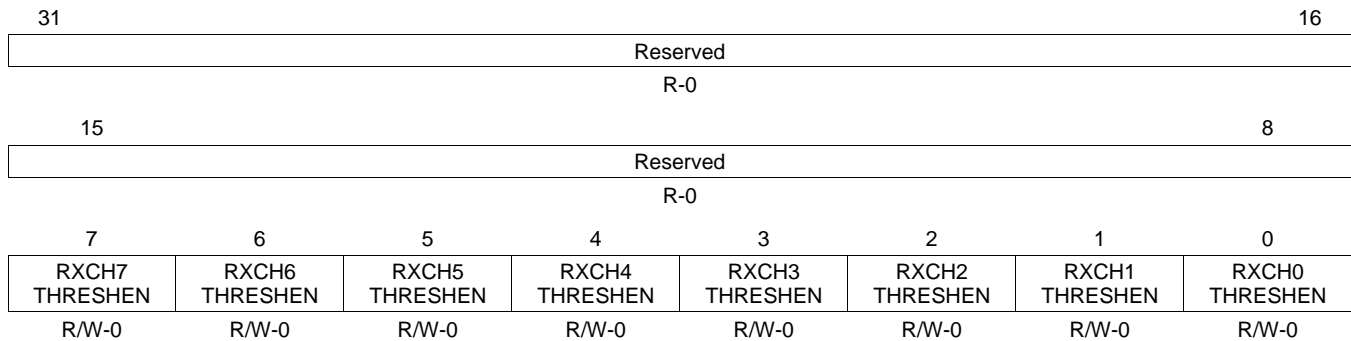

Table 22-21. Interrupt Control Register (INTCONTROL)

| Bit | Field | Value | Description |
|-------|-------------|--------|--|
| 31 | INTTEST | 0-1 | Interrupt Test – Test bit to the interrupt pacing blocks |
| 30-22 | Reserved | 0 | Reserved |
| 21 | C2TXPACEEN | 0 1 | Enable pacing for TX interrupt pulse generation on Interrupt Core 2 Pacing for TX interrupts on Core 2 disabled. Pacing for TX interrupts on Core 2 enabled. |
| 20 | C2RXPACEEN | 0 1 | Enable pacing for RX interrupt pulse generation on Interrupt Core 2 Pacing for RX interrupts on Core 2 disabled. Pacing for RX interrupts on Core 2 enabled. |
| 19 | C1TXPACEEN | 0 1 | Enable pacing for TX interrupt pulse generation on Interrupt Core 1 Pacing for TX interrupts on Core 1 disabled. Pacing for TX interrupts on Core 1 enabled. |
| 18 | C1RXPACEEN | 0 1 | Enable pacing for RX interrupt pulse generation on Interrupt Core 1 Pacing for RX interrupts on Core 1 disabled. Pacing for RX interrupts on Core 1 enabled. |
| 17 | C0TXPACEEN | 0 1 | Enable pacing for TX interrupt pulse generation on Interrupt Core 0 Pacing for TX interrupts on Core 0 disabled. Pacing for TX interrupts on Core 0 enabled. |
| 16 | C0RXPACEEN | 0 1 | Enable pacing for RX interrupt pulse generation on Interrupt Core 0 Pacing for RX interrupts on Core 0 disabled. Pacing for RX interrupts on Core 0 enabled. |
| 15-12 | Reserved | 0 | Reserved |
| 11-0 | INTPRESCALE | 0-7FFh | Number of VBUSP_CLK periods within a 4us time window. |

22.3.4 Interrupt Core Receive Threshold Interrupt Enable Registers (C0RXTHRESHEN-C2RXTHRESHEN)

The Interrupt Core 0-2 Receive Threshold Interrupt Enable Register (CnRXTHRESHEN) is shown in Figure 22-13 and described in Table 22-22.

Figure 22-13. Interrupt Core 0-2 Receive Threshold Interrupt Enable Register (CnRXTHRESHEN)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

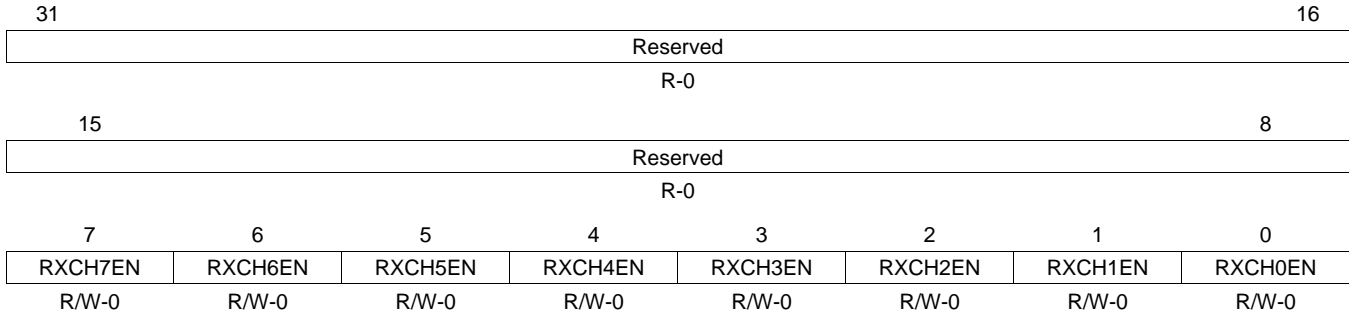

Table 22-22. Interrupt Core 0-2 Receive Threshold Interrupt Enable Register (CnRXTHRESHEN)

| Bit | Field | Value | Description |
|------|---------------|--------|---|
| 31-8 | Reserved | 0 | Reserved |
| 7 | RXCH7THRESHEN | 0 1 | Enable CnRXTHRESHPULSE interrupt generation for RX Channel 7 CnRXTHRESHPULSE generation is disabled for RX Channel 7. CnRXTHRESHPULSE generation is enabled for RX Channel 7. |
| 6 | RXCH6THRESHEN | 0 1 | Enable CnRXTHRESHPULSE interrupt generation for RX Channel 6 CnRXTHRESHPULSE generation is disabled for RX Channel 6. CnRXTHRESHPULSE generation is enabled for RX Channel 6. |
| 5 | RXCH5THRESHEN | 0 1 | Enable CnRXTHRESHPULSE interrupt generation for RX Channel 5 CnRXTHRESHPULSE generation is disabled for RX Channel 5. CnRXTHRESHPULSE generation is enabled for RX Channel 5. |
| 4 | RXCH4THRESHEN | 0 1 | Enable CnRXTHRESHPULSE interrupt generation for RX Channel 4 CnRXTHRESHPULSE generation is disabled for RX Channel 4. CnRXTHRESHPULSE generation is enabled for RX Channel 4. |
| 3 | RXCH3THRESHEN | 0 1 | Enable CnRXTHRESHPULSE interrupt generation for RX Channel 3 CnRXTHRESHPULSE generation is disabled for RX Channel 3. CnRXTHRESHPULSE generation is enabled for RX Channel 3. |
| 2 | RXCH2THRESHEN | 0 1 | Enable CnRXTHRESHPULSE interrupt generation for RX Channel 2 CnRXTHRESHPULSE generation is disabled for RX Channel 2. CnRXTHRESHPULSE generation is enabled for RX Channel 2. |
| 1 | RXCH1THRESHEN | 0 1 | Enable CnRXTHRESHPULSE interrupt generation for RX Channel 1 CnRXTHRESHPULSE generation is disabled for RX Channel 1. CnRXTHRESHPULSE generation is enabled for RX Channel 1. |
| 0 | RXCH0THRESHEN | 0 1 | Enable CnRXTHRESHPULSE interrupt generation for RX Channel 0 CnRXTHRESHPULSE generation is disabled for RX Channel 0. CnRXTHRESHPULSE generation is enabled for RX Channel 0. |

22.3.5 Interrupt Core Receive Interrupt Enable Registers (C0RXEN-C2RXEN)

The Interrupt Core 0-2 Receive Interrupt Enable Register (CnRXEN) is shown in Figure 22-14 and described in Table 22-23

Figure 22-14. Interrupt Core 0-2 Receive Interrupt Enable Register (CnRXEN)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

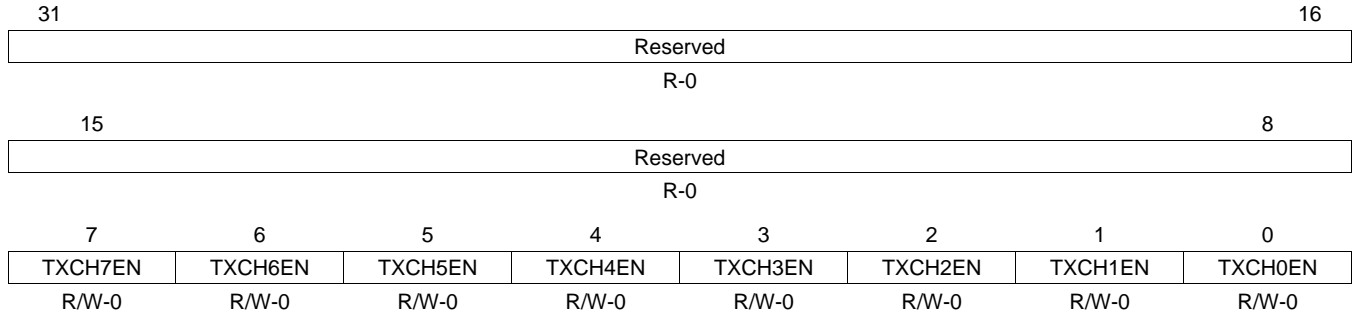

Table 22-23. Interrupt Core 0-2 Receive Interrupt Enable Register (CnRXEN)

| Bit | Field | Value | Description |
|------|----------|-------|--|
| 31-8 | Reserved | 0 | Reserved |
| 7 | RXCH7EN | 0 | Enable CnRXPULSE interrupt generation for RX Channel 7 |
| | | 0 | CnRXPULSE generation is disabled for RX Channel 7. |
| | | 1 | CnRXPULSE generation is enabled for RX Channel 7. |
| 6 | RXCH6EN | 0 | Enable CnRXPULSE interrupt generation for RX Channel 6 |
| | | 0 | CnRXPULSE generation is disabled for RX Channel 6. |
| | | 1 | CnRXPULSE generation is enabled for RX Channel 6. |
| 5 | RXCH5EN | 0 | Enable CnRXPULSE interrupt generation for RX Channel 5 |
| | | 0 | CnRXPULSE generation is disabled for RX Channel 5. |
| | | 1 | CnRXPULSE generation is enabled for RX Channel 5. |
| 4 | RXCH4EN | 0 | Enable CnRXPULSE interrupt generation for RX Channel 4 |
| | | 0 | CnRXPULSE generation is disabled for RX Channel 4. |
| | | 1 | CnRXPULSE generation is enabled for RX Channel 4. |
| 3 | RXCH3EN | 0 | Enable CnRXPULSE interrupt generation for RX Channel 3 |
| | | 0 | CnRXPULSE generation is disabled for RX Channel 3. |
| | | 1 | CnRXPULSE generation is enabled for RX Channel 3. |
| 2 | RXCH2EN | 0 | Enable CnRXPULSE interrupt generation for RX Channel 2 |
| | | 0 | CnRXPULSE generation is disabled for RX Channel 2. |
| | | 1 | CnRXPULSE generation is enabled for RX Channel 2. |
| 1 | RXCH1EN | 0 | Enable CnRXPULSE interrupt generation for RX Channel 1 |
| | | 0 | CnRXPULSE generation is disabled for RX Channel 1. |
| | | 1 | CnRXPULSE generation is enabled for RX Channel 1. |
| 0 | RXCH0EN | 0 | Enable CnRXPULSE interrupt generation for RX Channel 0 |
| | | 0 | CnRXPULSE generation is disabled for RX Channel 0. |
| | | 1 | CnRXPULSE generation is enabled for RX Channel 0. |

22.3.6 Interrupt Core Transmit Interrupt Enable Registers (C0TXEN-C2TXEN)

The Interrupt Core 0-2 Transmit Interrupt Enable Register (CnTXEN) is shown in [Figure 22-15](#) and described in [Table 22-24](#)

Figure 22-15. Interrupt Core 0-2 Transmit Interrupt Enable Register (CnTXEN)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 22-24. Interrupt Core 0-2 Transmit Interrupt Enable Register (CnTXEN)

| Bit | Field | Value | Description |
|------|----------|--------|---|
| 31-8 | Reserved | 0 | Reserved |
| 7 | TXCH7EN | 0 1 | Enable CnTXPULSE interrupt generation for TX Channel 7 CnTXPULSE generation is disabled for TX Channel 7. CnTXPULSE generation is enabled for TX Channel 7. |
| 6 | TXCH6EN | 0 1 | Enable CnTXPULSE interrupt generation for TX Channel 6 CnTXPULSE generation is disabled for TX Channel 6. CnTXPULSE generation is enabled for TX Channel 6. |
| 5 | TXCH5EN | 0 1 | Enable CnTXPULSE interrupt generation for TX Channel 5 CnTXPULSE generation is disabled for TX Channel 5. CnTXPULSE generation is enabled for TX Channel 5. |
| 4 | TXCH4EN | 0 1 | Enable CnTXPULSE interrupt generation for TX Channel 4 CnTXPULSE generation is disabled for TX Channel 4. CnTXPULSE generation is enabled for TX Channel 4. |
| 3 | TXCH3EN | 0 1 | Enable CnTXPULSE interrupt generation for TX Channel 3 CnTXPULSE generation is disabled for TX Channel 3. CnTXPULSE generation is enabled for TX Channel 3. |
| 2 | TXCH2EN | 0 1 | Enable CnTXPULSE interrupt generation for TX Channel 2 CnTXPULSE generation is disabled for TX Channel 2. CnTXPULSE generation is enabled for TX Channel 2. |
| 1 | TXCH1EN | 0 1 | Enable CnTXPULSE interrupt generation for TX Channel 1 CnTXPULSE generation is disabled for TX Channel 1. CnTXPULSE generation is enabled for TX Channel 1. |
| 0 | TXCH0EN | 0 1 | Enable CnTXPULSE interrupt generation for TX Channel 0 CnTXPULSE generation is disabled for TX Channel 0. CnTXPULSE generation is enabled for TX Channel 0. |

22.3.7 Interrupt Core Miscellaneous Interrupt Enable Registers (C0MISCEN-C2MISCEN)

The Interrupt Core 0-2 Miscellaneous Interrupt Enable Register (CnMISCEN) is shown in [Figure 22-16](#) and described in [Table 22-25](#)

Figure 22-16. Interrupt Core 0-2 Miscellaneous Interrupt Enable Register (CnMISCEN)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 22-25. Interrupt Core 0-2 Miscellaneous Interrupt Enable Register (CnMISCEN)

| Bit | Field | Value | Description |
|------|------------|--------|---|
| 31-4 | Reserved | 0 | Reserved |
| 3 | STATPENDEN | 0 1 | Enable CnMISCPULSE interrupt generation when EMAC statistics interrupts are generated CnMISCPULSE generation is disabled for EMAC STATPEND interrupts. CnMISCPULSE generation is enabled for EMAC STATPEND interrupts. |
| 2 | HOSTPENDEN | 0 1 | Enable CnMISCPULSE interrupt generation when EMAC host interrupts are generated CnMISCPULSE generation is disabled for EMAC HOSTPEND interrupts. CnMISCPULSE generation is enabled for EMAC HOSTPEND interrupts. |
| 1 | LINKINT0EN | 0 1 | Enable CnMISCPULSE interrupt generation when MDIO LINKINT0 interrupts (corresponding to USERPHYSEL0) are generated CnMISCPULSE generation is disabled for MDIO LINKINT0 interrupts. CnMISCPULSE generation is enabled for MDIO LINKINT0 interrupts. |
| 0 | USERINT0EN | 0 1 | Enable CnMISCPULSE interrupt generation when MDIO USERINT0 interrupts (corresponding to USERACCESS0) are generated CnMISCPULSE generation is disabled for MDIO USERINT0. CnMISCPULSE generation is enabled for MDIO USERINT0. |

22.3.8 Interrupt Core Receive Threshold Interrupt Status Registers (C0RXTHRESHSTAT-C2RXTHRESHSTAT)

The Interrupt Core 0-2 Receive Threshold Interrupt Status Register (CnRXTHRESHSTAT) is shown in Figure 22-17 and described in Table 22-26

Figure 22-17. Interrupt Core 0-2 Receive Threshold Interrupt Status Register (CnRXTHRESHSTAT)

| Bit | Field | Value | Description |
|------|--------------|--------|---|
| 31-4 | Reserved | 0 | Reserved |
| 3 | STATPENDSTAT | 0 1 | Interrupt status for EMAC STATPEND masked by the CnMISCEN register 0 EMAC STATPEND does not satisfy conditions to generate a CnMISCPULSE interrupt. 1 EMAC STATPEND satisfies conditions to generate a CnMISCPULSE interrupt. |
| 2 | HOSTPENDSTAT | 0 1 | Interrupt status for EMAC HOSTPEND masked by the CnMISCEN register 0 EMAC HOSTPEND does not satisfy conditions to generate a CnMISCPULSE interrupt. 1 EMAC HOSTPEND satisfies conditions to generate a CnMISCPULSE interrupt. |
| 1 | LINKINT0STAT | 0 1 | Interrupt status for MDIO LINKINT0 masked by the CnMISCEN register 0 MDIO LINKINT0 does not satisfy conditions to generate a CnMISCPULSE interrupt. 1 MDIO LINKINT0 satisfies conditions to generate a CnMISCPULSE interrupt. |
| 0 | USERINT0STAT | 0 1 | Interrupt status for MDIO USERINT0 masked by the CnMISCEN register 0 MDIO USERINT0 does not satisfy conditions to generate a CnMISCPULSE interrupt. 1 MDIO USERINT0 satisfies conditions to generate a CnMISCPULSE interrupt. |

22.3.12 Interrupt Core Receive Interrupts Per Millisecond Registers (C0RXIMAX-C2RXIMAX)

The Interrupt Core 0-2 Receive Interrupts Per Millisecond Register (CnRXIMAX) is shown in [Figure 22-21](#) and described in [Table 22-30](#)

Figure 22-21. Interrupt Core 0-2 Receive Interrupts Per Millisecond Register (CnRXIMAX)

LEGEND: R = Read only; R/W = Read/Write; -n = value after reset

Table 22-30. Interrupt Core 0-2 Receive Interrupts Per Millisecond Register (CnRXIMAX)

| Bit | Field | Value | Description |
|------|----------|-------|--|
| 31-6 | Reserved | 0 | Reserved |
| 5-0 | RXIMAX | 0-3Fh | RXIMAX is the maximum number of CnRXPULSE interrupts generated per millisecond when CnRXPACEEN is enabled in INTCONTROL. |

22.3.13 Interrupt Core Transmit Interrupts Per Millisecond Registers (C0TXIMAX-C2TXIMAX)

The Interrupt Core 0-2 Transmit Interrupts Per Millisecond Register (CnTXIMAX) is shown in [Figure 22-22](#) and described in [Table 22-31](#)

Figure 22-22. Interrupt Core 0-2 Transmit Interrupts Per Millisecond Register (CnTXIMAX)

LEGEND: R = Read only; R/W = Read/Write; -n = value after reset

Table 22-31. Interrupt Core 0-2 Transmit Interrupts Per Millisecond Register (CnTXIMAX)

| Bit | Field | Value | Description |
|------|----------|-------|--|
| 31-6 | Reserved | 0 | Reserved |
| 5-0 | TXIMAX | 0-3Fh | TXIMAX is the maximum number of CnTXPULSE interrupts generated per millisecond when CnTXPACEEN is enabled in INTCONTROL. |

22.4 MDIO Registers

Table 22-32 lists the memory-mapped registers for the MDIO module. The base address of these registers is 0x5C03 0000.

Table 22-32. Management Data Input/Output (MDIO) Registers

| Offset | Acronym | Register Description | Section |
|--------|------------------|--|-----------------|
| 0h | REVID | MDIO Revision ID Register | Section 22.4.1 |
| 4h | CONTROL | MDIO Control Register | Section 22.4.2 |
| 8h | ALIVE | PHY Alive Status register | Section 22.4.3 |
| Ch | LINK | PHY Link Status Register | Section 22.4.4 |
| 10h | LINKINTRAW | MDIO Link Status Change Interrupt (Unmasked) Register | Section 22.4.5 |
| 14h | LINKINTMASKED | MDIO Link Status Change Interrupt (Masked) Register | Section 22.4.6 |
| 20h | USERINTRAW | MDIO User Command Complete Interrupt (Unmasked) Register | Section 22.4.7 |
| 24h | USERINTMASKED | MDIO User Command Complete Interrupt (Masked) Register | Section 22.4.8 |
| 28h | USERINTMASKSET | MDIO User Command Complete Interrupt Mask Set Register | Section 22.4.9 |
| 2Ch | USERINTMASKCLEAR | MDIO User Command Complete Interrupt Mask Clear Register | Section 22.4.10 |
| 80h | USERACCESS0 | MDIO User Access Register 0 | Section 22.4.11 |
| 84h | USERPHYSEL0 | MDIO User PHY Select Register 0 | Section 22.4.12 |
| 88h | USERACCESS1 | MDIO User Access Register 1 | Section 22.4.13 |
| 8Ch | USERPHYSEL1 | MDIO User PHY Select Register 1 | Section 22.4.14 |

22.4.1 MDIO Revision ID Register (REVID)

The MDIO Revision ID Register (REVID) is shown in Figure 22-23 and described in Table 22-33.

Figure 22-23. MDIO Revision ID Register (REVID)

LEGEND: R = Read only; -n = value after reset

Table 22-33. MDIO Revision ID Register (REVID) Field Descriptions

| Bit | Field | Value | Description |
|------|-------|------------|--|
| 31-0 | REV | 0007 0105h | Identifies the MDIO Module revision. Current revision of the MDIO Module. |

22.4.2 MDIO Control Register (CONTROL)

The MDIO control register (CONTROL) is shown in [Figure 22-24](#) and described in [Table 22-34](#).

Figure 22-24. MDIO Control Register (CONTROL)

| | | | | |
|---------|----------|----------|----------------------|----------|
| 31 | 30 | 29 | 28 | 24 |
| IDLE | ENABLE | Reserved | HIGHEST_USER_CHANNEL | |
| R-1 | R/W-0 | R-0 | R-1 | |
| 23 | Reserved | | 21 | 20 |
| R-0 | | PREAMBLE | 19 | 18 |
| R-0 | | R/W-0 | R/WC-0 | R/W-0 |
| R-0 | | FAULT | 17 | 16 |
| R-0 | | R/W-0 | R/W-0 | R-0 |
| R-0 | | FAULTENB | INT_TEST_EN ABLE | Reserved |
| R-0 | | R/W-0 | R/W-0 | R-0 |
| 15 | CLKDIV | | | 0 |
| R/W-FFh | | | | |

LEGEND: R/W = R = Read only; R/W = Read/Write; WC = Write 1 to clear; -n = value after reset

Table 22-34. MDIO Control Register (CONTROL) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------------------|---------|--|
| 31 | IDLE | 0 1 | State machine IDLE status bit. State machine is not in idle state. State machine is in idle state. |
| 30 | ENABLE | 0 1 | State machine enable control bit. If the MDIO state machine is active at the time it is disabled, it will complete the current operation before halting and setting the idle bit. Disables the MDIO state machine. Enable the MDIO state machine. |
| 29 | Reserved | 0 | Reserved |
| 28-24 | HIGHEST_USER_CHANNEL | 0-1Fh | Highest user channel that is available in the module. It is currently set to 1. This implies that MDIOUserAccess1 is the highest available user access channel. |
| 23-21 | Reserved | 0 | Reserved |
| 20 | PREAMBLE | 0 1 | Preamble disable Standard MDIO preamble is used. Disables this device from sending MDIO frame preambles. |
| 19 | FAULT | 0 1 | Fault indicator. This bit is set to 1 if the MDIO pins fail to read back what the device is driving onto them. This indicates a physical layer fault and the module state machine is reset. Writing a 1 to it clears this bit. No failure Physical layer fault; the MDIO state machine is reset. |
| 18 | FAULTENB | 0 1 | Fault detect enable. This bit has to be set to 1 to enable the physical layer fault detection. Disables the physical layer fault detection. Enables the physical layer fault detection. |
| 17 | INT_TEST_ENABLE | 0 1 | Interrupt test enable. This bit can be set to 1 to enable the host to set the USERINT and LINKINT bits for test purposes. |
| 16 | Reserved | 0 | Reserved |
| 15-0 | CLKDIV | 0-FFFFh | Clock Divider bits. This field specifies the division ratio between the peripheral clock and the frequency of MDIO_CLK. MDIO_CLK is disabled when CLKDIV is cleared to 0. MDIO_CLK frequency = peripheral clock frequency/(CLKDIV + 1). |

22.4.3 PHY Acknowledge Status Register (ALIVE)

The PHY acknowledge status register (ALIVE) is shown in [Figure 22-25](#) and described in [Table 22-35](#).

Figure 22-25. PHY Acknowledge Status Register (ALIVE)

| | | |
|----|--------|----|
| 31 | ALIVE | 16 |
| | R/WC-0 | |
| 15 | ALIVE | 0 |
| | R/WC-0 | |

LEGEND: R/W = Read/Write; WC = Write 1 to clear; -n = value after reset

Table 22-35. PHY Acknowledge Status Register (ALIVE) Field Descriptions

| Bit | Field | Value | Description |
|------|-------|-------|---|
| 31-0 | ALIVE | | MDIO Alive bits. Each of the 32 bits of this register is set if the most recent access to the PHY with address corresponding to the register bit number was acknowledged by the PHY; the bit is reset if the PHY fails to acknowledge the access. Both the user and polling accesses to a PHY will cause the corresponding alive bit to be updated. The alive bits are only meant to be used to give an indication of the presence or not of a PHY with the corresponding address. Writing a 1 to any bit will clear it, writing a 0 has no effect. |
| | | 0 | The PHY fails to acknowledge the access. |
| | | 1 | The most recent access to the PHY with an address corresponding to the register bit number was acknowledged by the PHY. |

22.4.4 PHY Link Status Register (LINK)

The PHY link status register (LINK) is shown in [Figure 22-26](#) and described in [Table 22-36](#).

Figure 22-26. PHY Link Status Register (LINK)

| | | |
|----|------|----|
| 31 | LINK | 16 |
| | R-0 | |
| 15 | LINK | 0 |
| | R-0 | |

LEGEND: R = Read only; -n = value after reset

Table 22-36. PHY Link Status Register (LINK) Field Descriptions

| Bit | Field | Value | Description |
|------|-------|-------|--|
| 31-0 | LINK | | MDIO Link state bits. This register is updated after a read of the generic status register of a PHY. The bit is set if the PHY with the corresponding address has link and the PHY acknowledges the read transaction. The bit is reset if the PHY indicates it does not have link or fails to acknowledge the read transaction. Writes to the register have no effect. |
| | | 0 | The PHY indicates it does not have a link or fails to acknowledge the read transaction |
| | | 1 | The PHY with the corresponding address has a link and the PHY acknowledges the read transaction. |

22.4.5 MDIO Link Status Change Interrupt (Unmasked) Register (LINKINTRAW)

The MDIO link status change interrupt (unmasked) register (LINKINTRAW) is shown in [Figure 22-27](#) and described in [Table 22-37](#).

Figure 22-27. MDIO Link Status Change Interrupt (Unmasked) Register (LINKINTRAW)

LEGEND: R = Read only; R/W = Read/Write; WC = Write 1 to clear; -n = value after reset

Table 22-37. MDIO Link Status Change Interrupt (Unmasked) Register (LINKINTRAW) Field Descriptions

| Bit | Field | Value | Description |
|------|----------|-------|--|
| 31-2 | Reserved | 0 | Reserved |
| 1 | USERPHY1 | 0 | MDIO Link change event, raw value. When asserted, the bit indicates that there was an MDIO link change event (that is, change in the LINK register) corresponding to the PHY address in USERPHYSEL1. Writing a 1 will clear the event and writing a 0 has no effect. |
| | | 0 | No MDIO link change event. |
| | | 1 | An MDIO link change event (change in the LINK register) corresponding to the PHY address in MDIO user PHY select register USERPHYSEL1 |
| 0 | USERPHY0 | 0 | MDIO Link change event, raw value. When asserted, the bit indicates that there was an MDIO link change event (that is, change in the LINK register) corresponding to the PHY address in USERPHYSEL0. Writing a 1 will clear the event and writing a 0 has no effect. |
| | | 0 | No MDIO link change event. |
| | | 1 | An MDIO link change event (change in the LINK register) corresponding to the PHY address in MDIO user PHY select register USERPHYSEL0 |

22.4.6 MDIO Link Status Change Interrupt (Masked) Register (LINKINTMASKED)

The MDIO link status change interrupt (masked) register (LINKINTMASKED) is shown in Figure 22-28 and described in Table 22-38.

Figure 22-28. MDIO Link Status Change Interrupt (Masked) Register (LINKINTMASKED)

LEGEND: R = Read only; R/W = Read/Write; WC = Write 1 to clear; -n = value after reset

Table 22-38. MDIO Link Status Change Interrupt (Masked) Register (LINKINTMASKED) Field Descriptions

| Bit | Field | Value | Description |
|------|----------|-------|--|
| 31-2 | Reserved | 0 | Reserved |
| 1 | USERPHY1 | 0 | MDIO Link change interrupt, masked value. When asserted, the bit indicates that there was an MDIO link change event (that is, change in the LINK register) corresponding to the PHY address in USERPHYSEL1 and the corresponding LINKINTENB bit was set. Writing a 1 will clear the event and writing a 0 has no effect. |
| | | 1 | No MDIO link change event. |
| | | 1 | An MDIO link change event (change in the LINK register) corresponding to the PHY address in MDIO user PHY select register USERPHYSEL1 and the LINKINTENB bit in USERPHYSEL1 is set to 1. |
| 0 | USERPHY0 | 0 | MDIO Link change interrupt, masked value. When asserted, the bit indicates that there was an MDIO link change event (that is, change in the LINK register) corresponding to the PHY address in USERPHYSEL0 and the corresponding LINKINTENB bit was set. Writing a 1 will clear the event and writing a 0 has no effect. |
| | | 1 | No MDIO link change event. |
| | | 1 | An MDIO link change event (change in the LINK register) corresponding to the PHY address in MDIO user PHY select register USERPHYSEL0 and the LINKINTENB bit in USERPHYSEL0 is set to 1. |

22.4.7 MDIO User Command Complete Interrupt (Unmasked) Register (USERINTRAW)

The MDIO user command complete interrupt (unmasked) register (USERINTRAW) is shown in [Figure 22-29](#) and described in [Table 22-39](#).

Figure 22-29. MDIO User Command Complete Interrupt (Unmasked) Register (USERINTRAW)

LEGEND: R = Read only; R/W = Read/Write; WC = Write 1 to clear; -n = value after reset

Table 22-39. MDIO User Command Complete Interrupt (Unmasked) Register (USERINTRAW) Field Descriptions

| Bit | Field | Value | Description |
|------|-------------|-------|--|
| 31-2 | Reserved | 0 | Reserved |
| 1 | USERACCESS1 | 0 | MDIO User command complete event bit. When asserted, the bit indicates that the previously scheduled PHY read or write command using the USERACCESS1 register has completed. Writing a 1 will clear the event and writing a 0 has no effect. |
| | | 0 | No MDIO user command complete event. |
| | | 1 | The previously scheduled PHY read or write command using MDIO user access register USERACCESS1 has completed. |
| 0 | USERACCESS0 | 0 | MDIO User command complete event bit. When asserted, the bit indicates that the previously scheduled PHY read or write command using the USERACCESS0 register has completed. Writing a 1 will clear the event and writing a 0 has no effect. |
| | | 0 | No MDIO user command complete event. |
| | | 1 | The previously scheduled PHY read or write command using MDIO user access register USERACCESS0 has completed. |

22.4.8 MDIO User Command Complete Interrupt (Masked) Register (USERINTMASKED)

The MDIO user command complete interrupt (masked) register (USERINTMASKED) is shown in [Figure 22-30](#) and described in [Table 22-40](#).

Figure 22-30. MDIO User Command Complete Interrupt (Masked) Register (USERINTMASKED)

LEGEND: R = Read only; R/W = Read/Write; WC = Write 1 to clear; -n = value after reset

Table 22-40. MDIO User Command Complete Interrupt (Masked) Register (USERINTMASKED) Field Descriptions

| Bit | Field | Value | Description |
|------|-------------|-------|--|
| 31-2 | Reserved | 0 | Reserved |
| 1 | USERACCESS1 | 0 | Masked value of MDIO User command complete interrupt. When asserted, The bit indicates that the previously scheduled PHY read or write command using that particular USERACCESS1 register has completed. Writing a 1 will clear the interrupt and writing a 0 has no effect. |
| | | 0 | No MDIO user command complete event. |
| | | 1 | The previously scheduled PHY read or write command using MDIO user access register USERACCESS1 has completed and the corresponding bit in USERINTMASKSET is set to 1. |
| 0 | USERACCESS0 | 0 | Masked value of MDIO User command complete interrupt. When asserted, The bit indicates that the previously scheduled PHY read or write command using that particular USERACCESS0 register has completed. Writing a 1 will clear the interrupt and writing a 0 has no effect. |
| | | 0 | No MDIO user command complete event. |
| | | 1 | The previously scheduled PHY read or write command using MDIO user access register USERACCESS0 has completed and the corresponding bit in USERINTMASKSET is set to 1. |

22.4.9 MDIO User Command Complete Interrupt Mask Set Register (USERINTMASKSET)

The MDIO user command complete interrupt mask set register (USERINTMASKSET) is shown in Figure 22-31 and described in Table 22-41.

Figure 22-31. MDIO User Command Complete Interrupt Mask Set Register (USERINTMASKSET)

LEGEND: R = Read only; R/W = Read/Write; WS = Write 1 to set; -n = value after reset

Table 22-41. MDIO User Command Complete Interrupt Mask Set Register (USERINTMASKSET) Field Descriptions

| Bit | Field | Value | Description |
|------|-------------|-------|--|
| 31-2 | Reserved | 0 | Reserved |
| 1 | USERACCESS1 | 0 | MDIO user interrupt mask set for USERINTMASKED[1]. Setting a bit to 1 will enable MDIO user command complete interrupts for the USERACCESS1 register. MDIO user interrupt for USERACCESS1 is disabled if the corresponding bit is 0. Writing a 0 to this register has no effect. |
| | | 0 | MDIO user command complete interrupts for the MDIO user access register USERACCESS0 is disabled. |
| | | 1 | MDIO user command complete interrupts for the MDIO user access register USERACCESS0 is enabled. |
| 0 | USERACCESS0 | 0 | MDIO user interrupt mask set for USERINTMASKED[0]. Setting a bit to 1 will enable MDIO user command complete interrupts for the USERACCESS0 register. MDIO user interrupt for USERACCESS0 is disabled if the corresponding bit is 0. Writing a 0 to this register has no effect. |
| | | 0 | MDIO user command complete interrupts for the MDIO user access register USERACCESS0 is disabled. |
| | | 1 | MDIO user command complete interrupts for the MDIO user access register USERACCESS0 is enabled. |

22.4.10 MDIO User Command Complete Interrupt Mask Clear Register (USERINTMASKCLEAR)

The MDIO user command complete interrupt mask clear register (USERINTMASKCLEAR) is shown in Figure 22-32 and described in Table 22-42.

Figure 22-32. MDIO User Command Complete Interrupt Mask Clear Register (USERINTMASKCLEAR)

LEGEND: R = Read only; R/W = Read/Write; WC = Write 1 to clear; -n = value after reset

Table 22-42. MDIO User Command Complete Interrupt Mask Clear Register (USERINTMASKCLEAR) Field Descriptions

| Bit | Field | Value | Description |
|------|-------------|-------|---|
| 31-2 | Reserved | 0 | Reserved |
| 1 | USERACCESS1 | 0 | MDIO user command complete interrupt mask clear for USERINTMASKED[1]. Setting the bit to 1 will disable further user command complete interrupts for USERACCESS1. Writing a 0 to this register has no effect. |
| | | 1 | MDIO user command complete interrupts for the MDIO user access register USERACCESS1 is disabled. |
| 0 | USERACCESS0 | 0 | MDIO user command complete interrupt mask clear for USERINTMASKED[0]. Setting the bit to 1 will disable further user command complete interrupts for USERACCESS0. Writing a 0 to this register has no effect. |
| | | 1 | MDIO user command complete interrupts for the MDIO user access register USERACCESS0 is disabled. |

22.4.11 MDIO User Access Register 0 (USERACCESS0)

The MDIO user access register 0 (USERACCESS0) is shown in [Figure 22-33](#) and described in [Table 22-43](#).

Figure 22-33. MDIO User Access Register 0 (USERACCESS0)

LEGEND: R = Read only; R/W = Read/Write; WS = Write 1 to set; -n = value after reset

Table 22-43. MDIO User Access Register 0 (USERACCESS0) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|---------|---|
| 31 | GO | 0-1 | Go bit. Writing a 1 to this bit causes the MDIO state machine to perform an MDIO access when it is convenient for it to do so; this is not an instantaneous process. Writing a 0 to this bit has no effect. This bit is writeable only if the MDIO state machine is enabled. This bit will self clear when the requested access has been completed. Any writes to USERACCESS0 are blocked when the GO bit is 1. |
| 30 | WRITE | 0 1 | Write enable bit. Setting this bit to 1 causes the MDIO transaction to be a register write; otherwise, it is a register read. The user command is a read operation. The user command is a write operation. |
| 29 | ACK | 0-1 | Acknowledge bit. This bit is set if the PHY acknowledged the read transaction. |
| 28-26 | Reserved | 0 | Reserved |
| 25-21 | REGADR | 0-1Fh | Register address bits. This field specifies the PHY register to be accessed for this transaction |
| 20-16 | PHYADR | 0-1Fh | PHY address bits. This field specifies the PHY to be accessed for this transaction. |
| 15-0 | DATA | 0-FFFFh | User data bits. These bits specify the data value read from or to be written to the specified PHY register. |

22.4.13 MDIO User Access Register 1 (USERACCESS1)

The MDIO user access register 1 (USERACCESS1) is shown in [Figure 22-35](#) and described in [Table 22-45](#).

Figure 22-35. MDIO User Access Register 1 (USERACCESS1)

LEGEND: R = Read only; R/W = Read/Write; WS = Write 1 to set; -n = value after reset

Table 22-45. MDIO User Access Register 1 (USERACCESS1) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|---------|---|
| 31 | GO | 0-1 | Go bit. Writing 1 to this bit causes the MDIO state machine to perform an MDIO access when it is convenient for it to do so; this is not an instantaneous process. Writing 0 to this bit has no effect. This bit is writeable only if the MDIO state machine is enabled. This bit will self clear when the requested access has been completed. Any writes to USERACCESS0 are blocked when the GO bit is 1. |
| 30 | WRITE | 0 1 | Write enable bit. Setting this bit to 1 causes the MDIO transaction to be a register write; otherwise, it is a register read. 0 The user command is a read operation. 1 The user command is a write operation. |
| 29 | ACK | 0-1 | Acknowledge bit. This bit is set if the PHY acknowledged the read transaction. |
| 28-26 | Reserved | 0 | Reserved |
| 25-21 | REGADR | 0-1Fh | Register address bits. This field specifies the PHY register to be accessed for this transaction |
| 20-16 | PHYADR | 0-1Fh | PHY address bits. This field specifies the PHY to be accessed for this transaction. |
| 15-0 | DATA | 0-FFFFh | User data bits. These bits specify the data value read from or to be written to the specified PHY register. |

22.4.14 MDIO User PHY Select Register 1 (USERPHYSEL1)

The MDIO user PHY select register 1 (USERPHYSEL1) is shown in [Figure 22-36](#) and described in [Table 22-46](#).

Figure 22-36. MDIO User PHY Select Register 1 (USERPHYSEL1)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 22-46. MDIO User PHY Select Register 1 (USERPHYSEL1) Field Descriptions

| Bit | Field | Value | Description |
|------|------------|-------|--|
| 31-8 | Reserved | 0 | Reserved |
| 7 | LINKSEL | 0 | Link status determination select bit. Default value is 0, which implies that the link status is determined by the MDIO state machine. This is the only option supported on this device. |
| | | 1 | The link status is determined by the MDIO state machine. Not supported. |
| 6 | LINKINTENB | 0 | Link change interrupt enable. Set to 1 to enable link change status interrupts for the PHY address specified in PHYADDRMON. Link change interrupts are disabled if this bit is cleared to 0. |
| | | 1 | Link change interrupts are disabled. Link change status interrupts for PHY address specified in PHYADDRMON bits are enabled. |
| 5 | Reserved | 0 | PHY address whose link status is to be monitored. |
| 4-0 | PHYADDRMON | 0-1Fh | PHY address whose link status is to be monitored. |

22.5 EMAC Module Registers

Table 22-47 lists the memory-mapped registers for the EMAC. The base address of these registers is 0x5C01 0000.

Table 22-47. Ethernet Media Access Controller (EMAC) Registers

| Offset | Acronym | Register Description | Section |
|--------|-------------------|---|---------------------------------|
| 0h | TXREVID | Transmit Revision ID Register | Section 22.5.1 |

LEGEND: R = Read only; R/W = Read/Write; -n = value after reset

Table 22-68. Receive Multicast/Broadcast/Promiscuous Channel Enable Register (RXMBPENABLE) Field Descriptions

| Bit | Field | Value | Description |
|-------|-----------|-------|--|
| 31 | Reserved | 0 | Reserved |
| 30 | RXPASSCRC | 0 | Pass receive CRC enable bit |
| | | 0 | Received CRC is discarded for all channels and is not included in the buffer descriptor packet length field. |
| | | 1 | Received CRC is transferred to memory for all channels and is included in the buffer descriptor packet length. |
| 29 | RXQOSEN | 0 | Receive quality of service enable bit |
| | | 0 | Receive QOS is disabled. |
| | | 1 | Receive QOS is enabled. |
| 28 | RXNOCHAIN | 0 | Receive no buffer chaining bit |
| | | 0 | Received frames can span multiple buffers. |
| | | 1 | The Receive DMA controller transfers each frame into a single buffer, regardless of the frame or buffer size. All remaining frame data after the first buffer is discarded. The buffer descriptor buffer length field will contain the entire frame byte count (up to 65535 bytes). |
| 27-25 | Reserved | 0 | Reserved |
| 24 | RXCMFEN | 0 | Receive copy MAC control frames enable bit. Enables MAC control frames to be transferred to memory. MAC control frames are normally acted upon (if enabled), but not copied to memory. MAC control frames that are pause frames will be acted upon if enabled in MACCONTROL, regardless of the value of RXCMFEN. Frames transferred to memory due to RXCMFEN will have the CONTROL bit set in their EOP buffer descriptor. |
| | | 0 | MAC control frames are filtered (but acted upon if enabled). |
| | | 1 | MAC control frames are transferred to memory. |
| 23 | RXCSFEN | 0 | Receive copy short frames enable bit. Enables frames or fragments shorter than 64 bytes to be copied to memory. Frames transferred to memory due to RXCSFEN will have the FRAGMENT or UNDERSIZE bit set in their EOP buffer descriptor. Fragments are short frames that contain CRC / align / code errors and undersized are short frames without errors. |
| | | 0 | Short frames are filtered. |
| | | 1 | Short frames are transferred to memory. |

**Table 22-68. Receive Multicast/Broadcast/Promiscuous Channel Enable Register (RXMBPENABLE)
Field Descriptions (continued)**

| Bit | Field | Value | Description |
|-------|--|-------|---|
| 22 | RXCEFEN | 0 | Receive copy error frames enable bit. Enables frames containing errors to be transferred to memory. The appropriate error bit will be set in the frame EOP buffer descriptor. Frames containing errors are filtered. |
| | | 1 | Frames containing errors are transferred to memory. |
| 21 | RXCAFEN | 0 | Receive copy all frames enable bit. Enables frames that do not address match (includes multicast frames that do not hash match) to be transferred to the promiscuous channel selected by RXPROMCH bits. Such frames will be marked with the NOMATCH bit in their EOP buffer descriptor. Frames that do not address match are filtered. |
| | | 1 | Frames that do not address match are transferred to the promiscuous channel selected by RXPROMCH bits. |
| 20-19 | Reserved | 0 | Reserved |
| 18-16 | RXPROMCH | 0-7h | Receive promiscuous channel select |

22.5.22 Receive Unicast Enable Set Register (RXUNICASTSET)

The receive unicast enable set register (RXUNICASTSET) is shown in [Figure 22-58](#) and described in [Table 22-69](#).

Figure 22-58. Receive Unicast Enable Set Register (RXUNICASTSET)

LEGEND: R = Read only; R/W = Read/Write; WS = Write 1 to set, write of 0 has no effect; -n = value after reset

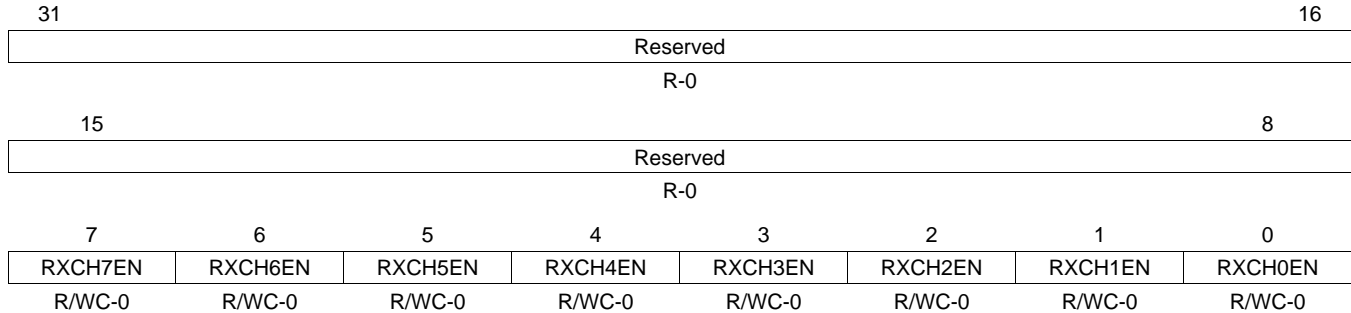

Table 22-69. Receive Unicast Enable Set Register (RXUNICASTSET) Field Descriptions

| Bit | Field | Value | Description |
|------|----------|-------|---|
| 31-8 | Reserved | 0 | Reserved |
| 7 | RXCH7EN | 0-1 | Receive channel 7 unicast enable set bit. Write 1 to set the enable, a write of 0 has no effect. May be read. |
| 6 | RXCH6EN | 0-1 | Receive channel 6 unicast enable set bit. Write 1 to set the enable, a write of 0 has no effect. May be read. |
| 5 | RXCH5EN | 0-1 | Receive channel 5 unicast enable set bit. Write 1 to set the enable, a write of 0 has no effect. May be read. |
| 4 | RXCH4EN | 0-1 | Receive channel 4 unicast enable set bit. Write 1 to set the enable, a write of 0 has no effect. May be read. |
| 3 | RXCH3EN | 0-1 | Receive channel 3 unicast enable set bit. Write 1 to set the enable, a write of 0 has no effect. May be read. |
| 2 | RXCH2EN | 0-1 | Receive channel 2 unicast enable set bit. Write 1 to set the enable, a write of 0 has no effect. May be read. |
| 1 | RXCH1EN | 0-1 | Receive channel 1 unicast enable set bit. Write 1 to set the enable, a write of 0 has no effect. May be read. |
| 0 | RXCH0EN | 0-1 | Receive channel 0 unicast enable set bit. Write 1 to set the enable, a write of 0 has no effect. May be read. |

22.5.23 Receive Unicast Clear Register (RXUNICASTCLEAR)

The receive unicast clear register (RXUNICASTCLEAR) is shown in [Figure 22-59](#) and described in [Table 22-70](#).

Figure 22-59. Receive Unicast Clear Register (RXUNICASTCLEAR)

LEGEND: R = Read only; R/W = Read/Write; WC = Write 1 to clear, write of 0 has no effect; -n = value after reset

Table 22-70. Receive Unicast Clear Register (RXUNICASTCLEAR) Field Descriptions

| Bit | Field | Value | Description |
|------|----------|-------|--|
| 31-8 | Reserved | 0 | Reserved |
| 7 | RXCH7EN | 0-1 | Receive channel 7 unicast enable clear bit. Write 1 to clear the enable, a write of 0 has no effect. |
| 6 | RXCH6EN | 0-1 | Receive channel 6 unicast enable clear bit. Write 1 to clear the enable, a write of 0 has no effect. |
| 5 | RXCH5EN | 0-1 | Receive channel 5 unicast enable clear bit. Write 1 to clear the enable, a write of 0 has no effect. |
| 4 | RXCH4EN | 0-1 | Receive channel 4 unicast enable clear bit. Write 1 to clear the enable, a write of 0 has no effect. |
| 3 | RXCH3EN | 0-1 | Receive channel 3 unicast enable clear bit. Write 1 to clear the enable, a write of 0 has no effect. |
| 2 | RXCH2EN | 0-1 | Receive channel 2 unicast enable clear bit. Write 1 to clear the enable, a write of 0 has no effect. |
| 1 | RXCH1EN | 0-1 | Receive channel 1 unicast enable clear bit. Write 1 to clear the enable, a write of 0 has no effect. |
| 0 | RXCH0EN | 0-1 | Receive channel 0 unicast enable clear bit. Write 1 to clear the enable, a write of 0 has no effect. |

22.5.24 Receive Maximum Length Register (RXMAXLEN)

The receive maximum length register (RXMAXLEN) is shown in [Figure 22-60](#) and described in [Table 22-71](#).

Figure 22-60. Receive Maximum Length Register (RXMAXLEN)

| | | |
|----|----------|----|
| 31 | Reserved | 16 |
| | R-0 | |
| 15 | RXMAXLEN | 0 |
| | R/W-5EEh | |

LEGEND: R = Read only; R/W = Read/Write; -n = value after reset

Table 22-71. Receive Maximum Length Register (RXMAXLEN) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|---------|--|
| 31-16 | Reserved | 0 | Reserved |
| 15-0 | RXMAXLEN | 0-FFFFh | Receive maximum frame length. These bits determine the maximum length of a received frame. The reset value is 5EEh (1518). Frames with byte counts greater than RXMAXLEN are long frames. Long frames with no errors are oversized frames. Long frames with CRC, code, or alignment error are jabber frames. |

22.5.25 Receive Buffer Offset Register (RXBUFFEROFFSET)

The receive buffer offset register (RXBUFFEROFFSET) is shown in [Figure 22-61](#) and described in [Table 22-72](#).

Figure 22-61. Receive Buffer Offset Register (RXBUFFEROFFSET)

| | | |
|----|----------------|----|
| 31 | Reserved | 16 |
| | R-0 | |
| 15 | RXBUFFEROFFSET | 0 |
| | R/W-0 | |

LEGEND: R = Read only; R/W = Read/Write; -n = value after reset

Table 22-72. Receive Buffer Offset Register (RXBUFFEROFFSET) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------------|---------|---|
| 31-16 | Reserved | 0 | Reserved |
| 15-0 | RXBUFFEROFFSET | 0-FFFFh | Receive buffer offset value. These bits are written by the EMAC into each frame SOP buffer descriptor Buffer Offset field. The frame data begins after the RXBUFFEROFFSET value of bytes. A value of 0 indicates that there are no unused bytes at the beginning of the data, and that valid data begins on the first byte of the buffer. A value of Fh (15) indicates that the first 15 bytes of the buffer are to be ignored by the EMAC and that valid buffer data starts on byte 16 of the buffer. This value is used for all channels. |

22.5.26 Receive Filter Low Priority Frame Threshold Register (RXFILTERLOWTHRESH)

The receive filter low priority frame threshold register (RXFILTERLOWTHRESH) is shown in [Figure 22-62](#) and described in [Table 22-73](#).

Figure 22-62. Receive Filter Low Priority Frame Threshold Register (RXFILTERLOWTHRESH)

| 31 | Reserved | | | 16 |
| R-0 | | | | |
| 15 | 8 | 7 | 0 | |
| Reserved | | | RXFILTERTHRESH | |
| R-0 | | | R/W-0 | |

LEGEND: R = Read only; R/W = Read/Write; -n = value after reset

Table 22-73. Receive Filter Low Priority Frame Threshold Register (RXFILTERLOWTHRESH) Field Descriptions

| Bit | Field | Value | Description |
|------|----------------|-------|--|
| 31-8 | Reserved | 0 | Reserved |
| 7-0 | RXFILTERTHRESH | 0-FFh | Receive filter low threshold. These bits contain the free buffer count threshold value for filtering low priority incoming frames. This field should remain 0, if no filtering is desired. |

22.5.27 Receive Channel Flow Control Threshold Registers (RX0FLOWTHRESH-RX7FLOWTHRESH)

The receive channel 0-7 flow control threshold register (RX n FLOWTHRESH) is shown in [Figure 22-63](#) and described in [Table 22-74](#).

Figure 22-63. Receive Channel n Flow Control Threshold Register (RX n FLOWTHRESH)

| | | | | |
|----------|----------|---|-------------------|----|
| 31 | Reserved | | | 16 |
| R-0 | | | | |
| 15 | 8 | 7 | 0 | |
| Reserved | | | RX n FLOWTHRESH | |
| R-0 | | | R/W-0 | |

LEGEND: R = Read only; R/W = Read/Write; -n = value after reset

Table 22-74. Receive Channel n Flow Control Threshold Register (RX n FLOWTHRESH) Field Descriptions

| Bit | Field | Value | Description |
|------|-------------------|-------|--|
| 31-8 | Reserved | 0 | Reserved |
| 7-0 | RX n FLOWTHRESH | 0-FFh | Receive flow threshold. These bits contain the threshold value for issuing flow control on incoming frames for channel n (when enabled). |

22.5.28 Receive Channel Free Buffer Count Registers (RX0FREEBUFFER-RX7FREEBUFFER)

The receive channel 0-7 free buffer count register (RX n FREEBUFFER) is shown in [Figure 22-64](#) and described in [Table 22-75](#).

Figure 22-64. Receive Channel n Free Buffer Count Register (RX n FREEBUFFER)

LEGEND: R = Read only; WI = Write to increment; - n = value after reset

Table 22-75. Receive Channel n Free Buffer Count Register (RX n FREEBUFFER) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------------|-------|--|
| 31-16 | Reserved | 0 | Reserved |
| 15-0 | RX n FREEBUF | 0-FFh | Receive free buffer count. These bits contain the count of free buffers available. The RXFILTERTHRESH value is compared with this field to determine if low priority frames should be filtered. The RX n FLOWTHRESH value is compared with this field to determine if receive flow control should be issued against incoming packets (if enabled). This is a write-to-increment field. This field rolls over to 0 on overflow. If hardware flow control or QOS is used, the host must initialize this field to the number of available buffers (one register per channel). The EMAC decrements the associated channel register for each received frame by the number of buffers in the received frame. The host must write this field with the number of buffers that have been freed due to host processing. |

22.5.29 MAC Control Register (MACCONTROL)

The MAC control register (MACCONTROL) is shown in [Figure 22-65](#) and described in [Table 22-76](#).

Figure 22-65. MAC Control Register (MACCONTROL)

| | | | | | | | |
|----------|--------|-------|----------|----------------|----------|----------|------------|
| Reserved | | | | | | | |
| R-0 | | | | | | | |
| Reserved | | | MACEXTEN | | GIGFORCE | | MACIFCTL_B |
| R-0 | | | R/W-0 | | R/W-0 | | R/W-0 |
| Reserved | TXPACE | GMIEN | TXFLOWEN | RXBUFFERFLOWEN | Reserved | LOOPBACK | FULLDUPLEX |
| R-0 | R/W-0 | R/W-0 | R/W-0 | R/W-0 | R-0 | R/W-0 | R/W-0 |

LEGEND: R = Read only; R/W = Read/Write; -n = value after reset

Table 22-76. MAC Control Register (MACCONTROL) Field Descriptions

| Bit | Field | Value | Description |
|-------|---------------|-------|---|
| 31-19 | Reserved | 0 | Reserved. |
| 18 | MACEXTEN | 0-1 | External Enable. Enables the full duplex and gigabit mode to be selected from the EXTFULLDUPLEXSEL and EXTGIGSEL input signals and not from the full duplex and gig bits contained in this register. This register bit is also output on the MAC_EXT_EN signal. |
| 17 | GIGFORCE | 0-1 | Gigabit Mode Force. This bit is used to force the EMAC into gigabit mode if the input GMII_MTCLK has been stopped by the PHY. For RMII interface the value should be zero. |
| 16 | MACIFCTL_B | 0-1 | Interface Control B. Intended as a general purpose output bit to be used to control external gaskets associated with the GMII (GMII to RGMII etc). For RMII interface this bit is unused. |
| 15 | MACIFCTL_A | 0-1 | Interface Control A – Intended as a general purpose output bit to be used to control external gaskets associated with the GMII (GMII to RGMII etc). For GMII interface this bit is unused. For RMII Interface, it is used to select transmit and receive speed. |
| | | 0 | Operate RMII interface in 10 Mbps speed mode. |
| | | 1 | Operate RMII interface in 100 Mbps speed mode. |
| 14 | RXOFFLENBLOCK | 0-1 | Receive offset / length word write block. |
| | | 0 | Do not block the DMA writes to the receive buffer descriptor offset / buffer length word. |
| | | 1 | Block all EMAC DMA controller receive buffer descriptor offset / buffer length words during packet processing. When this bit is set, the EMAC will never write the third word to any receive buffer descriptor. |
| 13 | RXOWNERSHIP | 0-1 | Receive ownership write bit value. |
| | | 0 | The EMAC writes the Receive ownership bit to 0 at the end of packet processing. |
| | | 1 | The EMAC writes the Receive ownership bit to 1 at the end of packet processing. If you do not use the ownership mechanism, you can set this mode to preclude the necessity of software having to set this bit each time the buffer descriptor is used. |
| 12 | Reserved | 0 | Reserved |
| 11 | CMDIDLE | 0-1 | Command Idle bit |
| | | 0 | Idle is not commanded. |
| | | 1 | Idle is commanded (read IDLE in the MACSTATUS register). |
| 10 | TXSHORTGAPEN | 0-1 | Transmit Short Gap Enable |
| | | 0 | Transmit with a short IPG is disabled. Normal 96-bit time IPG is inserted between packets. |
| | | 1 | Transmit with a short IPG is enabled. Shorter 88-bit time IPG is inserted between packets. |

Table 22-76. MAC Control Register (MACCONTROL) Field Descriptions (continued)

| Bit | Field | Value | Description |
|-----|----------------|-------|---|
| 9 | TXPTYPE | 0 | Transmit queue priority type The queue uses a round-robin scheme to select the next channel for transmission. |
| | | 1 | The queue uses a fixed-priority (channel 7 highest priority) scheme to select the next channel for transmission. |
| 8 | MEMTEST | 0 | FIFO RAM processor read/write enable (ram test mode) No host access to RX/TX FIFO RAM. |
| | | 1 | Host read/write access to RX/TX FIFO RAMS. |
| 7 | Reserved | 0 | Reserved |
| 6 | TXPACE | 0 | Transmit pacing enable bit Transmit pacing is disabled. |
| | | 1 | Transmit pacing is enabled. |
| 5 | GMIEN | 0 | GMII enable bit GMII RX and TX are held in reset. |
| | | 1 | GMII RX and TX are enabled for receive and transmit. |
| 4 | TXFLOWEN | 0 | Transmit flow control enable bit. This bit determines if incoming pause frames are acted upon in full-duplex mode. Incoming pause frames are not acted upon in half-duplex mode, regardless of this bit setting. The RXMBPENABLE bits determine whether or not received pause frames are transferred to memory. Transmit flow control is disabled. Full-duplex mode: incoming pause frames are not acted upon. |
| | | 1 | Transmit flow control is enabled. Full-duplex mode: incoming pause frames are acted upon. |
| 3 | RXBUFFERFLOWEN | 0 | Receive buffer flow control enable bit Receive flow control is disabled. Half-duplex mode: no flow control generated collisions are sent. Full-duplex mode: no outgoing pause frames are sent. |
| | | 1 | Receive flow control is enabled. Half-duplex mode: collisions are initiated when receive buffer flow control is triggered. Full-duplex mode: outgoing pause frames are sent when receive flow control is triggered. |
| 2 | Reserved | 0 | Reserved |
| 1 | LOOPBACK | 0 | Loopback mode. The loopback mode forces internal full-duplex mode regardless of the FULLDUPLEX bit. The loopback bit should be changed only when GMIEN bit is deasserted. Loopback mode is disabled. |
| | | 1 | Loopback mode is enabled. |
| 0 | FULLDUPLEX | 0 | Full duplex mode. Half-duplex mode is enabled. |
| | | 1 | Full-duplex mode is enabled. |

22.5.30 MAC Status Register (MACSTATUS)

The MAC status register (MACSTATUS) is shown in [Figure 22-66](#) and described in [Table 22-77](#).

Figure 22-66. MAC Status Register (MACSTATUS)

| | | | | | | | |

Table 22-77. MAC Status Register (MACSTATUS) Field Descriptions

| Bit | Field | Value | Description |
|-------|-----------|--|---|
| 31 | IDLE | 0 1 | EMAC idle bit. This bit is cleared to 0 at reset; one clock after reset, it goes to 1. The EMAC is not idle. The EMAC is in the idle state. |
| 30-24 | Reserved | 0 | Reserved |
| 23-20 | TXERRCODE | 0-Fh 0 1h 2h 3h 4h 5h 6h 7h-Fh | Transmit host error code. These bits indicate that EMAC detected transmit DMA related host errors. The host should read this field after a host error interrupt (HOSTPEND) to determine the error. Host error interrupts require hardware reset in order to recover. A 0 packet length is an error, but it is not detected. No error SOP error; the buffer is the first buffer in a packet, but the SOP bit is not set in software. Ownership bit not set in SOP buffer Zero next buffer descriptor pointer without EOP Zero buffer pointer Zero buffer length Packet length error (sum of buffers is less than packet length) Reserved |
| 19 | Reserved | 0 | Reserved |
| 18-16 | TXERRCH | 0-7h 0 1h 2h 3h 4h 5h 6h 7h | Transmit host error channel. These bits indicate which transmit channel the host error occurred on. This field is cleared to 0 on a host read. The host error occurred on transmit channel 0 The host error occurred on transmit channel 1 The host error occurred on transmit channel 2 The host error occurred on transmit channel 3 The host error occurred on transmit channel 4 The host error occurred on transmit channel 5 The host error occurred on transmit channel 6 The host error occurred on transmit channel 7 |

Table 22-77. MAC Status Register (MACSTATUS) Field Descriptions (continued)

| Bit | Field | Value | Description |
|-------|---------------------|---|--|
| 15-12 | RXERRCODE | 0-Fh 0 1h 2h 3h 4h 5h-Fh | Receive host error code. These bits indicate that EMAC detected receive DMA related host errors. The host should read this field after a host error interrupt (HOSTPEND) to determine the error. Host error interrupts require hardware reset in order to recover. No error Reserved Ownership bit not set in SOP buffer Reserved Zero buffer pointer Reserved |
| 11 | Reserved | 0 | Reserved |
| 10-8 | RXERRCH | 0-7h 0 1h 2h 3h 4h 5h 6h 7h | Receive host error channel. These bits indicate which receive channel the host error occurred on. This field is cleared to 0 on a host read. The host error occurred on receive channel 0 The host error occurred on receive channel 1 The host error occurred on receive channel 2 The host error occurred on receive channel 3 The host error occurred on receive channel 4 The host error occurred on receive channel 5 The host error occurred on receive channel 6 The host error occurred on receive channel 7 |
| 7-5 | Reserved | 0 | Reserved |
| 4 | EXTGIGSEL | 0-1 | External GIG – This is the value of the EXTGIGSEL input. |
| 3 | EXTFULLDUPL XSEL | 0-1 | External Fullduplex – This is the value of the EXTFULLDUPLEXSEL input. |
| 2 | RXQOSACT | 0 1 | Receive Quality of Service (QOS) active bit. When asserted, indicates that receive quality of service is enabled and that at least one channel freebuffer count (RXnFREEBUFFER) is less than or equal to the RXFILTERLOWTHRESH value. Receive quality of service is disabled. Receive quality of service is enabled. |
| 1 | RXFLOWACT | 0 1 | Receive flow control active bit. When asserted, at least one channel freebuffer count (RXnFREEBUFFER) is less than or equal to the channel's corresponding RXnFILTERTHRESH value. Receive flow control is inactive. Receive flow control is active. |
| 0 | TXFLOWACT | 0 1 | Transmit flow control active bit. When asserted, this bit indicates that the pause time period is being observed for a received pause frame. No new transmissions will begin while this bit is asserted, except for the transmission of pause frames. Any transmission in progress when this bit is asserted will complete. Transmit flow control is inactive. Transmit flow control is active. |

22.5.31 Emulation Control Register (EMCONTROL)

The emulation control register (EMCONTROL) is shown in [Figure 22-67](#) and described in [Table 22-78](#).

Figure 22-67. Emulation Control Register (EMCONTROL)

LEGEND: R = Read only; R/W = Read/Write; -n = value after reset

Table 22-78. Emulation Control Register (EMCONTROL) Field Descriptions

| Bit | Field | Value | Description |
|------|----------|-------|--|
| 31-2 | Reserved | 0 | Reserved |
| 1 | SOFT | 0 | Emulation soft bit. This bit is used in conjunction with FREE bit to determine the emulation suspend mode. This bit has no effect if FREE = 1. Soft mode is disabled. EMAC stops immediately during emulation halt. |
| | | 1 | Soft mode is enabled. During emulation halt, EMAC stops after completion of current operation. |
| 0 | FREE | 0 | Emulation free bit. This bit is used in conjunction with SOFT bit to determine the emulation suspend mode. Free-running mode is disabled. During emulation halt, SOFT bit determines operation of EMAC. |
| | | 1 | Free-running mode is enabled. During emulation halt, EMAC continues to operate. |

22.5.32 FIFO Control Register (FIFOCONTROL)

The FIFO control register (FIFOCONTROL) is shown in [Figure 22-68](#) and described in [Table 22-79](#).

Figure 22-68. FIFO Control Register (FIFOCONTROL)

LEGEND: R = Read only; R/W = Read/Write; -n = value after reset

Table 22-79. FIFO Control Register (FIFOCONTROL) Field Descriptions

| Bit | Field | Value | Description |
|------|--------------|-------|--|
| 31-2 | Reserved | 0 | Reserved |
| 1-0 | TXCELLTHRESH | 0-3h | Transmit FIFO cell threshold. Indicates the number of 64-byte packet cells required to be in the transmit FIFO before the packet transfer is initiated. Packets with fewer cells will be initiated when the complete packet is contained in the FIFO. The default value is 2, but 3 is also valid. 0 and 1 are not valid values. |
| | | 0-1h | Not a valid value. |
| | | 2h | Two 64-byte packet cells required to be in the transmit FIFO. |
| | | 3h | Three 64-byte packet cells required to be in the transmit FIFO. |

22.5.33 MAC Configuration Register (MACCONFIG)

The MAC configuration register (MACCONFIG) is shown in [Figure 22-69](#) and described in [Table 22-80](#).

Figure 22-69. MAC Configuration Register (MACCONFIG)

LEGEND: R = Read only; -n = value after reset

Table 22-80. MAC Configuration Register (MACCONFIG) Field Descriptions

| Bit | Field | Value | Description |
|-------|-------------|-------|--|
| 31-24 | TXCELLDEPTH | 3h | Transmit cell depth. These bits indicate the number of cells in the transmit FIFO. |
| 23-16 | RXCELLDEPTH | 3h | Receive cell depth. These bits indicate the number of cells in the receive FIFO. |
| 15-8 | ADDRESSTYPE | 2h | Address type |
| 7-0 | MACCFIG | 2h | MAC configuration value |

22.5.34 Soft Reset Register (SOFTRESET)

The soft reset register (SOFTRESET) is shown in [Figure 22-70](#) and described in [Table 22-81](#).

Figure 22-70. Soft Reset Register (SOFTRESET)

LEGEND: R = Read only; R/W = Read/Write; -n = value after reset

Table 22-81. Soft Reset Register (SOFTRESET) Field Descriptions

| Bit | Field | Value | Description |
|------|-----------|-------|--|
| 31-1 | Reserved | 0 | Reserved |
| 0 | SOFTRESET | 0 | Software reset complete status - read. |
| | | 1 | Software reset is applied - write. |

22.5.35 MAC Source Address Low Bytes Register (MACSRCADDRLO)

The MAC source address low bytes register (MACSRCADDRLO) is shown in [Figure 22-71](#) and described in [Table 22-82](#).

Figure 22-71. MAC Source Address Low Bytes Register (MACSRCADDRLO)

LEGEND: R = Read only; R/W = Read/Write; -n = value after reset

Table 22-82. MAC Source Address Low Bytes Register (MACSRCADDRLO) Field Descriptions

| Bit | Field | Value | Description |
|-------|-------------|-------|--|
| 31-16 | Reserved | 0 | Reserved |
| 15-8 | MACSRCADDR0 | 0-FFh | MAC source address lower 7-0 bits (byte 0) |
| 7-0 | MACSRCADDR1 | 0-FFh | MAC source address bits 15-8 (byte 1) |

22.5.36 MAC Source Address High Bytes Register (MACSRCADDRHI)

The MAC source address high bytes register (MACSRCADDRHI) is shown in [Figure 22-72](#) and described in [Table 22-83](#).

Figure 22-72. MAC Source Address High Bytes Register (MACSRCADDRHI)

LEGEND: R = Read only; R/W = Read/Write; -n = value after reset

Table 22-83. MAC Source Address High Bytes Register (MACSRCADDRHI) Field Descriptions

| Bit | Field | Value | Description |
|-------|-------------|-------|--|
| 31-24 | MACSRCADDR2 | 0-FFh | MAC source address bits 23-16 (byte 2) |
| 23-16 | MACSRCADDR3 | 0-FFh | MAC source address bits 31-24 (byte 3) |
| 15-8 | MACSRCADDR4 | 0-FFh | MAC source address bits 39-32 (byte 4) |
| 7-0 | MACSRCADDR5 | 0-FFh | MAC source address bits 47-40 (byte 5) |

22.5.37 MAC Hash Address Register 1 (MACHASH1)

The MAC hash registers allow group addressed frames to be accepted on the basis of a hash function of the address. The hash function creates a 6-bit data value (Hash_fun) from the 48-bit destination address (DA) as follows:

Hash_fun(0)=DA(0) XOR DA(6) XOR DA(12) XOR DA(18) XOR DA(24) XOR DA(30) XOR DA(36) XOR DA(42);

Hash_fun(1)=DA(1) XOR DA(7) XOR DA(13) XOR DA(19) XOR DA(25) XOR DA(31) XOR DA(37) XOR DA(43);

Hash_fun(2)=DA(2) XOR DA(8) XOR DA(14) XOR DA(20) XOR DA(26) XOR DA(32) XOR DA(38) XOR DA(44);

Hash_fun(3)=DA(3) XOR DA(9) XOR DA(15) XOR DA(21) XOR DA(27) XOR DA(33) XOR DA(39) XOR DA(45);

Hash_fun(4)=DA(4) XOR DA(10) XOR DA(16) XOR DA(22) XOR DA(28) XOR DA(34) XOR DA(40) XOR DA(46);

Hash_fun(5)=DA(5) XOR DA(11) XOR DA(17) XOR DA(23) XOR DA(29) XOR DA(35) XOR DA(41) XOR DA(47);

This function is used as an offset into a 64-bit hash table stored in MACHASH1 and MACHASH2 that indicates whether a particular address should be accepted or not.

The MAC hash address register 1 (MACHASH1) is shown in [Figure 22-73](#) and described in [Table 22-84](#).

Figure 22-73. MAC Hash Address Register 1 (MACHASH1)

LEGEND: R = Read only; R/W = Read/Write; -n = value after reset

Table 22-84. MAC Hash Address Register 1 (MACHASH1) Field Descriptions

| Bit | Field | Value | Description |
|------|----------|--------------|---|
| 31-0 | MACHASH1 | 0-FFFF FFFFh | Least-significant 32 bits of the hash table corresponding to hash values 0 to 31. If a hash table bit is set, then a group address that hashes to that bit index is accepted. |

22.5.38 MAC Hash Address Register 2 (MACHASH2)

The MAC hash address register 2 (MACHASH2) is shown in [Figure 22-74](#) and described in [Table 22-85](#).

Figure 22-74. MAC Hash Address Register 2 (MACHASH2)

LEGEND: R = Read only; R/W = Read/Write; -n = value after reset

Table 22-85. MAC Hash Address Register 2 (MACHASH2) Field Descriptions

| Bit | Field | Value | Description |
|------|----------|--------------|---|
| 31-0 | MACHASH2 | 0-FFFF FFFFh | Most-significant 32 bits of the hash table corresponding to hash values 32 to 63. If a hash table bit is set, then a group address that hashes to that bit index is accepted. |

22.5.39 Back Off Test Register (BOFFTEST)

The back off test register (BOFFTEST) is shown in [Figure 22-75](#) and described in [Table 22-86](#).

Figure 22-75. Back Off Random Number Generator Test Register (BOFFTEST)

LEGEND: R = Read only; -n = value after reset

Table 22-86. Back Off Test Register (BOFFTEST) Field Descriptions

| Bit | Field | Value | Description |
|-------|-----------|--------|---|
| 31-26 | Reserved | 0 | Reserved |
| 25-16 | RNDNUM | 0-3FFh | Backoff random number generator. This field allows the Backoff Random Number Generator to be read. Reading this field returns the generator's current value. The value is reset to 0 and begins counting on the clock after the deassertion of reset. |
| 15-12 | COLLCOUNT | 0-Fh | Collision count. These bits indicate the number of collisions the current frame has experienced. |
| 11-10 | Reserved | 0 | Reserved |
| 9-0 | TXBACKOFF | 0-3FFh | Backoff count. This field allows the current value of the backoff counter to be observed for test purposes. This field is loaded automatically according to the backoff algorithm, and is decremented by one for each slot time after the collision. |

22.5.40 Transmit Pacing Algorithm Test Register (TPACETEST)

The transmit pacing algorithm test register (TPACETEST) is shown in [Figure 22-76](#) and described in [Table 22-87](#).

Figure 22-76. Transmit Pacing Algorithm Test Register (TPACETEST)

LEGEND: R = Read only; -n = value after reset

Table 22-87. Transmit Pacing Algorithm Test Register (TPACETEST) Field Descriptions

| Bit | Field | Value | Description |
|------|----------|-------|--|
| 31-5 | Reserved | 0 | Reserved |
| 4-0 | PACEVAL | 0-1Fh | Pacing register current value. A nonzero value in this field indicates that transmit pacing is active. A transmit frame collision or deferral causes PACEVAL to be loaded with 1Fh (31); good frame transmissions (with no collisions or deferrals) cause PACEVAL to be decremented down to 0. When PACEVAL is nonzero, the transmitter delays four Inter Packet Gaps between new frame transmissions after each successfully transmitted frame that had no deferrals or collisions. If a transmit frame is deferred or suffers a collision, the IPG time is not stretched to four times the normal value. Transmit pacing helps reduce capture effects, which improves overall network bandwidth. |

22.5.41 Receive Pause Timer Register (RXPAUSE)

The receive pause timer register (RXPAUSE) is shown in [Figure 22-77](#) and described in [Table 22-88](#).

Figure 22-77. Receive Pause Timer Register (RXPAUSE)

LEGEND: R = Read only; -n = value after reset

Table 22-88. Receive Pause Timer Register (RXPAUSE) Field Descriptions

| Bit | Field | Value | Description |
|-------|------------|-------|---|
| 31-16 | Reserved | 0 | Reserved |
| 15-0 | PAUSETIMER | 0-FFh | Receive pause timer value. These bits allow the contents of the receive pause timer to be observed. The receive pause timer is loaded with FF00h when the EMAC sends an outgoing pause frame (with pause time of FFFFh). The receive pause timer is decremented at slot time intervals. If the receive pause timer decrements to 0, then another outgoing pause frame is sent and the load/decrement process is repeated. |

22.5.42 Transmit Pause Timer Register (TXPAUSE)

The transmit pause timer register (TXPAUSE) is shown in [Figure 22-78](#) and described in [Table 22-89](#).

Figure 22-78. Transmit Pause Timer Register (TXPAUSE)

LEGEND: R = Read only; -n = value after reset

Table 22-89. Transmit Pause Timer Register (TXPAUSE) Field Descriptions

| Bit | Field | Value | Description |
|-------|------------|-------|---|
| 31-16 | Reserved | 0 | Reserved |
| 15-0 | PAUSETIMER | 0-FFh | Transmit pause timer value. These bits allow the contents of the transmit pause timer to be observed. The transmit pause timer is loaded by a received (incoming) pause frame, and then decremented at slot time intervals down to 0, at which time EMAC transmit frames are again enabled. |

22.5.43 MAC Address Low Bytes Register (MACADDRLO)

The MAC address low bytes register used in address matching (MACADDRLO), is shown in [Figure 22-79](#) and described in [Table 22-90](#).

Figure 22-79. MAC Address Low Bytes Register (MACADDRLO)

LEGEND: R = Read only; R/W = Read/Write; -n = value after reset; -x = value is indeterminate after reset

Table 22-90. MAC Address Low Bytes Register (MACADDRLO) Field Descriptions

| Bit | Field | Value | Description |
|-------|-----------|--------|---|
| 31-21 | Reserved | 0 | Reserved |
| 20 | VALID | 0 1 | Address valid bit. This bit should be cleared to zero for unused address channels Address is not valid and will not be used for matching or filtering incoming packets Address is valid and will be used for matching or filtering incoming packets |
| 19 | MATCHFILT | 0 1 | Match or filter bit The address will be used (if the VALID bit is set) to filter incoming packet addresses The address will be used (if the VALID bit is set) to match incoming packet addresses |
| 18-16 | CHANNEL | 0-7h | Channel select. Determines which receive channel a valid address match will be transferred to. The channel is a don't care if MATCHFILT is cleared to 0. |
| 15-8 | MACADDR0 | 0-FFh | MAC address lower 7-0 bits (byte 0) |
| 7-0 | MACADDR1 | 0-FFh | MAC address bits 15-8 (byte 1) |

22.5.44 MAC Address High Bytes Register (MACADDRHI)

The MAC address high bytes register (MACADDRHI) is shown in [Figure 22-80](#) and described in [Table 22-91](#).

Figure 22-80. MAC Address High Bytes Register (MACADDRHI)

LEGEND: R/W = Read/Write; -x = value is indeterminate after reset

Table 22-91. MAC Address High Bytes Register (MACADDRHI) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|-------|---|
| 31-24 | MACADDR2 | 0-FFh | MAC source address bits 23-16 (byte 2) |
| 23-16 | MACADDR3 | 0-FFh | MAC source address bits 31-24 (byte 3) |
| 15-8 | MACADDR4 | 0-FFh | MAC source address bits 39-32 (byte 4) |
| 7-0 | MACADDR5 | 0-FFh | MAC source address bits 47-40 (byte 5). Bit 40 is the group bit. It is forced to 0 and read as 0. Therefore, only unicast addresses are represented in the address table. |

22.5.45 MAC Index Register (MACINDEX)

The MAC index register (MACINDEX) is shown in [Figure 22-81](#) and described in [Table 22-92](#).

Figure 22-81. MAC Index Register (MACINDEX)

LEGEND: R = Read only; R/W = Read/Write; -n = value after reset

Table 22-92. MAC Index Register (MACINDEX) Field Descriptions

| Bit | Field | Value | Description |
|------|----------|-------|---|
| 31-5 | Reserved | 0 | Reserved |
| 4-0 | MACINDEX | 0-1Fh | Mac Address Index. The 53-bits of each address location are written with three consecutive 32-bit VBUS accesses. The host must write the index into the ram in the MACINDEX(4:0) register, followed by the upper 32-bits of address (which are stored in a holding register), followed by the lower 16- bits of address (with control bits). The 53-bit indexed ram location is written when the low location is written. |

22.5.46 Transmit Channel DMA Head Descriptor Pointer Registers (TX0HDP-TX7HDP)

The transmit channel 0-7 DMA head descriptor pointer register (TX n HDP) is shown in [Figure 22-82](#) and described in [Table 22-93](#).

Figure 22-82. Transmit Channel n DMA Head Descriptor Pointer Register (TX n HDP)

LEGEND: R/W = Read/Write; - n = value after reset; -x = value is indeterminate after reset

Table 22-93. Transmit Channel n DMA Head Descriptor Pointer Register (TX n HDP) Field Descriptions

| Bit | Field | Value | Description |
|------|------------|--------------|---|
| 31-0 | TX n HDP | 0-FFFF FFFFh | Transmit channel n DMA Head Descriptor pointer. Writing a transmit DMA buffer descriptor address to a head pointer location initiates transmit DMA operations in the queue for the selected channel. Writing to these locations when they are nonzero is an error (except at reset). Host software must initialize these locations to 0 on reset. |

22.5.47 Receive Channel DMA Head Descriptor Pointer Registers (RX0HDP-RX7HDP)

The receive channel 0-7 DMA head descriptor pointer register (RX n HDP) is shown in [Figure 22-83](#) and described in [Table 22-94](#).

Figure 22-83. Receive Channel n DMA Head Descriptor Pointer Register (RX n HDP)

LEGEND: R/W = Read/Write; - n = value after reset; -x = value is indeterminate after reset

Table 22-94. Receive Channel n DMA Head Descriptor Pointer Register (RX n HDP) Field Descriptions

| Bit | Field | Value | Description |
|------|------------|--------------|--|
| 31-0 | RX n HDP | 0-FFFF FFFFh | Receive channel n DMA Head Descriptor pointer. Writing a receive DMA buffer descriptor address to this location allows receive DMA operations in the selected channel when a channel frame is received. Writing to these locations when they are nonzero is an error (except at reset). Host software must initialize these locations to 0 on reset. |

22.5.48 Transmit Channel Completion Pointer Registers (TX0CP-TX7CP)

The transmit channel 0-7 completion pointer register (TX n CP) is shown in [Figure 22-84](#) and described in [Table 22-95](#).

Figure 22-84. Transmit Channel n Completion Pointer Register (TX n CP)

LEGEND: R/W = Read/Write; - n = value after reset; - x = value is indeterminate after reset

Table 22-95. Transmit Channel n Completion Pointer Register (TX n CP) Field Descriptions

| Bit | Field | Value | Description |
|------|-----------|--------------|---|
| 31-0 | TX n CP | 0-FFFF FFFFh | Transmit channel n completion pointer register is written by the host with the buffer descriptor address for the last buffer processed by the host during interrupt processing. The EMAC uses the value written to determine if the interrupt should be deasserted. |

22.5.49 Receive Channel Completion Pointer Registers (RX0CP-RX7CP)

The receive channel 0-7 completion pointer register (RX n CP) is shown in [Figure 22-85](#) and described in [Table 22-96](#).

Figure 22-85. Receive Channel n Completion Pointer Register (RX n CP)

LEGEND: R/W = Read/Write; - n = value after reset; - x = value is indeterminate after reset

Table 22-96. Receive Channel n Completion Pointer Register (RX n CP) Field Descriptions

| Bit | Field | Value | Description |
|------|-----------|--------------|--|
| 31-0 | RX n CP | 0-FFFF FFFFh | Receive channel n completion pointer register is written by the host with the buffer descriptor address for the last buffer processed by the host during interrupt processing. The EMAC uses the value written to determine if the interrupt should be deasserted. |

NOTE: The value read is the completion pointer (interrupt acknowledge) value that was written by the CPGMAC dma controller (port). The value written to this register by the host is compared with the value that the port wrote to determine if the interrupt should remain asserted. The value written is not actually stored in the location. The interrupt is deasserted if the two values are equal.

22.5.50 Network Statistics Registers

The EMAC has a set of statistics that record events associated with frame traffic. The statistics values are cleared to zero 38 clocks after the rising edge of VBUSP_RST_N. When the GMIIEN bit in the MACCONTROL register is set, all statistics registers (see [Figure 22-86](#)) are write-to-decrement. The value written is subtracted from the register value with the result stored in the register. If a value greater than the statistics value is written, then zero is written to the register (writing FFFF FFFFh clears a statistics location). When the GMIIEN bit is cleared, all statistics registers are read/write (normal write direct, so writing 0000 0000h clears a statistics location). All write accesses must be 32-bit accesses.

The statistics interrupt (STATPEND) is issued, if enabled, when any statistics value is greater than or equal to 8000 0000h. The statistics interrupt is removed by writing to decrement any statistics value greater than 8000 0000h. The statistics are mapped into internal memory space and are 32-bits wide. All statistics rollover from FFFF FFFFh to 0000 0000h.

Figure 22-86. Statistics Register

LEGEND: R/W = Read/Write; WD = Write to decrement; -n = value after reset

22.5.50.1 Good Receive Frames Register (RXGOODFRAMES)

The total number of good frames received on the EMAC. A good frame is defined as having all of the following:

- Any data or MAC control frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- Was of length 64 to RXMAXLEN bytes inclusive
- Had no CRC error, alignment error, or code error

See [Section 22.2.5.5](#) for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

22.5.50.2 Broadcast Receive Frames Register (RXBCASTFRAMES)

The total number of good broadcast frames received on the EMAC. A good broadcast frame is defined as having all of the following:

- Any data or MAC control frame that was destined for address FF-FF-FF-FF-FF-FFh only
- Was of length 64 to RXMAXLEN bytes inclusive
- Had no CRC error, alignment error, or code error

See [Section 22.2.5.5](#) for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

22.5.50.3 Multicast Receive Frames Register (RXMCASTFRAMES)

The total number of good multicast frames received on the EMAC. A good multicast frame is defined as having all of the following:

- Any data or MAC control frame that was destined for any multicast address other than FF-FF-FF-FF-FF-FFh
- Was of length 64 to RXMAXLEN bytes inclusive
- Had no CRC error, alignment error, or code error

See [Section 22.2.5.5](#) for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

22.5.50.4 Pause Receive Frames Register (RXPAUSEFRAMES)

The total number of IEEE 802.3X pause frames received by the EMAC (whether acted upon or not). A pause frame is defined as having all of the following:

- Contained any unicast, broadcast, or multicast address
- Contained the length/type field value 88.08h and the opcode 0001h
- Was of length 64 to RXMAXLEN bytes inclusive
- Had no CRC error, alignment error, or code error
- Pause-frames had been enabled on the EMAC (TXFLOWEN bit is set in MACCONTROL).

The EMAC could have been in either half-duplex or full-duplex mode. See [Section 22.2.5.5](#) for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

22.5.50.5 Receive CRC Errors Register (RXCRCERRORS)

The total number of frames received on the EMAC that experienced a CRC error. A frame with CRC errors is defined as having all of the following:

- Was any data or MAC control frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- Was of length 64 to RXMAXLEN bytes inclusive
- Had no alignment or code error
- Had a CRC error. A CRC error is defined as having all of the following:
 - A frame containing an even number of nibbles
 - Fails the frame check sequence test

See [Section 22.2.5.5](#) for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

22.5.50.6 Receive Alignment/Code Errors Register (RXALIGNCODEERRORS)

The total number of frames received on the EMAC that experienced an alignment error or code error. Such a frame is defined as having all of the following:

- Was any data or MAC control frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- Was of length 64 to RXMAXLEN bytes inclusive
- Had either an alignment error or a code error
 - An alignment error is defined as having all of the following:
 - A frame containing an odd number of nibbles
 - Fails the frame check sequence test, if the final nibble is ignored
 - A code error is defined as a frame that has been discarded because the EMACs MII_RXER pin is driven with a one for at least one bit-time's duration at any point during the frame's reception.

Overruns have no effect on this statistic.

CRC alignment or code errors can be calculated by summing receive alignment errors, receive code errors, and receive CRC errors.

22.5.50.7 Receive Oversized Frames Register (RXOVERSIZED)

The total number of oversized frames received on the EMAC. An oversized frame is defined as having all of the following:

- Was any data or MAC control frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- Was greater than RXMAXLEN in bytes
- Had no CRC error, alignment error, or code error

See [Section 22.2.5.5](#) for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

22.5.50.8 Receive Jabber Frames Register (RXJABBER)

The total number of jabber frames received on the EMAC. A jabber frame is defined as having all of the following:

- Was any data or MAC control frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- Was greater than RXMAXLEN bytes long
- Had a CRC error, alignment error, or code error

See [Section 22.2.5.5](#) for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

22.5.50.9 Receive Undersized Frames Register (RXUNDERSIZED)

The total number of undersized frames received on the EMAC. An undersized frame is defined as having all of the following:

- Was any data frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- Was less than 64 bytes long
- Had no CRC error, alignment error, or code error

See [Section 22.2.5.5](#) for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

22.5.50.10 Receive Frame Fragments Register (RXFRAGMENTS)

The total number of frame fragments received on the EMAC. A frame fragment is defined as having all of the following:

- Any data frame (address matching does not matter)
- Was less than 64 bytes long
- Had a CRC error, alignment error, or code error
- Was not the result of a collision caused by half duplex, collision based flow control

See [Section 22.2.5.5](#) for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

22.5.50.11 Filtered Receive Frames Register (RXFILTERED)

The total number of frames received on the EMAC that the EMAC address matching process indicated should be discarded. Such a frame is defined as having all of the following:

- Was any data frame (not MAC control frame) destined for any unicast, broadcast, or multicast address
- Did not experience any CRC error, alignment error, code error
- The address matching process decided that the frame should be discarded (filtered) because it did not match the unicast, broadcast, or multicast address, and it did not match due to promiscuous mode.

To determine the number of receive frames discarded by the EMAC for any reason, sum the following statistics (promiscuous mode disabled):

- Receive fragments
- Receive undersized frames
- Receive CRC errors
- Receive alignment/code errors
- Receive jabbers
- Receive overruns
- Receive filtered frames

This may not be an exact count because the receive overruns statistic is independent of the other statistics, so if an overrun occurs at the same time as one of the other discard reasons, then the above sum double-counts that frame.

22.5.50.12 Receive QOS Filtered Frames Register (RXQOSFILTERED)

The total number of frames received on the EMAC that were filtered due to receive quality of service (QOS) filtering. Such a frame is defined as having all of the following:

- Any data or MAC control frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- The frame destination channel flow control threshold register (RX n FLOWTHRESH) value was greater than or equal to the channel's corresponding free buffer register (RX n FREEBUFFER) value
- Was of length 64 to RXMAXLEN
- RXQOSEN bit is set in RXMBPENABLE
- Had no CRC error, alignment error, or code error

See [Section 22.2.5.5](#) for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

22.5.50.13 Receive Octet Frames Register (RXOCTETS)

The total number of bytes in all good frames received on the EMAC. A good frame is defined as having all of the following:

- Any data or MAC control frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- Was of length 64 to RXMAXLEN bytes inclusive
- Had no CRC error, alignment error, or code error

See [Section 22.2.5.5](#) for definitions of alignment, code, and CRC errors. Overruns have no effect on this statistic.

22.5.50.14 Good Transmit Frames Register (TXGOODFRAMES)

The total number of good frames transmitted on the EMAC. A good frame is defined as having all of the following:

- Any data or MAC control frame that was destined for any unicast, broadcast, or multicast address
- Was any length
- Had no late or excessive collisions, no carrier loss, and no underrun

22.5.50.15 Broadcast Transmit Frames Register (TXBCASTFRAMES)

The total number of good broadcast frames transmitted on the EMAC. A good broadcast frame is defined as having all of the following:

- Any data or MAC control frame destined for address FF-FF-FF-FF-FF-FFh only
- Was of any length
- Had no late or excessive collisions, no carrier loss, and no underrun

22.5.50.16 Multicast Transmit Frames Register (TXMCASTFRAMES)

The total number of good multicast frames transmitted on the EMAC. A good multicast frame is defined as having all of the following:

- Any data or MAC control frame destined for any multicast address other than FF-FF-FF-FF-FF-FFh
- Was of any length
- Had no late or excessive collisions, no carrier loss, and no underrun

22.5.50.17 Pause Transmit Frames Register (TXPAUSEFRAMES)

The total number of IEEE 802.3X pause frames transmitted by the EMAC. Pause frames cannot underrun or contain a CRC error because they are created in the transmitting MAC, so these error conditions have no effect on this statistic. Pause frames sent by software are not included in this count. Since pause frames are only transmitted in full-duplex mode, carrier loss and collisions have no effect on this statistic.

Transmitted pause frames are always 64-byte multicast frames so appear in the multicast transmit frames register and 64 octet frames register statistics.

22.5.50.18 Deferred Transmit Frames Register (TXDEFERRED)

The total number of frames transmitted on the EMAC that first experienced deferment. Such a frame is defined as having all of the following:

- Was any data or MAC control frame destined for any unicast, broadcast, or multicast address
- Was any size
- Had no carrier loss and no underrun
- Experienced no collisions before being successfully transmitted
- Found the medium busy when transmission was first attempted, so had to wait.

CRC errors have no effect on this statistic.

22.5.50.19 Transmit Collision Frames Register (TXCOLLISION)

The total number of times that the EMAC experienced a collision. Collisions occur under two circumstances:

- When a transmit data or MAC control frame has all of the following:
 - Was destined for any unicast, broadcast, or multicast address
 - Was any size
 - Had no carrier loss and no underrun
 - Experienced a collision. A jam sequence is sent for every non-late collision, so this statistic increments on each occasion if a frame experiences multiple collisions (and increments on late collisions).
- When the EMAC is in half-duplex mode, flow control is active, and a frame reception begins.

CRC errors have no effect on this statistic.

22.5.50.20 Transmit Single Collision Frames Register (TXSINGLECOLL)

The total number of frames transmitted on the EMAC that experienced exactly one collision. Such a frame is defined as having all of the following:

- Was any data or MAC control frame destined for any unicast, broadcast, or multicast address

- Was any size
- Had no carrier loss and no underrun
- Experienced one collision before successful transmission. The collision was not late.

CRC errors have no effect on this statistic.

22.5.50.21 Transmit Multiple Collision Frames Register (TXMULTICOLL)

The total number of frames transmitted on the EMAC that experienced multiple collisions. Such a frame is defined as having all of the following:

- Was any data or MAC control frame destined for any unicast, broadcast, or multicast address
- Was any size
- Had no carrier loss and no underrun
- Experienced 2 to 15 collisions before being successfully transmitted. None of the collisions were late.

CRC errors have no effect on this statistic.

22.5.50.22 Transmit Excessive Collision Frames Register (TXEXCESSIVECOLL)

The total number of frames when transmission was abandoned due to excessive collisions. Such a frame is defined as having all of the following:

- Was any data or MAC control frame destined for any unicast, broadcast, or multicast address
- Was any size
- Had no carrier loss and no underrun
- Experienced 16 collisions before abandoning all attempts at transmitting the frame. None of the collisions were late.

CRC errors have no effect on this statistic.

22.5.50.23 Transmit Late Collision Frames Register (TXLATECOLL)

The total number of frames when transmission was abandoned due to a late collision. Such a frame is defined as having all of the following:

- Was any data or MAC control frame destined for any unicast, broadcast, or multicast address
- Was any size
- Had no carrier loss and no underrun
- Experienced a collision later than 512 bit-times into the transmission. There may have been up to 15 previous (non-late) collisions that had previously required the transmission to be reattempted. The late collisions statistic dominates over the single, multiple, and excessive collisions statistics. If a late collision occurs, the frame is not counted in any of these other three statistics.

CRC errors, carrier loss, and underrun have no effect on this statistic.

22.5.50.24 Transmit Underrun Error Register (TXUNDERRUN)

The number of frames sent by the EMAC that experienced FIFO underrun. Late collisions, CRC errors, carrier loss, and underrun have no effect on this statistic.

22.5.50.25 Transmit Carrier Sense Errors Register (TXCARRIERSENSE)

The total number of frames on the EMAC that experienced carrier loss. Such a frame is defined as having all of the following:

- Was any data or MAC control frame destined for any unicast, broadcast, or multicast address
- Was any size
- The carrier sense condition was lost or never asserted when transmitting the frame (the frame is not retransmitted)

CRC errors and underrun have no effect on this statistic.

22.5.50.26 Transmit Octet Frames Register (TXOCTETS)

The total number of bytes in all good frames transmitted on the EMAC. A good frame is defined as having all of the following:

- Any data or MAC control frame that was destined for any unicast, broadcast, or multicast address
- Was any length
- Had no late or excessive collisions, no carrier loss, and no underrun

22.5.50.27 Transmit and Receive 64 Octet Frames Register (FRAME64)

The total number of 64-byte frames received and transmitted on the EMAC. Such a frame is defined as having all of the following:

- Any data or MAC control frame that was destined for any unicast, broadcast, or multicast address
- Did not experience late collisions, excessive collisions, underrun, or carrier sense error
- Was exactly 64-bytes long. (If the frame was being transmitted and experienced carrier loss that resulted in a frame of this size being transmitted, then the frame is recorded in this statistic).

CRC errors, alignment/code errors, and overruns do not affect the recording of frames in this statistic.

22.5.50.28 Transmit and Receive 65 to 127 Octet Frames Register (FRAME65T127)

The total number of 65-byte to 127-byte frames received and transmitted on the EMAC. Such a frame is defined as having all of the following:

- Any data or MAC control frame that was destined for any unicast, broadcast, or multicast address
- Did not experience late collisions, excessive collisions, underrun, or carrier sense error
- Was 65-bytes to 127-bytes long

CRC errors, alignment/code errors, underruns, and overruns do not affect the recording of frames in this statistic.

22.5.50.29 Transmit and Receive 128 to 255 Octet Frames Register (FRAME128T255)

The total number of 128-byte to 255-byte frames received and transmitted on the EMAC. Such a frame is defined as having all of the following:

- Any data or MAC control frame that was destined for any unicast, broadcast, or multicast address
- Did not experience late collisions, excessive collisions, underrun, or carrier sense error
- Was 128-bytes to 255-bytes long

CRC errors, alignment/code errors, underruns, and overruns do not affect the recording of frames in this statistic.

22.5.50.30 Transmit and Receive 256 to 511 Octet Frames Register (FRAME256T511)

The total number of 256-byte to 511-byte frames received and transmitted on the EMAC. Such a frame is defined as having all of the following:

- Any data or MAC control frame that was destined for any unicast, broadcast, or multicast address
- Did not experience late collisions, excessive collisions, underrun, or carrier sense error
- Was 256-bytes to 511-bytes long

CRC errors, alignment/code errors, underruns, and overruns do not affect the recording of frames in this statistic.

22.5.50.31 Transmit and Receive 512 to 1023 Octet Frames Register (FRAME512T1023)

The total number of 512-byte to 1023-byte frames received and transmitted on the EMAC. Such a frame is defined as having all of the following:

- Any data or MAC control frame that was destined for any unicast, broadcast, or multicast address
- Did not experience late collisions, excessive collisions, underrun, or carrier sense error
- Was 512-bytes to 1023-bytes long

CRC errors, alignment/code errors, and overruns do not affect the recording of frames in this statistic.

22.5.50.32 Transmit and Receive 1024 to RXMAXLEN Octet Frames Register (FRAME1024TUP)

The total number of 1024-byte to RXMAXLEN-byte frames received and transmitted on the EMAC. Such a frame is defined as having all of the following:

- Any data or MAC control frame that was destined for any unicast, broadcast, or multicast address
- Did not experience late collisions, excessive collisions, underrun, or carrier sense error
- Was 1024-bytes to RXMAXLEN-bytes long

CRC/alignment/code errors, underruns, and overruns do not affect frame recording in this statistic.

22.5.50.33 Network Octet Frames Register (NETOCTETS)

The total number of bytes of frame data received and transmitted on the EMAC. Each frame counted has all of the following:

- Was any data or MAC control frame destined for any unicast, broadcast, or multicast address (address match does not matter)
- Was of any size (including less than 64-byte and greater than RXMAXLEN-byte frames)

Also counted in this statistic is:

- Every byte transmitted before a carrier-loss was experienced
- Every byte transmitted before each collision was experienced (multiple retries are counted each time)
- Every byte received if the EMAC is in half-duplex mode until a jam sequence was transmitted to initiate flow control. (The jam sequence is not counted to prevent double-counting).

Error conditions such as alignment errors, CRC errors, code errors, overruns, and underruns do not affect the recording of bytes in this statistic. The objective of this statistic is to give a reasonable indication of Ethernet utilization.

22.5.50.34 Receive FIFO or DMA Start of Frame Overruns Register (RXSOFOVERRUNS)

The total number of frames received on the EMAC that had either a FIFO or DMA start of frame (SOF) overrun. An SOF overrun frame is defined as having all of the following:

- Was any data or MAC control frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- Was of any size (including less than 64-byte and greater than RXMAXLEN-byte frames)
- The EMAC was unable to receive it because it did not have the resources to receive it (cell FIFO full or no DMA buffer available at the start of the frame).

CRC errors, alignment errors, and code errors have no effect on this statistic.

22.5.50.35 Receive FIFO or DMA Middle of Frame Overruns Register (RXMOFOVERRUNS)

The total number of frames received on the EMAC that had either a FIFO or DMA middle of frame (MOF) overrun. An MOF overrun frame is defined as having all of the following:

- Was any data or MAC control frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- Was of any size (including less than 64-byte and greater than RXMAXLEN-byte frames)
- The EMAC was unable to receive it because it did not have the resources to receive it (cell FIFO full or no DMA buffer available after the frame was successfully started - no SOF overrun).

CRC errors, alignment errors, and code errors have no effect on this statistic.

22.5.50.36 Receive DMA Overruns Register (RXDMAOVERRUNS)

The total number of frames received on the EMAC that had either a DMA start of frame (SOF) overrun or a DMA middle of frame (MOF) overrun. A receive DMA overrun frame is defined as having all of the following:

- Was any data or MAC control frame that matched a unicast, broadcast, or multicast address, or matched due to promiscuous mode
- Was of any size (including less than 64-byte and greater than RXMAXLEN-byte frames)
- The EMAC was unable to receive it because it did not have the DMA buffer resources to receive it (zero head descriptor pointer at the start or during the middle of the frame reception).

CRC errors, alignment errors, and code errors have no effect on this statistic.

22.6 EMAC/MDIO Glossary

Broadcast MAC Address— A special Ethernet MAC address used to send data to all Ethernet devices on the local network. The broadcast address is FFh-FFh-FFh-FFh-FFh-FFh. The LSB of the first byte is odd, qualifying it as a group address; however, its value is reserved for broadcast. It is classified separately by the EMAC.

Descriptor (Packet Buffer Descriptor)— A small memory structure that describes a larger block of memory in terms of size, location, and state. Descriptors are used by the EMAC and application to describe the memory buffers that hold Ethernet data.

Device — In this document, device refers to the processor.

Ethernet MAC Address (MAC Address)— A unique 6-byte address that identifies an Ethernet device on the network. In an Ethernet packet, a MAC address is used twice, first to identify the packet's destination, and second to identify the packet's sender or source. An Ethernet MAC address is normally specified in hexadecimal, using dashes to separate bytes. For example, 08h-00h-28h-32h-17h-42h.

The first three bytes normally designate the manufacturer of the device. However, when the first byte of the address is odd (LSB is 1), the address is a group address (broadcast or multicast). The second bit specifies whether the address is globally or locally administrated (not considered in this document).

Ethernet Packet (Packet)— An Ethernet packet is the collection of bytes that represents the data portion of a single Ethernet frame on the wire.

Full Duplex— Full-duplex operation allows simultaneous communication between a pair of stations using point-to-point media (dedicated channel). Full-duplex operation does not require that transmitters defer, nor do they monitor or react to receive activity, as there is no contention for a shared medium in this mode. Full-duplex mode can only be used when all of the following are true:

- The physical medium is capable of supporting simultaneous transmission and reception without interference.
- There are exactly two stations connected with a full duplex point-to-point link. As there is no contention for use of a shared medium, the multiple access (that is, CSMA/CD) algorithms are unnecessary.
- Both stations on the LAN are capable of, and have been configured to use, full-duplex operation.

The most common configuration envisioned for full-duplex operation consists of a central bridge (also known as a switch) with a dedicated LAN connecting each bridge port to a single device.

Full-duplex operation constitutes a proper subset of the MAC functionality required for half-duplex operation.

Half Duplex— In half-duplex mode, the CSMA/CD media access method is the means by which two or more stations share a common transmission medium. To transmit, a station waits (defers) for a quiet period on the medium, that is, no other station is transmitting. It then sends the intended message in bit-serial form. If, after initiating a transmission, the message collides with that of another station, then each transmitting station intentionally transmits for an additional predefined period to ensure propagation of the collision throughout the system. The station remains silent for a random amount of time (backoff) before attempting to transmit again.

Host— The host is an intelligent system resource that configures and manages each communications control module. The host is responsible for allocating memory, initializing all data structures, and responding to port (EMAC) interrupts. In this document, host refers to the device.

Jabber— A condition wherein a station transmits for a period of time longer than the maximum permissible packet length, usually due to a fault condition.

Link— The transmission path between any two instances of generic cabling.

Multicast MAC Address— A class of MAC address that sends a packet to potentially more than one recipient. A group address is specified by setting the LSB of the first MAC address byte to 1. Thus, 01h-02h-03h-04h-05h-06h is a valid multicast address. Typically, an Ethernet MAC looks for only certain multicast addresses on a network to reduce traffic load. The multicast address list of acceptable packets is specified by the application.

Physical Layer and Media Notation— To identify different Ethernet technologies, a simple, three-field, type notation is used. The Physical Layer type used by the Ethernet is specified by these fields: <data rate in Mb/s><medium type><maximum segment length (×100m)>
The definitions for the technologies mentioned in this document are in [Table 22-97](#).

Table 22-97. Physical Layer Definitions

| Term | Definition |
|--------------|---|
| 10Base-T | IEEE 802.3 Physical Layer specification for a 10 Mb/s CSMA/CD local area network over two pairs of twisted-pair telephone wire. |
| 100Base-T | IEEE 802.3 Physical Layer specification for a 100 Mb/s CSMA/CD local area network over two pairs of Category 5 unshielded twisted-pair (UTP) or shielded twisted-pair (STP) wire. |
| Twisted pair | A cable element that consists of two insulated conductors twisted together in a regular fashion to form a balanced transmission line. |

Port— Ethernet device.

Promiscuous Mode— EMAC receives frames that do not match its address.

High-End CAN Controller (HECC)

This document contains a general description of the controller area network (CAN). The CAN uses established protocol to communicate serially with other controllers in harsh environments. This document describes the Standard CAN controller (SCC) and the High-End CAN controller (HECC) modules. Unless otherwise stated in the text, all information is related to both the SCC and HECC.

23.1 CAN Overview

The CAN controller is available in two different implementations that are both fully compliant with the CAN protocol, version 2.0B. The two different CAN controller versions use the same CAN protocol kernel module to perform the basic CAN protocol tasks. Only the message controller differs between the two CAN controller versions.

Key features of the CAN module include:

- Common CAN protocol kernel (CPK) to perform protocol tasks
- Standard CAN controller (SCC) for standard CAN applications
 - Sixteen message-object acceptance-filtering
- High-end CAN controller (HECC) for complex applications
 - Thirty-two message objects full-mask acceptance-filtering

Table 23-1. SCC and HECC Features Overview

| Feature | SCC | HECC |
|--|---------------------|---------------------|
| Number of message objects | 16 Receive/Transmit | 32 Receive/Transmit |
| Number of receive identifier masks | 3 | 32 |
| CAN, version 2.0B compliant | X | X |
| Low-power mode | X | X |
| Programmable wake-up on bus activity | X | X |
| Programmable interrupt scheme | X | X |
| Automatic reply to a remote request | X | X |
| Automatic retransmission in case of error | X | X |
| Protect against reception of new message | X | X |
| 32-bit time stamp | | X |
| Local network time counter | | X |
| Programmable priority register for each message | | X |
| Programmable transmission and reception time-out | | X |

23.1.1 CAN Protocol Processor Features

The CAN protocol kernel (CPK) performs the basic CAN protocol tasks according to CAN protocol specification 2.0B. The CPK is the basic module of all CAN controller implementations. The CPK provides the following features:

- Full implementation of CAN protocol, version 2.0B
 - Standard and extended identifiers
 - Data and remote frames
- Bus speed of up to 1 Mbps
- Programmable prescaler from 1 to 256

- Programmable bit time according to the CAN specification
- Programmable sampling mode
 - One or three samples used to determine the received bit value
- Selectable edge of receive bit flow for synchronization
 - Both edges or falling edge only
- Automatic retransmission of a frame in case of loss of arbitration
- Low-power mode
- Bus failure diagnostic
 - Bus on/off
 - Error passive/active
 - Bus error warning
 - Bus stuck dominant
 - Frame error report: cyclic redundancy check (CRC), stuff, form, bit, and acknowledgment errors
 - Readable error counters
- Self-test mode
 - Operate in a loop-back mode (receiving its own message)
 - Dummy acknowledge

23.1.2 **Standard CAN Controller (SCC) Features**

The SCC provides the following features:

- All the CAN protocol kernel (CPK) features
 - Full implementation of CAN protocol, version 2.0B
- Sixteen message objects, each with the following properties:
 - Configurable as receive or transmit
 - Configurable with standard or extended identifier
 - Protects against reception of new message
 - Supports data and remote frame
 - Composed of 0 to 8 bytes of data
 - Employs a programmable interrupt scheme with two interrupt levels
 - Has a message priority based on object number
- Two programmable local identifier masks for objects 0-2 and 3-5
 - Configurable as standard or extended message identifier
 - Has an acceptance mask register for identifier extension bit
- One global programmable identifier mask for objects 6-15
 - Configurable as standard or extended message identifier
 - Has an acceptance mask register for identifier extension bit
- Low-power mode
- Programmable wake-up on bus activity
- Automatic reply to a remote request message
- Automatic retransmission of a frame in case of loss of arbitration or error

23.1.3 **High-End CAN Controller (HECC) Features**

The HECC provides the following features:

- All the CAN protocol kernel (CPK) features
 - Full implementation of CAN protocol, version 2.0B
- Thirty-two message objects, each with the following properties:
 - Configurable as receive or transmit
 - Configurable with standard or extended identifier
 - Has a programmable receive mask

- Supports data and remote frame
- Composed of 0 to 8 bytes of data
- Uses a 32-bit time stamp on receive and transmit message
- Protects against reception of new message
- Holds the dynamically programmable priority of transmit message
- Employs a programmable interrupt scheme with two interrupt levels
- Employs a programmable alarm on transmission or reception time-out
- Low-power mode
- Programmable wake-up on bus activity
- Automatic reply to a remote request message
- Automatic retransmission of a frame in case of loss of arbitration or error
- 32-bit local network time counter synchronized by a specific message (communication in conjunction with mailbox 16)
- SCC-compatible mode
 - Upward-compatible software
 - Software written for the SCC can run without any changes on the HECC
 - SCC-compatible mode is automatically activated after RESET

23.2 CAN Network and Module Overview

The controller area network (CAN) uses a serial multimaster communication protocol that efficiently supports distributed real-time control, with a very high level of security, and a communication rate of up to 1 Mbps. The CAN bus is ideal for applications operating in noisy and harsh environments, such as in the automotive and other industrial fields that require reliable communication or multiplexed wiring.

Prioritized messages of up to eight bytes in data length can be sent on a multimaster serial bus using an arbitration protocol and an error-detection mechanism for a high level of data integrity.

23.2.1 CAN Protocol Overview

The CAN protocol supports four different frame types for communication:

- Data frames that carry data from a transmitter node to the receiver nodes
- Remote frames that are transmitted by a node to request the transmission of a data frame with the same identifier
- Error frames that are transmitted by any node on a bus-error detection
- Overload frames that provide an extra delay between the preceding and the succeeding data frames or remote frames.

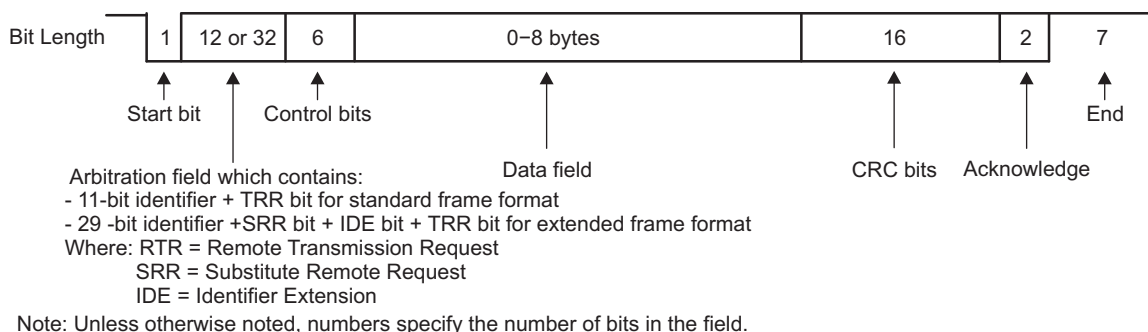

In addition, CAN specification version 2.0B defines two different formats that differ in the length of the identifier field: standard frames with an 11-bit identifier and extended frames with 29-bit identifier.

CAN standard data frames contain from 44 to 108 bits and CAN extended data frames contain 64 to 128 bits. Furthermore, up to 23 stuff bits can be inserted in a standard data frame, and up to 28 stuff bits in an extended data frame, depending on the data-stream coding. The overall maximum data frame length is then 131 bits for a standard frame and 156 bits for an extended frame.

Bit fields within the data frame, shown in [Figure 23-1](#), identify:

- Start of the frame
- Arbitration field containing the identifier and the type of message being sent
- Control field containing the number of data bytes
- Up to 8 bytes of data
- Cyclic redundancy check (CRC)
- Acknowledgment
- End-of-frame bits

Figure 23-1. CAN Data Frame

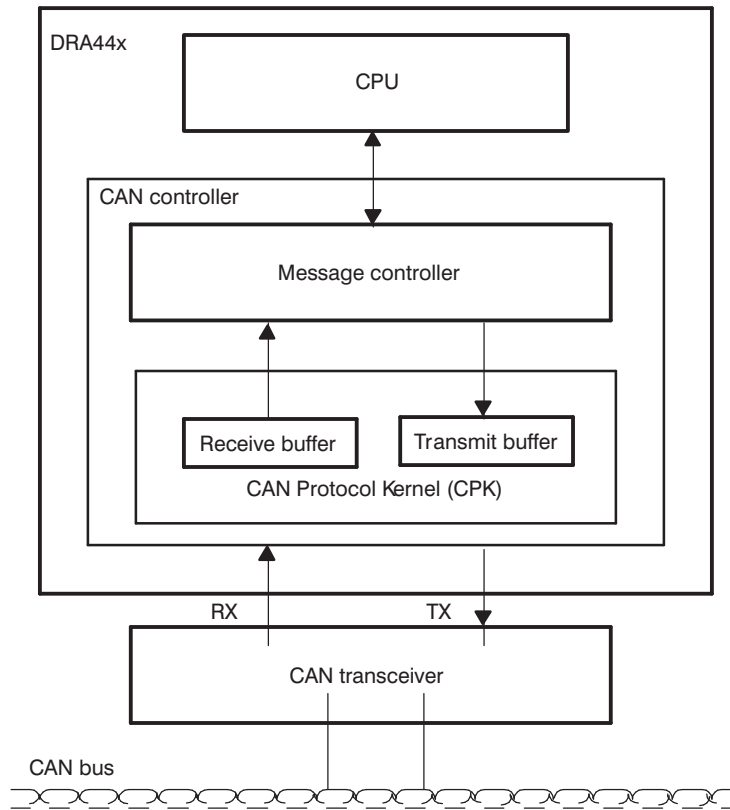

23.2.2 CAN Controller Overview

The CAN controllers provide the CPU with full functionality of the CAN protocol, version 2.0B. The CAN controller minimizes the CPU load in communication overhead and enhances the CAN standard by providing additional features.

The architecture of both the SCC and the HECC controllers is composed of a CAN protocol kernel (CPK) and a message controller ([Figure 23-2](#)).

Figure 23-2. Architecture of the SCC and HECC CAN Controllers

Two functions of the CAN protocol kernel (CPK) are to decode all messages received on the CAN bus according to the CAN protocol and to transfer these messages into a receive buffer. Another CPK function is to transmit messages on the CAN bus according to the CAN protocol.

The message controller of a CAN controller is responsible for determining if any message received by the CPK must be preserved for the CPU use or be discarded. At the initialization phase, the CPU specifies to the message controller all message identifiers used by the application. The message controller is also responsible for sending the next message to transmit to the CPK according to the message's priority.

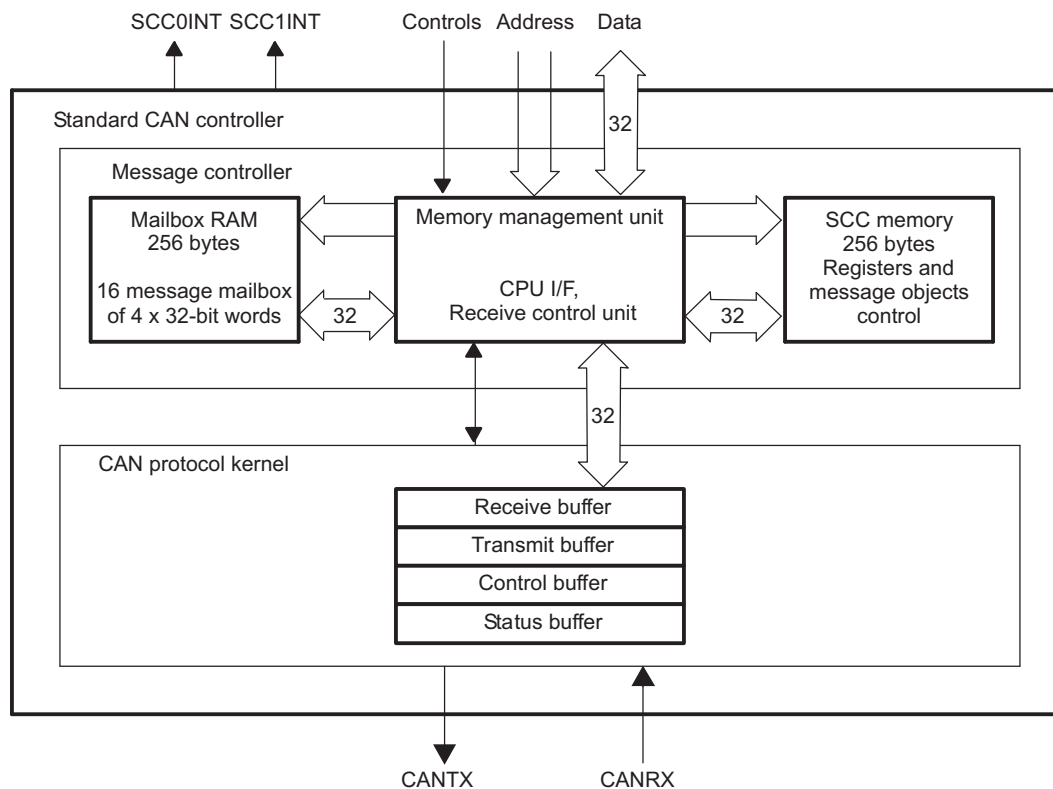

The SCC and the HECC differ only by their message controller - the CPK always offers the same services. The message management of the message controller is not part of the CAN protocol specification.

23.3 Standard CAN Controller (SCC) Overview

The SCC is a standard CAN controller with an internal 32-bit architecture, upwardly compatible with HECC. The SCC consists of:

- The CAN protocol kernel (CPK)
- The message controller:
 - The memory management unit (MMU) including the CPU interface and the receive control unit (acceptance filtering)
 - 256 bytes of mailbox RAM enabling the storage of 16 messages
 - 256 bytes of space register containing the global and the local identifier masks.

Figure 23-3. SCC Functional Block Diagram

After the reception of a valid message by the CAN protocol kernel (CPK), the receive control unit of the message controller determines if the message must be stored into one of the 16 message objects of the mailbox RAM. The receive control unit checks the state, the identifier, and the mask of all message objects to determine the appropriate mailbox location. The received message is stored into the first mailbox passing the acceptance filtering. If the receive control unit could not find any mailbox to store the received message, the message is discarded.

A message is composed of an identifier of 11 or 29 bits (contained in the arbitration field), a control field, and up to 8 bytes of data.

When a message must be transmitted, the message controller transfers the message into the transmit buffer of the CPK in order to start the message transmission at the next bus-idle state. When more than one message must be transmitted, the message with the highest priority is transferred into the CPK by the message controller.

The memory registers contain the global identifier mask and the two dedicated identifier masks for the message objects 0-2 and 3-5. After the reception of a valid identifier, the receive control unit checks the state and the identifier of all objects to determine if the received message must be stored into one of the message object's buffers.

To initiate a data transfer, the transmission-request bit has to be set in the corresponding control register. The entire transmission procedure and possible error handling is then done without any CPU involvement. If a mailbox has been configured to receive messages, the CPU easily reads its data registers using CPU read instructions. The mailbox may be configured to interrupt the CPU after every successful message transmission or reception.

23.3.1 SCC Memory Map

The SCC module has two different offset addresses mapped in memory. The first offset address, *SCC_Offset*, is used to access the control and status registers, and the acceptance masks of the message objects. This memory range can only be accessed 32-bits wide. The second offset address, *Mailbox_RAM_Offset*, is used to access the message mailboxes. This memory range can be accessed 8-bits, 16-bits, and 32-bits wide. Each of these two memory blocks uses 256 bytes of address space.

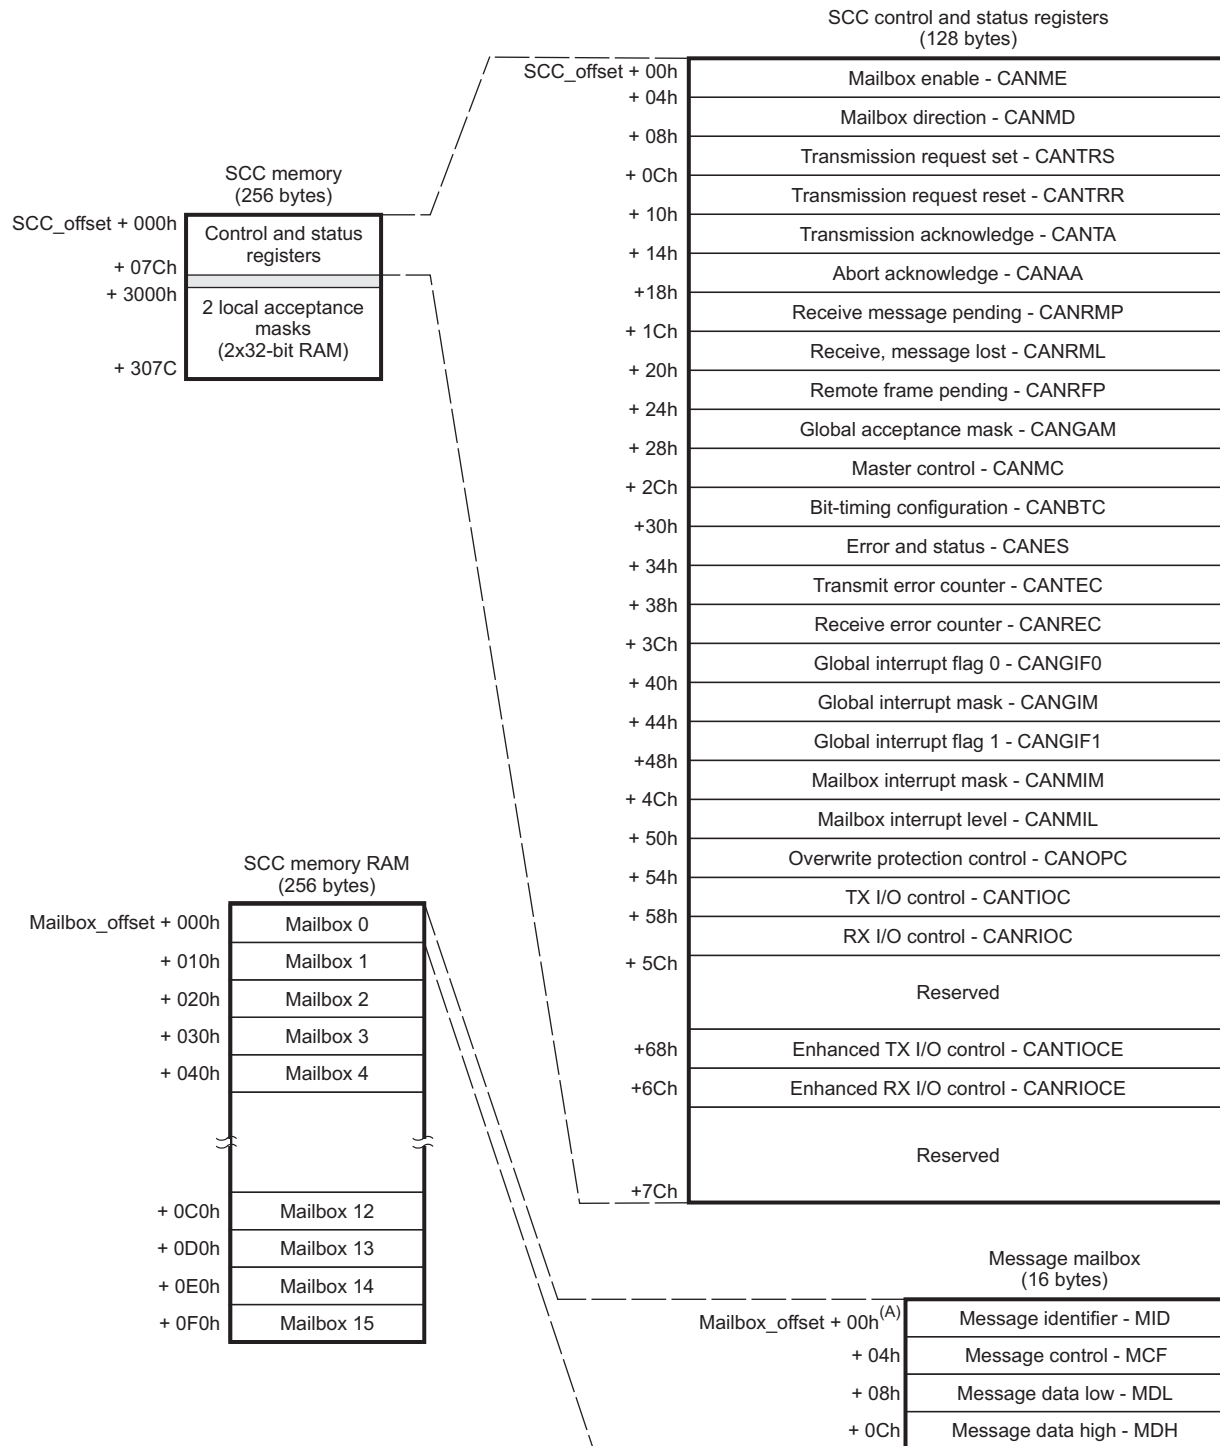

The message storage is implemented by RAM that is addressed by the CAN controller or the CPU. The CPU controls the CAN controller by modifying the various mailboxes in the RAM or the additional registers. The contents of the various storage elements are used to perform acceptance filtering, message transmission, and interrupt handling.

The mailbox module in the SCC provides 16 message mailboxes of 8-byte data lengths, a 29-bit identifier, and several control bits. Each mailbox can be configured to either transmit or receive data.

Unused Message Mailboxes

NOTE: All RAM areas are byte-writable and may be used as normal memory. In this case, it must be ensured that no CAN function uses the RAM area. This assurance is reached by disabling the corresponding mailbox or by disabling the corresponding functions.

The SCC and HECC registers, listed in [Section 23.10](#), are used by the CPU to configure and control the CAN controller and the message objects

Figure 23-4. SCC Memory Map

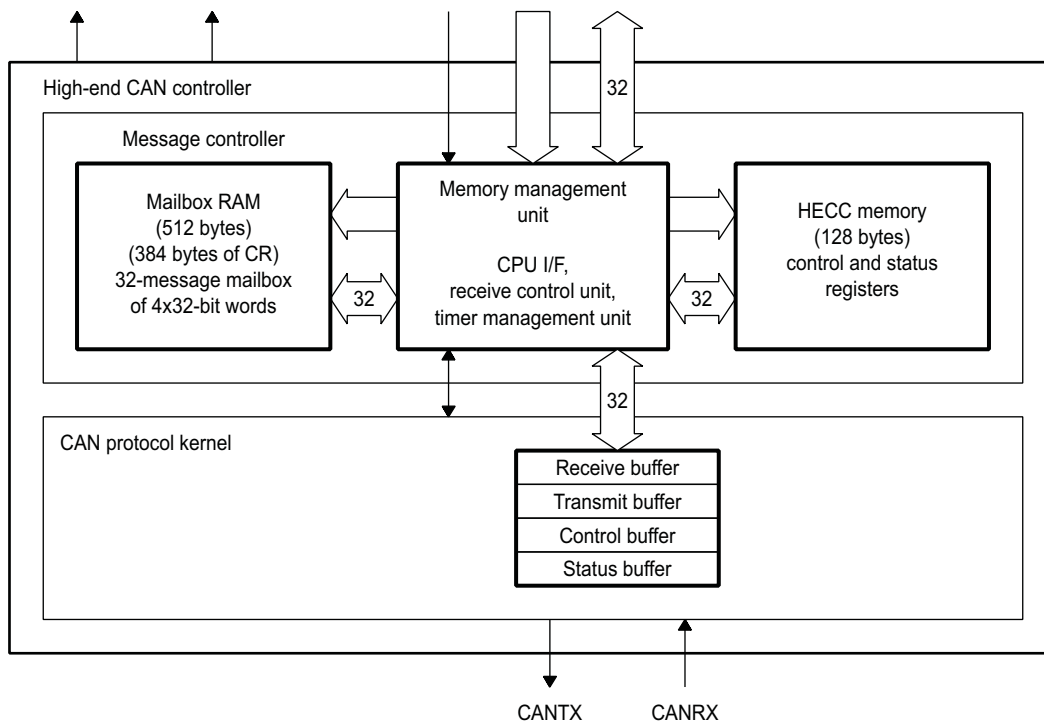

^(A)Mailbox_offset = Mailbox_offset + (Mailbox# x 0x10)

23.4 High-End CAN Controller (HECC) Overview

The HECC is a new-generation, Texas Instruments, advanced CAN controller with an internal 32-bit architecture. The HECC, shown in Figure 23-5, consists of:

- The CAN protocol kernel (CPK)
- The message controller:
 - The memory management unit (MMU), including the CPU interface and the receive control unit (acceptance filtering), and the timer management unit
 - 512 bytes of mailbox RAM enabling the storage of 32 messages
 - 128 bytes of memory comprising the registers and the message objects control
 - 384 bytes of control RAM comprising the message objects control registers

Figure 23-5. HECC Functional Block Diagram

After the reception of a valid message by the CAN protocol kernel (CPK), the receive control unit of the message controller determines if the received message must be stored into one of the 32 message objects of the mailbox RAM. The receive control unit checks the state, the identifier, and the mask of all message objects to determine the appropriate mailbox location. The received message is stored into the first mailbox passing the acceptance filtering. If the receive control unit could not find any mailbox to store the received message, the message is discarded.

A message is composed of an identifier of 11 or 29 bits, a control field, and up to 8 bytes of data.

When a message must be transmitted, the message controller transfers the message into the transmit buffer of the CPK in order to start the message transmission at the next bus-idle state. When more than one message must be transmitted, the message with the highest priority (defined by the message-object-priority register) that is ready to be transmitted is transferred into the CPK by the message controller.

The timer management unit comprises a local network time counter and applies a time stamp to all messages received or transmitted. The timer management unit controls all message reception and transmission, and generates an alarm when a message has not been received or transmitted during an allowed period of time (time-out).

To initiate a data transfer, the transmission request bit has to be set in the corresponding control register. The entire transmission procedure and possible error handling are then performed without any CPU involvement. If a mailbox has been configured to receive messages, the CPU easily reads its data registers using CPU read instructions. The mailbox may be configured to interrupt the CPU after every successful message transmission or reception.

23.4.1 SCC-Compatible Mode

The HECC can be used in SCC mode. In this mode, all functions specific to the HECC are not available and the HECC behaves exactly as the SCC. This mode is selected by default in order to allow any application software written for the SCC to run on the HECC without any modification. When using the HECC in SCC-compatible mode, you must refer to the SCC specification only. The SCC-compatible mode is selected with the SCM bit in the master control register (CANMC).

23.4.2 HECC Memory Map

The HECC module has two different offset addresses mapped in memory. The first offset address, *HECC_Offset*, is used to access the control register, the status register, the acceptance mask, the time stamp, and the time-out of the message objects. The access to the control and status registers (memory range: *HECC_Offset ... HECC_Offset + 07Ch*) is limited to 32-bit-wide accesses. The local acceptance masks, the time stamp registers, and the time-out registers can be accessed 8-bits, 16-bits, and 32-bits wide. The second offset address, *Mailbox_RAM_Offset*, is used to access the mailboxes. This memory range can be accessed 8-bits, 16-bits, and 32-bits wide. Each of these two memory blocks uses 512 bytes of address space.

The message storage is implemented by RAM that can be addressed by the CAN controller or the CPU. The CPU controls the CAN controller by modifying the various mailboxes in the RAM or the additional registers. The contents of the various storage elements are used to perform the functions of the acceptance filtering, message transmission, and interrupt handling.

The mailbox module in the HECC provides 32 message mailboxes of 8-byte data lengths, a 29-bit identifier, and several control bits. Each mailbox can be configured as either transmit or receive. In the HECC, each mailbox has an individual acceptance mask.

Unused Message Mailboxes

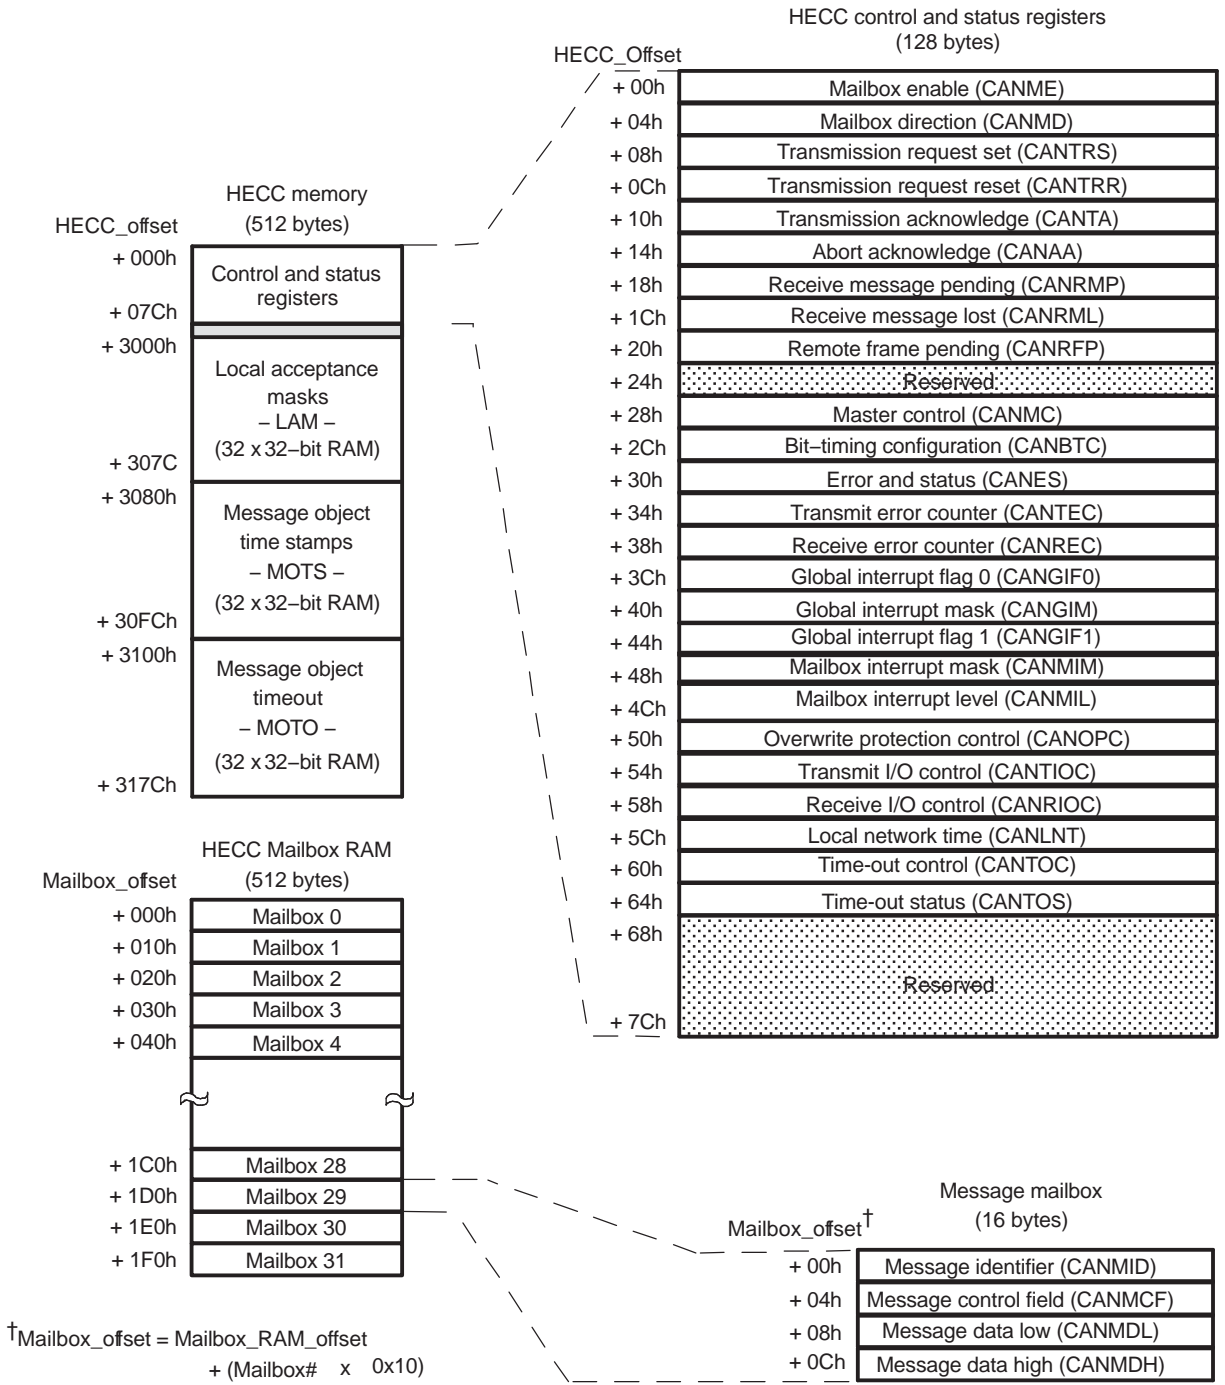

NOTE: All RAM areas are byte-writable and may be used as normal memory. In this case, it must be ensured that no CAN function uses the RAM area. This assurance is reached by disabling the corresponding mailbox or by disabling the corresponding functions.

HECC Used in SCC Mode

When the HECC is used in SCC mode, refer to the SCC memory map.

The SCC and HECC registers, listed in [Section 23.10](#), are used by the CPU to configure and control the CAN controller and the message objects.

Figure 23-6. HECC Memory Map

23.5 Message Objects

23.5.1 SCC Message Objects

The message controller of the SCC handles 16 different mailboxes. Each mailbox is configured to either transmit or receive. In the SCC, mailboxes 0 to 2, 3 to 5, and 6 to 15 share the same acceptance masks.

An SCC mailbox consists of 20 bytes of RAM distributed, as shown in [Table 23-2](#), as:

- A message mailbox RAM comprising
 - The 29-bit message identifier
 - The message control register
 - 8 bytes of message data
- A 29-bit acceptance mask

Furthermore, corresponding control and status bits located in the SCC registers allow control of the message objects.

Table 23-2. SCC Message Object Description

| Offset Address ⁽¹⁾ | Mnemonic | Name | Section |
|---|----------|------------------------|------------------------------------|
| Mailbox_RAM_Offset + (Mailbox# + 10h) + 00h | CANMID | Message identifier | Section 23.10.4.1 |
| Mailbox_RAM_Offset + (Mailbox# + 10h) + 04h | CANMCF | Message control field | Section 23.10.4.2 |
| Mailbox_RAM_Offset + (Mailbox# + 10h) + 08h | CANMDL | Message data low word | Section 23.10.4.3 |
| Mailbox_RAM_Offset + (Mailbox# + 10h) + 0Ch | CANMDH | Message data high word | Section 23.10.4.3 |
| SCC_Offset + 3000h " for objects 0 to 2 | CANLAM0 | Local acceptance mask | Section 23.10.4.4 |
| SCC_Offset + 300Ch " for objects 3 to 5 | CANLAM3 | Local acceptance mask | Section 23.10.4.4 |
| SCC_Offset + 24h " for objects 6 to 15 | CANGAM | Global acceptance mask | Section 23.10.1.10 |

⁽¹⁾ The actual addresses of the message objects are device-specific. See the device-specific datasheet to verify the SCC module memory offset and RAM offset.

Unused Message Mailboxes

NOTE: Message mailboxes not used by the application for CAN message (disabled in the CANME register) may be used as general memory by the CPU.

23.5.2 HECC Message Objects

The message controller of the HECC handles 32 different mailboxes. Each mailbox is configured to either transmit or receive. In the HECC, each mailbox has an individual acceptance mask.

A HECC mailbox consists of 28 bytes of RAM distributed, as shown in [Table 23-3](#), as:

- A message mailbox RAM comprising
 - The 29-bit message identifier
 - The message control register
 - 8 bytes of message data
- A 29-bit acceptance mask
 - A 32-bit time stamp
 - A 32-bit time-out

Furthermore, corresponding control and status bits located in the HECC registers allow control of the message objects.

Table 23-3. HECC Message Object Description

| Offset/Address ⁽¹⁾ | Mnemonic | Name | Section |
|---|----------|---------------------------|-----------------------------------|
| Mailbox_RAM_Offset + (Mailbox# + 10h) + 00h | CANMID | Message identifier | Section 23.10.4.1 |
| Mailbox_RAM_Offset + (Mailbox# + 10h) + 04h | CANMCF | Message control field | Section 23.10.4.2 |
| Mailbox_RAM_Offset + (Mailbox# + 10h) + 08h | CANMDL | Message data low word | Section 23.10.4.3 |
| Mailbox_RAM_Offset + (Mailbox# + 10h) + 0Ch | CANMDH | Message data high word | Section 23.10.4.3 |
| HECC_Offset + (Mailbox# x 4) + 3000h | CANLAM | Local acceptance mask | Section 23.10.4.4 |
| HECC_Offset + (Mailbox# x 4) + 3080h | CANMOTS | Message object time stamp | Section 23.10.2.2 |
| HECC_Offset + (Mailbox# x 4) + 3100h | CANMOTO | Message object time-out | Section 23.10.3.1 |

⁽¹⁾ The actual addresses of the message objects are device-specific. See the device-specific datasheet to verify the HECC module memory offset and RAM offset.

HECC Used in SCC Mode

NOTE: When the HECC is used in SCC mode, you must refer to the SCC message objects description (see [Table 23-2](#)).

Unused Message Mailboxes

NOTE: Message mailboxes not used by the application for CAN message (disabled in the CANME register) may be used as general memory by the CPU.

23.5.3 CAN Message Mailbox

The message mailboxes are the RAM area where the CAN messages are actually stored after they were received or before they are transmitted. The CPU may use the RAM area of the message mailboxes that are not used for storing messages as normal memory. This RAM area, unlike the register area, can be accessed by byte. Each mailbox contains:

- The message identifier
 - 29 bits for extended identifier
 - 11 bits for standard identifier
- Identifier extension (IDE) bit in the message identifier register (CANMID)
- Acceptance mask enable (AME) bit in the message identifier register (CANMID)
- Auto answer mode (AAM) bit in the message identifier register (CANMID)
- Remote transmission request (RTR) bit in the message control field register (CANMCF)
- Data length code (DLC) bits in the message control field register (CANMCF)
- Up to eight bytes for the data field
- On the HECC, transmit priority level (TPL) bits in the message control field register (CANMCF).

Each of the mailboxes can be configured as one of four message object types (see [Table 23-4](#)). Transmit and receive message objects are used for data exchange between one sender and multiple receivers (1-to-*n* communication link); whereas, request and reply message objects are used to set up a one-to-one communication link.

Table 23-4. Message Object Types

| Message Object Types | MD _{<i>n</i>} bit in CANMD | AAM bit in CANMID | RTR bit in CANMCF |
|-------------------------|-------------------------------------|-------------------|-------------------|
| Transmit message object | 0 | 0 | 0 |
| Receive message object | 1 | 0 | 0 |
| Request message object | 1 | 0 | 1 |
| Reply message object | 0 | 1 | 0 |

23.5.3.1 Transmit Mailbox

The CPU stores the data to be transmitted in a mailbox configured as transmit mailbox. After writing the data and the identifier into the RAM, the message is sent if the corresponding TRS_{*n*} bit in the transmit request set register (CANTRS) is set.

If more than one mailbox is configured as a transmit mailbox and more than one corresponding TRS_{*n*} bit is set, the messages are sent one after another in descending order beginning with the mailbox with the highest priority.

In the SCC, the priority of the mailbox transmission depends on the mailbox number. The highest mailbox number (15) comprises the highest transmit priority.

In the HECC, the priority of the mailbox transmission depends on the setting of the TPL bits in the message control field register (CANMCF). The mailbox with the highest value in the TPL bits is transmitted first. Only when two mailboxes have the same value in the TPL bits is the higher numbered mailbox transmitted first. See [Section 23.10.4.2](#) for more information about CANMCF.

If a transmission fails due to a loss of arbitration or an error, the message transmission is re-attempted. Before re-attempting the transmission, the CAN module checks if other transmissions are requested and then transmits the mailbox with the highest priority.

23.5.3.2 Receive Mailbox

The identifier of each incoming message is compared to the identifiers held in the receive mailboxes using the appropriate mask. When equality is detected, the received identifier, the control bits, and the data bytes are written into the matching RAM location. At the same time, the corresponding RMP_{*n*} bit in the receive message pending register (CANRMP) is set and a receive interrupt is generated if enabled. If no match is detected, the message is not stored.

When a message is received, the message controller starts looking for a matching mailbox at the mailbox with the highest mailbox priority. Mailbox 15 of the SCC and of the HECC in SCC-compatible mode has the highest receive priority; mailbox 31 has the highest receive priority of the HECC in HECC mode.

NOTE: While operating in loop back mode:

- mailbox 0 receives data even if it is not programmed to receive data, or
 - the last used reception mailbox, whether in loop back mode or normal operation mode, receives data even if none of the mailboxes is programmed to receive data.
-

The RMP_n bit has to be reset by the CPU after reading the data. If a second message has been received for this mailbox and the RMP_n bit is already set, the corresponding RML_n bit in the receive message lost register (CANRML) is set. In this case, the stored message is overwritten with the new data if the corresponding OPC_n bit in the overwrite protection control register (CANOPC) is cleared; otherwise, the next mailboxes are checked.

23.5.3.3 Handling of Remote Frames

If a remote frame is received (the incoming message has the RTR bit in the message control field register, CANMCF, set to 1), the CAN module compares the identifier to all identifiers of the mailboxes using the appropriate masks starting at the highest mailbox number in descending order.

- In the case of a matching identifier (with the message object configured as a send mailbox and the AAM bit in the message identifier register, CANMID, set to 1 in this message object), this message object is marked to be sent (corresponding TRS_n bit in the transmit request set register (CANTRS) is set).
- In the case of a matching identifier (with the message object configured as a send mailbox and the AAM bit in CANMID cleared to 0 in this message object), this message is not received. After finding a matching identifier in a send mailbox, no further compare is done.
- In the case of a matching identifier and the message object configured as a receive mailbox, this message is handled like a data frame and the corresponding RMP_n bit in the receive message pending register (CANRMP) is set. The CPU then has to decide how to handle this situation.

If the CPU wants to change the data in a message object that is configured as a remote frame mailbox (the AAM bit in CANMID is set to 1), the CPU has to set the MBNR bits and the CDR bit in the master control register (CANMC). The CPU may then perform the access and clear the CDR bit to inform the CAN module that the access is finished. Until the CDR bit is cleared, the transmission of this mailbox is not performed by the CAN module. Since CANTRS is not affected by the CDR bit, a pending transmission is started after the CDR bit is cleared; thus, the newest data is sent.

In order to change the identifier in that mailbox, the message object first must be disabled (the ME_n bit in the mailbox enable register, CANME, is cleared to 0).

If the CPU wants to request data from another node, it may configure the message object as a receive mailbox and set the corresponding TRS_n bit in CANTRS. In this case, the CAN module sends a remote frame request and receives the data frame in the same mailbox that sent the request. Therefore, only one mailbox is necessary to do a remote request. Note that the CPU must set the RTR bit in CANMCF to enable a remote frame transmission.

The behavior of the message object n is configured with the MD_n bit in CANMD, the AAM bit in CANMID, and the RTR bit in CANMCF. [Table 23-4](#) shows how to configure a message object according to the desired behavior.

To summarize, a message object can be configured with four different behaviors:

1. Transmit message object: only able to transmit messages.
2. Receive message object: only able to receive messages.
3. Request message object: able to transmit a remote request frame and to wait for the corresponding data frame.
4. Reply message object: able to transmit a data frame whenever a remote request frame is received for the corresponding identifier.

Remote Transmission Request Bit

NOTE: When a remote transmission request is successfully transmitted with a message object configured in request mode, the TAn bit in the transmission acknowledge register (CANTA) is not set and no interrupt is generated. When the remote reply message is received, the behavior of the message object is the same as a message object configured in receive mode.

23.5.3.4 CPU Message Mailbox Access

Write accesses to the identifier is only accomplished when the mailbox is disabled (the ME_n bit in the mailbox enable register, CANME, is cleared to 0). During access to the data field, it is critical that the data does not change while the CAN module is reading it; hence, a write access to the data field is disabled for a receive mailbox.

For send mailboxes, an access is usually denied if the $TRSn$ bit in CANTRS or the TRR_n bit in CANTRR is set. In these cases, an interrupt may be asserted. A way to access those mailboxes is to set the CDR bit in CANMC before accessing the mailbox data.

After the CPU access is finished, the CPU must clear the CDR bit in CANMC by writing a 0 to the CDR bit. The CAN module checks the CDR bit before and after reading the mailbox. If the CDR bit is set during those checks, the CAN module does not transmit the message but continues to look for other transmit requests. The setting of the CDR bit also stops the write-denied interrupt (WDI) from being asserted.

23.5.4 CAN Acceptance Filter

In the SCC and in the HECC there are two different implementations of the handling of the masks for the mailboxes. If the SCM bit is set in the master control register (CANMC), SCC-compatible mode is enabled and the HECC behaves like the SCC.

The identifier of the incoming message is first compared to the message identifier of the mailbox (that is stored in the mailbox). Then, the appropriate acceptance mask is used to mask out the bits of the identifier that should not be compared.

23.5.4.1 SCC Acceptance Filtering

In the SCC (or in the HECC in SCC-compatible mode), the global acceptance mask register (CANGAM) is used for mailboxes 6 to 15. An incoming message is stored in the highest numbered mailbox with a matching identifier. If there is no matching identifier in mailboxes 15 to 6, the incoming message is compared to the identifier stored in mailboxes 5 to 3 and then 2 to 0.

The mailboxes 5 to 3 use the local acceptance mask register CANLAM3 of the SCC registers. The mailboxes 2 to 0 use the local acceptance mask register CANLAM0 of the SCC registers. See [Section 23.10.4.4](#).

To modify the two local acceptance mask registers of the SCC (CANLAM0 and CANLAM3), the CAN module must be set in the initialization mode. See [Section 23.6](#).

23.5.4.2 HECC Acceptance Filtering

Each of the 32 mailboxes of the HECC has its own local acceptance mask register, CANLAM0 to CANLAM31. There is no global acceptance mask register in the HECC.

23.6 CAN Module Initialization

The CAN module must be initialized before being used. Initialization is only possible if the CAN module is in initialization mode, see [Figure 23-7](#). Programming the CCR bit in the master control register (CANMC) to 1 sets the initialization mode. The initialization is performed only when the CCE bit in the error and status register (CANES) is set to 1. Afterwards, the configuration registers may be written.

In order to modify the two local acceptance mask registers of the SCC (CANLAM0 and CANLAM3), the CAN module also must be set in the initialization mode. The global acceptance mask register (CANGAM) can be modified in normal mode and initialization mode. The module is activated again by programming the CCR bit in CANMC to 0. After a hardware reset, the initialization mode is active.

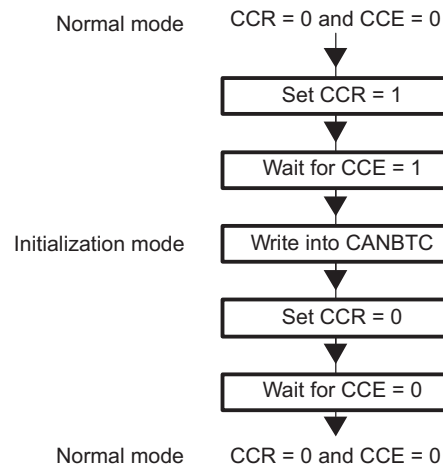

Bit-Timing Configuration Register (CANBTC) With Zero Value

NOTE: If the bit-timing configuration register (CANBTC) is programmed to 0, or left with the initial value, the CAN module never leaves the initialization mode; that is, the CCE bit in CANES remains set to 1 when clearing the CCR bit in CANMC.

Enter/Exit Initialization Mode

The transition between initialization mode and normal mode, and conversely, is performed in synchronization with the CAN network. That is, the CAN controller waits until it detects a bus idle sequence (11 recessive bits) before it changes the mode. In the event of a stuck-to-dominant bus error, the CAN controller cannot detect a bus-idle condition and is unable to perform a mode transition.

Figure 23-7. Configuration Sequence

23.6.1 CAN Bit-Timing Configuration

As shown in [Figure 23-8](#), the CAN protocol specification partitions the nominal bit time into four different time segments:

- SYNC_SEG: this part of bit time is used to synchronize the various nodes on the bus. An edge is expected to lie within this segment. This segment is always 1 TIME QUANTUM (TQ).
- PROP_SEG: this part of the bit time is used to compensate for the physical delay times within the network. It is twice the sum of the signal propagation time on the bus line, the input comparator delay, and the output driver delay. This segment is programmable from 1 to 8 TIME QUANTA (TQ).
- PHASE_SEG1: this phase is used to compensate for positive edge phase error. This segment is programmable from 1 to 8 TIME QUANTA (TQ) and can be lengthened by resynchronization.
- PHASE_SEG2: this phase is used to compensate for negative edge phase error. This segment is programmable from 2 to 8 TIME QUANTA (TQ) and can be shortened by resynchronization.

Figure 23-8. Partition of the Bit Time

All controllers on a CAN bus must have the same bit rate and bit length. At different clock frequencies of the individual controllers, the bit rate has to be adjusted by the time segments.

In the SCC/HECC modules, the length of a bit on the CAN bus is determined by the parameters in the bit-timing configuration register (CANBTC): TSEG1, TSEG2, and BRP (*BRPrescaler* is the binary value of BRP + 1).

TSEG1 combines the two time segments PROP_SEG and PHASE_SEG1 as defined by the CAN protocol. TSEG2 defines the length of the time segment PHASE_SEG2.

The following bit-timing rules have to be fulfilled when determining the bit segment values:

- $TSEG1_{CALC(min)} \geq TSEG2_{CALC}$
- $IPT \leq TSEG1_{CALC} \leq 16 TQ$ (IPT = Information Processing Time)
- $IPT \leq TSEG2_{CALC} \leq 8 TQ$
- $IPT = 3/BRP_{CALC}$ (the resulting IPT has to be rounded up to the next integer value)

NOTE: For the special case of baud rate prescaler value $BRP_{CALC} = 1$, the Information Processing Time (IPT) is equal to three time quanta. This is not compliant to the ISO 11898 Standard, where the Information Processing Time is defined to be less than or equal to two time quanta. Thus the usage of this mode ($BRP_{CALC} = 1$) is not allowed.

- $1 TQ \leq SJW_{CALC} \leq \min[4 TQ, TSEG2_{CALC}]$ (SJW = Synchronization Jump Width)
- To utilize three-time sampling mode $BRP_{CALC} \geq 5$ has to be selected

23.6.2 CAN Bit Rate Calculation

The bit rate is calculated as follows (in bits per second):

$$Bitrate = \frac{InternalBus\ CLK}{BRPrescaler \times BitTime}$$

Where *BitTime* is the number of time quanta (TQ) per bit. *Internal Bus CLK* is the CAN module system clock frequency. *BRPrescaler* is the BRP bits in the bit-timing configuration register (CANBTC) + 1.

$$BRPrescaler = BRP + 1$$

$$BitTime (TQ) = TSEG1 + TSEG2 + 1$$

Example:

With *Internal Bus CLK* = 26 MHz and *BRPrescaler* = 4, if a bit rate of 0.8125 Mbits/s is required, the bit-timing parameters is programmed as follows:

$$TQ = \frac{InternalBus\ CLK}{BRPrescaler \times Bitrate} = \frac{26\ MHz}{4 \times 0.8125\ Mbits/s} = 8$$

$$TQ = TSEG1 + TSEG2 + 1 = 4 + 3 + 1 = 8$$

TSEG1 = 4 TQ and TSEG2 = 3 TQ, so TQ = 8.

With this setting, a threefold sampling of the bus is not possible; thus the SAM bit in the bit-timing configuration register (CANBTC) must be cleared to 0. Since the SJW bits in CANBTC are not allowed to be greater than TSEG2 (that is set to 3 TQ), SJW = 3. (See [Section 23.10.1.12](#) for more information about CANBTC.)

BTC = 0000021Ah

The value programmed into CANBTC.SJW has to be decremented by 1, because of the 2-bit size of the binary SJW value:

$SJWCANBTC = SJW - 1$

23.7 CAN Interrupts

There are two different types of interrupts. One type of interrupt is a mailbox-related interrupt; for example, the receive-message-pending interrupt or the abort-acknowledge interrupt. The other type of interrupt is a system interrupt that handles errors or system-related interrupt sources; for example, the error-passive interrupt or the wake-up interrupt. See [Figure 23-9](#).

The following events may initiate one of the two interrupts:

- Mailbox interrupts
 - Message reception interrupt: a message was received
 - Message transmission interrupt: a message was transmitted successfully
 - Abort-acknowledge interrupt: a sent transmission was aborted
 - Receive-message-lost interrupt: an old message was overwritten by a new message
 - Message alarm interrupt (HECC only): one of the messages was not transmitted or received within a predefined time frame
- System interrupts
 - Write-denied interrupt: the CPU tried to write to a mailbox but was not allowed to
 - Wake-up interrupt: this interrupt is generated after a wake up
 - Bus-off interrupt: the CAN module enters the bus-off state
 - Error-passive interrupt: the CAN module enters the error-passive mode
 - Warning level interrupt: one or both error counters are greater than or equal to 96
 - Time counter overflow interrupt (HECC only): the local network time stamp counter had an overflow

Figure 23-9. SCC Interrupts Scheme Block Diagram

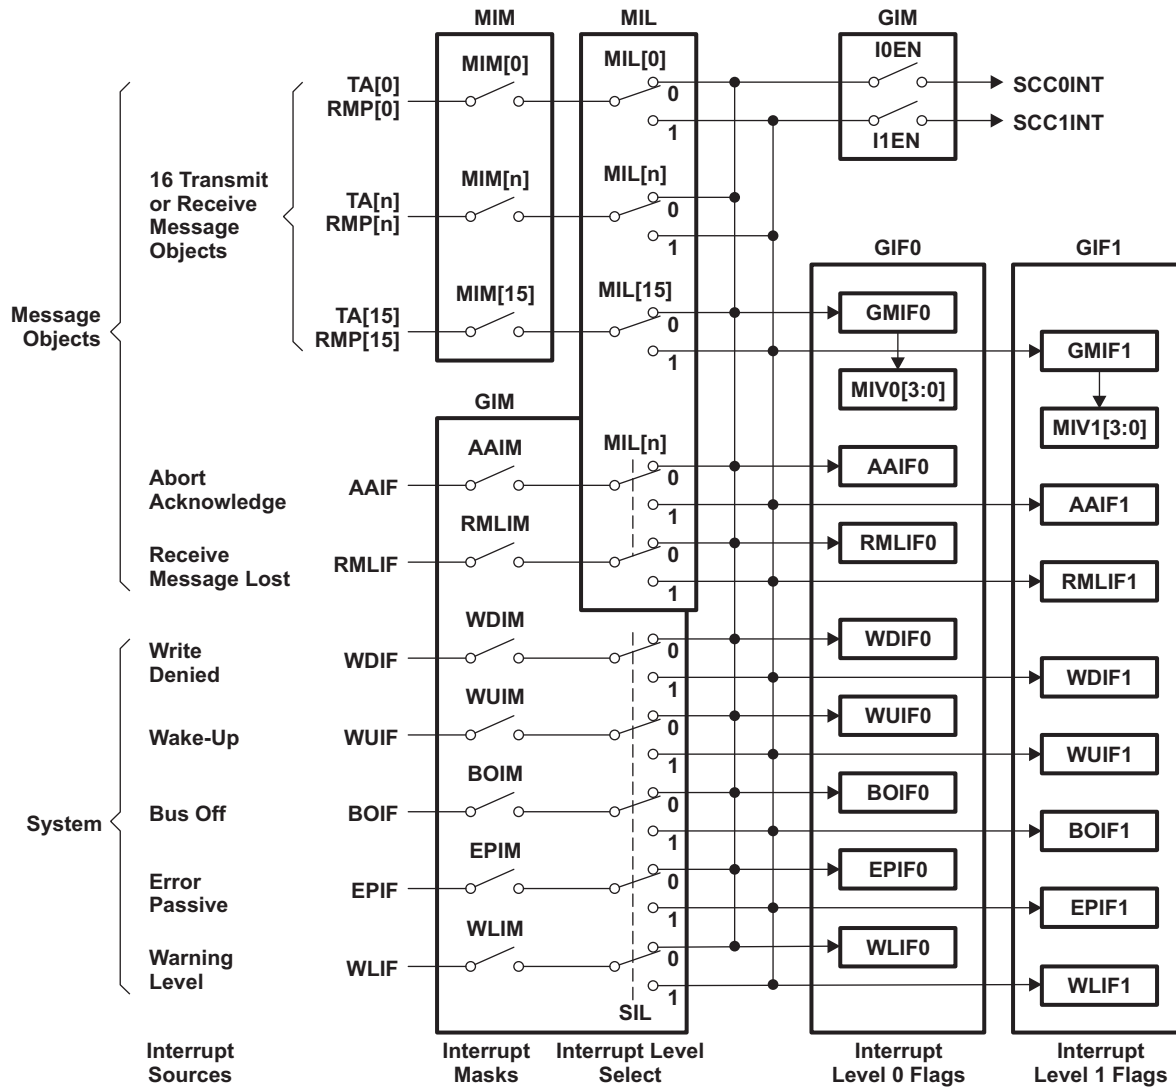

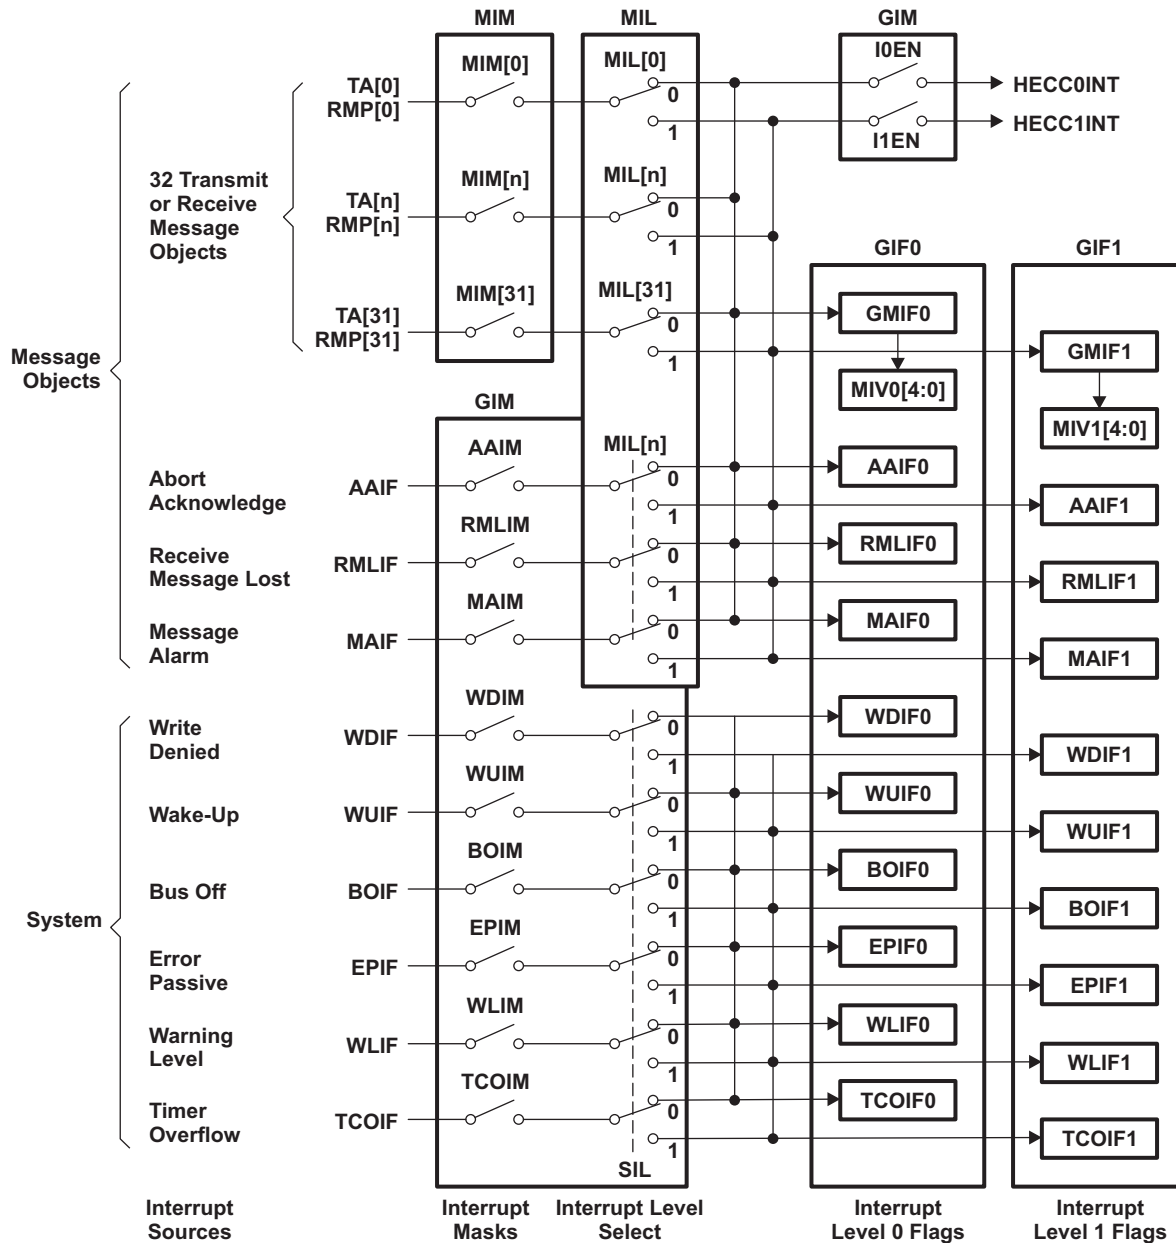

Figure 23-10. HECC Interrupts Scheme Diagram

23.7.1 Interrupts Scheme

The GMIF0/GMIF1 bit in the global interrupt flag register (CANGIF0/CANGIF1) is set depending on the setting of the MIL n bit, in the mailbox interrupt level register (CANMIL), that corresponds to the mailbox originating that interrupt. If the MIL n bit is set, the corresponding message object interrupt flag sets the GMIF1 bit in CANGIF1; otherwise, it sets the GMIF0 bit in CANGIF0.

If all interrupt flags are cleared and a new interrupt flag is set, the CAN module interrupt output line (SCC0INT/HECC0INT or SCC1INT/HECC1INT) is activated if the corresponding interrupt mask bit is set. The interrupt line stays active until the interrupt flag is cleared by the CPU by writing a 1 to the appropriate bit.

The GMIF0 or GMIF1 bit must be cleared by writing a 1 to the appropriate bit in the transmission acknowledge register (CANTA) or in the receive message pending register (CANRMP) (depending on mailbox configuration) and cannot be cleared in CANGIF0/CANGIF1.

After clearing one or more interrupt flags, and one or more interrupt flags are still pending, a new interrupt is generated. The interrupt flags are cleared by writing a 1 to the corresponding bit location. If the GMIF0 or GMIF1 bit is set, the interrupt vector bit, MIV0 in CANGIF0 or MIV1 in CANGIF1, indicates the mailbox number of the mailbox that caused the setting of the GMIF0/GMIF1. It always displays the highest mailbox interrupt vector assigned to that interrupt line.

23.7.2 Message Object Interrupt

Each of the 32 mailboxes in the HECC or the 16 mailboxes in the SCC may initiate an interrupt on one of the two interrupt output lines 1 or 0. These interrupts are receive or transmit interrupts depending on the mailbox configuration.

There is one interrupt mask (MIM n) bit and one interrupt level (MIL n) bit dedicated to each mailbox. To generate a mailbox interrupt upon a receive/transmit event, the corresponding MIM n bit in the mailbox interrupt mask register (CANMIM) has to be set. If a CAN message is received in a receive mailbox (the RMP n bit in the receive message pending register, CANRMP, is set to 1) or is transmitted from a transmit mailbox (the TAN bit in the transmission acknowledge register, CANTA, is set to 1), an interrupt is asserted. If a mailbox is configured as a remote request mailbox (the MD n bit in the mailbox direction register, CANMD, is set to 1 and the RTR bit in the message control field register, MCF, is set to 1), an interrupt occurs upon reception of the reply frame. A remote reply mailbox generates an interrupt upon successful transmission of the reply frame (the MD n bit in CANMD is cleared to 0 and the AAM bit in the message identifier register, MID, is set to 1).

Setting the RMP n bit in CANRMP or the TAN bit in CANTA also sets the GMIF0/GMIF1 bit in the global interrupt flag register (CANGIF0/CANGIF1), if the corresponding interrupt mask bit is set. The GMIF0/GMIF1 bit then generates an interrupt and the corresponding mailbox vector (mailbox number) is read from the MIV0/MIV1 bits in CANGIF0/CANGIF1. If more than one mailbox interrupts are pending, the actual value of the MIV0/MIV1 bits reflects the highest priority interrupt vector. The interrupt generated depends on the setting of the MIL n bit in the mailbox interrupt level register (CANMIL).

The AAN bit in the abort acknowledge register (CANAA) and the AAIF0/AAIF1 bit in CANGIF0/CANGIF1 are set when a transmit message is aborted by setting the TRR n bit in the transmit request reset register (CANTRR). An interrupt is asserted upon transmission abortion, if the AAIM bit in the global interrupt mask register (CANGIM) is set. Clearing the AAN bit(s) does not reset the AAIF0/AAIF1 bit. The interrupt bit has to be cleared separately. The interrupt line for the abort acknowledge interrupt is selected in accordance with the MIL n bit in CANMIL of the concerned mailbox.

A lost receive message is notified by setting the RML n bit in the receive message lost register (CANRML) and the RMLIF0/RMLIF1 bit in CANGIF0/CANGIF1. If an interrupt shall be generated upon the lost receive message event, the RMLIM bit in CANGIM has to be set. Clearing the RML n bit does not reset the RMLIF0/RMLIF1 bit. The interrupt bit has to be cleared separately. The interrupt line for the receive message lost interrupt is selected in accordance with the MIL n bit in CANMIL of the concerned mailbox.

Each mailbox of the HECC (in HECC mode only) is linked to a message object time-out register (CANMOTO). If a time-out event occurs (the TOS n bit in the time-out status register, CANTOS, is set to 1), a message alarm interrupt is asserted to one of the two interrupt lines if the MAIM bit in CANGIM is set. The interrupt line for the message alarm interrupt is selected in accordance with the MIL n bit in CANMIL of the concerned mailbox. Clearing the TOS n bit does not reset the MAIF0/MAIF1 bit in CANGIF0/CANGIF1.

23.8 CAN Power-Down Mode

There are two different power-down modes: the global power-down mode, when all clocks are stopped by the CPU; and the local power-down mode, when only the CAN module internal clock is deactivated by the CAN module itself. Therefore, it is possible to have a local power down, where only the clock of the CAN module logic is disabled, or a global power down when the clock for the complete device is disabled.

23.8.1 Local Power Down

The local power-down mode is requested by writing a 1 to the PDR bit in the master control register (CANMC). When the CAN module enters the local power-down mode, the power-down mode acknowledge (PDA) bit in the error and status register (CANES) is set to 1.

During local power-down mode, the clock of the CAN module is turned off and only the wake-up logic is still active. Since the clock is enabled for every access on an Internal Bus request, the contents of any register can be read-back even during power down.

The module leaves the local power-down mode when the PDR bit in CANMC is cleared or if any bus activity is detected on the CAN bus line (if the wake-up-on bus activity is enabled).

The automatic wake-up-on bus activity is enabled or disabled with the WUBA bit in CANMC. If there is any activity on the CAN bus line, the module begins its power-up sequence. The module waits until it detects 11 consecutive recessive bits on the CANRX pin and then it goes bus-active.

CAUTION

First Message Received During Power-Down Mode is Lost

The first CAN message, which initiates the bus activity, cannot be received. This means that the first message received in power-down and automatic wake-up mode, is lost.

After leaving the sleep mode, the PDR and PDA bits in CANMC are cleared. The CAN error counters remain unchanged.

If the module is transmitting a message when the PDR bit is set, the transmission is continued until a successful transmission, a lost arbitration, or an error condition on the CAN bus line occurs. Then, the PDA bit is activated. Thus, the module causes no error condition on the CAN bus line.

To implement the local power-down mode, two separate clocks are used within the CAN module. One clock stays active all the time to ensure power-down operation (the wake-up logic). The other clock is enabled depending on the setting of the PDA bit or Internal Bus access.

Accessing HECC Mailboxes

NOTE: HECC mailboxes can be accessed in LPD mode. Contents of the mailbox registers can be READ or WRITTEN to even after the PDA bit is set in the CANES.

23.8.2 Global Power Down

Global power-down mode is requested by the system module (SYS LPM). When the module is able to enter the global power-down mode, all clocks to the CAN module are disabled.

During global power-down mode, a dominant signal on the CAN bus may generate a wake-up interrupt, thus enabling the CPU to exit global power-down mode. There is no internal filtering for the CAN bus line. The WUIF0/WUIF1 bit is set asynchronously to enable the assertion of an interrupt without any running clocks.

23.9 Timer Management Unit

Several functions are implemented in the HECC to control the time when messages are transmitted. A separate state machine is included in the HECC to handle the time-control functions. This state machine has lower priority than the CAN state machine when accessing the registers. Therefore, the time-control functions may be delayed by other on-going actions.

23.9.1 Time-Stamp Functions

To get an indication of the time of reception or transmission of a message, a free-running 32-bit local network time counter (LNT) is implemented in the module. The value of the LNT is stored in the local network time register (CANLNT). When a received message is stored or a message has been transmitted, the content of LNT is written into the message object time-stamp register (CANMOTS) of the corresponding mailbox.

The counter is driven from the bit clock of the CAN bus line. The timer is stopped during the initialization mode or if the module is in sleep or suspend mode. After power-up reset, the free-running counter is cleared.

The most-significant bit of the local network time register (CANLNT) is cleared by writing a 1 to the LNTM bit in the master control register (CANMC). The CANLNT may also be cleared when mailbox 16 transmitted or received a message successfully (depending on the setting of the MD16 bit in the mailbox direction register, CANMD) by setting the LNTC bit to 1 in CANMC. Therefore, it is possible to use mailbox 16 for global time synchronization of the network. The CPU can read and write the counter.

Overflow of the counter is detected by the LNT counter overflow interrupt (TCOIF0/TCOIF1) bit in the global interrupt flag register (CANGIF0/CANGIF1). An overflow occurs when the highest bit of the LNT counter changes to 1. Thus, the CPU has enough time to handle this situation.

See [Section 23.10.2](#) for the time-stamp registers.

23.9.2 Time-Out Functions

To ensure that all messages are sent or received within a predefined period, each mailbox has its own message time-out register (CANMOTO). If a message has not been sent or received by the time indicated in CANMOTO and the corresponding TOC_n bit in the time-out control register (CANTOC) is set to 1, a TOS_n bit in the time-out status register (CANTOS) is set to 1.

For transmit mailboxes, the TOS_n bit is cleared when the TOC_n bit is cleared or when the corresponding TRS_n bit in the transmit request set register (CANTRS) is cleared, no matter whether due to successful transmission or abortion of the transmit request. For receive mailboxes, the TOS_n bit is cleared when the corresponding TOC_n bit is cleared.

The CPU may also clear the TOS_n bits by writing a 1 into CANTOS.

The CANMOTO is implemented as a RAM. The state machine scans all the CANMOTOs and compares them to the LNT counter value. If the value in CANLNT is equal to or greater than the value in CANMOTO, while the corresponding TRS_n bit is set (applies to transmit mailboxes only) and the TOC_n bit is set, then the appropriate TOS_n bit is set. Since all the time-out registers are scanned sequentially, there may be a delay before the TOS_n bit is set.

See [Section 23.10.3](#) for the time-out registers.

23.9.3 Behavior/Usage of MAIF0/1 Bit in User Applications

The MAIF0/1 bit is automatically cleared by the CAN protocol kernel (CPK) (along with the CANTOS.n bit) upon transmission/reception by the mailbox, which asserted this flag in the first place. It can also be cleared by the user (via the CPU). On a time out condition, the MAIF0/1 bit (and the CANTOS.n bit) is set. On an (eventual) successful communication, these bits are automatically cleared by the CPK. The following are the possible behaviors/usages for the MAIF0/1 bit:

1. Time-out condition occurs. Both the MAIF0/1 and CANTOS.n bits are set. Communication is never successful, i.e., the frame was never transmitted (or received). An interrupt is asserted. Application handles the issue and eventually clears both MAIF0/1 and CANTOS.n bits.
2. Time-out condition occurs. Both the MAIF0/1 and CANTOS.n bits are set. However, communication is eventually successful, i.e., the frame gets transmitted (or received). Both the MAIF0/1 and CANTOS.n bits are cleared automatically by the CPK. When the interrupt service routine (ISR) scans the CANGIF register, it does not see the MAIF0/1 bit set. This is the phantom interrupt scenario. The application merely returns to the main code.
3. Time-out condition occurs. Both the MAIF0/1 and CANTOS.n bits are set. While executing the ISR pertaining to time-out, communication is successful. This situation must be handled carefully. The application must not re-transmit a mailbox if the mailbox is sent between the time the interrupt is asserted, and the time the ISR is attempting to take corrective action. One way of doing this is to poll the TM/RM bits in the CANES register. These bits indicate if the CPK is currently transmitting/receiving. If so, the application must wait until the communication is over and then check the CANTOS.n bit again. If the communication is still not successful, the application must take corrective action.

23.10 Registers

The SCC and HECC registers listed in [Table 23-5](#) are used by the CPU to configure and control the CAN controller and the message objects. All CAN registers support 8-, 16-, and 32-bit accesses. Reserved register bits must be written as 0.

NOTE: System behavior is undefined for accesses to reserved registers and must be avoided.

Table 23-5. SCC/HECC Registers

| Offset Address ⁽¹⁾ | Acronym | SCC Register Name | HECC Register Name | Section |
|-------------------------------|---------|------------------------------|------------------------------|------------------------------------|

23.10.1 SCC/HECC control registers

23.10.1.1 Mailbox Enable Register (CANME)

Each mailbox n is enabled or disabled by a corresponding bit n in this register.

Figure 23-11. Mailbox Enable Register (CANME) [00h]

LEGEND: R/W = Read/Write; R = Read only; - n = value after reset

Table 23-6. Mailbox Enable Register (CANME) Field Descriptions

| Bit | Field | Value | Description |
|------|-------|-------|--|
| 31-0 | ME | | Mailbox Enable Register. After power-up, all bits in CANME are cleared to 0. Disabled mailboxes may be used as additional memory for the CPU. |
| | | 0 | The corresponding mailbox n is disabled. |
| | | 1 | The corresponding mailbox n is enabled for the CAN module. The mailbox must be disabled before writing to the contents of any identifier field. If the corresponding bit in CANME is set, the write access to the identifier of a message object is discarded. |

23.10.1.2 Mailbox Direction Register (CANMD)

Each mailbox n is configured as a transmit or a receive mailbox by a corresponding bit n in this register.

Figure 23-12. Mailbox Direction Register (CANMD) [04h]

LEGEND: R/W = Read/Write; R = Read only; - n = value after reset

⁽¹⁾ HECC only, reserved in the SCC

Table 23-7. Mailbox Direction Register (CANMD) Field Descriptions

| Bit | Field | Value | Description |
|------|-------|-------|---|
| 31-0 | MD | | Mailbox Direction Register. After power-up, all bits in CANMD are cleared to 0. |
| | | 0 | The corresponding mailbox n is configured as a transmit mailbox. |
| | | 1 | The corresponding mailbox n is configured as a receive mailbox. |

23.10.1.3 Transmission Request Set Register (CANTRS)

When mailbox n is ready to be transmitted, the CPU sets the corresponding TRS n bit to 1 in this register to start the transmission. A successful transmission also sets the GMIF0/GMIF1 bit in the global interrupt flag register (CANGIF0/CANGIF1) and initiates a global mailbox interrupt, if the corresponding mailbox interrupt mask (MIM n) bit in the mailbox interrupt mask register (CANMIM) is set.

The TRS n bit is set by the CPU and reset by the CAN module logic. It is also set by the CAN module in the case of a remote frame request. The TRS n bit is reset in the case of a successful transmission or an aborted transmission (if requested). If a mailbox n is configured as a receive mailbox (MD n bit in the mailbox direction register, CANMD, is set), the corresponding TRS n bit is ignored. If the TRS n bit of a remote request mailbox is set, a remote frame is transmitted. If the CPU tries to set a bit while the CAN module tries to clear it, the bit is set.

Setting the TRS n bit causes the particular message n to be transmitted. Several bits can be set simultaneously. Therefore, all messages with the TRS n bit set are transmitted in turn, starting with the mailbox having the highest mailbox number (highest priority).

The bits in CANTRS are set by writing a 1 from the CPU; writing a 0 has no effect. After power-up, all bits in CANTRS are cleared to 0.

Figure 23-13. Transmission Request Set Register (CANTRS) [08h]

LEGEND: R/W = Read/Write; R = Read only; - n = value after reset

⁽¹⁾ HECC only, reserved in the SCC

Table 23-8. Transmission Request Set Register (CANTRS) Field Descriptions

| Bit | Field | Value | Description |
|------|-------|-------|---|
| 31-0 | TRS | | Transmit Request Set Register. After power-up, all bits in CANTRS are cleared to 0. |
| | | 0 | No operation |
| | | 1 | If the corresponding message is configured as a transmit mailbox or remote request mailbox, the data or remote message of this mailbox will be transmitted. |

23.10.1.4 Transmission Request Reset Register (CANTRR)

Setting the TRR n bit of the message n causes a transmission request to be cancelled, if it was initiated by the corresponding TRS n bit in the transmission request set register (CANTRS) and is not currently being processed. If the corresponding message is currently being processed, the TRR n bit is reset in the case of a successful transmission (normal operation) or an aborted transmission due to a lost arbitration or an error condition detected on the CAN bus line. In the case of an aborted transmission, the corresponding AAN bit in the abort acknowledge register (CANAA) is set; in the case of a successful transmission, the corresponding TAN bit in the transmission acknowledge register (CANTA) is set.

The TRR n bit is set by the CPU and reset by the internal logic. The TRR n bit is reset in the case of a successful transmission or an aborted transmission. If the CPU tries to set a bit while the CAN module tries to clear it, the bit is set.

If a transmission reset is requested for a transmit mailbox with the corresponding TRS n bit cleared in CANTRS, for a disabled mailbox, or for a receive mailbox, then the CAN module clears the TRR n bit and sets the AAN bit in order to respond to the request.

The bits in CANTRR are set by writing a 1 from the CPU; writing a 0 has no effect.

Figure 23-14. Transmission Request Reset Register (CANTRR) [0Ch]

Table 23-9. Transmission Request Reset Register (CANTRR) Field Descriptions

| Bit | Field | Value | Description |
|------|-------|-------|---|
| 31-0 | TRR | | Transmit Request Reset Register. |
| | | 0 | No operation. |
| | | 1 | Setting the TRR n bit causes a transmission request to be cancelled, if it was initiated by the corresponding TRS n bit in the transmission request set register (CANTRS) and is not currently being processed. |

23.10.1.5 Transmission Acknowledge Register (CANTA)

If the message of mailbox n is transmitted successfully, the TAn bit is set in this register. A successful transmission also sets the GMIF0/GMIF1 bit in the global interrupt flag register (CANGIF0/CANGIF1) and initiates a global mailbox interrupt, if the corresponding mailbox interrupt mask (MIM n) bit in the mailbox interrupt mask register (CANMIM) is set.

The CPU resets the bits in CANTA by writing a 1. Writing a 1 also clears the interrupt, if an interrupt had been generated; writing a 0, has no effect. If the CPU tries to reset the bit while the CAN module tries to set it, the bit is set. After power-up, all bits in CANTA are cleared to 0.

Figure 23-15. Transmission Acknowledge Register (CANTA) [10h]

| | | |
|----|-----------------------|----|
| 31 | TA.31:16 | 16 |
| | R/WC-0 ⁽¹⁾ | |
| 15 | TA.15:0 | 0 |
| | R/WC-0 | |

Table 23-10. Transmission Acknowledge Register (CANTA) Field Descriptions

| Bit | Field | Value | Description |
|------|-------|-------|---|
| 31-0 | TA | | Transmit Acknowledge Register. |
| | | 0 | The message is not sent. |
| | | 1 | If the message of mailbox n is sent successfully, bit n is set. |

23.10.1.6 Abort Acknowledge Register (CANAA)

If the transmission of the message in mailbox *n* is aborted, the corresponding abort acknowledge (AA*n*) bit is set in this register. An aborted transmission also sets the AAIF0/AAIF1 bit in the global interrupt flag register (CANGIF0/CANGIF1) and initiates an interrupt, if the corresponding AAIM bit in the global interrupt mask register (CANGIM) is set.

Additional Conditions That Set the AA *n* Bit

NOTE: The AA*n* bit is set if a transmission reset is requested and the TRSn bit in CANTRS of the corresponding transmit mailbox is not set, a receive mailbox or a disabled mailbox is concerned.

The CPU resets the bits in CANAA by writing a 1; writing a 0, has no effect. If the CPU tries to reset the bit while the CAN module tries to set it, the bit is set. After power-up, all bits in CANAA are cleared to 0.

Figure 23-16. Abort Acknowledge Register (CANAA) [14h]

LEGEND: R/WC = Read/Write 1 to clear, write of 0 has no effect; R = Read only; -*n* = value after reset

⁽¹⁾ HECC only, reserved in the SCC

Table 23-11. Abort Acknowledge Register (CANAA) Field Descriptions

| Bit | Field | Value | Description |
|------|-------|-------|---|
| 31-0 | AA | | Abort Acknowledge Register. |
| | | 0 | The transmission is not aborted. |
| | | 1 | If the transmission of the message in mailbox <i>n</i> is aborted, bit <i>n</i> is set. |

23.10.1.7 Receive Message Pending Register (CANRMP)

If mailbox n contains a received message, the RMP_n bit in this register is set. The RMP_n bit is only reset by the CPU and set by the internal logic. A new incoming message overwrites the stored message, if the OPC_n bit in the overwrite protection control register (CANOPC) is cleared to 0; otherwise, the next mailboxes are checked for a matching identification. If a message is overwritten, the corresponding RML_n bit in the receive message lost register (CANRML) is set. The bits in CANRMP and CANRML are cleared to 0 by a write access to the base address of CANRMP, with a 1 at the corresponding bit location. If the CPU tries to reset the bit while the CAN module tries to set it, the bit is set.

The proper sequence to clear RMP_n bits is shown below.

1. Read the RMP_n bits (don't clear it)
2. When RMP_n is set, read the message
3. Clear the RMP_n bit

A received message also sets the GMIF0/GMIF1 bit in the global interrupt flag register (CANGIF0/CANGIF1) and initiates an interrupt, if the corresponding MIM_n bit in the mailbox interrupt mask register (CANMIM) is set.

Figure 23-17. Receive Message Pending Register (CANRMP) [18h]

LEGEND: R/WC = Read/Write 1 to clear, write of 0 has no effect; - n = value after reset

Table 23-12. Receive Message Pending Register (CANRMP) Field Descriptions

| Bit | Field | Value | Description |
|------|-------|-------|---|
| 31-0 | RMP | | Receive Message Pending Register. |
| | | 0 | The mailbox does not contain a message. |
| | | 1 | If mailbox n contains a received message, bit n is set. |

23.10.1.8 Receive Message Lost Register (CANRML)

If an old message is overwritten by a new message in message object n , the RML_n bit in this register is set. The RML_n bit is only reset by the CPU and set by the internal logic. The RML_n bit is cleared by a write access to the base address of the receive message pending register (CANRMP), with a 1 at the corresponding bit location. If the CPU tries to reset the bit while the CAN module tries to set it, the bit is set. The content of CANRML is not changed, if the OPC_n bit in the overwrite protection control register (CANOPC) is set.

If one or more of the RML_n bits in CANRML are set, the $RMLIF0/RMLIF1$ bit in the global interrupt flag register (CANGIF0/CANGIF1) is set and initiates an interrupt, if the $RMLIM$ bit in the global interrupt mask register (CANGIM) is set.

Figure 23-18. Receive Message Lost Register (CANRML) [1Ch]

Table 23-13. Receive Message Lost Register (CANRML) Field Descriptions

| Bit | Field | Value | Description |
|------|-------|-------|--|
| 31-0 | RML | | Receive Message Lost Register. |
| | | 0 | No message was lost. |
| | | 1 | An old unread message has been overwritten by a new one in that mailbox. |

23.10.1.9 Remote Frame Pending Register (CANRFP)

Whenever a remote frame request is received by the CAN module, the corresponding RFP n bit in this register is set. If a remote frame is stored in a receive mailbox n (AAM = 0 in the message identifier register, CANMID, and MD n = 1 in the mailbox direction register, CANMD), the CPU has to initiate the reply frame transmission and has to reset the RFP n bit. If a mailbox configured in auto-answer mode (AAM = 1 and MD n = 0) receives a remote frame, the CAN module clears the RFP n bit after the reply frame has been successfully transmitted.

In order to prevent an auto-answer mailbox from replying to a remote frame request, the CPU clears the RFP n bit and the TRS n bit in the transmission request set register (CANTRS) by setting the corresponding TRR n bit in the transmission request reset register (CANTRR). The AAM bit may also be cleared by the CPU to stop the CAN module from sending the message.

If the CPU tries to reset the bit while the CAN module tries to set it, the bit is not set. The CPU cannot interrupt an on-going transfer.

Figure 23-19. Remote Frame Pending Register (CANRFP) [20h]

LEGEND: R/WC = Read/write 1 to clear, write of 0 has no effect; - n = value after reset

⁽¹⁾ HECC only, reserved in the SCC

Table 23-14. Remote Frame Pending Register (CANRFP) Field Descriptions

| Bit | Field | Value | Description |
|------|-------|-------|--|
| 31-0 | RFP | | Remote Frame Pending Register |
| | | 0 | No remote frame request was received. |
| | | 1 | A remote frame request was received by the CAN module. |

23.10.1.10 Global Acceptance Mask Register (CANGAM)

The global acceptance mask is used by the SCC or HECC in SCC-compatible mode. The global acceptance mask is used for mailboxes 6 to 15, if the AME bit in the message identifier register (CANMID) of the corresponding mailbox is set. A received message is only stored in the first mailbox with a matching identifier.

The global acceptance mask is used for mailboxes 6 to 15 of the SCC.

Figure 23-20. Global Acceptance Mask Register (CANGAM) [24h]

| | | | | | | |
|-------|----------|----|-----------|----|----|-----------|
| 31 | 30 | 29 | 28 | 18 | 17 | 16 |
| AMI | Reserved | | GAM.28:18 | | | GAM.17:16 |
| R/W-0 | R-0 | | R/W-0 | | | R/W-0 |
| 15 | GAM.15:0 | | | | | 0 |
| R/W-0 | | | | | | |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 23-15. Global Acceptance Mask Register (CANGAM) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|-------|---|
| 31 | AMI | | Acceptance Mask Identifier Extension bit. |
| | | 0 | The identifier extension bit stored in the mailbox determines which messages shall be received. |
| | | 1 | Standard and extended frames are received. In the case of an extended frame, all 29 bits of the identifier are stored in the mailbox and all 29 GAM bits are used for the filter. In the case of a standard frame, only the first 11 bits (28 to 18) of the identifier and the GAM bits are used. |
| 30-29 | Reserved | | Reads are undefined and writes have no effect. |
| 28-0 | GAM | | Global Acceptance Mask. These bits allow any identifier bits of an incoming message to be masked. |
| | | 0 | Received identifier bit value must match the corresponding identifier bit in the message identifier register (CANMID). |
| | | 1 | Accept a 0 or a 1 (don't care) for the corresponding bit of the received identifier. |

23.10.1.11 Master Control Register (CANMC)

This register is used to control the settings of the CAN module.

Update Data With CDR Bit Mechanism

NOTE: When using the CDR bit to update the data field of a mailbox, the SCC and the HECC behave differently. The SCC always considers new data after an arbitration loss or bus error. The HECC tries to send the former data if the message was loaded into the internal transmit buffer prior to the data update. If the software wants to force the HECC to transmit updated data as soon as possible, it has to perform a dummy write to the transmit request set register (CANTRS), for example CANTRS = 0000 0000h, after the data update is finished (CDR bit is cleared).

Figure 23-21. Master Control Register (CANMC) [28h]

⁽¹⁾ HECC only, reserved in the SCC

⁽¹⁾ HECC only, reserved in the SCC

Table 23-16. Master Control Register (CANMC) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|-------|--|
| 31-16 | Reserved | | Reads are undefined and writes have no effect. |
| 15 | LNTC | | Local Network Time Clear Bit. |
| | | 0 | Local network time register (CANLNT) is not reset. |
| | | 1 | Local network time register (CANLNT) is reset to zero after a successful transmission or reception of mailbox 16. |
| 14 | LNTM | | Local Network Time MSB Clear Bit. |
| | | 0 | Local network time register (CANLNT) is not changed. |
| | | 1 | The most-significant bit of the local network time register (CANLNT) is reset to zero. The LNTM bit is reset after one clock cycle by the internal logic. |
| 13 | SCM | | SCC-Compatibility Mode. |
| | | 0 | HECC operates in SCC-compatibility mode only mailboxes 15 to 0 can be used. You must refer to the SCC specification in order to operate the HECC in this mode. Since this mode is selected by default, all software developed for the SCC runs without any change to the HECC module. |
| | | 1 | HECC operates in normal mode. |
| 12 | CCR | | Change Configuration Request. |
| | | 0 | The CPU requests normal operation. This can only be done after the bit-timing configuration register (CANBTC) is set to the allowed values. |
| | | 1 | The CPU requests write access to the bit-timing configuration register (CANBTC) and the acceptance mask registers (CANGAM, CANLAM0, and CANLAM3) of the SCC. After setting this bit, the CPU must wait until the CCE bit in the error and status register (CANES) is 1 before proceeding to CANBTC (see Section 23.10.1.12). This could also mean that the CAN module is in the bus off state (see the BO bit in CANES, Section 23.10.1.13). |
| 11 | PDR | | Power-Down-Mode Request. |
| | | 0 | The CAN module power-down mode is not requested (normal operation). |

Table 23-16. Master Control Register (CANMC) Field Descriptions (continued)

| Bit | Field | Value | Description |
|-----|-------|-------|--|
| | | 1 | The CAN module power-down mode is requested. |
| 10 | DBO | | Data Byte Order. This bit selects the byte order of the message data field of the message data registers, CANMDL and CANMDH (see Section 23.10.4.3). |
| | | 0 | The data is received or transmitted most-significant byte first. |
| | | 1 | The data is received or transmitted least-significant byte first. |
| 9 | WUBA | | Wake Up on Bus Activity. |
| | | 0 | The CAN module leaves the power-down mode only after writing a 0 to the PDR bit. |
| | | 1 | The CAN module leaves the power-down mode after detecting any bus activity. |
| 8 | CDR | | Change Data Request. This bit allows fast data message update. |
| | | 0 | The CPU requests normal operation. |
| | | 1 | The CPU requests write access to the data field of the mailbox specified by the MBNR bits. The CPU must clear the CDR bit after accessing the mailbox. The CAN module does not transmit the mailbox content while the CDR bit is set. This is checked by the state machine before and after it reads the data from the mailbox to store it in the transmit buffer. |
| 7 | ABO | | Auto Bus On. |
| | | 0 | Bus-offstate can only be left by clearing the CCR bit after 128 \blacklozenge 11 recessive bits. |
| | | 1 | After bus-off state, the module goes back automatically into the bus-on state after 128 \blacklozenge 11 recessive bits. |
| 6 | STM | | Self-Test Mode. |
| | | 0 | The CAN module is in normal mode. |
| | | 1 | The CAN module is in self-test mode. In this mode, the CAN module generates its own acknowledge (ACK) signal, thus enabling operation without a bus connected to the module. The message is not sent, but read back and stored in the appropriate mailbox. |
| 5 | SRES | | Software Reset. This is a write-only bit and is always read as zero. |
| | | 0 | No effect |
| | | 1 | A write access to this register causes a software reset of the CAN module, that is, all parameters, except the bits listed in Table 23-17 , are reset to their default values. The mailbox contents and the error counters are not modified. Pending and on-going transmissions are canceled without disturbing the communication. |
| 4-0 | MBNR | 0-1Fh | Mailbox Number. The CPU requests write access to the data field of the mailbox specified by the MBNR bits. This field is used in conjunction with the CDR bit. |

Table 23-17. Bits Not Changed After Software Reset

23.10.1.12 Bit-Timing Configuration Register (CANBTC)

This register is used to configure the CAN node with the appropriate network-timing parameters. This register must be programmed before using the CAN module. This register can only be written in initialization mode, see [Section 23.6.1](#).

CAUTION

Unallowable Configuration Values
 To avoid unpredictable behavior of the CAN module, do not program CANBTC with values not allowed by the CAN protocol specification and by the bit timing rules listed in [Section 23.6.1](#).

Figure 23-22. Bit-Timing Configuration Register (CANBTC) [2Ch]

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset; -x = value is indeterminate after reset

Table 23-18. Bit-Timing Configuration Register (CANBTC) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|--------|--|
| 31-24 | Reserved | | Reads are undefined and writes have no effect. |
| 23-16 | BRP | 0-FFh | Time Quantum Prescaler bits specify the duration of a time quantum (TQ) in CAN module system clock units. See Section 23.6.1 . BRP PRESCALER is programmable from 1 to 256. The value programmed into CANBTC has to be decremented by 1, because of the 8-bit size of the BRP value: $BRP_{CANBTC.SJW} = BRP \text{ PRESCALER} - 1$ |
| 15-11 | Reserved | | Reads are undefined and writes have no effect. |
| 10 | ERM | 0 1 | Edge Resynchronization Mode bit selects the synchronization mode with the receive data stream on the CAN bus. 0 The CAN module resynchronizes on the falling edge only. 1 The CAN module resynchronizes on both rising and falling edges. |
| 9-8 | SJW | 0-3h | Synchronization Jump Width bits indicate how many TQ units a bit is allowed to be lengthened or shortened when resynchronizing with the receive data stream on the CAN bus. The synchronization is performed either with the falling edge (ERM = 0) or with both edges (ERM = 1) of the bus signal. SJW is programmable from 1 to 4 TQ. The maximum value of SJW is determined by the minimum value of TSEG2 _{CALC} and 4TQ. $SJW_{CALC(max)} \leq \min[4TQ, TSEG2_{CALC}]$ The value programmed into the CANBTC register has to be decremented by 1, because of the 2-bit size of the binary SJW value (SJW.1.0): $SJW_{BTC} = SJW_{CALC} - 1$ SJW _{CALC} Result of the calculation. $1 \leq SJW_{CALC} \leq 4$ SJW _{BTC} Value to be programmed into the CANBTC register. $0 \leq SJW_{BTC} \leq 3$ |
| 7 | SAM | 0 | Sample point bits set the number of samples used by the CAN module to determine the actual level of the CAN bus. When the SAM bit is set, the level determined by the CAN bus corresponds to the result from the majority decision of the last three values. The sample points are at the sample point and twice before with a distance of $\frac{1}{2}$ TQ. 0 The CAN module samples only once at the sampling point. |

Table 23-18. Bit-Timing Configuration Register (CANBTC) Field Descriptions (continued)

| Bit | Field | Value | Description |
|-----|-------|-------|--|
| | | 1 | The CAN module samples three times and makes a majority decision. The triple sample mode shall be selected only for bit rate prescale values greater than 4 (BRP > 4). |
| 6-3 | TSEG1 | 0-Fh | <p>TSEG1 3:0 Time Segment 1</p> <p>This parameter specifies the length of the TSEG1 segment in TQ units. The value of TSEG1 is calculated as follows:</p> $\text{TSEG1} = 1 + \text{TSEG1.0} + (2 * \text{TSEG1.1}) + (4 * \text{TSEG1.2}) + (8 * \text{TSEG1.3})$ <p>TSEG1 combines PROP_SEG and PHASE_SEG1 segments:</p> $\text{TSEG1} = \text{PROP_SEG} + \text{PHASE_SEG1}$ <p>Where PROP_SEG and PHASE_SEG1 are the length of these two segments in TQ units.</p> <p>TSEG1_{CALC} value is programmable in the range of 1 TQ to 16 TQ and has to fulfill the following timing rule: TSEG1 must be greater than or equal to TSEG2 and IPT (for more details about IPT, refer to Section 23.6.1).</p> <p>The value programmed into the CANBTC register has to be decremented by 1 because of the 4-bit size of the binary TSEG1 value (TSEG1.3:0):</p> $\text{TSEG1}_{\text{BTC}} = \text{TSEG1}_{\text{CALC}} - 1$ <p>TSEG1_{CALC} Result of the calculation.</p> $2 \leq \text{TSEG1}_{\text{CALC}} \leq 16$ <p>TSEG1_{BTC} Value to be programmed into the CANBTC register.</p> $1 \leq \text{TSEG1}_{\text{BTC}} \leq 15$ |
| 2-0 | TSEG2 | 0-7h | <p>TSEG2 2:0 Time Segment 2</p> <p>TSEG2 defines the length of the PHASE_SEG2 segment in TQ units, and is calculated as follows:</p> $\text{TSEG2} = 1 + \text{TSEG2.0} + (2 * \text{TSEG2.1}) + (4 * \text{TSEG2.2})$ <p>TSEG2_{CALC} is programmable in the range of 1 TQ to 8 TQ and has to fulfill the following timing rule: TSEG2 must be smaller than or equal to TSEG1 and must be greater than or equal to IPT. For more details about IPT, refer to Section 23.6.1.</p> <p>The value programmed into the CANBTC register has to be decremented by 1 because of the 3-bit size of the binary TSEG2 value (TSEG2 3:0):</p> $\text{TSEG2}_{\text{BTC}} = \text{TSEG2}_{\text{CALC}} - 1$ <p>TSEG2_{CALC} Result of the calculation.</p> <p>TSEG2_{BTC} Value to be programmed into the CANBTC.</p> |

23.10.1.13 Error and Status Register (CANES)

The error and status register comprises information about the actual status of the CAN module and displays bus error flags as well as error status flags. The way of storing the bus error flags (FE, BE, CRCE, SE, and ACKE) and the error status flags (BO, EP, and EW) in this register is subject to a special mechanism. If one of these error flags is set, then the current state of all other error flags is frozen. In order to update this register to the actual values of the error flags, the error flag that is set has to be acknowledged by writing a 1 to it. This mechanism allows the software to distinguish between the first error and all following errors.

Figure 23-23. Error and Status Register (CANES) [30h]

Table 23-19. Error and Status Register (CANES) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|-------|---|
| 31-25 | Reserved | | Reads are undefined and writes have no effect. |
| 24 | FE | 0 | No form error is detected. |
| | | 1 | A form error occurred on the bus. This means that one or more of the fixed-form bit fields had the wrong level on the bus. |
| 23 | BE | 0 | No bit error is detected. |
| | | 1 | The received bit does not match the transmitted bit outside of the arbitration field or during transmission of the arbitration field, a dominant bit was sent but a recessive bit was received. |
| 22 | SA1 | 0 | The CAN module detected a recessive bit. |
| | | 1 | The CAN module never detected a recessive bit. |
| 21 | CRCE | 0 | The CAN module never received a wrong CRC. |
| | | 1 | The CAN module received a wrong CRC. |
| 20 | SE | 0 | No stuff bit error occurred. |
| | | 1 | A stuff bit error occurred. |
| 19 | ACKE | 0 | All messages have been correctly acknowledged. |
| | | 1 | The CAN module received no acknowledge. |
| 18 | BO | 0 | Normal operation |
| | | 1 | There is an abnormal rate of errors on the CAN bus. This condition occurs when the transmit error counter register (CANTEC) reaches the limit of 256. During bus off, no messages are received or transmitted. The only ways to exit this state are by clearing the CCR bit in the master control register (CANMC) or by setting the ABO bit in CANMC. After leaving bus off, the error counters are cleared. |
| 17 | EP | | Error Passive State. This bit is cleared when a 1 is written to this bit. |

Table 23-19. Error and Status Register (CANES) Field Descriptions (continued)

| Bit | Field | Value | Description |
|------|----------|-------|--|
| 16 | EW | 0 | The CAN module is in error-active mode. |
| | | 1 | The CAN module is in error-passive mode. |
| | | 0 | Warning Status. This bit is cleared when a 1 is written to this bit. |
| | | 1 | Both error counter registers (CANREC and CANTEC) are less than 96. |
| 15-6 | Reserved | 0 | Both error counter registers (CANREC or CANTEC) has reached the warning level of 96. |
| | | 1 | One of the two error counter registers (CANREC or CANTEC) has reached the warning level of 96. |
| 5 | SMA | | Reads are undefined and writes have no effect. |
| 4 | CCE | 0 | Suspend Mode Acknowledge bit is set after a latency of one clock cycle—up to the length of one frame- after the suspend mode was activated. The suspend mode is activated with the debugger tool when the circuit is not in run mode. During the suspend mode, the CAN module is frozen and cannot receive or transmit any frame. However, if the CAN module is transmitting or receiving a frame when the suspend mode is activated, the module enters suspend mode only at the end of the frame. |
| | | 1 | The CAN module is not in suspend mode. |
| | | 0 | The CAN module has entered suspend mode. |
| | | 1 | The CAN module has entered suspend mode. |
| 3 | PDA | 0 | Change Configuration Enable bit displays the configuration access. This bit is set after a latency of one clock cycle up to the length of one frame. |
| | | 1 | The CPU is denied write access to the configuration registers. |
| 2 | Reserved | 0 | The CPU has write access to the configuration registers. |
| | | 1 | The CPU has write access to the configuration registers. |
| 1 | RM | 0 | Power Down Mode Acknowledge. |
| | | 1 | Normal operation |
| 0 | TM | 0 | The CAN module has entered the power-down mode. |
| | | 1 | Reads are undefined and writes have no effect. |
| | | 0 | CAN protocol kernel (CPK) Receive Mode bit reflects what the CPK is actually doing regardless of mailbox configuration. |
| | | 1 | The CAN protocol kernel is receiving a message. |
| | | 0 | The CAN protocol kernel is not receiving a message. |
| | | 1 | The CAN protocol kernel is receiving a message. |
| | | 0 | CAN protocol kernel (CPK) Transmit Mode bit reflects what the CPK is actually doing regardless of mailbox configuration. |
| | | 1 | The CAN protocol kernel is transmitting a message. |
| | | 0 | The CAN protocol kernel is not transmitting a message. |
| | | 1 | The CAN protocol kernel is transmitting a message. |

23.10.1.14 Transmit Error Counter Register (CANTEC)

The CAN module contains two error counters: the receive error counter (CANREC) and the transmit error counter (CANTEC). The values of both counters are read by way of the CPU interface. These counters are incremented or decremented according to the CAN protocol specification version 2.0.

After reaching the bus-offstate, the transmit error counter is undefined while the receive error counter changes its function. After leaving initialization mode, the error counters are cleared.

Figure 23-24. Transmit Error Counter Register (CANTEC) [34h]

LEGEND: R = Read only; -n = value after reset; -x = value is indeterminate after reset

23.10.1.15 Receive Error Counter Register (CANREC)

The CAN module contains two error counters: the receive error counter (CANREC) and the transmit error counter (CANTEC). The values of both counters are read by way of the CPU interface. These counters are incremented or decremented according to the CAN protocol specification version 2.0.

After reaching or exceeding the error passive limit (128), the receive error counter is not incremented. When a message is received correctly, the counter is set again to a value between 119 and 127 (compare with CAN specification). After reaching the bus-off state, the transmit error counter is undefined while the receive error counter changes its function.

After reaching the bus-off state, the receive error counter is cleared and is incremented after every 11 consecutive recessive bits on the bus. These 11 bits correspond to the gap between two frames on the bus. If the counter reaches 128, the CAN module automatically changes back to the bus-on status if this feature is enabled (ABO bit in the master control register, CANMC is set). All internal flags are reset and the error counters are cleared. After leaving initialization mode, the error counters are cleared.

Figure 23-25. Receive Error Counter Register (CANREC) [38h]

LEGEND: R = Read only; -n = value after reset; -x = value is indeterminate after reset

23.10.1.16 Global Interrupt Flag Registers (CANGIF0, CANGIF1)

These registers allow the CPU to identify the interrupt source.

Table 23-20. Global Interrupt Flag Registers (CANGIF) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|-------|---|
| 31-18 | Reserved | | Reads are undefined and writes have no effect. |
| 17 | MAIF | 0 | No time out for the mailboxes occurred. |
| | | 1 | One of the mailboxes did not transmit or receive a message within the specified time frame. |
| 16 | TCOIF | 0 | Local Network Time Counter Overflow Flag. |
| | | 1 | The MSB of the local network time register (CANLNT) is 1. |
| 15 | GMIF | 0 | Global Mailbox Interrupt Flag |
| | | 1 | One of the mailboxes transmitted or received a message successfully. |
| 14 | AAIF | 0 | Abort-Acknowledge Interrupt Flag |
| | | 1 | No transmission has been aborted. |

Table 23-20. Global Interrupt Flag Registers (CANGIF) Field Descriptions (continued)

| Bit | Field | Value | Description |
|-----|----------|-------|---|
| 13 | WDIF | 1 | A transmission request has been aborted. |
| | | 0 | Write-Denied Interrupt Flag |
| 12 | WUIF | 0 | The CPU write access to the mailbox was successful. |
| | | 1 | The CPU write access to the mailbox was not successful. |
| 11 | RMLIF | 0 | Wake-Up Interrupt Flag |
| | | 1 | The CAN module is still in sleep mode or normal operation. |
| | | 1 | During local power down, the CAN module has left sleep mode. During global power-down, there is activity on the CAN bus lines. This bit is also set when a global power-down is requested by the CPU, but the CAN module is not ready to enter power-down mode. |
| 10 | BOIF | 0 | Receive-Message-Lost Interrupt Flag |
| | | 1 | No message has been lost. |
| 9 | EPIF | 0 | At least for one of the receive mailboxes, an overflow condition has occurred. |
| | | 1 | Bus-Off Interrupt Flag |
| 8 | WLIF | 0 | The CAN module is still in bus-on mode. |
| | | 1 | The CAN module is in bus-off mode. |
| 7-5 | Reserved | 0 | Error-Passive Interrupt Flag |
| | | 1 | The CAN module is not in error-passive mode. |
| 4-0 | MIV | 0 | The CAN module is in error-passive mode. |
| | | 1 | Warning Level Interrupt Flag |
| 7-5 | Reserved | 0 | None of the error counter registers (CANREC or CANTEC) has reached the warning level. |
| | | 1 | At least one of the error counter registers (CANREC or CANTEC) has reached the warning level. |
| 7-5 | Reserved | | Reads are undefined and writes have no effect. |
| 4-0 | MIV | 0-1Fh | Message Interrupt Vector bits indicate the number of the message object that activated the global mailbox interrupt bit (GMIF0/GMIF1). These bits are held until the appropriate TAn bit in the transmission acknowledge register (CANTA) or $RMPn$ bit in the receive message pending register (CANRMP) is cleared, or when a higher priority mailbox interrupt occurred. Then, the highest interrupt vector is displayed. In the HECC, mailbox 31 has the highest priority; in the SCC or SCC-compatible mode, mailbox 15 has the highest priority. When the GMIF0/GMIF1 bit is 0, the corresponding MIV0/MIV1 bits are undefined. MIV0.4 and MIV1.4 are not available in the SCC. |

23.10.1.17 Global Interrupt Mask Register (CANGIM)

This register allows the various interrupts to be enabled. If a bit is set, the corresponding interrupt is enabled.

| | | 0 | RMLIF interrupt is disabled. |
| | | 1 | RMLIF interrupt is enabled. |
| 10 | BOIM | | Bus Off Interrupt Mask |
| | | 0 | BOIF interrupt is disabled. |
| | | 1 | BOIF interrupt is enabled. |
| 9 | EPIM | | Error Passive Interrupt Mask |
| | | 0 | EPIF interrupt is disabled. |
| | | 1 | EPIF interrupt is enabled. |
| 8 | WLIM | | Warning Level Interrupt Mask |
| | | 0 | WLIF interrupt is disabled. |
| | | 1 | WLIF interrupt is enabled. |
| 7-3 | Reserved | | Reads are undefined and writes have no effect. |

Table 23-21. Global Interrupt Mask Register (CANGIM) Field Descriptions (continued)

| Bit | Field | Value | Description |
|------------|--------------|--------------|--|
| 2 | SIL | | System Interrupt Level. Define the interrupt level for TCOIF, WDIF, WUIF, BOIF, EPIF, AAIF, RMLIF and WLIF. |
| | | 0 | All global interrupts are mapped to the HECC0INT/SCC0INT interrupt line. |
| | | 1 | All system interrupts are mapped to the HECC1INT/SCC1INT interrupt line. |
| 1 | I1EN | | Interrupt Line 1 Enable |
| | | 0 | The HECC1INT/SCC1INT interrupt line is globally disabled. |
| | | 1 | Globally enables all interrupts for the HECC1INT/SCC1INT interrupt line, if the corresponding masks are set. |
| 0 | I0EN | | Interrupt Line 0 Enable |
| | | 0 | The HECC0INT/SCC0INT interrupt line is globally disabled. |
| | | 1 | Globally enables all interrupts for the HECC0INT/SCC0INT interrupt line, if the corresponding masks are set. |

23.10.1.18 Mailbox Interrupt Mask Register (CANMIM)

There is one interrupt bit available for each mailbox. This may be a receive or a transmit interrupt depending on the configuration register. After power up, all interrupt mask bits are cleared and all interrupts are disabled.

Figure 23-29. Mailbox Interrupt Mask Register (CANMIM) [48h]

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

⁽¹⁾ HECC only, reserved in the SCC

Table 23-22. Mailbox Interrupt Mask Register (CANMIM) Field Descriptions

| Bit | Field | Value | Description |
|------|-------|-------|--|
| 31-0 | MIM | | Mailbox Interrupt Mask bits allow any mailbox interrupt to be masked individually. |
| | | 0 | Mailbox interrupt is disabled. |
| | | 1 | Mailbox interrupt is enabled. An interrupt is generated if a message has been transmitted successfully (in case of a transmit mailbox) or if a message has been received without any error (in case of a receive mailbox). |

23.10.1.19 Mailbox Interrupt Level Register (CANMIL)

Each mailbox may initiate an interrupt on one of the two interrupt lines. Depending on the setting in this register, the interrupt is generated on the HECC0INT/SCC0INT interrupt line ($MIL_n = 0$) or on the HECC1INT/SCC1INT interrupt line ($MIL_n = 1$).

Figure 23-30. Mailbox Interrupt Level Register (CANMIL) [4Ch]

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

⁽¹⁾ HECC only, reserved in the SCC

Table 23-23. Mailbox Interrupt Level Register (CANMIL) Field Descriptions

| Bit | Field | Value | Description |
|------|-------|-------|---|
| 31-0 | MIL | | Mailbox Interrupt Level bits allow any mailbox interrupt level to be selected individually. |
| | | 0 | The mailbox interrupt is generated on HECC0INT/SCC0INT interrupt line. |
| | | 1 | The mailbox interrupt is generated on HECC1INT/SCC1INT interrupt line. |

23.10.1.20 Overwrite Protection Control Register (CANOPC)

If there is an overflow condition for mailbox *n*, the RMP*n* bit in the receive message pending register (CANRMP) is set to 1 and a new receive message would fit for mailbox *n*, the new message is stored depending on the settings in CANOPC.

- If the corresponding OPC*n* bit is set to 1, the old message is protected against being overwritten by the new message; thus, the next mailboxes are checked for a matching identification. If no other mailbox is found, the message is lost without further notification.
- If the corresponding OPC*n* bit is cleared to 0, the old message is overwritten by the new message.

An overwrite condition is monitored by the setting of the corresponding RML*n* bit in the receive message lost register (CANRML).

Figure 23-31. Overwrite Protection Control Register (CANOPC) [50h]

LEGEND: R/W = Read/Write; R = Read only; -*n* = value after reset

⁽¹⁾ HECC only, reserved in the SCC

Table 23-24. Overwrite Protection Control Register (CANOPC) Field Descriptions

| Bit | Field | Value | Description |
|------|-------|-------|--|
| 31-0 | OPC | | Overwrite Protection Control |
| | | 0 | The old message may be overwritten by a new message |
| | | 1 | An old message stored in that mailbox is protected against being overwritten by the new message. |

23.10.1.21 Transmit I/O Control Register (CANTIOC)

The CANTX pin may be configured as a normal I/O pin, if the HECC/SCC is not used, using CANTIOC.

CANTX Pin

NOTE: When the CANTX pin is configured for CAN transmit functions (TXFUNC = 1), the TXDIR and TXOUT bits have no meaning and can be set to either 0 or 1. The TXIN bit always shows the actual value of the CANTX pin.

Figure 23-32. Transmit I/O Control Register (CANTIOC) [54h]

LEGEND: R = Read only; R/W = Read/write; -n = value after reset; -x = value is indeterminate after reset

Table 23-25. Transmit I/O Control Register (CANTIOC) Field Descriptions

| Bit | Field | Value | Description |
|------|----------|-------|--|
| 31-4 | Reserved | | Reads are undefined and writes have no effect. |
| 3 | TXFUNC | 0 | The CANTX pin is used as an I/O pin, the CAN protocol kernel (CPK) output is unconnected. |
| | | 1 | The CANTX pin is used for the CAN transmit functions. |
| 2 | TXDIR | 0 | The CANTX pin is used as an input pin, if CANTX is configured as an I/O pin (TXFUNC = 0). |
| | | 1 | The CANTX pin is used as an output pin, if CANTX is configured as an I/O pin (TXFUNC = 0). |
| 1 | TXOUT | | Output value for CANTX pin. This value is output on the CANTX pin, if CANTX is configured as an I/O pin (TXFUNC = 0) and as an output (TXDIR = 1). |
| 0 | TXIN | | Reflects the value on the CANTX pin. |
| | | 0 | Logic 0 present on CANTX pin. |
| | | 1 | Logic 1 present on CANTX pin. |

23.10.1.22 Receive I/O Control Registers (CANRIOC)

The CANRX pin may be configured as a normal I/O pin, if the HECC/SCC is not used, using CANRIOC.

CANRX Pin

NOTE: When the CANRX pin is configured for CAN receive functions (RXFUNC = 1), the RXDIR and RXOUT bits have no meaning and can be set to either 0 or 1. The RXIN bit always shows the actual value of the CANRX pin.

Figure 23-33. Receive I/O Control Register (CANRIOC) [58h]

LEGEND: R = Read only; R/W = Read/write; -n = value after reset; -x = value is indeterminate after reset

Table 23-26. Receive I/O Control Register (CANRIOC) Field Descriptions

| Bit | Field | Value | Description |
|------|----------|-------|--|
| 31-4 | Reserved | | Reads are undefined and writes have no effect. |
| 3 | RXFUNC | 0 | The CANRX pin is used as an I/O pin. The RX signal is still internally connected to the CAN protocol kernel (CPK). |
| | | 1 | The CANRX pin is used for the CAN receive functions. |
| 2 | RXDIR | 0 | The CANRX pin is used as an input pin, if CANRX is configured as an I/O pin (RXFUNC = 0). |
| | | 1 | The CANRX pin is used as an output pin, if CANRX is configured as an I/O pin (RXFUNC = 0). |
| 1 | RXOUT | | Output value for CANRX pin. This value is output on the CANRX pin, if CANRX is configured as an I/O pin (RXFUNC = 0) and as an output (RXDIR = 1). |
| 0 | RXIN | | Reflects the value on the CANRX pin. |
| | | 0 | Logic 0 present on CANRX pin. |
| | | 1 | Logic 1 present on CANRX pin. |

23.10.2 Time Stamp Registers

Time Stamp Registers

NOTE: The time stamp registers are available on the HECC only. The offset addresses are reserved in the SCC.

23.10.2.1 Local Network Time Register (CANLNT)

Figure 23-34. Local Network Time Register (CANLNT)

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 23-27. Local Network Time Register (CANLNT) Field Descriptions

| Bit | Field | Value | Description |
|------|-------|--------------|--|
| 31-0 | LNT | 0-FFFF FFFFh | Local Network Time Register. Value of the local network time counter (LNT) used for the time-stamp and the time-out functions. |

23.10.2.2 Message Object Time Stamp Registers (CANMOTS)

Figure 23-35. Message Object Time Stamp Register (CANMOTS) [100h]

LEGEND: R/W = Read/write; -n = value after reset; -x = value is indeterminate after reset

Table 23-28. Message Object Time Stamp Register (CANMOTS) Field Descriptions

| Bit | Field | Value | Description |
|------|-------|--------------|---|
| 31-0 | MOTS | 0-FFFF FFFFh | Message Object Time Stamp Register. Value of the local network time counter (LNT) when the message has been actually received or transmitted. |

23.10.3 Time-Out Registers

Time-Out Registers

NOTE: The time-out registers are available on the HECC only. The offset addresses are reserved in the SCC.

23.10.3.1 Message Object Time-Out Registers (CANMOTO)

Figure 23-36. Message Object Time-Out Registers (CANMOTO) [180h]

| | | |
|----|------------|----|
| 31 | MOTO.31:16 | 16 |
| | R/W-x | |
| 15 | MOTO.15:0 | 0 |
| | R/W-x | |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset; -x = value is indeterminate after reset

Table 23-29. Message Object Time-Out Registers (CANMOTO) Field Descriptions

| Bit | Field | Value | Description |
|------|-------|--------------|--|
| 31-0 | MOTO | 0-FFFF FFFFh | Message Object Time-Out Register. Limit value of the local network time counter (LNT) to actually transmit or receive the message. |

23.10.3.2 Time-Out Control Register (CANTOC)

Figure 23-37. Time-Out Control Register (CANTOC) [60h]

| | | |
|----|-----------|----|
| 31 | TOC.31:16 | 16 |
| | R/W-0 | |
| 15 | TOC.15:0 | 0 |
| | R/W-0 | |

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 23-30. Time-Out Control Register (CANTOC) Field Descriptions

| Bit | Field | Value | Description |
|------|-------|-------|--|
| 31-0 | TOC | | Time-Out Control Register. |
| | | 0 | The time-out function is disabled. The TOS _n bit is never set in the time-out status register (CANTOS). |
| | | 1 | The TOC _n bit has to be set by the CPU in order to enable the time-out function for mailbox <i>n</i> . Before setting the TOC _n bit, load the corresponding message object time-out register (CANMOTO) with the time-out value relative to the local network time counter (LNT). |

23.10.3.3 Time-Out Status Register (CANTOS)
Figure 23-38. Time-Out Status Register (CANTOS) [64h]

LEGEND: R/W = Read/Write; R = Read only; -n = value after reset

Table 23-31. Time-Out Status Register (CANTOS) Field Descriptions

| Bit | Field | Value | Description |
|------|-------|-------|---|
| 31-0 | TOS | | Time-Out Status Register. |
| | | 0 | No time-out occurred or a specified mailbox is disabled. |
| | | 1 | The value in the local network time register (CANLNT) is larger or equal to the value in the message object time-out register (CANMOTO) that corresponds to mailbox <i>n</i> and the TOC <i>n</i> bit is set in the time-out control register (CANTOC). |

23.10.4 Message Mailbox Registers

23.10.4.1 Message Identifier Register (CANMID)

This register is only written if mailbox n is disabled (the ME_n bit in the mailbox enable register, CANME, is cleared to 0).

Figure 23-39. Message Identifier Register (CANMID) [00h]

| | | | | | | | | | | | | | | | | |

| R/W-x | | | | | | | | | | | | | | | | |

LEGEND: R/W = Read any time, write when mailbox is disabled or configured for transmission; - n = value after reset; - x = value is indeterminate after reset

Table 23-32. Message Identifier Register (CANMID) Field Descriptions

| Bit | Field | Value | Description |
|------|-------|-------|---|
| 31 | IDE | | Identifier Extension Bit |
| | | 0 | Standard identifier (11 bits). The received message or the message to be sent has a standard identifier. |
| | | 1 | Extended identifier (29 bits). The received message or the message to be sent has an extended identifier. |
| 30 | AME | | Acceptance Mask Enable Bit. AME is only used for receiver mailboxes. It must not be set for automatic reply ($AAM_n=1$, $MD_n=0$) mailboxes; otherwise, the mailbox behavior is undefined. This bit is not modified by a message reception. |
| | | 0 | No acceptance mask will be used, all identifier bits must match to receive the message. |
| | | 1 | The corresponding acceptance mask is used. |
| 29 | AAM | | Auto Answer Mode Bit. This bit is only valid for message mailboxes configured as transmit. For receive mailboxes, this bit has no effect: the mailbox is always configured for normal receive operation. This bit is not modified by a message reception. |
| | | 0 | Normal transmit mode. The mailbox does not reply to remote requests. The reception of a remote request frame has no effect on the message mailbox. |
| | | 1 | Auto answer mode. If a matching remote request is received, the CAN module answers to the remote request by sending the contents of the mailbox. |
| 28-0 | ID | | Message Identifier. |
| | | | In standard identifier mode, if the IDE bit = 0, the message identifier is stored in ID bits 28-18. In this case, ID bits 17-0 have no meaning. |
| | | | In extended identifier mode, if the IDE bit = 1, the message identifier is stored in ID bits 28-0. |

23.10.4.2 Message Control Field Register (CANMCF)

This register is only written if mailbox n is configured for transmission (MD n bit in the mailbox direction register, CANMD, is cleared to 0) or if the mailbox is disabled (ME n bit in the mailbox enable register, CANME, is cleared to 0).

Figure 23-40. Message Control Field Register (CANMCF) [04h]

LEGEND: R/W = Read at any time, write when the mailbox is disabled or configured in transmission; - n = value after reset; - x = value is indeterminate after reset

⁽¹⁾ HECC only, reserved in the SCC

Table 23-33. Message Control Field Register (CANMCF) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|--------|---|
| 31-14 | Reserved | | Reserved |
| 13-8 | TPL | 0-3Fh | Transmit Priority Level. This 6-bit field in the HECC (reserved in the SCC) defines the priority of this mailbox as compared to the other 31 mailboxes. The highest number has the highest priority. In the case that two mailboxes have the same priority, the one with the higher mailbox number is transmitted. TPL applies only for transmit mailboxes. TPL is not used when in SCC-compatibility mode. |
| 7-5 | Reserved | | Reserved |
| 4 | RTR | 0 1 | Remote Transmission Request Bit. 0 No remote frame is requested. 1 For receive mailbox: If the TRS n bit in the transmit request set register (CANTRS) is set, a remote frame is transmitted and the corresponding data frame will be received in the same mailbox. For transmit mailbox: If the TRS n bit in CANTRS is set, a remote frame is transmitted, but the corresponding data frame has to be received in another mailbox. |
| 3-0 | DLC | 0-8h | Data Length Code. The number in these bits determines how many data bytes are sent or received. Valid value range is from 0 to 8. Values from 9 to 15 are not allowed. |

23.10.4.3 Message Data Registers (CANMDL, CANMDH)

Eight bytes of the mailbox are used to store the data field of a CAN message. The setting of the DBO bit in the master control register (CANMC) determines the ordering of stored data. The data is transmitted or received from the CAN bus, starting with byte 0.

- When DBO = 1, the data is stored or read starting with the least-significant byte of CANMDL and ending with the most-significant byte of CANMDH.
- When DBO = 0, the data is stored or read starting with the most-significant byte of CANMDL and ending with the least-significant byte of CANMDH.

CANMDL n and CANMDH n are only written if mailbox n is configured for transmission (MD n bit in the mailbox direction register, CANMD, is cleared to 0) or if the mailbox is disabled (ME n bit in the mailbox enable register, CANME, is cleared to 0). If the TRS n bit in the transmission request set register (CANTRS) is set to 1, CANMDL n and CANMDH n cannot be written, unless the CDR bit in CANMC is set, with the MBNR bits in CANMC set to n . These settings also apply for a message object configured in reply mode (AAM bit in the message identifier register, CANMID, is set to 1).

Data Field

NOTE: The data field beyond the valid received data is modified by any message reception and is indeterminate.

23.10.4.4 Local Acceptance Mask Register (CANLAM)

The local acceptance filtering allows you to locally mask (don't care) any identifier bits of the incoming message.

In the SCC, the local acceptance mask register 0 (CANLAM0) is used for mailboxes 2 to 0. The local acceptance mask register 3 (CANLAM3) is used for mailboxes 5 to 3. For mailboxes 6 to 15, the global acceptance mask register (CANGAM) is used. CANLAM0 is located at address 80h of the SCC register memory; CANLAM3 is located at address 8Ch of SCC register memory.

After a hardware or a software reset of the SCC module, CANLAM0 and CANLAM3 are reset to zero. After a reset of the HECC, the CANLAM registers are not modified.

In the HECC, each mailbox (0 to 31) has its own mask register, CANLAM0 to CANLAM31. An incoming message is stored in the highest numbered mailbox with a matching identifier.

Figure 23-45. Local Acceptance Mask Register (CANLAM) [3000h]

| | | | | | | |
|----------|----------|----|----|-----------|----|-----------|
| 31 | 30 | 29 | 28 | 18 | 17 | 16 |

| 15 | | | | | | 0 |
| LAM.15:0 | | | | | | |
| R/W-x | | | | | | |

LEGEND: R/W = Read/write; -n = value after reset; -x = value is indeterminate after reset for HECC, 0 for SCC

Table 23-34. Local Acceptance Mask Register (CANLAM) Field Descriptions

| Bit | Field | Value | Description |
|-------|----------|-------|--|
| 31 | LAMI | | Local Acceptance Mask Identifier Extension Bit. |
| | | 0 | The identifier extension bit stored in the mailbox determines which messages shall be received. |
| | | 1 | Standard and extended frames can be received. In case of an extended frame, all 29 bits of the identifier are stored in the mailbox and all 29 bits of the local acceptance mask register are used for the filter. In case of a standard frame, only the first eleven bits (bits 28 to 18) of the identifier and the local acceptance mask are used. |
| 30-29 | Reserved | | Reads are undefined and writes have no effect. |
| 28-0 | LAM | | Local Acceptance Mask. These bits enable the masking of any identifier bit of an incoming message. |
| | | 0 | Received identifier bit value must match the corresponding identifier bit of the message identifier register (CANMID). |
| | | 1 | Accept a 0 or a 1 (don't care) for the corresponding bit of the received identifier. |

Applications Processor Initialization

This chapter introduces the general-purpose device initialization.

| Topic | Page |
|--|-------------|
| 24.1 Initialization Overview | 2680 |
| 24.2 Preinitialization | 2682 |
| 24.3 Power, Clocks, and Reset Power-Up Sequence | 2692 |
| 24.4 Device Initialization by ROM Code | 2692 |
| 24.5 Debug Configuration | 2740 |
| 24.6 Revision History | 2742 |

24.1 Initialization Overview

This chapter provides an overview of the requirements for initializing the processor from power-on to firmware execution. An overview of the overall initialization process is given, including hardware- and software-related steps, a general overview of the boot ROM code operational requirements, and behavior expectations.

NOTE: Some features may not be available or supported in your particular device. For more information, see Chapter 1, the *Device Family* section, and your device-specific data manual.

24.1.1 Terminology

- **Bootstrap:** Initial software (SW) that is launched by the ROM code during the memory booting phase.
- **Certificate:** Data block plus trusted signature of the data block
- **Downloaded SW:** Initial SW that is downloaded into the internal SRAM by the ROM code during the peripheral booting phase
- **eFuse:** A one-time programmable memory location usually set at the factory
- **Flash loader:** Downloaded SW launched by the ROM code in preflashing. It also programs an image into external memories.
- **GP device:** General-purpose device. A type of device in which the security features, including the cryptographic HWA, are disabled. Intended for production.
- **Initial SW:** Software that is executed by any of the ROM code mechanisms (memory booting or peripheral booting). Initial SW is a generic term for bootstrap and downloaded SW.
- **Memory booting:** ROM code mechanism that consists of executing an Initial SW from external memory
- **Peripheral booting:** ROM code mechanism that consists of polling selected interfaces, downloading, and executing an Initial SW (in this, case called downloaded SW) in the internal RAM.
- **Permanent booting device:** Memory device containing, by default, the image to be executed during the booting sequence. It is the default memory booting device. The permanent booting device is used after warm reset.
- **Preflashing:** A specific case of peripheral booting where the ROM code mechanism is used to program the external flash memory
- **R&D certificate:** Certificate where the data block contains development configuration parameters
- **ROM code:** The on-chip SW in the processor's ROM which implements booting and security features
- **Secure environment:** Execution and storage environment, built with hardware and SW components, whose access is enabled when the processor runs in secure mode
- **Secure mode:** MPU secure working state, active when the ARM secure state is set, and reinforced by secure state machine (SSM) policy and attack countermeasures.
- **Secure RAM:** Writable area of the OCM-RAM. Protected applications are loaded for execution and secure data is temporarily stored in this area. Can only be accessed when the processor is in secure mode, or by a secure DMA channel.
- **Secure ROM:** Read-only memory inside the chip. Programmed at the chip manufacturing phase. Can be accessed only when the processor is in secure mode.

24.1.2 Initialization Process

A brief overview of the whole initialization process and its steps are shown in the [Figure 24-1](#). Initialization consists of several steps:

- Preinitialization
- Power/clock/reset ramp sequence
- Boot ROM
- Boot loader
- OS/application

Each of these steps, up to OS/applications running, is explained in detail in the following sections.

Figure 24-1. Initialization Process

The first two steps in the initialization process are hardware oriented; however, they do require a good understanding of the process of configuring those system interface pins (balls on the device), which have SW configurable functionality. This configuration is an essential part of chip configuration and is application-dependent. This chapter refers to those pins and the associated configuration registers which are vital for proper device initialization.

See your device data manual for more information regarding the use of multiplexing configuration.

24.2 Preinitialization

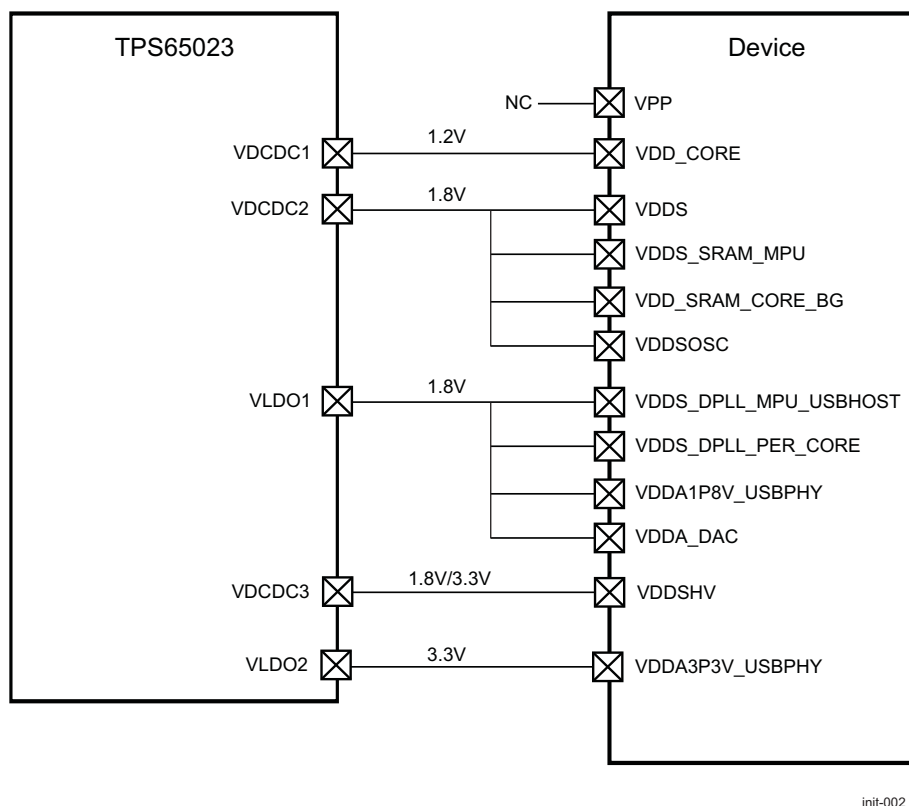

Certain hardware configuration settings must be made in order to accomplish a successful boot-up operation with a GP device. Clock, reset, and power connections, as well as pins involved in setting the boot memory space for the microprocessor unit (MPU), must be connected and driven properly for successful device initialization. The following sections detail the specific requirements for the preinitialization stage.

24.2.1 Power Connections

The device can be supplied by an external power IC. Texas Instruments provides a global solution with the processor connected to the TPS65023 power IC.

Figure 24-2 shows the power connections between the device and the TPS65023 power IC.

Figure 24-2. Power Connections

NOTE: Figure 24-2 is an example of power connections between the device and the TPS65023.

NOTE:

- The sys_clkreq output signal switches the system clock on or off.
- After power-on reset, the hardware configuration enables the internal oscillator (assuming the input clock comes from a crystal). The decision whether to bypass the internal oscillator is controlled by the polarity of the sys_boot[6] pin.

Table 24-1 describes of the power pins.

Table 24-1. Power Pin Descriptions

| I/O Voltage Name | Description |
|-----------------------------|---|
| VDD_CORE | Core power supply. |
| VDDS_SRAM_MPU | Analog power supply for MPU SLDO. |
| VDD_SRAM_CORE_BG | Analog power supply for CORE SLDO. |
| VDDSOSC | OSC VDDS supply. |
| VDDS_DPLL_MPU_USBHOST | Analog Power Supply for MPUSS/USBHOST DPLL. |
| VDDS_DPLL_PER_CORE | Analog supply for CORE/PER PLL & HSDIVIDER. |
| VDDA1P8V_USBPHY | 1.8V supply for USB transceiver. |
| VDDA_DAC | Analog Power Supply for AVDAC. |
| VDDA3P3V_USBPHY | 3.3V power supply for USB transceiver. |
| VDDSHV | 1.8/3.3V IOs supply. |
| VDDS | Bias supply for IOs. |
| VPP | eFuse programming. |

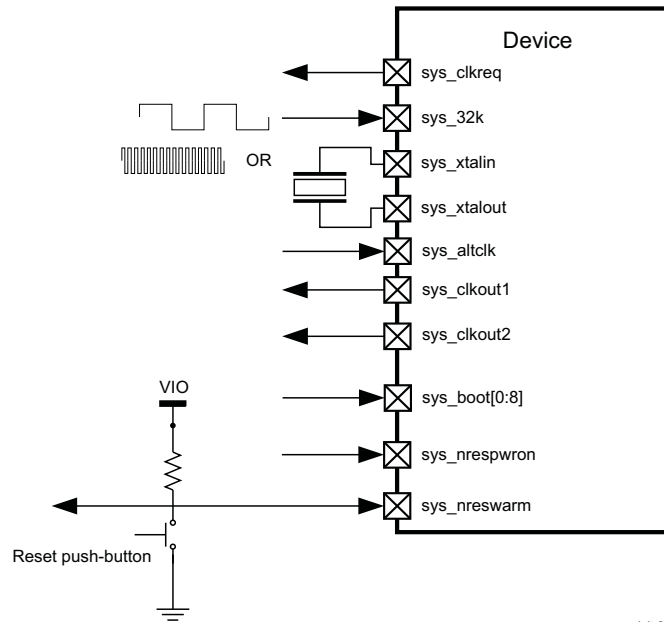

For a complete description of the power pins on the device package, see your device-specific data manual. For more information on power management, see the *Power, Reset, and Clock Management* chapter.

24.2.2 Clock and Reset

24.2.2.1 Clock and Reset Overview

Figure 24-3 shows the clock and reset environment which gathers the clocks and reset signals related at system level, as well as system expansion signals.

Figure 24-3. Clock and Reset Environment

inil-004

The main features of the system interface are:

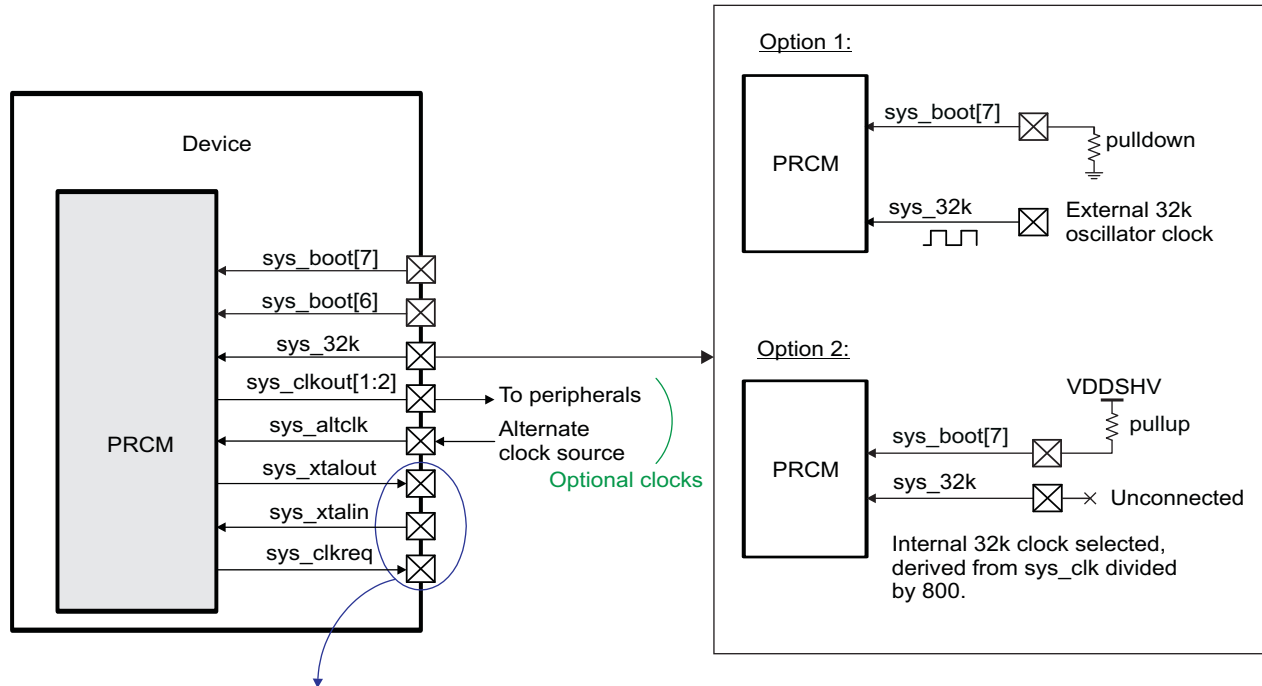

- A clock request output to an external square clock source
- 26MHz of system clock as reference clock input from either the external crystal oscillator or the digital clock input
- 32KHz clock for low frequency operation supplied either from external oscillator or generated internally
- An additional clock input up to 54 MHz
- Two configurable output clocks
- Nine input signals to define the boot mode
- Two reset sources
 - Power-on reset (cold reset)
 - Bidirectional warm reset

24.2.2.2 Clock Configuration

24.2.2.2.1 Required System Input Clocks

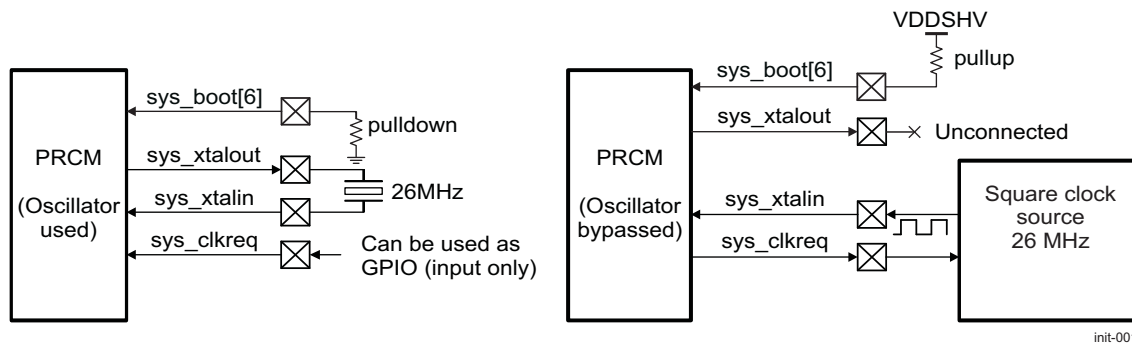

Figure 24-4 shows the clocks interface.

Figure 24-4. Clock Interface

Solution 1: Use of internal oscillator:

Solution2: Use of an external square clock source:

NOTE:

- The SYS_CLKOUT output clock cannot be provided to peripherals when the core is off.
- The sys_clkreq output signal switches the system clock on or off.
- After power-on reset, the hardware configuration enables the internal oscillator (assuming the input clock comes from a crystal). The decision whether to bypass the internal oscillator is controlled by the polarity of the sys_boot[6] pin.
- Internal generation of 32K clock is enabled by providing pull-up on sys_boot[7] pin at power-on-reset.

The device operation requires two external input clocks as follows:

1. Sys_32k: The 32KHz clock for low frequency operation is supplied in following ways:

- External – Supplied by an oscillator on sys_32K pin.
- Internal – 32K clock generation using a fixed divider on HS system clock (26MHz).

2. Sys_xtal (in/out): The 26MHz system clock is the main clock source of the device. The system clock input can be connected in either of the two following ways:
 - Crystal quartz through the SYS_XTALIN and SYS_XTALOUT pins, using an internal oscillator.
 - CMOS digital clock (square clock) through the SYS_XTALIN pin. The oscillator is bypassed.

Table 24-2 lists the mapping for input sources.

Table 24-2. Mapping for Input Sources

| Input Source | Mapping | Comment |
|--------------------------------|--------------------------------------|-------------------------------------|
| Crystal quartz | SYS_XTALIN and SYS_XTALOUT | Requires use of internal oscillator |
| Square clock (1.8 CMOS signal) | SYS_XTALIN (SYS_XTALOUT unconnected) | Internal oscillator is bypassed |

Only one source input at a time can be used because sys_32k, SYS_XTALIN and SYS_XTALOUT have permanently assigned pin locations with no pad configuration for these pins through a system control module register.

24.2.2.2.2 Optional System Input Clock: SYS_ALTCLK

An additional clock can be provided through the SYS_ALTCLK input pin to supply internal peripherals, phase-locked loops (PLLs), a precise clock for NTSC (54 MHz), USB full-speed controller (48 MHz). If not used as a clock input, this pin can be configured as a general-purpose input/output (GPIO), using the system control module CONTROL.CONTROL_PADCONF_I2C3_SDA register. As an example, to use the SYS_ALTCLK pin, the CONTROL.CONTROL_PADCONF_I2C3_SDA[18:16] MUXMODE1 field must be set to 0x01.

24.2.2.2.3 Optional System Output Clock: SYS_CLKOUT1 and SYS_CLKOUT2

Two output clocks (SYS_CLKOUT1 and SYS_CLKOUT2 pins) are available:

- SYS_CLKOUT1 can output the oscillator clock. Its OFF state polarity is programmable.
- SYS_CLKOUT2 can output the system clock (26MHz), the core clock (CORE DPLL output), 96 MHz, or 54 MHz. SYS_CLKOUT2 can be divided by 2, 4, 8, or 16, and its OFF state polarity is programmable.

CAUTION

Clock configurations depend on core voltage, and maximum clock frequencies may not be applicable to production. Please refer to your device-specific data manual for a description of the supported voltage levels and maximum clock frequencies.

The clocks can be managed by SW with the appropriate register in the power, reset, clock, management (PRCM) module:

- SYS_CLKOUT1 is managed using PRCM.PRM_CLKOUT_CTRL and PRCM.PRM_POLCTRL[2].
- SYS_CLKOUT2 is managed using PRCM.CM_CLKOUT_CTRL and PRCM.CM_CLKSEL1_PLL[28:27].

24.2.2.3 Reset Configuration

The sys_nrespwron reset pin is used to reset the entire chip during the power-on reset.

The sys_nreswarm reset pin is used to reset the entire chip when the device is supplied and operating, except for the following:

- Part of Memory Subsystem
- Part of PRCM
- Control module

- Watchdog
- 32-kHz synchronization timer
- DPLLs

CAUTION

sys_nrespwron must be driven low during a power-up sequence.

sys_nreswarm is a bidirectional reset. When an internal reset occurs, sys_nreswarm goes low and resets all the peripherals.

Both sys_nrespwron and sys_nreswarm have permanently assigned pin locations.

At reset, the cause of reset is stored in the PRCM.RM_RSTST_MPU register and used by the boot ROM code.

24.2.3 Boot Configuration

Six external pins (sys_boot[5:0]) are used to select interfaces or devices used for booting. The sys_boot[6] pin is used to select whether the internal oscillator is bypassed. The sys_boot[7] pin is used to select whether to use external 32K clock supply or 32K clock is generated internally.

Boot configuration pins sys_boot[5:0] are sampled and latched onto CONTROL.CONTROL_STATUS register and sys_boot[8:7] are sampled and latched onto CONTROL.CONTROL_DEVCONF2 register following a power-on reset. After booting, these pins can optionally be used for other functions and the associated CONTROL.CONTROL_STATUS bits are not updated by the new functionality. For more information about pad multiplexing configuration, see the *System Control Module* chapter.

NOTE: If used as GPIOs, these pins must be used in the output mode. To ensure the sys_boot[8:0] input values are selected by the pullup and pulldown on sys_boot[8:0] pins at power-on reset, these GPIOs must be used only in output mode. As these balls have no pullup or pulldown capacity, care must be taken when choosing to use these GPIOs.

Table 24-3, Table 24-4, and Table 24-5 are decoding tables for sys_boot pins. Depending on sys_boot pin configuration during the reset (first column), the ROM code tries to boot on the first device listed. If the boot failed on this first device, the ROM code tries the second device, then the third, then the fourth.

The following names are used in the tables:

- Memory types:
 - XIP: XIP memory without wait monitoring enabled (NOR flash memories)
 - XIP wait: XIP memory with wait monitoring
 - DOC: DiskOnChip™ memory (H3 device types)
 - NAND: NAND flash memories (non XIP)
 - OneNAND: OneNAND flash memories
 - MMC1: MMC or SD flash cards with active primary partition of type FAT12/16/32 connected to the first multimedia card/secure digital/secure digital I/O (MMC/SD/SDIO1) card interface
 - MMC2: MMC or SD flash cards with active primary partition of type FAT12/16/32 connected to the second multimedia card/secure digital/secure digital I/O (MMC/SD/SDIO2) card interface
- Peripheral interfaces:
 - Ethernet: EMAC RMII interface
 - USB: HS/FS USB
 - UART3: UART interface
- Permanent booting devices are in *italics*.

Table 24-3 and Table 24-4 list the sys_boot pin configuration after a power-on reset (POR).

CAUTION

- UART boot: UART3 is the only possible UART from which boot can be performed. Additionally, only UART3 pads that provide UART3 functionality in their MUXMODE 0 can be used. No other UART configuration allows booting from the UART.

Table 24-3. Memory Booting Configuration Pins after POR

| sys_boot [4:0] | Booting Sequence When SYS.BOOT[5] = 0 | | | |
|----------------|---|--------|-------------------------|--------|
| | Memory Booting Preferred Order | | | |
| | First | Second | Third | Fourth |

24.3 Power, Clocks, and Reset Power-Up Sequence

See the section *Power-Up Sequence* in the *Power, Reset, and Clock Management* chapter for the power-on sequence, including power supplies, clocks, and reset signals.

See your device data manual for more information regarding the device power-up sequence.

24.4 Device Initialization by ROM Code

This section describes the high-level booting concepts and provides basic knowledge of booting on the device.

24.4.1 Booting Overview

CAUTION

To use the level 2 (L2) cache with the device, the ROM code provides three primitive services. These services are implemented in monitor mode and do not use any resources outside the MPU subsystem. The services are described below. To call a service, a register r12 must be set to service ID and the SMI instruction must be executed.

- r12=1: To use the L2 cache, all L2 line data must be invalidated through the CP15 registers. This service invalidates the entire L2 cache and must be performed after a POR or a loss of L2 cache after reset. This register can also be read.
- r12=2: This service writes the value of the central processing unit (CPU) register R0 in the L2 cache auxiliary control register. This register can also be read.
- r12=3: This service writes the value of the CPU register R0 in the auxiliary control. This register can also be read. For more information about ARM L2 cache and registers, see the *Cortex-A8 Technical Reference Manual*. For more information about ARM CP15 registers, see the *ARM Architecture Reference Manual*.

24.4.1.1 Booting Types

Bootting is the process of starting a bootstrap from one of the booting memories.

The ROM code has two functionalities for booting: peripheral booting and memory booting.

- In peripheral booting, the ROM code polls a selected communication interface such as UART or USB, downloads the executable code over the interface, and executes it in internal RAM. Downloaded software from an external host can be used to program flash memories connected to the device. This special case of peripheral booting is called preflashing; software downloaded for preflashing is called the flash loader. The flash loader burns a new client application image in external flash memory. Initial software is a generic term for bootstrap, downloaded software, and flash loader. After the image is burned, a software reset can be performed.
- In memory booting, the ROM code finds the bootstrap in permanent memories such as flash memory or memory cards and executes it. This process is normally performed after cold or warm device reset.

The ROM code detects whether the device should download software from a peripheral interface (USB, UART3 or EMAC) by using the sys_boot pin configuration. This mechanism encompasses initial flashing in production (external memory is empty) and reflashing in service (external memory is already programmed).

[Table 24-6](#) lists the pin multiplexing according to boot peripheral.

Table 24-6. Pin Multiplexing According to Boot Peripheral

| Boot Device | Pins |
|--------------|---|
| NAND/OneNAND | General-purpose memory controller (GPMC) pins in mode 0 |
| XIP memory | GPMC pins in mode 0 |
| DiskOnChip | GPMC pins in mode 0 |
| MMC/SD1 | MMC1 pins in mode 0 |
| MMC/SD2 | MMC2 pins in mode 0 |
| UART3 | UART3 pins in mode 0 |
| EMAC | EMAC pins in mode 0 |

CAUTION

- UART boot: UART3 is the only possible UART from which boot can be performed. Additionally, only UART3 pads that provide UART3 functionality in their MUXMODE 0 can be used. No other UART configuration allows booting from the UART.

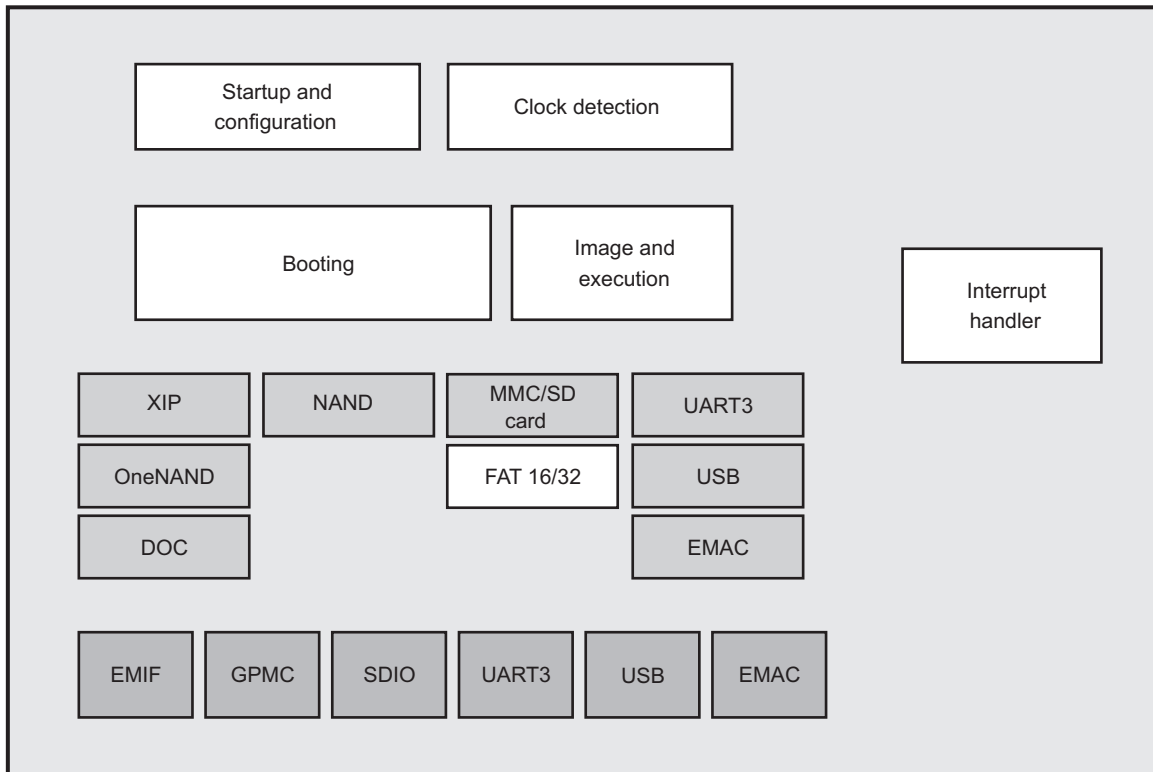

24.4.1.2 Main Features

The ROM code architecture is shown in [Figure 24-5](#). The ROM code is made up of several modules:

- The start-up module takes care of basic system configuration and dispatches control into the booting module.
- The clock detection module supports start-up.
- The booting module uses several device drivers as it must boot from one of the external devices.
- The device drivers implement device protocols and perform logical operation on a device. They are abstracted from interface hardware by several interface drivers which are responsible for interacting with hardware interface facilities.
- The interrupt handler module provides services used among all modules. It allows registering interrupt service routines (ISRs) and calls them when an interrupt occurs.

[Figure 24-5](#) shows each module.

Figure 24-5. ROM Code Architecture

init-006

24.4.2 Memory Map

24.4.2.1 ROM Memory Map

Figure 24-6 shows the ROM memory map.

Figure 24-6. 32KB ROM Memory Map

- ROM exception vectors
Exceptions are redirected to ROM exception vectors (see [Table 24-7](#)). The reset exception is redirected to the public ROM code startup. Other exceptions are redirected to RAM handlers by loading appropriate addresses in the PC register.

Table 24-7. ROM Exception Vectors

| Address | Exception | Content |
|---------|--------------------------|---------------------------------------|
| 14000h | Reset | Branch to the public ROM code startup |
| 14004h | Undefined | PC = 4020FFC8h |
| 14008h | Software interrupt (SWI) | PC = 4020FFCCh |
| 1400Ch | Prefetch abort | PC = 4020FFD0h |
| 14010h | Data abort | PC = 4020FFD4h |
| 14014h | Unused | PC = 4020FFD8h |
| 14018h | IRQ | PC = 4020FFDCh |
| 1401Ch | FIQ | PC = 4020FFE0h |

- ROM code cyclic redundancy check (CRC)
The ROM code CRC is calculated as 32-bit CRC code (CRC-32-IEEE 802.3) for the address range 14000h–1BFFFh. The 4-byte CRC code is stored at location 14020h, which is filled with FFFF FFFFh before the CRC is calculated.
- Dead loops
Dead loops are branch instructions coded in ARM mode. They have multiple purposes (see [Table 24-8](#)).

Table 24-8. Dead Loops

| Address | Purpose |
|---------|--|
| 14080h | Undefined exception default handler |
| 14084h | SWI exception default handler |
| 14088h | Prefetch abort exception default handler |
| 1408Ch | Data abort exception default handler |
| 14090h | Unused exception default handler |
| 14094h | IRQ exception default handler |
| 14098h | FIQ exception default handler |
| 1409Ch | Validation tests Pass |
| 140A0h | Validation tests Fail |
| 140A4h | Bootling failed: No more devices |
| 140A8h | Image not executed or returned |
| 140ACh | Reserved |
| 140B0h | Reserved |
| 140B4h | Reserved |
| 140B8h | Reserved |
| 140BCh | Reserved |

The fixed location of these dead loops facilitates debugging and testing. The first seven dead loops are default exception handlers linked with RAM exception vectors.

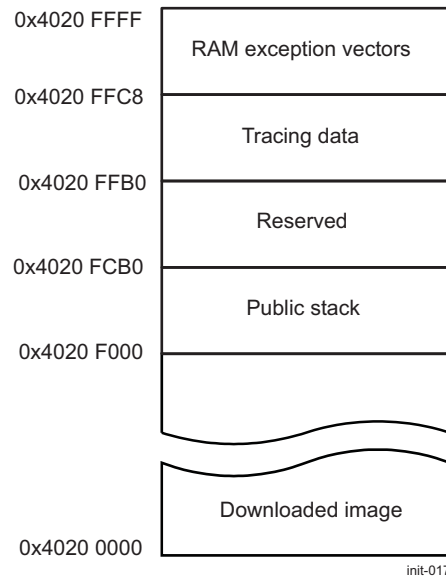

Dead loops can be called directly from code, but there is also a special function called from ROM code to execute a dead loop. This function is at address 140C0h. The function is assembly code in ARM mode, which takes the dead loop address from the R0 register. The main purpose of the function is to issue a global software reset before going to a dead loop. In addition, the function clears the global cold reset status before issuing the global software reset.

- Code
This space is used to keep code.
- Code and data
This space is used to keep code and other data.
- ROM code version
The ROM code version consists of two decimal numbers: major and minor. The major number is always 14. The minor number identifies the ROM code version. The minor number is not aligned with the ROM code release number, but it can identify it. The ROM code version is coded as hexadecimal readable values (for example, ROM version 14.04 is coded as a 3-bit word: 00001404h).

24.4.2.2 RAM Memory Map

Figure 24-7 shows RAM memory map. The shown partitioning of the on-chip SRAM is only used during the booting process.

Figure 24-7. 64KB RAM Memory Map of GP Devices

- **Downloaded image**
This space is used by the public ROM code to store a downloaded booting image.
- **Public stack**
Space reserved for stacks.
- **Tracing data**
The public ROM code tracing data is described in [Table 24-9](#). More information about ROM code tracing can be found in [Section 24.4.9, Tracing](#).

Table 24-9. Tracing Data

| Address | Size [bytes] | Description |
|------------|--------------|--|
| 0x4020FFB0 | 4 | Current tracing vector, word 1 |
| 0x4020FFB4 | 4 | Current tracing vector, word 2 |
| 0x4020FFB8 | 4 | Current copy of the PRM_RSTST register (reset reasons) |
| 0x4020FFBC | 4 | Cold reset run tracing vector, word 1 |
| 0x4020FFC0 | 4 | Cold reset run tracing vector, word 2 |
| 0x4020FFC4 | 4 | Reserved |

- **RAM exception vectors**

The RAM exception vectors provide an easy way to redirect exceptions to the custom handler. [Table 24-10](#) shows the contents of the RAM space reserved for RAM vectors. The first seven addresses are ARM instructions which load into the PC the value located in the next seven addresses. These instructions are executed when an exception occurs, since they are called from ROM exception vectors. By default, all exceptions are redirected to the exception dead loops. Users can redirect an exception to other handler by writing its address to the appropriate position from 0x4020FFE4 to 0x4020FFFC, or by overriding instructions between addresses from 0x4020FFC8 to 0x4020FFE0.

Table 24-10. RAM Exception Vectors

| Address | Exception | Content |
|------------|-----------------|-------------------|
| 0x4020FFC8 | Undefined | PC = [0x4020FFE4] |
| 0x4020FFCC | SWI | PC = [0x4020FFE8] |
| 0x4020FFD0 | Pre-fetch abort | PC = [0x4020FFEC] |
| 0x4020FFD4 | Data abort | PC = [0x4020FFF0] |

Table 24-10. RAM Exception Vectors (continued)

| Address | Exception | Content |
|------------|-----------------|-------------------|
| 0x4020FFD8 | Unused | PC = [0x4020FFF4] |
| 0x4020FFDC | IRQ | PC = [0x4020FFF8] |
| 0x4020FFE0 | FIQ | PC = [0x4020FFFC] |
| 0x4020FFE4 | Undefined | 0x14080 |
| 0x4020FFE8 | SWI | 0x14084 |
| 0x4020FFEC | Pre-fetch abort | 0x14088 |
| 0x4020FFF0 | Data abort | 0x1408C |
| 0x4020FFF4 | Unused | 0x14090 |
| 0x4020FFF8 | IRQ | 0x14094 |
| 0x4020FFFC | FIQ | 0x14098 |

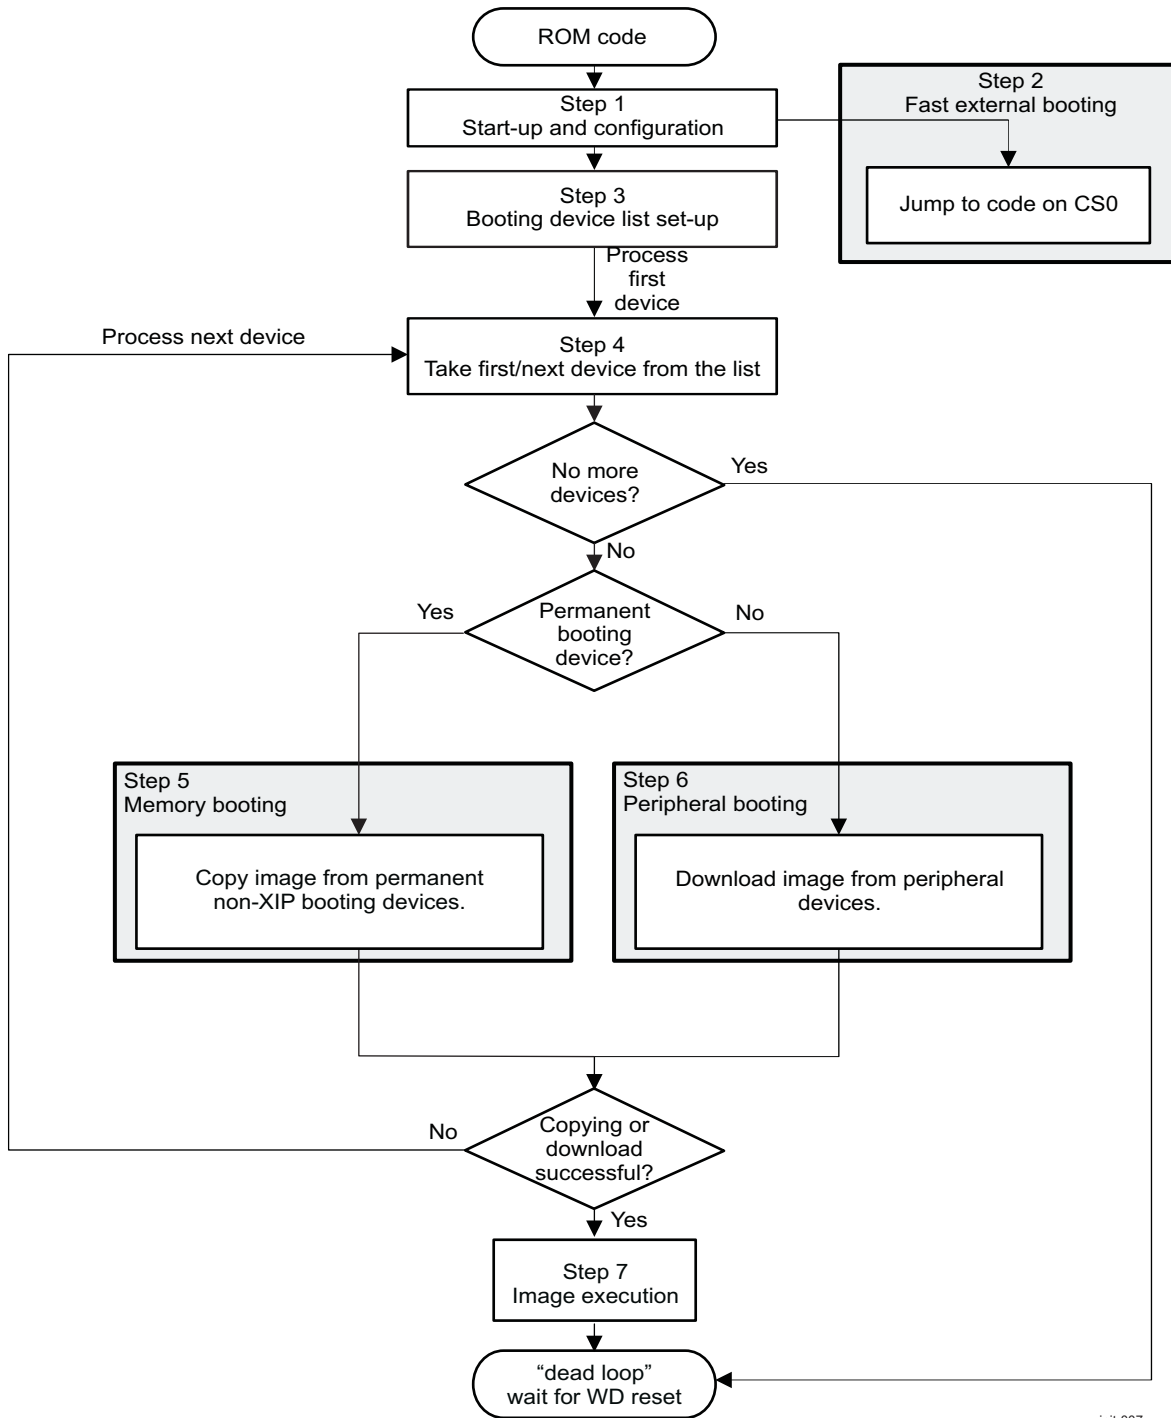

24.4.3 Overall Booting Sequence

Figure 24-8 shows the ROM code flowchart.

The main loop of the booting module goes through the booting device list and tries to get an image from the currently selected booting device. The ROM code follows these steps:

- Step 1. The ROM code performs basic configurations and initializations.
- Step 2. The path named fast external boot is a special low-latency boot mode. It consists of a blind jump to the external addressable memory as soon as possible.
- Step 3. A booting device list is created (see [Section 24.4.4.3, Booting Device List Setup](#)). The list consists of all devices to be searched for a booting image. The list is created based on the sys_boot pins.
- Step 4. Once the booting device list is set, the booting procedure examines the devices on the list serially and either executes memory booting or peripheral booting, depending on current booting device type:
 - Memory booting is executed when the booting device is permanent: XIP memory, NAND, DiskOnChip™, OneNAND, or MMC/SD cards.
 - The peripheral booting is executed when device is temporary: USB, UART or EMAC.
- Step 5. The memory booting procedure reads data from memory type devices. The memory booting is described in detail in [Section 24.4.7, Memory Booting](#).
- Step 6. The peripheral booting procedure downloads data from communication interfaces. The ROM code uses a simple logical protocol with peripheral booting. First, the processor sends an ASIC ID structure to inform the host about peripheral booting start. Next, the host responds by sending a booting message that can have one of the following meanings: skip peripheral booting, continue peripheral booting, or change the booting device. If the message is to continue, the host sends the whole image preceded by its size. The peripheral booting is described in detail in [Section 24.4.5, Peripheral Booting](#).
- Step 7. The image is simply started.

Figure 24-8. Overall Booting Sequence

init-007

24.4.4 Start-Up and Configuration

24.4.4.1 Start-Up

The ROM code starts at address 0x0001 4000.

24.4.4.2 Clocking Configuration

The ROM code configures the clocks and DPLLs required for ROM code execution.

The configured DPLLs are:

- Peripheral DPLL, set to provide 96 MHz and 48 MHz for peripheral blocks.
- MPU DPLL, set to provide 48 MHz for the MPU.
- Core DPLL, set to provide 192, 96, 48, or 24 MHz for various blocks, such as interconnect, clocked by this DPLL output.

The multipliers and dividers of the DPLLs are set to values which depend on the input clock.

Table 24-11 summarizes the ROM code default settings for key clocks.

Table 24-11. ROM Code Default Clock Settings

| Clock | Frequency [MHz] | Source |
|----------|-----------------|---------------------------------|
| CORE.CLK | 192 | CORE DPLL output |
| L3x2.CLK | 192 | CORE.CLK |
| L3.ICLK | 96 | CORE.CLK/2 |
| L4.ICLK | 48 | L3.ICLK/2 |
| RM clock | 24 | L4.ICLK/2 |
| MPU | 48 | CORE.CLK/4 (MPU DPLL in bypass) |

The DPLLs and other settings are configured by default after each type of reset to give the ROM code the same working conditions.

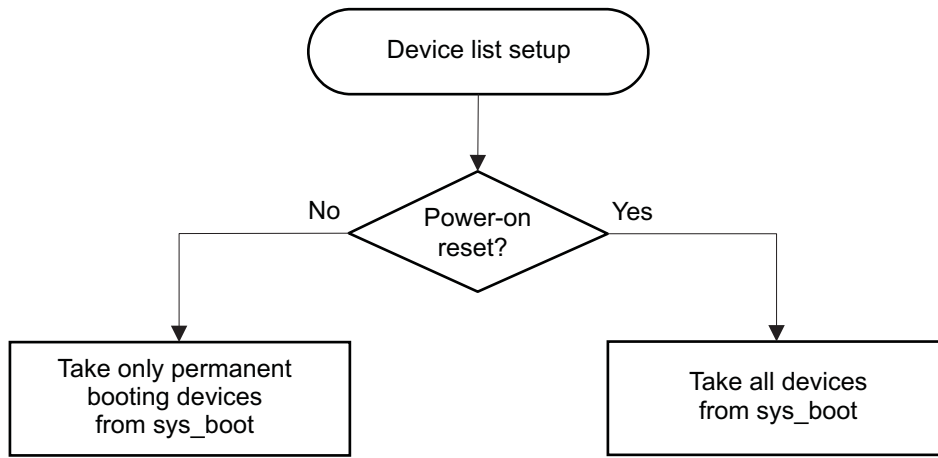

24.4.4.3 Booting Device List Set-Up

The ROM code creates the device list based on the values of sys_boot[5:0]. The sys_boot[5:0] pins are used to index the device table from which the list of devices is extracted.

Figure 24-9 shows how the ROM code sets up the device list depending on the reset source.

NOTE: Only permanent booting devices are put on the list when reset is non power-on and devices are taken from the sys_boot pins.

Figure 24-9. Device List Set-Up

init-008

24.4.5 Peripheral Booting

24.4.5.1 Overview

The ROM code can boot from different peripherals:

- HS/FS USB: High/Full-speed USB Interface.
- UART 3: Baud rate 115.2K bps, 8 bits, even parity, 1 stop-bit.
- Ethernet : EMAC RMII Interface.

The purpose of booting from a peripheral is to boot from an external host, such as a PC. This booting method is mostly used for programming flash memories connected to the processor. The protocol used is common to all peripherals. Some minor exceptions are described in the following sections. The common peripheral booting protocol is shown in [Figure 24-10](#).

Figure 24-10. Common Peripheral Booting Protocol

init-009

The ROM code first initializes the interface and sends a message called ASIC ID to a host. The content of this message is summarized in [Table 24-12](#). The host uses this message to send only appropriate data to the processor according to the identification codes sent.

The ROM code waits 300 ms for an answer from the host. If a time-out occurs, the peripheral booting returns to the main booting procedure with TIMEOUT status.

Table 24-12. ASIC ID Structure

| ASIC ID Item | Size [Bytes] | Description |
|-----------------------------|--------------|-----------------------------------|
| Items | 1 | Number of subblocks |
| ID subblock | 7 | Device identification information |
| Reserved for non-GP devices | 4 | Reserved |
| ID subblock | 23 | Identification data |
| Reserved for non-GP devices | 23 | Reserved |
| Checksum subblock | 11 | CRC (4 bytes) |

The host can send different messages as described in [Table 24-13](#). If the second or third message is not received, the ROM code stops the current peripheral booting procedure and returns to the main booting, which determines the next booting device according to the boot message received.

If the first message is received without a time-out, the image size (as a 32-bit word) and the image itself are expected to be received. The image is downloaded directly at address 0x40200000 in the internal RAM.

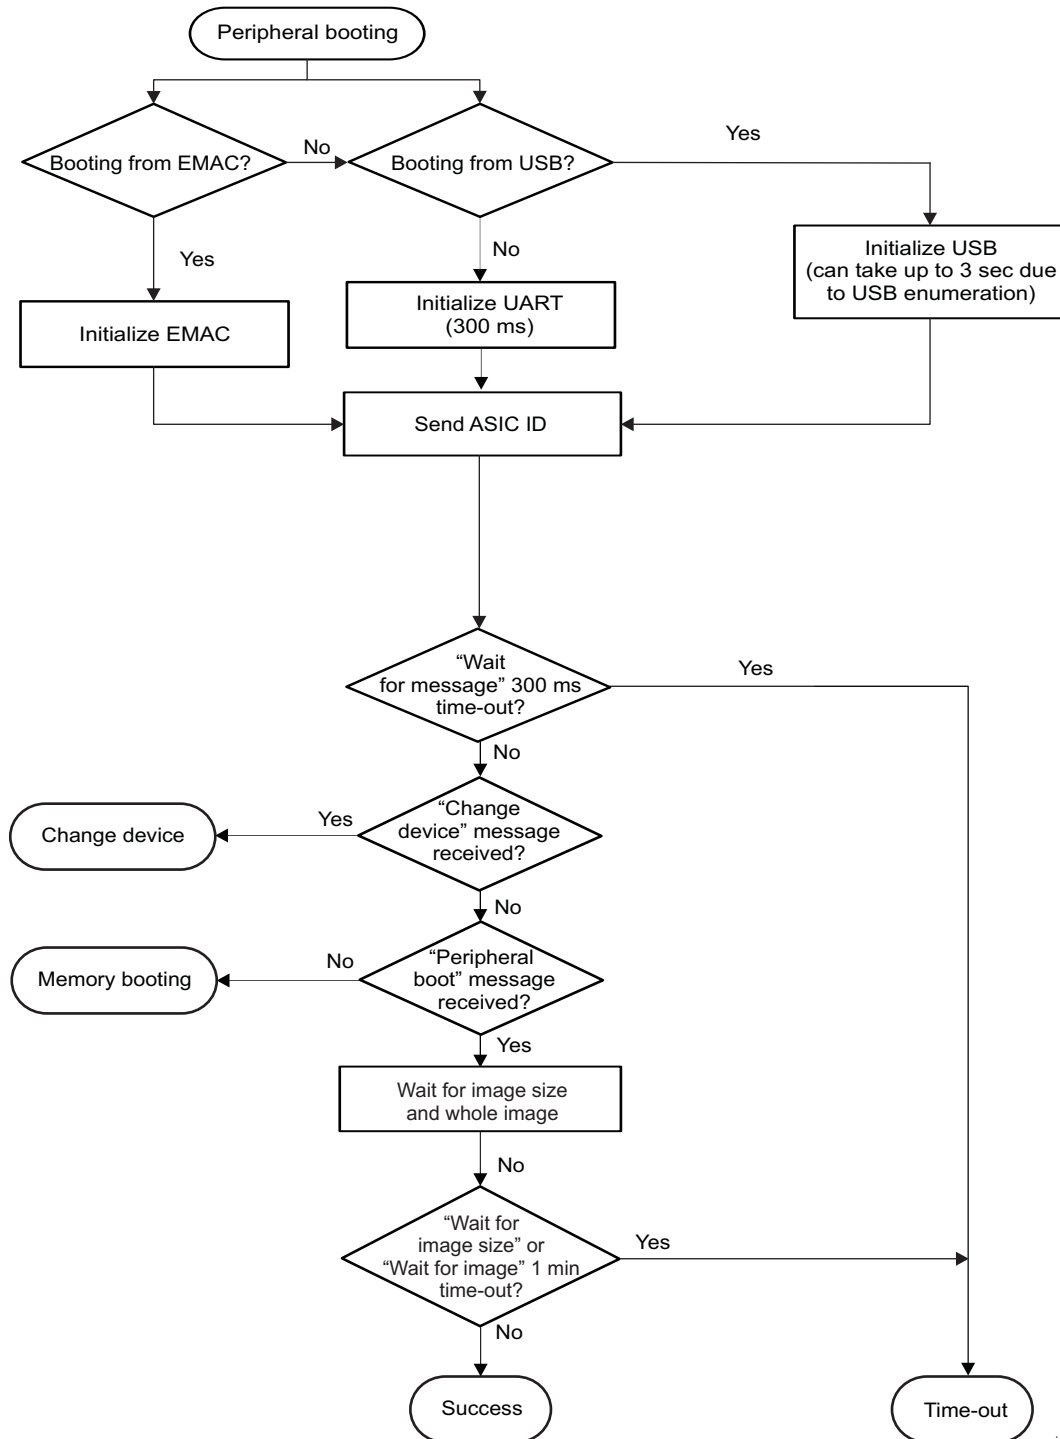

The ROM code waits up to one minute for completion. If the downloading procedure does not complete before this period, the peripheral booting fails. If the download passes, the peripheral booting succeeds and the image can be executed.

Table 24-13. Boot Messages

| Message Name | Value | Description |
|-----------------|-------------|---|
| Peripheral boot | 0xF003 0002 | Continue peripheral booting. |
| Change device | 0xF003XX06 | Skip current peripheral booting and continue booting from device type indicated by XX: 0x00 - Void, no device 0x01 - XIP memory 0x02 - NAND 0x03 - OneNAND 0x04 - Reserved 0x05 - MMC/SD2 0x06 - MMC/SD1 0x07 - XIP memory with wait monitoring 0x08..0x0F - Reserved 0x10 - UART 0x11 - HS USB 0x12 - EMAC 0x13 - EMAC Others - Reserved |
| Next device | 0xFFFF FFFF | Skip current device and move to the next device on the device list. |
| Memory booting | Others | Skip current peripheral booting and move to the first device for memory booting. |

The peripheral booting procedure is summarized in Figure 24-11.

Figure 24-11. Peripheral Booting Procedure

init-010

24.4.5.2 UART

The ROM code supports booting from a UART interface with the following characteristics:

- UART interface 3.
- Communication parameters set to 115.2k baud, 8 bits, even parity, 1 stop-bit.
- Two-pin interface: RX/TX with SW flow control (XON/XOFF). The other UART pins are left at their default configuration.
- The UART time-out is 300 ms.

24.4.5.3 USB

The ROM code supports booting from a USB interface with the following characteristics:

- HS USB interface.
- The enumeration time-out is 3 seconds.

The ROM code USB driver conforms with the USB 2.0 specification and the USB on-the-go (OTG) supplement. It supports transactions at HS (that is, 480 Mbps) and FS (that is, 12 Mbps). During peripheral booting, only the USB device functionality is used. The driver resides in the on-chip memory (OCM) ROM, which is small. The driver therefore contains the minimum functionality needed as a USB device and is not a full-fledged driver. It does not contain the functionality needed for a USB host. The device functionality of the USB OTG controller is used for the peripheral booting process in the ROM code.

24.4.5.3.1 USB Driver Descriptors

USB devices report their attributes using descriptors. A descriptor is a data structure with a defined format. Each descriptor begins with a byte-wide field that contains the total number of bytes in the descriptor followed by a byte-wide field that identifies the descriptor type. Using descriptors allows concise storage of the attributes of individual configurations so that each configuration can reuse descriptors or portions of descriptors from other configurations that have the same characteristics. Where appropriate, descriptors contain references to string descriptors. String descriptors contain displayable, human-readable information that describes a descriptor. These descriptor details can be used for tool development or debugging:

- Device descriptor.

A device descriptor contains general information about a USB device, including information that applies globally to the device and all device configurations. A USB device has only one device descriptor.

Because the ROM code uses the HS feature of the USB core, a device-qualifier descriptor is required. [Table 24-14](#) describes the device descriptors.

Table 24-14. Device Descriptor

| Field | Value | Description |
|-----------------|--|---|
| bLength | 0x12 | Size of this descriptor in bytes |
| bDescriptorType | 0x01 | Device descriptor type |
| bcdUSB | 0x0210 | USB specification release number in binary coded decimal (BCD) format |
| bDeviceClass | Vendor-specific (0xFF) | Class code |
| bDeviceSubClass | Vendor-specific (0xFF) | Subclass code |
| bDeviceProtocol | Vendor-specific (0xFF) | Protocol code |
| bMaxPacketSize0 | 0x40 | Maximum packet size for endpoint 0 |
| idVendor | 0x0451 | Vendor ID |
| idProduct | 0xD009 | Product ID |
| bcdDevice | 0x0000 | Device release number |
| iManufacturer | See values in Section 24.4.5.3.2 . | Index of string descriptor describing manufacturer |
| iProduct | See values in Section 24.4.5.3.2 . | Index of string descriptor describing product |

Table 24-14. Device Descriptor (continued)

| Field | Value | Description |
|--------------------|--|--|
| iSerialNumber | See values in Section 24.4.5.3.2 . | Index of string descriptor describing device serial number |
| bNumConfigurations | 0x01 | Number of possible configurations |

- Device-qualifier descriptor

The device-qualifier descriptor contains information about a HS-capable device that changes if the device operates at its other speed. This descriptor is retrieved by the host using the GetDescriptor() request (standard device request). [Table 24-15](#) describes a device-qualifier descriptor.

Table 24-15. Device-Qualifier Descriptor

| Field | Value | Description |
|--------------------|--------|---|
| bLength | 0x0a | Size of this descriptor in bytes |
| bDescriptorType | 0x06 | Device-qualifier descriptor type |
| bcdUSB | 0x0210 | USB specification release number in BCD |
| bDeviceClass | 0xFF | Class code |
| bDeviceSubClass | 0xFF | Subclass code |
| bDeviceProtocol | 0xFF | Protocol code |
| bMaxPacketSize0 | 0x40 | Maximum packet size for endpoint 0 |
| bNumConfigurations | 0x01 | Number of possible configurations |
| bReserved | 0x00 | Reserved for future use |

- Configuration descriptor

This descriptor gives information about a specific device configuration. The descriptor describes the number of interfaces supported by the configuration. See [Table 24-16](#) for details.

Table 24-16. Configuration Descriptor

| Field | Value | Description |
|---------------------|-------|--|
| bLength | 0x09 | Size of this descriptor in bytes |
| bDescriptorType | 0x02 | Configuration descriptor type |
| wTotalLength | – | Combined length of all descriptors |
| bNumInterfaces | 0x01 | Number of interfaces supported |
| bConfigurationValue | 0x01 | Value to use as an argument for the SetConfiguration() request |
| iConfiguration | Index | Index of string descriptor describing this configuration |
| bmAttributes | 0xc0 | Power setting and remote wake-up |
| bMaxPower | 0x32 | Maximum power consumption of the USB device |

- Other speed configuration descriptor

This descriptor describes the configuration of a HS-capable device if it operates at its other possible speed. See [Table 24-17](#) for details.

Table 24-17. Other Speed Configuration Descriptor

| Field | Value | Description |
|---------------------|-------|--|
| bLength | 0x09 | Size of this descriptor in bytes |
| bDescriptorType | 0x07 | Other speed configuration descriptor type |
| wTotalLength | – | Combined length of all descriptors |
| bNumInterfaces | 0x01 | Number of interfaces supported |
| bConfigurationValue | 0x01 | Value to use as an argument for the SetConfiguration() request |
| iConfiguration | Index | Index of string descriptor describing this configuration |

Table 24-17. Other Speed Configuration Descriptor (continued)

| Field | Value | Description |
|--------------|-------|---|
| bmAttributes | 0xc0 | Power setting and remote wake-up |
| bMaxPower | 0x32 | Maximum power consumption of the USB device |

- Interface descriptor

This descriptor describes a specific interface in a configuration. See [Table 24-18](#) for details.

Table 24-18. Interface Descriptor

| Field | Value | Description |
|--------------------|-------|--|
| bLength | 0x09 | Size of this descriptor in bytes |
| bDescriptorType | 0x04 | Interface descriptor type |
| bInterfaceNumber | 0x00 | Number of this descriptor |
| bAlternateSetting | 0x00 | Value to select the alternate setting |
| bNumEndpoints | 0x02 | Number of endpoints used for this interface |
| bInterfaceClass | 0xFF | Class code |
| bInterfaceSubClass | 0xFF | Subclass code |
| bInterfaceProtocol | 0xFF | Protocol code |
| iInterface | Index | Index of string descriptor describing this interface |

- Endpoint descriptor

Each endpoint used for an interface has its own descriptor. This descriptor contains information required by the host to determine the bandwidth requirements of each endpoint. This descriptor is returned as part of the GetDescriptor(Configuration) request. See [Table 24-19](#) and [Table 24-20](#) for details.

Table 24-19. BULK IN Endpoint Descriptor

| Field | Value | Description |
|------------------|----------------------|---|
| bLength | 0x07 | Size of this descriptor in bytes |
| bDescriptorType | 0x05 | Endpoint descriptor type |
| bEndpointAddress | 0x81 (1 IN) | Address of the endpoint on the USB device |
| bmAttributes | 0x02 (Bulk) | Type of transfer |
| wMaxPacketSize | See ⁽¹⁾ . | Number of endpoints used for this interface |
| bInterval | 0x00 | Maximum NAK rate |

⁽¹⁾ The maximum size is 0x0200 (512 bytes) for HS bulk endpoint and 0x0040 (64 bytes) for FS bulk endpoint.

Table 24-20. BULK OUT Endpoint Descriptor

| Field | Value | Description |
|------------------|----------------------|---|
| bLength | 0x07 | Size of this descriptor in bytes |
| bDescriptorType | 0x05 | Endpoint descriptor type |
| bEndpointAddress | 0x01 (1 OUT) | Address of the endpoint on the USB device |
| bmAttributes | 0x02 (Bulk) | Type of transfer |
| wMaxPacketSize | See ⁽¹⁾ . | Number of endpoints used for this interface |
| bInterval | 0x00 | Maximum NAK rate |

⁽¹⁾ The maximum size is 0x0200 (512 bytes) for HS bulk endpoint and 0x0040 (64 bytes) for FS bulk endpoint.

- String descriptors

String descriptors use UNICODE encoding. The strings in a USB device can support multiple languages. When requesting a string descriptor, the requester specifies the desired language using a 16-bit language ID (LANGID) defined by the USB interface. String index 0 for all languages returns a string descriptor that contains an array of 2-byte LANGID codes supported by the device.

See the tables describing string descriptors:

- The language ID string descriptor ([Table 24-21](#))
- The manufacturer ID string descriptor ([Table 24-22](#))
- The product ID string descriptor ([Table 24-23](#))
- The configuration string descriptor ([Table 24-24](#))
- The interface string descriptor ([Table 24-25](#))

Table 24-21. Language ID String Descriptor

| Field | Value | Description |
|-----------------|---------------------|----------------------------------|
| bLength | 0x04 | Size of this descriptor in bytes |
| bDescriptorType | 0x03 | String descriptor type |
| wLangId | 0x0409 (US English) | Language ID code |

Table 24-22. Manufacturer ID String Descriptor

| Field | Value | Description |

| bLength | 0x07 | Size of this descriptor in bytes |
| bDescriptorType | 0x03 | String descriptor type |
| bString | pbi | Interface string |

24.4.5.3.2 USB Customized Descriptors

There are two parameters in USB descriptors that customers can define after the chip is created: vendor ID (VID) and product ID (PID). The ROM code uses dedicated eFuses that hold VID and PID values. Other parameters can also be changed based on VID value. The ROM code has an encoded set of parameters for customers who have defined their requirements before the ROM code has been done. [Table 24-26](#) lists the parameters that depend on VID value.

Table 24-26. Customized Descriptor Parameters

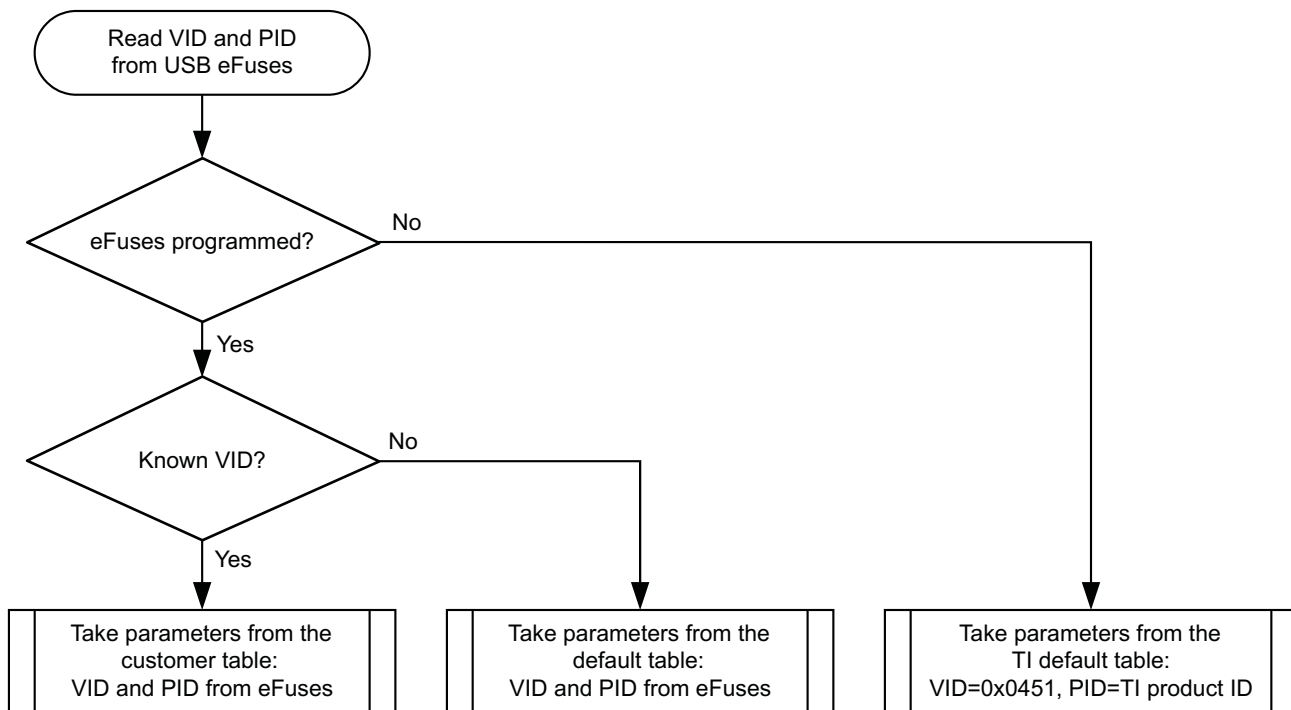

| Parameter | Size [Bytes] | Default Values | TI Default Values |
|-----------------|--------------|----------------|-------------------|
| Device ID code | 2 | 0x0000 | 0x0000 |
| Device class | 1 | 0xFF | 0xFF |
| Device subclass | 1 | 0xFF | 0xFF |
| Device protocol | 1 | 0xFF | 0xFF |

Table 24-26. Customized Descriptor Parameters (continued)

| Parameter | Size [Bytes] | Default Values | TI Default Values |
|---------------|--------------|-------------------------------------|-------------------------------------|
| Manufacturer | String | N/A | TI |
| Product | String | processor or specific vendor string | processor or specific vendor string |
| Serial number | String | N/A | N/A |

Figure 24-12 describes an additional customer parameter selection method. It is based on the VID burned in the USB eFuses.

Figure 24-12. Customer USB Descriptor Selection

init-011

24.4.5.3.3 USB Driver Functionality

- Transactions supported
The following transactions are supported:
 - Control transactions: Used for standard device requests
 - Bulk transactions: Used for data transfer in the image downloading stage. The ASIC ID is sent on the Bulk IN endpoint and the image is transferred over the Bulk OUT endpoint from the host.
 The processor's USB device first attaches to the host as an FS device. In the reset mechanism, the USB core requests HS operation. If the HS negotiation in the reset phase is successful, further transactions are at HS; otherwise, they are at FS. After reset, the USB driver checks for the speed of the device, whether it is FS or HS. Depending on the speed configured by the host, the standard USB device requests are responded to with the corresponding descriptors.
- Standard device request restrictions

Because the USB driver is used only by the ROM code for peripheral booting, some standard device requests are not supported by the driver. Table 24-27 lists the standard device requests supported by the driver.

Table 24-27. Standard Device Requests Supported

| Request | Description | Support |
|-------------------|--|---|
| CLEAR_FEATURE | Sets/clears a specific feature | Supported only for ENDPOINT_HALT feature |
| GET_CONFIGURATION | Returns the current device configuration value | Yes |
| GET_DESCRIPTOR | Returns the specified descriptor | Yes |
| GET_INTERFACE | Returns the selected alternate setting for the specified interface | Yes |
| GET_STATUS | Returns the status for the specified recipient | Yes |
| SET_ADDRESS | Sets the device address | Yes |
| SET_CONFIGURATION | Sets the device configuration | Yes |
| SET_DESCRIPTOR | Updates existing descriptors or adds new descriptors | No. Runtime updating of descriptors is not supported. |
| SET_FEATURE | Sets or enables a specific feature | Supported only for ENDPOINT_HALT feature |
| SET_INTERFACE | Selects an alternate setting in an interface | No. Runtime setting of alternate features is not supported. |
| SYNCH_FRAME | Sets and reports an endpoint synchronization frame | No, because isochronous transfers are not used |

24.4.5.4 EMAC

The ROM code supports boot over the network. The image obtained over the network is first shadowed into SRAM and then it is executed. The following requirements are to be met for using Ethernet boot.

- The EMAC is configured for full duplex, 100MBPS mode.
- Once the switch has been configured, the ROM code broadcasts the ASIC ID on the LAN using a UDP datagram.
- The ASIC ID packet is sent only once. The server then responds with hex value 0xF003 0002 (Boot Message). The server then sends the size of the boot image.
- The server then sends the boot image binary.
- The MAC address is obtained from below control module registers:
 - Ethernet MAC Address (LSB-24bits) --> 0x4800 2380 (Refer to system control module for more details.)
 - Ethernet MAC Address (MSB-24bits) --> 0x4800 2384 (Refer to system control module for more details.)
- The download address & max size of images used for EMAC boot are exactly the same as USB/UART boot.

24.4.5.4.1 Boot Host Servers

Host servers have two schemes that send the boot image over the LAN in response to broadcasted boot announce frame (which has ASIC ID).

- Dumb Server Response
- Smart Server Response

Dumb servers do not wait for ASIC ID to be received. Instead, dumb servers have a list of EMAC addresses that they use to transmit the boot message, image size, and the image packets. The dumb server sends the image binary packets continuously to every EMAC address.

Figure 24-13. Dumb Servers Boot Response

init-012

Smart servers can be present in each subnet or LAN, to respond to a boot announce frame which consists ASIC ID. As a back up, they can also use a statically configured list of EMAC addresses.

Once the smart boot server receives a boot announce frame, it starts transmitting the boot message, image size, and the image binary in subsequent packets to the MAC address that was sent in the boot announce frame. Each time the device receives a packet, it will send the sequence number of the successfully received packet to the smart boot server as acknowledgement.

When the boot server receives the ACK packet from the device, it will send the next packet. This sequence continues until the entire image is transmitted.

Table 24-28. Boot Announce Frame

| Field | Value |
|---------------------------------|-------------------------------|
| Destination MAC address | FF:FF:FF:FF:FF:FF |
| Source MAC address | From e-fuse |
| Protocol | IP (0x0800) |
| Header length and version | IPV4 |
| Type of service | 0 |
| Total length of data and header | Calculated and stored |
| Identification | 0x1 (unused) |
| Fragment offset field and flag | 0 |
| Time to live | 0xFF (max) |
| Protocol | UDP (17) |
| Checksum | Calculated and stored |
| Source IP address | 0:0:0:0 |
| Destination IP address | 255.255.255.255 |
| UDP source port | 55556 |
| UDP destination port | 55555 |
| Length of UDP header and data | Calculated and stored |
| Checksum | 0 (Not used) |
| Start of Data marker | Always 0xFF |
| Sequence number (8bit) | Incrementing, starting from 0 |
| Data – ASIC ID | |

24.4.5.4.2 EMAC Boot UseCase

If the device needs to boot a 768 byte image, the boot server will split the image into three 256 byte packages and continue looping while the packages are being transmitted. The boot server will keep increasing the sequence number in each package. In addition to the three 256 byte packets, the boot server will also send one packet with the boot message and one packet with the image size.

The messages will be sent in the following sequence:

1. On Power ON Reset the device transmits the Boot Announce frame with ASIC ID.
2. The boot server receives the boot announce frame, gets the MAC address of the device, and transmits the boot message to the device with the sequence number in the frame set to 0.
3. The boot server then transmits the size of the image binary to the device with the sequence number in

Table 24-29. Frame transmitted by the Boot Server

| Field | Value |
|---------------------------------|---|
| Destination MAC address | From the boot announce frame source MAC address |
| Source MAC address | Boot server's MAC address |
| Protocol | IP (0x0800) |
| Header length and version | IPV4 |
| Type of service | 0 |
| Total length of data and header | Calculated and stored |
| Identification | 0x1 (unused) |
| Fragment offset field and flag | 0 |
| Time to live | 0xFF (max) |
| Protocol | UDP (17) |
| Checksum | Calculated and stored |
| Source IP address | Boot server's IP address |
| Destination IP address | 255.255.255.255 |
| UDP source port | 55556 |
| UDP destination port | 55555 |
| Length of UDP header and data | Calculated and stored |
| Checksum | 0 (Not used) |
| Start of Data marker | Always 0xFF |
| Sequence number (8bit) | Incrementing, starting from 0 |
| Data ⁽¹⁾ | |

(1)

- (a) When the sequence number is 0, Data is the BOOT MESSAGE that ROM code frame work expects.
- (b) When the sequence number is 1, Data is the size of the image binary.
- (c) When the sequence number is greater than or equal to 2, Data is the image binary, split into 256byte chunks.

Table 24-30. ACK frame sent by the Device to the Boot Server

| Field | Value |
|---------------------------------|---|
| Destination MAC address | From the boot announce frame source MAC address |
| Source MAC address | From E-Fuse |
| Protocol | IP (0x0800) |
| Header length and version | IPV4 |
| Type of service | 0 |
| Total length of data and header | Calculated and stored |
| Identification | 0x1 (unused) |
| Fragment offset field and flag | 0 |
| Time to live | 0xFF (max) |
| Protocol | UDP (17) |
| Checksum | Calculated and stored |
| Source IP address | 0.0.0.0 |
| Destination IP address | From the boot server frame source ip address |
| UDP source port | 55556 |
| UDP destination port | 55555 |
| Length of UDP header and data | Calculated and stored |
| Checksum | 0 (Not used) |
| Start of Data marker | Always 0xFF |
| Sequence number (8bit) | From the last boot server frame |
| Pad – 24 bytes | To make the Ethernet packet greater than 64 bytes |

24.4.6 Fast External Booting

24.4.6.1 Overview

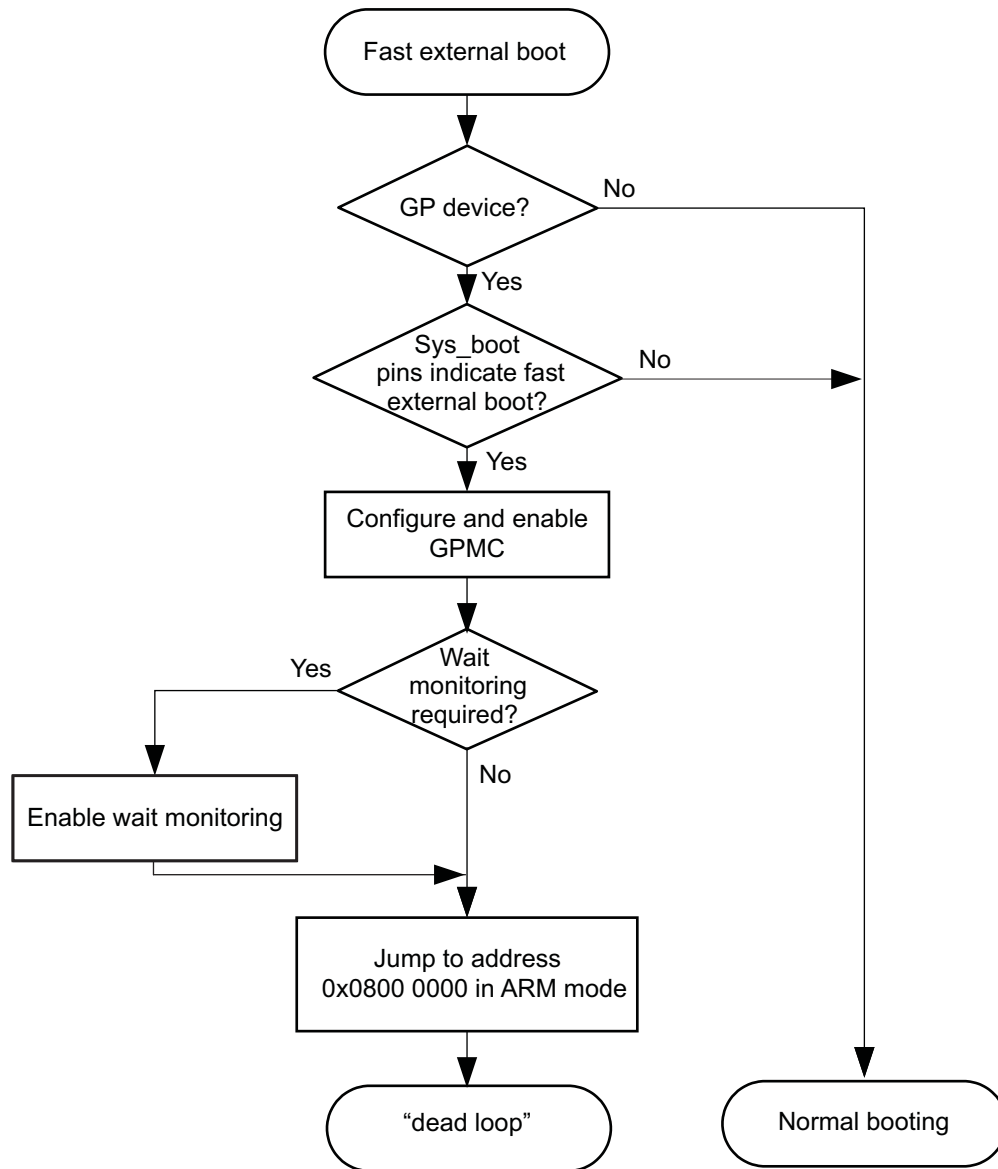

The fast external boot is a special memory booting mode. It is a blind jump to a code in an external XIP device connected to CS0. Fast external booting lets customers create their own booting code.

The jump is performed with minimum on-chip ROM code execution.

24.4.6.2 External Booting

Figure 24-15 shows the fast external boot procedure. The code is at the beginning of the public part and is written in assembly. The code does not use any RAM.

Figure 24-15. Fast External Boot

init-013

24.4.7 Memory Booting

24.4.7.1 Overview

The memory booting process takes care of starting an external code in memory type devices. These devices are called permanent booting devices because the processor always uses them for booting. The supported permanent booting devices are:

- NOR all devices up to 1G bit (128M bytes)
- NAND devices from 64M bits
- OneNAND devices from 512M bits
- SD/MMC flash cards with active primary partition of type FAT12/16/32
- DiskOnChip™ H3 devices
- SPI EEPROM

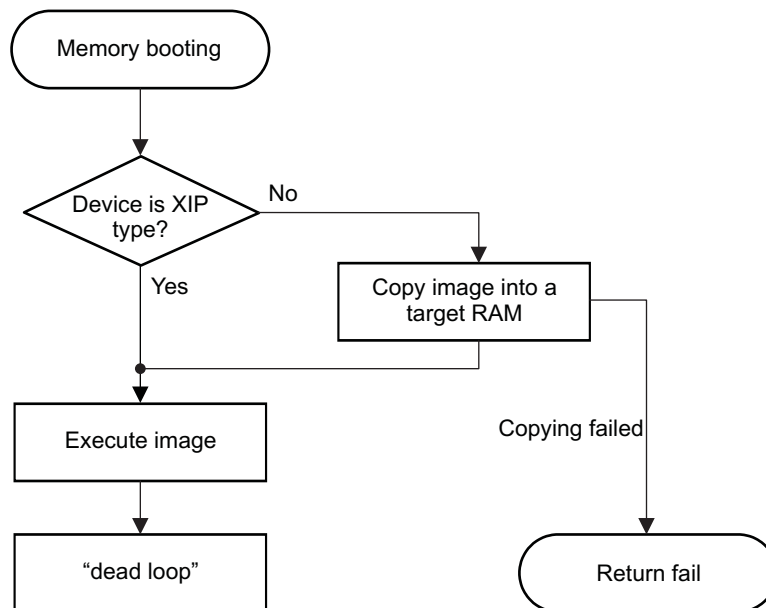

There are two main groups of permanent booting devices distinguished by code shadowing. Code shadowing means copying a code from a nondirectly addressable device (non-XIP) into RAM, where the code can be executed. Directly addressable devices are called eXecute-in-place (XIP) devices.

The memory booting flowchart shown in [Figure 24-16](#) is an overview of common procedure for all types of devices. The first step is to shadow the image, if the device is not XIP. The last step is image authentication and execution.

Unsuccessful authentication or return from image results in dead loop.

If shadowing fails, memory booting returns to the main booting procedure, which selects the next device for booting.

Figure 24-16. Memory Booting

init-014

24.4.7.2 Non-XIP Memory

[Figure 24-17](#) details the procedure used when memory booting runs with non-XIP devices. The grayed procedures are specific to each device. NAND and OneNAND devices use up to four copies of the image in the first four physical blocks. Therefore, the ROM code searches for the image in the first four physical blocks of these devices. Other devices use only one copy of the image and the block loop runs only once.

Figure 24-17. Detailed Memory Booting for Non-XIP Devices

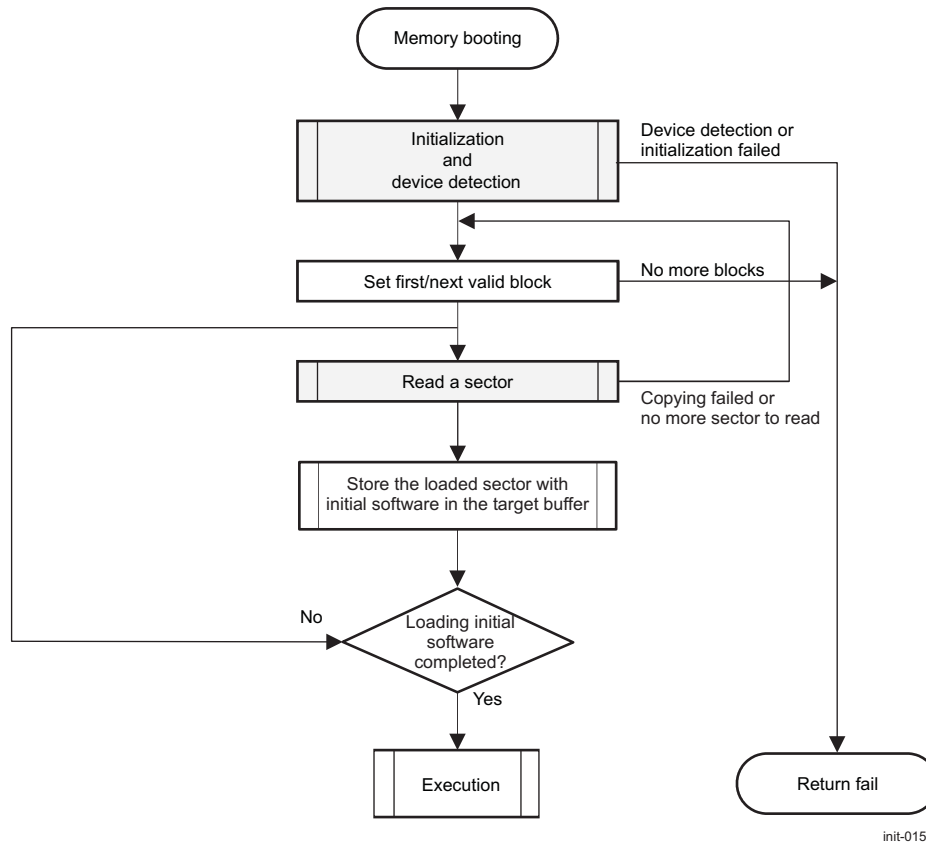

Table 24-31 summarizes numbers of blocks and sectors which are searched during the memory booting from devices requiring image shadowing. NANDs and OneNAND are organized with blocks, which are erasable units. DOC memory has only one block reserved for booting purposes, which overlaps the XIP part. MMC/SD card booting consists of reading a file. Since there is only one file read, it can be considered as one block trial.

Table 24-31. Blocks and Sectors Searched on Non-XIP Memories

| Memory | Maximum Number of Checked Blocks | Number of Sectors Searched |
|--------------------|----------------------------------|---|
| NAND | First 4 | Number of sectors in a block ⁽¹⁾ |
| OneNAND | First 4 | 8 |
| DOC ⁽²⁾ | 1 | 4 |
| MMC/SD | One file | 1 |

⁽¹⁾ Depends on NAND type.

⁽²⁾ DOC memory image must contain first sector filled with 0xFF or 0x00 because XIP booting always precedes DOC booting and the same data is used for XIP area. Therefore, a void sector at the beginning makes XIP booting failed and moves to DOC booting.

The following sections detail each supported device type.

For more details about the GPMC module, see the *Memory Subsystem* chapter.

24.4.7.3 XIP Memory

The ROM code can boot directly from XIP devices. Typical XIP devices are NOR flash memories. Supported XIP devices have the following characteristics:

- The GPMC is used as the communication interface.
- Memories up to 1G bit (128M bytes) can be connected.
- x16 data bus width only

- Asynchronous protocol and address/data multiplexed mode
- The GPMC clock is 48 MHz.
- The device is connected to cs0 mapped to address 0x0800 0000.
- The wait pin signal gpmc_wait0 is monitored according to the sys_boot configuration pins.

Depending on the sys_boot option, the GPMC can be configured to use the wait signal connected or not to the gpmc_wait0 pin. Wait pin polarity is set to stall accessing memory when gpmc_wait0 is low. Wait monitoring is to be used with memories that require a long time for initialization after reset, or that must pause while reading data. An example of such memory is DiskOnChip™.

For an XIP memory booting, no user intervention is needed; the following steps are described for debugging.

The booting from an XIP device can be described in the following points:

1. Configure the GPMC for XIP device access.
2. Set the image location to 0x0800 0000.
3. Verify that a bootable image is present at the image location.
4. Execute the image if it is found.
5. If the image is not found, return from XIP booting to the main booting loop.

24.4.7.3.1 GPMC Initialization

[Table 24-32](#) describes the timing settings of GPMC set for XIP and other address-data accessible devices, like DiskOnChip or OneNAND. [Table 24-32](#) is included for debug information.

Table 24-32. XIP Timing Parameters

| Parameter | Value [Clock Cycles] | Register Initialization (i = 0–7) | Reset Value |
|------------------|----------------------|---|-------------|
| Write cycle time | 17 | The GPMC_CONFIG5_i[12:8] WRCYCLETIME bit field is set to 0x11. | 0x11 |
| Read cycle time | 17 | The GPMC_CONFIG5_i[4:0] RDCYCLETIME bit field is set to 0x11. | 0x11 |
| CS low time | 1 | The GPMC_CONFIG2_i[3:0] CSONTIME bit field is set to 0x1. | 0x1 |
| CS high time | 16 | The GPMC_CONFIG2_i[12:8] CSRDOFFTIME bit field is set to 0x10. | 0x10 |
| ADV low time | 1 | The GPMC_CONFIG3_i[3:0] ADVONTIME bit field is set to 0x1. | 0x1 |
| ADV high time | 2 | The GPMC_CONFIG3_i[12:8] ADVRDOFFTIME bit field is set to 0x2. | 0x2 |
| OE low time | 3 | The GPMC_CONFIG4_i[3:0] OEONTIME bit field is set to 0x3. | 0x3 |
| OE high time | 16 | The GPMC_CONFIG4_i[12:8] OEOFFTIME bit field is set to 0x10. | 0x10 |
| WE low time | 3 | The GPMC_CONFIG4_i[19:16] WEONTIME bit field is set to 0x3. | 0x03 |
| WE high time | 15 | The GPMC_CONFIG4_i[28:24] WEOFFTIME bit field is set to 0xF. | 0x10 |
| Data latch time | 15 | The GPMC_CONFIG5_i[20:16] RDACCESSTIME bit field is set to 0xF. | 0x0F |

24.4.7.4 NAND

NAND flash memory is not an XIP device; it requires shadowing before the code can be executed. ROM code support for the NAND flash devices has the following characteristics:

- The GPMC is the communication interface.
- Device from 64 Mb (8MB)
- x8 and x16 bus width

- Small page size (512 bytes + 16 bytes) and large page size (2048 bytes + 64 bytes)
- Chip enable (CE) don't care devices only
- Single level cell (SLC)
- Device identification is based on standard identification data or ID2 protocol.
- One-bit error checking and correction (ECC) is used to protect a 512-byte sector.
- GPMC timings are adjusted for NAND access.
- The GPMC clock is 48 MHz.
- The device is connected to CS0.
- The wait pin signal gpmc_wait0 is connected to the NAND BUSY output.
- Four physical blocks are searched for image. Block size depends on the device.

For NAND memory booting, no user intervention is needed; the information in the following subsections is included for debugging.

24.4.7.4.1 Initialization and NAND Detection

The initialization routine for NAND consists of three parts: GPMC initialization, device detection with parameter determination, and bad block detection/verification.

- GPMC initialization

The GPMC interface is configured so that it can access NANDs. Because NANDs do not need the address bus, it is released. The data bus width is initially set to 8 bits. If necessary, it is changed to 16 bits after the device parameters are determined. [Table 24-33](#) shows the GPMC configuration used during NAND boot. [Table 24-33](#) is included for debug information.

Table 24-33. NAND Timing Parameters

| Parameter | Value [Clock Cycles] | Register Initialization (i = 0–7) | Reset Value |
|------------------|----------------------|---|-------------|
| Write cycle time | 20 | The GPMC_CONFIG5_i[12:8] WRCYCLETIME bit field is set to 0x14. | 0x11 |
| Read cycle time | 20 | The GPMC_CONFIG5_i[4:0] RDCYCLETIME bit field is set to 0x14. | 0x11 |
| CS low time | 0 | The GPMC_CONFIG2_i[3:0] CSONTIME bit field is set to 0x0. | 0x1 |
| OE low time | 5 | The GPMC_CONFIG4_i[3:0] OEONTIME bit field is set to 0x5. | 0x3 |
| OE high time | 16 | The GPMC_CONFIG4_i[12:8] OEOFFTIME bit field is set to 0x10. | 0x10 |
| WE low time | 3 | The GPMC_CONFIG4_i[19:16] WEONTIME bit field is set to 0x3. | 0x3 |
| WE high time | 15 | The GPMC_CONFIG4_i[28:24] WEOFFTIME bit field is set to 0xF. | 0x10 |
| Data latch time | 14 | The GPMC_CONFIG5_i[20:16] RDACCESSTIME bit field is set to 0xE. | 0xF |

- Device detection and parameters

The ROM code must first identify the NAND type connected on the GPMC interface. The GPMC is initialized using 8 bits, asynchronous mode. The NAND device is reset and its status is polled until it is ready for operation, then the Read ID command is issued. If the Read Device ID is recognized as a supported device, the device parameters are extracted from an internal ROM code table. [Table 24-34](#) lists the supported devices.

Table 24-34. Supported NAND Devices

| Capacity | Device ID | Bus Width | Page Size in KB |
|----------|-----------|-----------|-----------------|
| 64Mb | E6h | 8 | 512 |
| 128Mb | 33h | 8 | 512 |
| 128Mb | 73h | 8 | 512 |

Table 24-34. Supported NAND Devices (continued)

| Capacity | Device ID | Bus Width | Page Size in KB |
|----------|-----------|-----------|-----------------|
| 128Mb | 43h | 16 | 512 |
| 128Mb | 53h | 16 | 512 |
| 256Mb | 35h | 8 | 512 |
| 256Mb | 75h | 8 | 512 |
| 256Mb | 45h | 16 | 512 |
| 256Mb | 55h | 16 | 512 |

Table 24-34. Supported NAND Devices (continued)

| Capacity | Device ID | Bus Width | Page Size in KB |
|----------|-----------|-----------|-----------------|
| 64Gb | A Eh | 8 | 2048 |
| 64Gb | B Eh | 16 | 2048 |

After retrieving parameters from the table, page size and block size are updated based on the fourth byte of the NAND ID data. Because of inconsistency among manufacturers, only devices recognized to be at least 2Gb have these parameters updated. Therefore, the ROM code supports 4-KB page devices, but only if their size, according to the table, is at least 2Gb. Devices smaller than 2Gb have the block size parameter set to 32KB when the page size is 512KB and to 128KB when the page size is 2048KB.

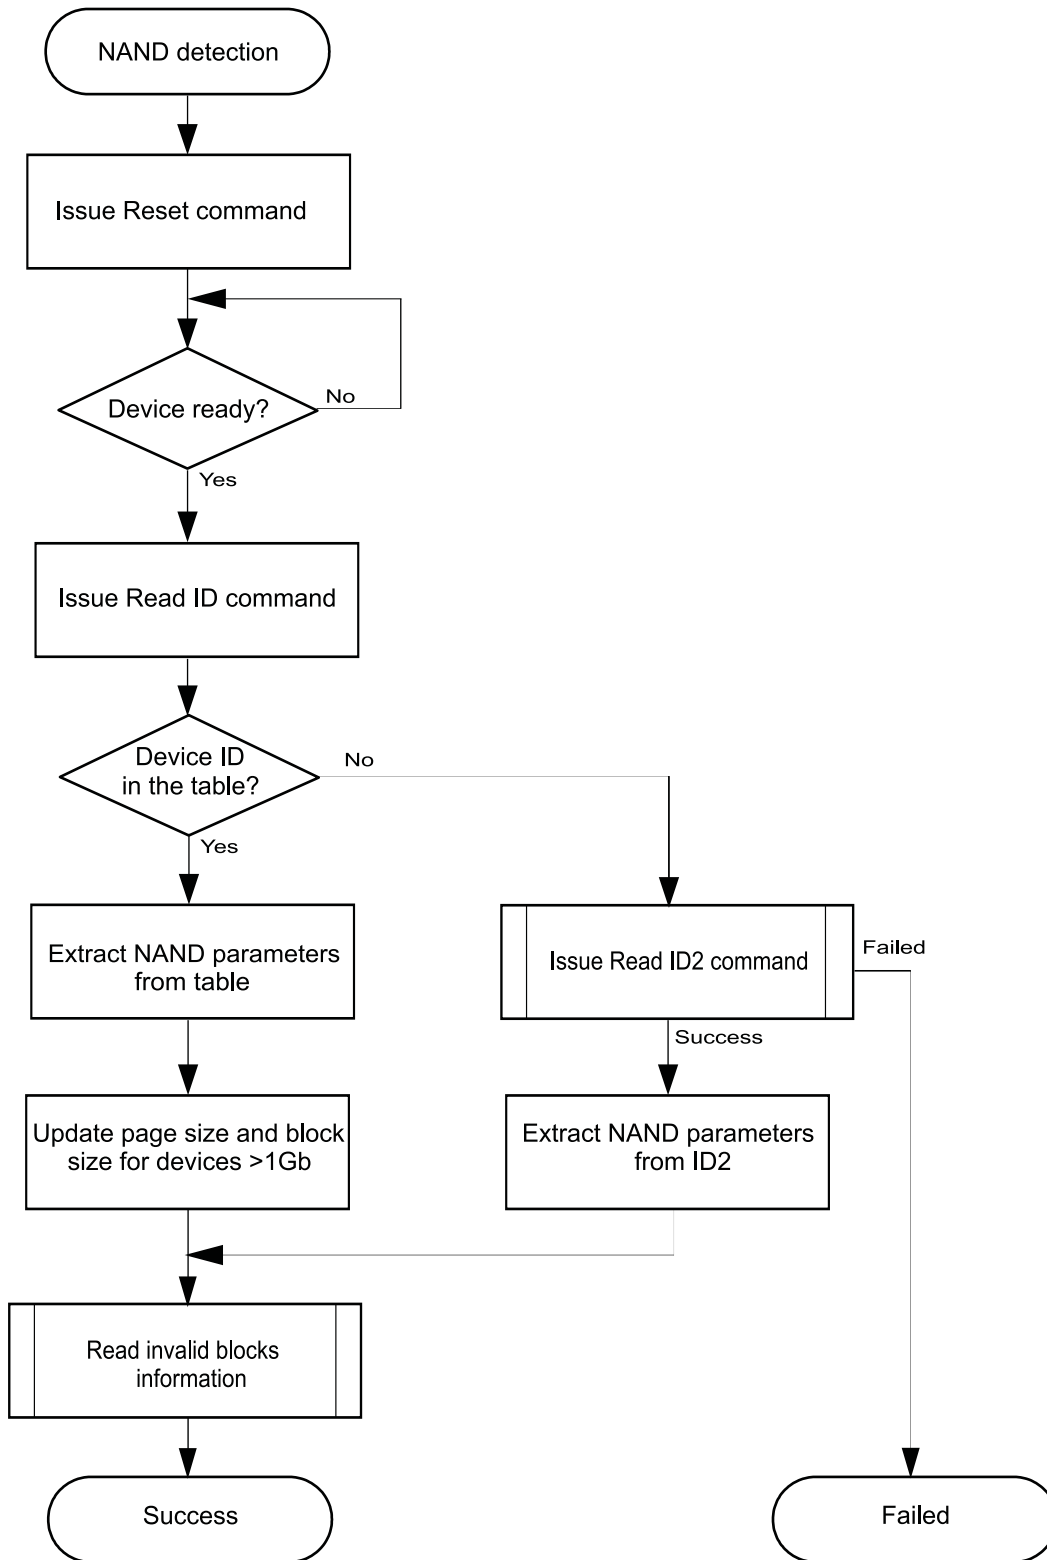

[Table 24-35](#) shows the fourth ID data byte encoding used in the ROM code.

Table 24-35. Fourth NAND ID Data Byte

| Item | Description | I/O Number | | | | | | | |
|-------------------|-------------|------------|---|---|---|---|---|---|---|
| | | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Page Size | 1KB | | | | | | | 0 | 0 |
| | 2KB | | | | | | | 0 | 1 |
| | 4KB | | | | | | | 1 | 0 |
| | 8KB | | | | | | | 1 | 1 |
| Block Size | 64KB | | | 0 | 0 | | | | |
| | 128KB | | | 0 | 1 | | | | |
| | 256KB | | | 1 | 0 | | | | |
| | 512KB | | | 1 | 1 | | | | |

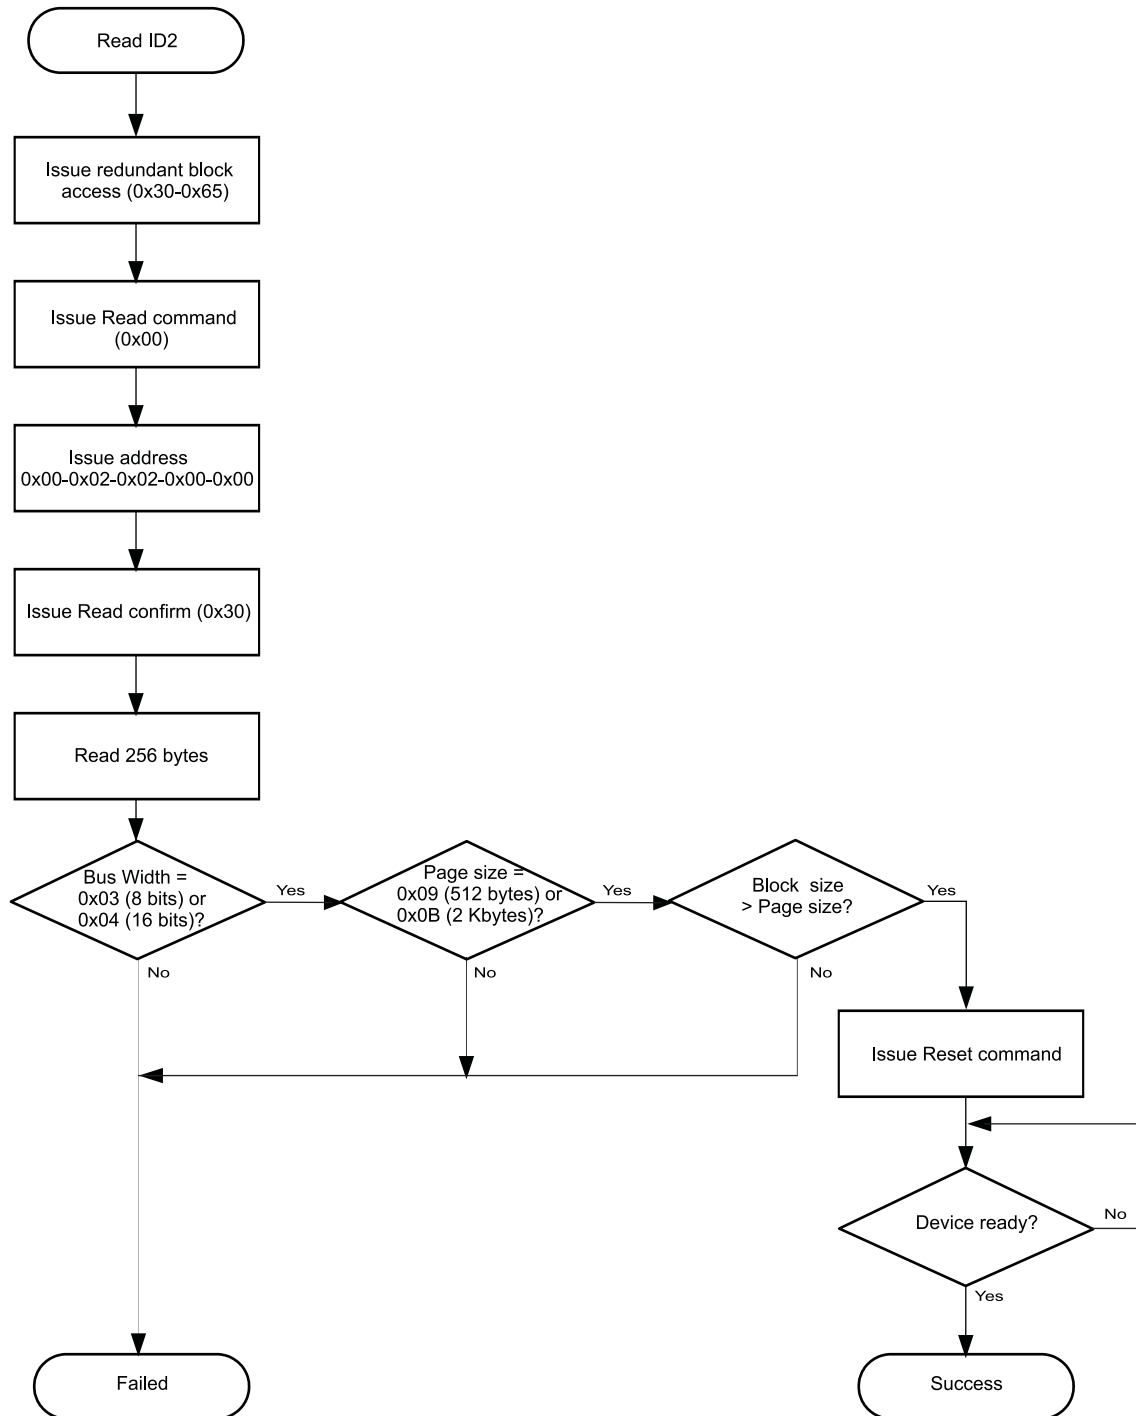

The detection procedure is described in [Figure 24-18](#). If the device ID is not recognized, the ROM code tries to read ID2 from the device; the sequence is described in [Figure 24-19](#). The description of the ID2 data content is summarized in [Table 24-36](#). If the ROM code fails to identify device ID or ID2, it returns with FAIL. When the device is successfully detected, the ROM code changes the GPMC to 16-bit bus width if necessary.

- **Bad block detection/verification**

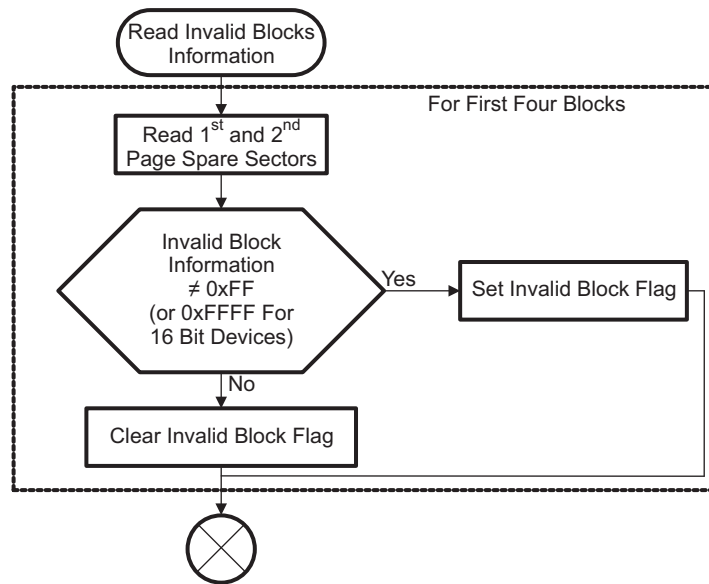

Invalid blocks contain invalid bits whose reliability cannot be ensured by the manufacturer. These bits are identified in the factory or during the programming and reported in the initial invalid block information in the spare area on the first and second page of each block. Because the ROM code looks for an image in the first four blocks, it detects the validity status of these blocks. Blocks detected as invalid are not accessed later. Blocks validity status is coded in the spare areas of the first two pages of a block. [Table 24-37](#) describes validity status coding for all four NAND families.

Table 24-37. Bad Block Marks Locations in NAND Spare Areas

| | Small Page NAND | Large Page NAND |
|---|--|--|
| 8 bit Device | | |
| Block invalid when any byte not equal FFh | 6th byte in 1st page 6th byte in 2nd page | 1st byte in 1st page 1st byte in 2nd page |
| 16 bit Device | | |
| Block invalid when any work not equal FFFFh | 1st word in 1st page 6th work in 1st page 1st word in 2nd page 6th word in 2nd page | 1st word in 1st page 1st work in 2nd page |

Figure 24-20 depicts the invalid block detection routine. The routine consist in reading spare areas and checking data according to the conditions. The flags are used internally to convey information about each block validity.

Figure 24-20. NAND Invalid Block Detection

24.4.7.4.2 Read Sector Procedure

During the booting procedure, the ROM code reads 512-byte sectors from the NAND device. The reading fails in two cases:

- The accessed sector is in a block marked as invalid.
- The accessed sector contains an error that cannot be corrected with ECC.

Pages can contain errors caused by memory alteration. To correct these errors, the ROM code uses ECC, based on Hamming codes for SLC NAND. The computed ECC is compared to ECC stored in the spare area of the corresponding page. If there are uncorrectable errors, the ROM code returns with FAIL.

24.4.7.5 OneNAND

ROM code support for OneNAND devices has the following characteristics:

- Devices from 512Mb
- The GPMC is the communication interface.
- x16 data bus width only
- Asynchronous protocol and address/data multiplexed mode
- GPMC reset default timings are used.

- The GPMC clock is 48 MHz.
- The device is connected to CS0 mapped to address 0x0800 0000.
- The wait pin signal gpmc_wait0 is not monitored.
- Four physical blocks are searched for image. The block size is 128KB.

The OneNAND device is a NAND matrix coupled with RAM buffers and a NOR-type interface. ECC correction handling is done automatically by the internal state-machine. The page to be accessed is first loaded in the RAM buffer using memory-mapped registers. Then, the page is read directly from the buffer using a NOR-type interface.

For OneNAND memory booting, no user intervention is needed. The information in the following subsections is included for debugging.

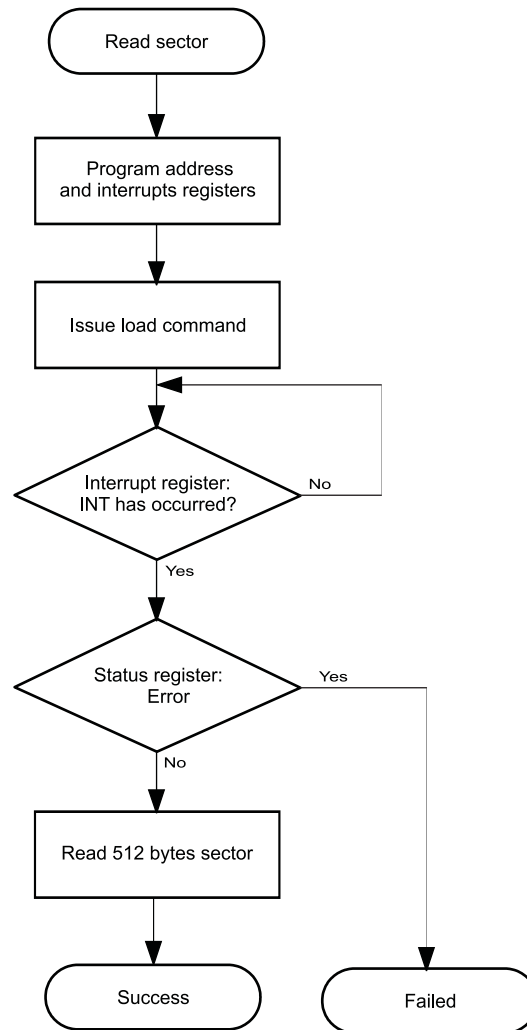

24.4.7.5.1 Initialization and OneNAND Detection

The initialization routine for OneNAND consists of two parts: GPMC initialization and device detection with parameter determination:

- GPMC initialization
The ROM code first initializes the GPMC interface the same way as for an XIP memory (that is, asynchronous 16-bit multiplexed mode). Wait signal monitoring is disabled. See [Table 24-32](#).
- Device detection and parameters
The ROM code identifies a OneNAND device by reading the device identification data. There are two ways to read identification data: using serial commands and reading from fixed memory mapped registers. The ROM code reads identification data using both methods and compares the result. When the comparison passes, the ROM code assumes that the OneNAND device is connected. If the device is successfully recognized, the ROM code reads the device configuration (amount and size of data buffers) and configures it for asynchronous mode (default).

24.4.7.5.2 OneNAND Read Sector Procedure

When booting requests a sector from the OneNAND device, the ROM code issues the load operation, which transfers the content of the requested sector to the data buffer RAM. The ROM code waits until the operation completes, polling the OneNAND interrupt register. The status register is then checked and the ROM code returns FAIL if the operation completes with an error. Otherwise, the data buffer RAM is copied to the destination buffer. [Figure 24-21](#) shows this procedure.

Figure 24-21. OneNAND Read Sector

init-025

24.4.7.6 MMC/SD Cards

The ROM code supports MMC/SD cards, with some limitations:

- Supports MMC/SD cards compliant with the *Multimedia Card System Specification v4.2* from the MMCA Technical Committee and the *SD I/O Card Specification v 2 .0* from the SD Association. Includes high-capacity (size >2GB) cards: HC-SD and HC MMC
- 1.8V or 3.3V I/O voltage on PORT 1
- 1.8V or 3.3V I/O voltage on PORT 2. External transceiver mode on PORT 2 is not supported.
- Initial 1-bit MMC mode, 4-bit SD mode
- Clock frequency:
 - Identification mode: 400 kHz
 - Data transfer mode: 20 MHz
- Only one card connected to the bus
- Raw mode, image data read directly from card sectors
- FAT12/16/32 support, with or without a master boot record (MBR).
- In case of a FAT (12/16/32) formatted memory card, the booting file must not exceed 128 KB.
- In case of a raw mode memory card, the booting image must not exceed 128 KB.

For MMC memory booting, no user intervention is needed. The information in the following subsections is included for debugging. Failure in MMC/SD card detection causes a return to the main booting procedure, which selects the next device for booting.

The HS MMC/SD/SDIO host controllers (MMCHS) handle the physical layer, while the ROM code handles the simplified logical protocol layer (read-only protocol). A limited range of commands is implemented in the ROM code. The MMC/SD specification defines two operating voltages for standard or HS cards. The ROM code supports only 1.8V or 3.3V MMC/SD cards, depending on VDDSHV.

The ROM code reads a booting file from the card file system and boots from it. [Figure 24-22](#) shows the complete procedure.

Figure 24-22. MMC/SD Booting

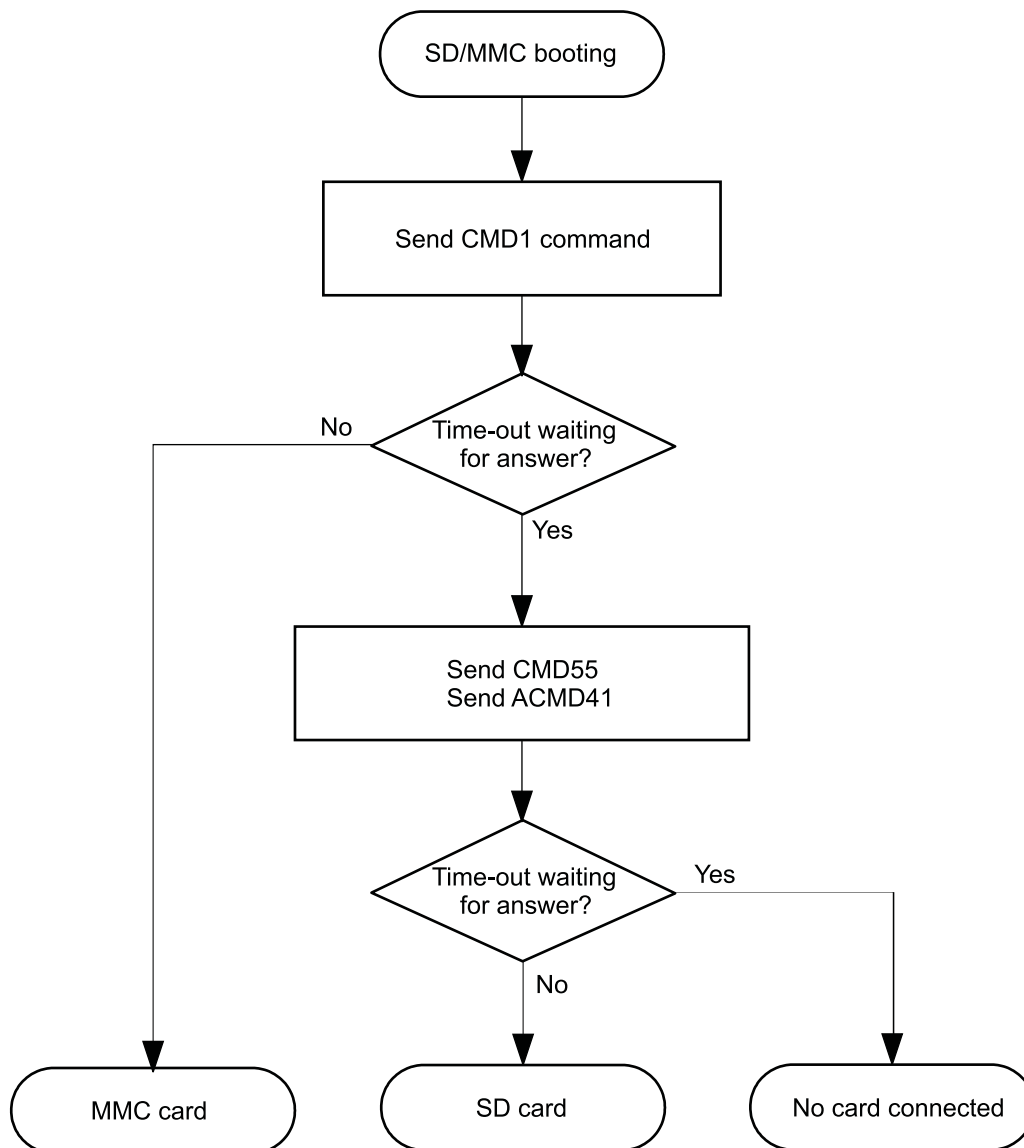

init-016

24.4.7.6.1 Initialization and MMC/SD Card Detection

The ROM code initializes the card connected on interface 1 using the voltage dictated by VDDSHV.. If no card is present, the ROM code goes to the next booting device. The standard identification process and relative card address (RCA) assignment are used. However, the ROM code searches for only one card connected on the bus. This is done using the CMD line common to the SD and MMC cards. The MMC and SD standards describe this phase as the initialization phase. They differ in the first commands, CMD1 and ACMD41. The ROM code uses this command difference to differentiate between MMC and SD cards; that is, CMD1 is supported only by MMC and ACMD41 is supported only by SD. The ROM code first sends a CMD1 to the card and gets an answer only if an MMC card is connected. If no answer is received, ACMD41 (a combination of CMD55 and ACMD41) is sent, and an answer is expected from an SD card. If no answer is received, no cards are connected and the ROM code exits MMC/SD booting with FAIL.

Figure 24-23 shows the MMC/SD detection procedure.

Figure 24-23. MMC/SD Detection Procedure

init-026

24.4.7.6.2 Read Sector Procedure

- Raw mode
In raw mode, an image can be at offset 0 or 128KB and must not be bigger than 128KB. Raw mode is detected by reading sector 0. ROM Code decides to switch into the raw mode if the first read sector contains a TOC structure with an MLO item. If raw mode is not detected, file system mode is assumed. Image data is read directly from continuous sectors of a card.
- File system handling
The sector read procedure uses the standard MMC/SD read data procedure. The sector address is generated based on the booting memory file map collected during initialization. Thus, the ROM code can address sectors freely in the booting file space.

24.4.7.6.3 File System Handling

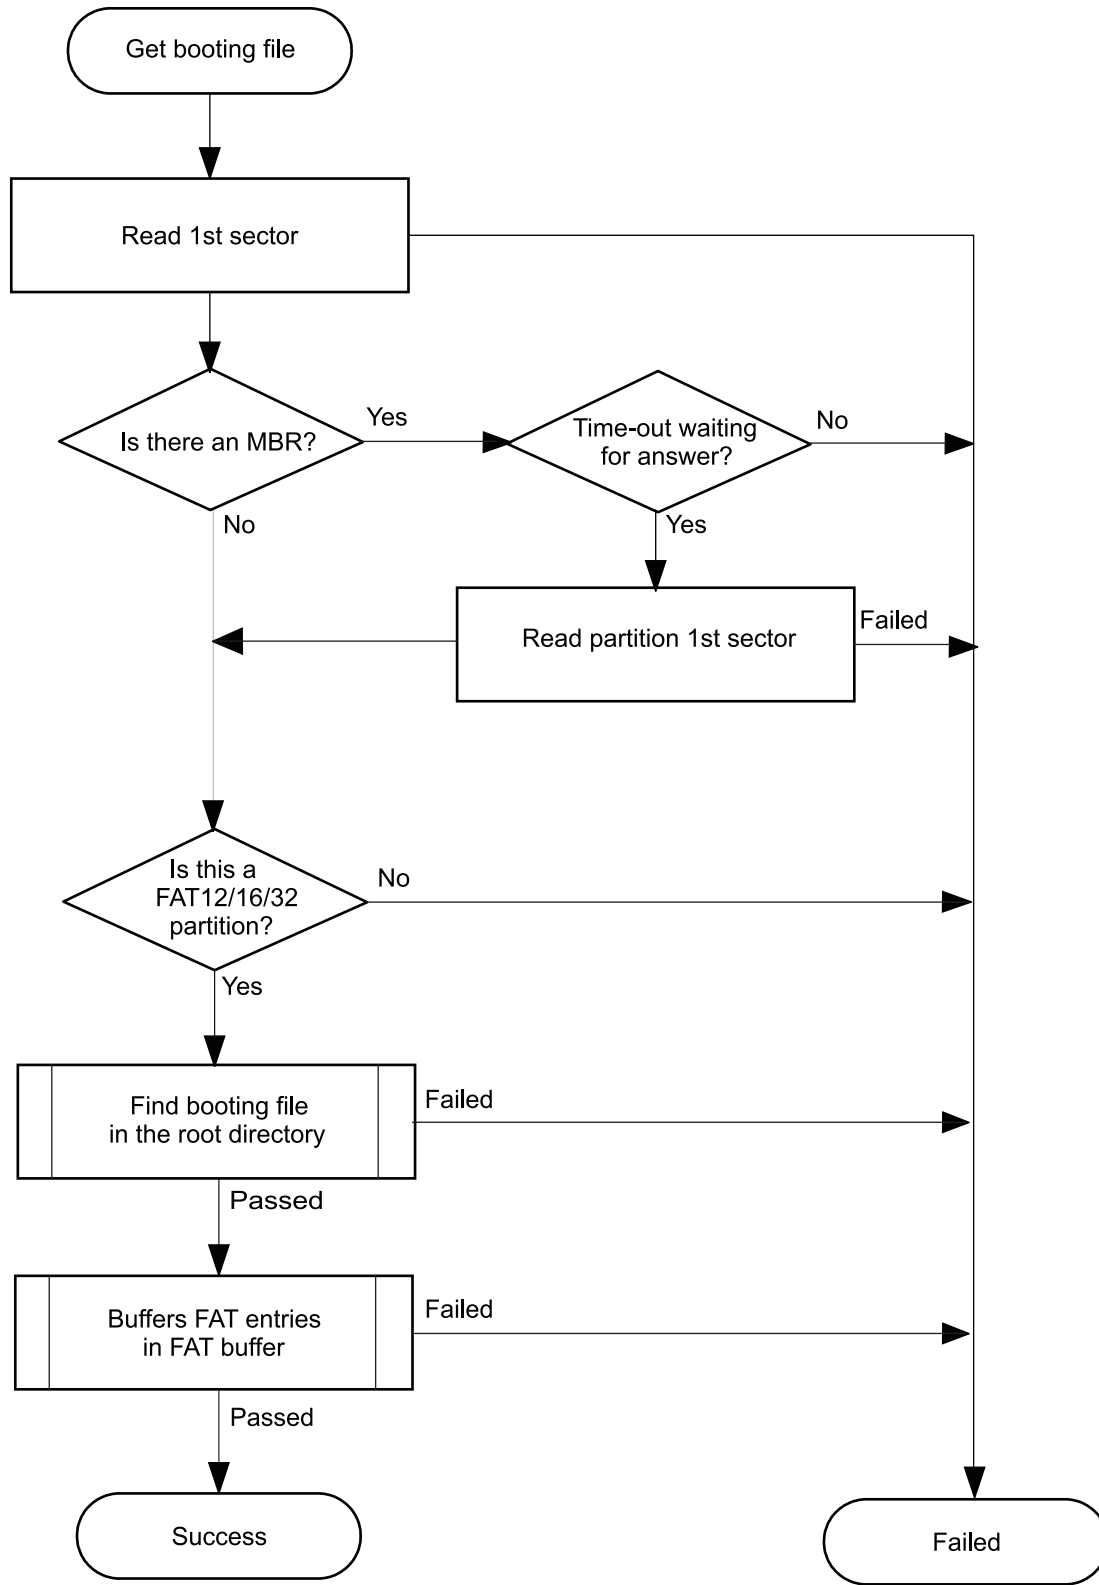

MMC/SD Cards may hold a file system which ROM Code reads. The image used by the Booting procedure is taken from a specific booting file named MLO. This file has to be located in the root directory on an active primary partition of type FAT12/16 or FAT32.

An MMC/SD card can be configured as floppy-like or hard-drive-like:

- When acting like a floppy, the content of the card is a single FAT12/16/32 file system without an MBR holding a partition table.
- When acting like a hard drive, an MBR is present in the first sector of the card. This MBR holds a table of partitions, one of which must be FAT12/16/32, primary, and active.

According to the *MultiMediaCard FAT16 File System Specification* from the MMCA Technical Committee, the card should always hold an MBR, except for MMC cards using a floppy-like file system. However, depending on the operating system used, the MMC/SD card is formatted with or without partition(s) (using an MBR). The ROM code supports both types: floppy-like or hard-drive-like. The ROM code retrieves a map of the booting file from the FAT table. The booting file map is a collection of all FAT table entries related to the booting file (a FAT entry points to a cluster holding part of the file). The booting procedure uses this map to access any 512-byte sector in the booting file without involving the ROM code FAT module. [Figure 24-24](#) shows the complete process.

Figure 24-24. SD/MMC Booting

init-027

- MBR and FAT file system

This paragraph describes functionalities used by the ROM code to recognize whether an MBR with a FAT is used. It is not intended to fully describe the MBR and the FAT file system detection and reading procedure. The ROM code can detect FAT12/16/32 allocation table types. It cannot boot on devices with NTFS or Linux FS partitions. Some memory devices that support file systems can be formatted with or without MBR; therefore, the first task of the ROM code is to detect whether the device is holding an MBR in the first sector.

The MBR is the first sector of a memory device. It consists of executable code, four partition entries, and one signature. The aim of such a structure is to divide the hard disk in partitions used primarily to boot different systems (for instance, Microsoft Windows™). This structure is described in [Table 24-38](#); partition table entry is described in [Table 24-39](#).

Table 24-38. Master Boot Record Structure

| Offset | Length [Bytes] | Entry Description |
|--------|----------------|-----------------------|
| 0000h | 446 | Optional code |
| 01BEh | 16 | Partition table entry |
| 01CEh | 16 | Partition table entry |
| 01DEh | 16 | Partition table entry |
| 01EEh | 16 | Partition table entry |
| 01FEh | 2 | Signature (= 0xAA55) |

Table 24-39. Partition Table Entry

| Offset | Length [Bytes] | Entry Description | Value |
|--------|----------------|--|--|
| 0000h | 1 | Partition state | 00h: Inactive 80h: Active |
| 0001h | 1 | Partition start head | Hs |
| 0002h | 2 | Partition start cylinder and sector | Cs[7:0]–Cs[9:8]–Ss[5:0] |
| 0004h | 1 | Partition type | 01h: FAT12 04h, 06h, 0Eh: FAT16 0Bh, 0Ch, 0Fh: FAT32 |
| 0005h | 16 | Partition end head | He |
| 0006h | 2 | Partition end cylinder and sector | Ce[7:0]–Ce[9:8]–Se[5:0] |
| 0008h | 4 | First sector position relative to the beginning of media | LBAs = Cs.H.S+ Hs.S+ Ss–1 |
| 000Ch | 4 | Number of sectors in partition | LBAe = Ce.H.S+ He.S+ Se–1 Nb s= LBAe–LBAs + 1 |

1. Find the booting file

When a partition is found, the root directory entries are searched for a specific booting file named “MLO” inside the Root Directory of the FAT12/16/32 file system. The file is not searched in any other location. For a FAT12/16 file system, the Root Directory has a fixed location which is cluster 0. For a FAT32 file system, its cluster location is given by BPB_RootClus. The formula to find the sector number (relative to device sector 0, not partition sector 0) of a cluster is given by:

$$Cluster_{sector} = BPB_HiddSec + BPB_RsvdSecCnt + BPB_NumFATs \cdot BPB_FATSz + Cluster \cdot BPB_SecPerCLus$$

init-E001

(23)

NOTE: BPB_FatSz is BPB_FatSz16 for FAT12/16 or BPB_FatSz32 for FAT32

NOTE: The BPB_HiddSec field can contain 0 even though the FAT file system is located somewhere other than on sector 0 (floppy-like). The ROM Code actually uses the partition offset taken from the MBR instead of this field which can be wrong. If no MBR was found (floppy-like) the value 0 is used.

Each entry in the Root Directory is 32 bytes long and hold information about the file, i.e. filename, date of creation, rights, cluster location etc. This is described in [Table 24-40](#).

The ROM Code checks each entry in the Root Directory until either the booting file is found or the entry is empty (first byte is 00h) or when the end of the Root Directory has been reached. Entries with ATTR_LONG_NAME attribute (LFN) and with first byte at E5h (erased file) are ignored. When found, the first cluster offset of the file is read from the DIR_FstClusHi/DIR_FstClusLo fields.

There is a slight difference between FAT12/16 and FAT32 when handling the Root Directory. On FAT12/16, this directory has a fixed location (see above) and length fixed by BPB_RootEntCnt which is the total number of 32 bytes entries. Handling this directory is therefore straight forward. On FAT32, the Root Directory is like a standard file, the File Allocation Table (FAT) has to be used in order to retrieve each sector of the Directory. The way the FAT is handled is described in the following paragraph.

Table 24-40. FAT Directory Entry

| Offset | Length [Bytes] | Name | Description |
|--------|----------------|------------------|--|
| 0000h | 11 | DIR_Name | Short name (8 + 3) |
| 000Bh | 1 | DIR_Attr | File Attributes: ATTR_READ_ONLY 01h ATTR_HIDDEN 02h ATTR_SYSTEM 04h ATTR_VOLUME_ID 08h ATTR_DIRECTORY 10h ATTR_ARCHIVE 20h ATTR_READ_ONLY I ATTR_HIDDEN I ATTR_LONG_NAME ATTR_SYSTEM I ATTR_VOLUME_ID |
| 000Ch | 1 | DIR_NTRes | Reserved, set to 00h |
| 000Dh | 1 | DIR_CrtTimeTenth | Millisecond stamp at file creation |
| 000Eh | 2 | DIR_CrtTime | Time file was created |
| 0010h | 2 | DIR_CrtDate | Date file was created |
| 0012h | 2 | DIR_LstAccDate | Last Access date |
| 0014h | 2 | DIR_FstClusHi | High word of this entry's first cluster number |
| 0016h | 2 | DIR_WrtTime | Time of last write |
| 0018h | 2 | DIR_WrtDate | Date of last write |
| 001Ah | 2 | DIR_FstClusLo | Low word of this entry's first cluster number |
| 001Ch | 4 | DIR_FileSize | File size in bytes |

2. Buffer FAT entries in the FAT buffer

When the booting file is found, the ROM code reads the FAT and buffers the singly-linked chain of clusters in a FAT buffer used by booting to access the file directly, sector by sector. For FAT12/16 and for FAT32, multiple copies of the FAT exist (ROM code supports only two copies) located after the Boot Sector:

$$FATn_{sector} = BPB_HiddSec + BPB_RsvdSecCnt + BPB_FatSz \cdot n_{init-E002}$$

(24)

The size of the FAT buffer is given by BPB_FATSz16 or BPB_FATSz32. The ROM code checks each copy of the FAT if they are identical. If the values are different, the ROM code uses the value from the last FAT copy. With the FAT32 file system, the copy system can be disabled according to a flag in BPB_ExtFlags[7]. If this flag is set, the FAT BPB_ExtFlags[3:0] bit field is used. In this case no verification is made by the ROM code with other copies of FAT.

The FAT is a simple array of values, each referring to a cluster located in the data area. One entry of the array is 12, 16, or 32 bits, depending on the file system in use. The value in an entry defines whether the cluster is being used or not, and if another cluster must be considered. This creates a singly-linked chain of clusters defining the file. The meaning of an entry is described in [Table 24-41](#).

NOTE: For compatibility, clusters 0 and 1 are not used for files and those entries must contain FF8h and FFFh (for FAT12); FFF8h and FFFFh (for FAT16); ?FFFFFF8h and ?FFFFFFFh (for FAT32).

Table 24-41. FAT Entry Description

| FAT12 | FAT16 | FAT32 | Description |
|-----------|---------------|-----------------------|--|
| 000h | 0000h | ?0000000h | Free Cluster |
| 001h | 0001h | ?0000001h | Reserved Cluster |
| 002h-FEFh | 0002h-FFEFh | 00000002h-?FFFFFFEFh | Used Cluster; value points to next cluster |
| FF0h-FF6h | FFFF0h-FFFF6h | ?FFFFFFF0h-?FFFFFFF6h | Reserved values |
| FF7h | FFFF7h | ?FFFFFFF7h | Bad Cluster |
| FF8h-FFFh | FFF8h-FFFh | ?FFFFFFFh-?FFFFFFFh | Last Cluster in File |

NOTE: FAT32 uses only bits [27:0]; the upper 4 bits are usually 0 and must be left untouched.

When accessing the root directory for FAT32, the ROM code starts from the root directory cluster entry and follows the linked chain to retrieve the clusters.

When the booting file has been found, the ROM code buffers each FAT entry corresponding to the file in a sector way. This means each cluster is translated to one or several sectors, depending on how many sectors are in a cluster (BPB_SecPerClus). This buffer is used later by the booting procedure to access the file.

24.4.7.7 DiskOnChip™

The ROM code support for DiskOnChip™ devices has the following characteristics:

- DiskOnChip™ H3
- 1.8-V power supply
- Density from 256M bits

The DiskOnChip™ contains an XIP part that can hold a boot image. In this case, the DiskOnChip™ is connected just like a regular NOR device, and uses the same procedure as for NOR described in [Section 24.4.7.3](#).

If booting determines that it must boot from DOC, the ROM code initializes the GPMC using standard asynchronous, 16-bit, multiplexed mode. The DOC device is then detected using the M-System driver. This proprietary driver handles all DiskOnChip protocols and identification. If the device cannot be identified, the ROM code returns a failed code. Otherwise, booting directly requests sectors from the M-System driver.

SD/MMC booting consists of several steps:

1. MBR detection

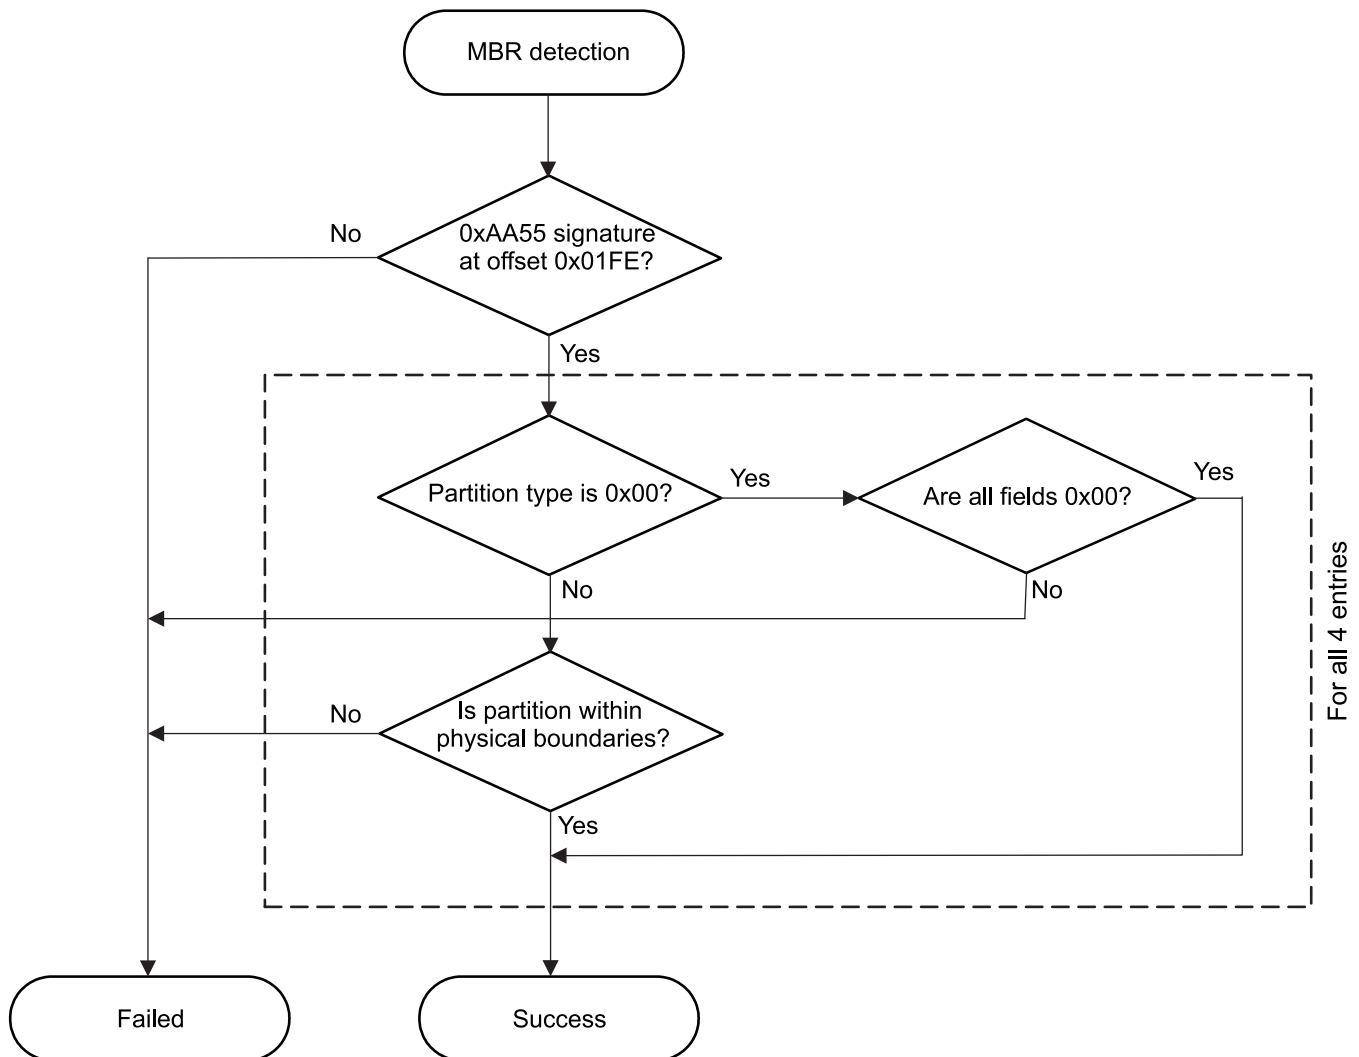

The ROM code first checks whether the MBR signature is present and then it searches an active FAT12/16/32 partition in all four MBR partition entries, based on the Type field. If the MBR entries are not valid or if no usable partition is found, the ROM code returns to the booting procedure with FAIL. The extended partitions are not checked; the booting file must reside in a primary partition. Each

partition entry is checked:

- (a) If its type is set to 00h, all fields in the entry must be 00h.
- (b) The partition is checked to be within physical boundaries (that is, the partition is inside and it fits the total physical sectors).

See [Figure 24-25](#) for more information about MBR detection.

Figure 24-25. MBR Detection Procedure

init-028

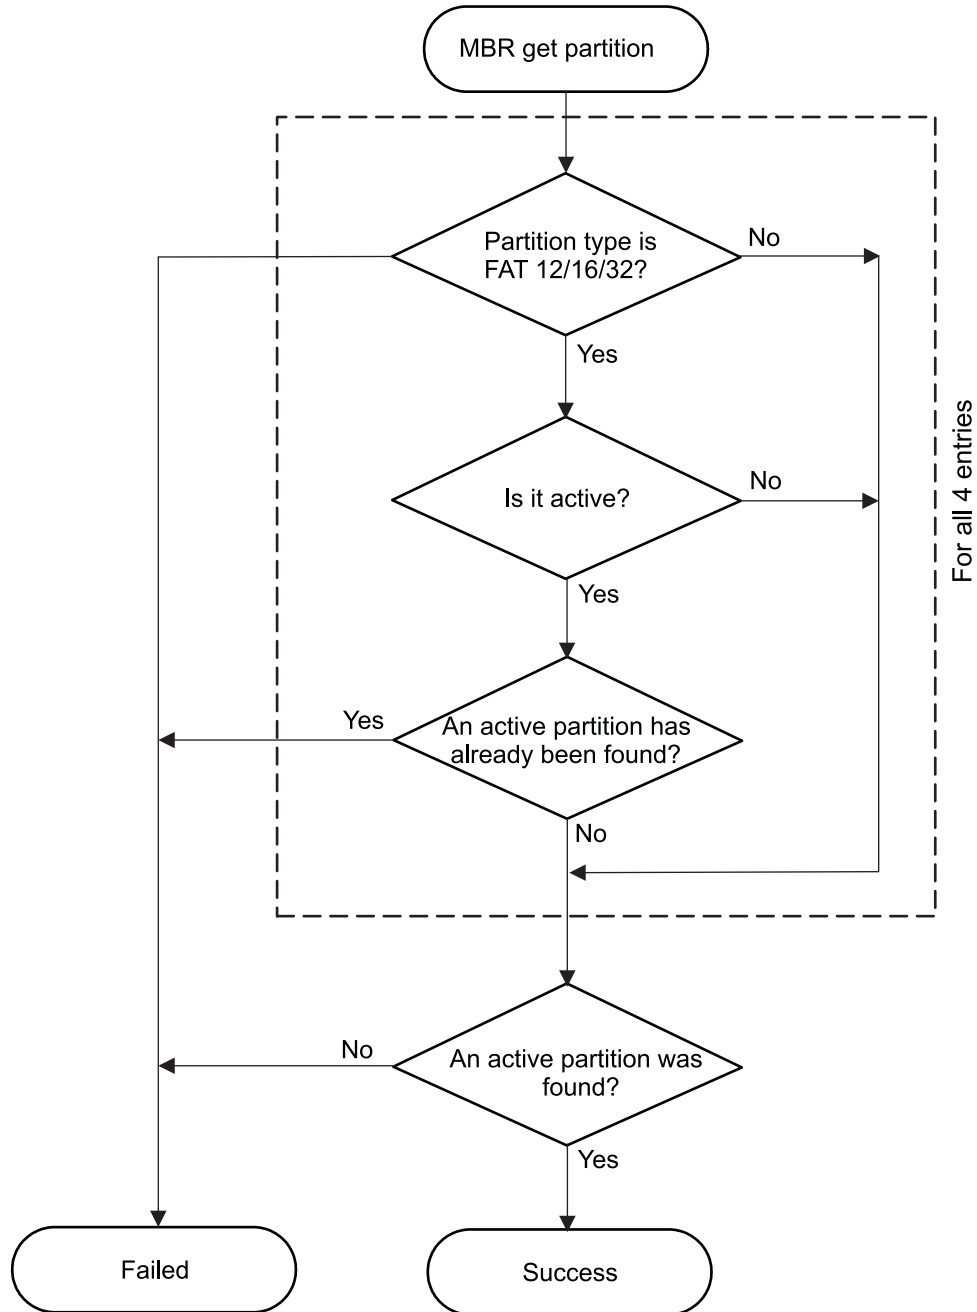

2. Get the MBR partition.

Once identified, the ROM code gets the partition using the procedure described in [Figure 24-25](#). The partition type is checked to be FAT12/16 or FAT32. Its state must be 00h (inactive) or 80h (active.) The ROM code returns with FAIL if no active primary FAT12/16/32 is found, or if there is more than one active partition, the test fails. If an active partition is found, its first sector is read and used later. If no MBR is present (in case of a floppy-like system), the first sector of the device is read and used later. The read sector is checked to be a valid FAT12/16 or FAT32 partition. If this fails, if another partition type is used (for instance, Linux® FS) or if the partition is not valid, the ROM code returns with FAIL. The FAT file system consists of several parts:

- Boot sector, which holds the BIOS parameter block (BPB). Not all are used by the ROM code.
- FAT, which describes the use of each cluster of the partition
- Data area, which holds the files, directories, and root directory (for FAT12/16, the root directory has a specific fixed location).

To check whether a sector holds a valid FAT12/16/32 partition, many fields of the boot sector (used by all FAT types) that must have specific values are checked. Figure 24-26 shows more information about getting the MBR partition.

Figure 24-26. Get MBR Partition

init-029

24.4.7.8 SPI Flash

ROM code supports SPI flashes that have the following characteristics:

- Only 24 bit addressable flashes are supported
- Only flash sizes between 128KBytes and 16 MBytes are supported
- Only Mode 3 flashes are supported (Phase = 1, Polarity = 1)
- The SPI flash must be connected to CS0

- Only 4 pin mode is supported (spi_clk, spi_cs0, spi_somi, spi_simo)
- SPI clock frequency is 12 MHz

SPI Sector Read Procedure

The ROM code searches the first four sectors of the SPI flash looking for a valid image. If the first two words of any sector is neither 0x0000 0000 or 0xFFFF FFFF, then ROM code assumes a valid image is present.

Once the ROM code detects a valid image, it reads the size of the image from the header, copies the image to the destination address mentioned in the header and executes it.

The ROM code assumes one sector is 512 bytes. To read a particular address from the SPI flash, the ROM code issues a READ command (0x03) followed by the 24 bit address of the byte to be read from the flash. The ROM code then reads the desired number of bytes, 4 bytes at a time.

The chip select is controlled by the ROM code, and is asserted before sending the read command. It is de-asserted only once the required number of bytes are read.

24.4.8 Image Format

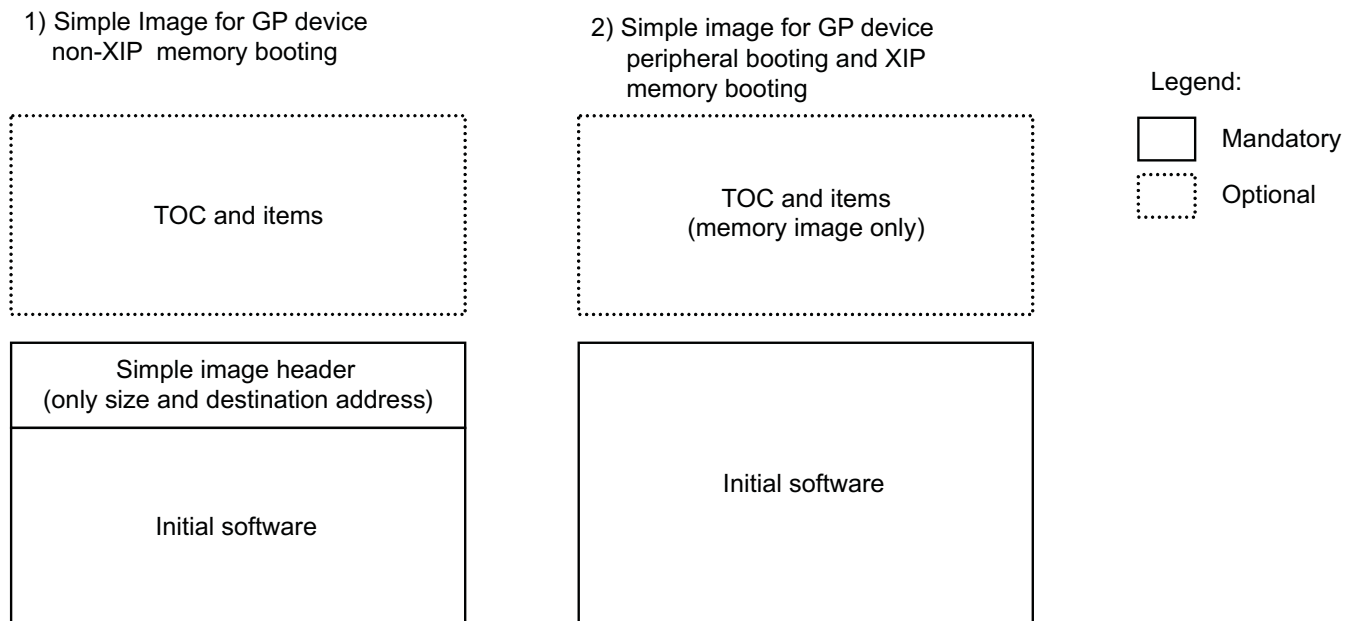

24.4.8.1 Overview

The image is the SW which is loaded into the memory and executed.

An overview of the image formats is shown in [Figure 24-27](#). There are two image types for GP devices:

1. GP non-XIP memory booting:
This image type is used for memories that require shadowing. The image must begin with a simple header that contains information on size to copy and destination. This format is detailed in [Section 24.4.8.3, Image Format for GP Devices](#).
2. GP XIP memory booting and peripheral booting:
GP image on XIP memory contains only code. The GP peripheral booting image contains only code.

Figure 24-27. Image Format

init-018

24.4.8.2 Image Header

The beginning of the image is a table of contents (TOC) pointing to each item. This is described in [Figure 24-28](#). Each TOC item is a simple structure described in [Table 24-42](#). The complete image header (TOC and items) should fit in a 512-byte sector.

The ROM code reads the first TOC item and if it contains a known string (MLO) then the TOC is identified and searched until a 0xFFFF FFFF offset is found.

Figure 24-28. Image Header Format

Table 24-42. TOC Item

| Offset | Field | Size [bytes] | Description |
|--------|----------|--------------|--|
| 0x0000 | Start | 4 | Offset from the start address of TOC to the actual address of a section |
| 0x0004 | Size | 4 | Size of a section |
| 0x0008 | reserved | 4 | Unused |
| 0x000C | reserved | 4 | Unused |
| 0x0010 | reserved | 4 | Unused |
| 0x0014 | Filename | 12 | 12-character long name of a section, including the zero (\0) terminator. |

24.4.8.3 Image Format for GP Devices

For a GP device, no security is enabled and, therefore, neither keys nor certificates are required. The image is simple and must contain a small header having the size of the SW to load and the destination address of where to store it when a device is other than XIP. The XIP device image is even simpler and starts with executable code. The image format is described in [Table 24-43](#). The header is used only for memory booting. The peripheral booting image does not have any header and starts directly with executable code.

Table 24-43. GP Device SW Image

| Filed | Non-XIP Device | | XIP Device | Size (Bytes) | Description |
|-------------|----------------|--------|------------|--------------|----------------------------------|
| | Offset | | Offset | | |
| Size | 0x0000 | - | | 4 | Size of the image |
| Destination | 0x0004 | - | | 4 | Address where to store the image |
| Image | 0x0008 | 0x0000 | | x | The Image |

24.4.8.4 Image Execution

The image is executed when the ROM code performs a branch instruction to the first executable instruction inside the Initial SW. The execution address is the first word after the image header. After the branch, the ARM runs in public ARM supervisor mode. The R0 register points to the booting parameter structure that contains some information about the booting process. [Table 24-44](#) details the booting parameters structure.

Table 24-44. Booting Parameters Structure

| Offset | Field | Size [Bytes] | Description |
|--------|------------------------|--------------|---|
| 0x00 | Booting message | 4 | Last received Booting Message. |
| 0x04 | Current booting device | 1 | Code of device used for booting: 0x01: XIP memory 0x02: NAND 0x03: OneNAND 0x04: DOC 0x05: MMC/SD2 0x06: MMC/SD1 0x07: XIP memory with wait monitoring 0x10: UART 0x11: HS USB 0x12: EMAC 0x13: EMAC |
| 0x05 | Reserved | 1 | Reserved |
| 0x06 | Reset reason | 1 | Current reset reason bit mask (bit = 1, event present): [0]: Power-on reset [1]: Global SW reset [3]: Violation reset [4]: MPU watchdog reset [5]: Watchdog reset [6]: External warm reset Other bits: Reserved |
| 0x07 | Reserved | 1 | Reserved |
| 0x08 | Device descriptor | 4 | Pointer to the device descriptor structure. This pointer is required when current booting device driver functions are called. |

24.4.9 Tracing

Tracing in the public ROM code consists in a 64-bit vector in which each bit corresponds to a certain point of the ROM code execution flow. The tracing vector is divided into two 32-bit words. [Table 24-45](#) lists the location and organization of the tracing data in RAM. Tracing data is initialized at the beginning of the start-up phase.

There are two sets of tracing data: the first set is the current trace information, the second set holds tracing collected during the first ROM code run following a cold reset. This cold reset tracing is copied into its location during the tracing initialization of the second ROM code run after the cold reset run. These data can be used for debugging purposes.

Table 24-45. Tracing Vector

| Bit No. | Group | Meaning |
|---------|-----------------|---|
| 0 | General | Reset |
| 1 | General | ROM code C main |
| 2 | General | ROM code runs after the cold reset |
| 3 | Boot | Booting started |
| 4 | Memory boot | Memory booting started |
| 5 | Boot | No more device to check |
| 6 | Peripheral boot | Peripheral booting started |
| 7 | Boot | Booting message change device |
| 8 | Boot | Booting message skip per. booting |
| 9 | Reserved | Reserved |
| 10 | Reserved | Reserved |
| 11 | Memory boot | Image header correct |
| 12 | Peripheral boot | Device initialized |
| 13 | Peripheral boot | ASIC ID sent |
| 14 | Peripheral boot | Booting message received |
| 15 | Peripheral boot | Image received |
| 16 | Peripheral boot | Peripheral booting failed |
| 17 | Peripheral boot | UART |
| 18 | Peripheral boot | USB |
| 19 | Peripheral boot | EMAC |
| 20 | Reserved | Reserved |
| 21 | Peripheral boot | NULL device |
| 22 | Execute | Image executed |
| 23 | Reserved | Reserved for non-GP devices |
| 24 | Reserved | Reserved for non-GP devices |
| 25 | Reserved | Reserved for non-GP devices |
| 26 | Reserved | Reserved for non-GP devices |
| 27 | Reserved | Reserved for non-GP devices |
| 28 | Reserved | Reserved for non-GP devices |
| 29 | Boot | Software booting configuration section 1 found |
| 30 | General | Software booting configuration clocking section found |
| 31 | Reserved | Reserved |
| 32 | Memory boot | Null device |
| 33 | Memory boot | XIP |
| 34 | Memory boot | NAND |
| 35 | Memory boot | OneNAND |
| 36 | Memory boot | DOC |
| 37 | Memory boot | MMC/SD2 |
| 38 | Memory boot | MMC/SD1 |
| 39 | Memory boot | XIP memory with wait monitoring |
| 40 | Memory boot | SPI |

24.5 Debug Configuration

24.5.1 Overview

This section provides information for using a debugger on the public ARM Cortex™-A8 in the processor. The debug capability is accessible through the JTAG interface with a limited number of pins.

24.5.2 JTAG Port Signal Description

The target debug interface uses the five standard IEEE 1149.1 (JTAG) signals (nTRST, TCK, TMS, TDI, and TDO), a return clock (RTCK), and the two instrumentations pins (EMU0, EMU1). For more information, see [Table 24-46](#).

Table 24-46. Debug POR Signals

| Pin | Type ⁽¹⁾ | Name | Description |
|-------|---------------------|---------------------|---|
| nTRST | I | Test logic reset | When asserted (active low), causes all test and debug logic in the device to be reset with the IEEE 1149.1 interface |
| TCK | I | Test clock | This is the test clock used to drive an IEEE 1149.1 test access port (TAP) state-machine and logic. Depending on the emulator attached to the processor, this is a free-running clock or a gated clock, depending on RTCK monitoring. |
| RTCK | O | Returned test clock | Synchronized TCK. Depending on the emulator attached to the processor, the JTAG signals are clocked from RTCK or RTCK is monitored by the emulator to gate TCK. |
| TMS | I | Test mode select | Directs the next state of the IEEE 1149.1 TAP state-machine |
| TDI | I | Test data input | Scan data input to the device. |
| TDO | O | Test data output | Scan data output of the device. |
| EMU0 | I/O | Emulation 0 | Channel 0 trigger: Boot mode |
| EMU1 | I/O | Emulation 1 | Channel 1 trigger: Boot mode |

⁽¹⁾ I = Input, O = Output

24.5.3 Initial Scan Chain Configuration

The general-purpose ports that can provide access to many test support functions built into the device (including the test logic defined by the IEEE 1149.1 standard) are the TAP.

The first level of the debug interface that sees the scan controller is the TAP router module.

The debugger can configure the TAP router to serially link to 16 TAP controllers or to individually scan one TAP controller without disrupting the instruction register (IR) state of the other TAPs. The initial scan chain configuration of the device is determined from the level of the EMU0 and EMU1 pins on the release of POR. At POR, EMU0 and EMU1 are automatically configured as inputs. The EMU0 and EMU1 pins should be pulled high at POR to configure the initial scan chain of the device to TAP router-only mode. In the TAP router-only configuration, no secondary TAPs are selected. The TAP router is the only TAP between the device-level TDI and TDO.

The router TAP has an IR length of 6 bits. This is the recommended boot mode. The third-party debugger must assume that the TAP router is the only TAP between TDI and TDO at boot.

24.5.4 Debugger Address Space

The CoreSight components are interfaced with the TAP router through the DAP. As recommended by the CoreSight architecture, the DAP is directly interfaced to the device bus. The debugger can directly access the entire memory space without requiring the processor to enter debug state and be programmed with a load or store instruction. [Table 24-47](#) lists the modules that are mapped to the DAP address, and the address space detail.

Table 24-47. Debugger Address Space

| Start Addr (Hex) | End Addr (Hex) | Size | Description |
|------------------|----------------|------|---|
| 0xD401 0000 | 0xD401 0FFF | 4KB | ARM embedded trace macrocell (ETM) module |
| 0xD401 1000 | 0xD401 1FFF | 4KB | Cortex-A8 module |
| 0xD401 9000 | 0xD401 9FFF | 4KB | Trace port interface unit (TPIU) |
| 0xD401 B000 | 0xD401 BFFF | 4KB | ARM embedded trace buffer (ETB) module |

The DBGEM signal on the Cortex-A8 is driven by setting bit 13 at address 0xD401 D030 in the DAP-APB address space.

24.6 Revision History

Table 24-48 lists the changes made since the previous version of this document.

Table 24-48. Document Revision History

| Reference | Additions/Modifications/Deletions |
|--------------------|---|
| Global | Removed SW Booting Configuration. |
| Section 24.2.3 | Changed sys_boot[8:0] to sys_boot[5:0] in 2nd paragraph 1st sentence. |
| Table 24-3 | Added new boot configuration to boot sequence. |
| Table 24-4 | Added new boot configuration to boot sequence. |
| Table 24-5 | Added new boot configuration to boot sequence. |
| Section 24.4.1.2 | Changed 2nd bullet. |
| Section 24.4.3 | Removed last 3 sentences from step 3 and deleted last paragraph. |
| Figure 24-8 | Removed the check for configuration header in step 5 from figure. |
| Section 24.4.4.2 | Removed software configuration information including: 2nd sentence of 4th paragraph, 5th paragraph, and last bulleted list. |
| Section 24.4.4.3 | Changed 1st sentence and removed bulleted list. |
| Figure 24-9 | Removed software configuration from the flow chart figure. |
| Section 24.4.7.1 | Added last bullet and removed 2nd and 3rd sentence from 3rd paragraph. |
| Figure 24-16 | Removed check for Configuration Header (CH) from figure. |
| Section 24.4.7.2 | Removed 2nd paragraph. |
| Figure 24-17 | Removed Configuration Header (CH) path from figure. |
| Section 24.4.7.3 | Removed Configuration Header (CH) information from 3rd paragraph and from ordered list. |
| Section 24.4.7.4 | Removed 2nd and 3rd sentences from 2nd paragraph. |
| Section 24.4.7.5 | Removed 3rd and 4th sentences from 3rd paragraph. |
| Section 24.4.7.6 | Updated 2nd and 3rd bullets and 3rd paragraph. |
| Section 24.4.7.6.1 | Changed 1st sentence, 1st paragraph. |
| Section 24.4.7.6.2 | Updated RAW mode bullet. |
| Section 24.4.7.8 | Added subsection. |
| Figure 24-27 | Removed Configuration header from figure. |
| Section 24.4.8.2 | Removed 1st paragraph and bulleted list. |
| Figure 24-28 | Updated figure. |
| | Removed CHSETTINGS subsection. |
| | Removed CHRAM subsection. |
| | Removed CHFLASH subsection. |
| | Removed CHMMCSD subsection. |
| Table 24-44 | Changed Offset 0x07 to reserved. |
| Table 24-45 | Changed bit 10 to reserved, bit 19 meaning to EMAC, and added bit 40. |

IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, modifications, enhancements, improvements, and other changes to its products and services at any time and to discontinue any product or service without notice. Customers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All products are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its hardware products to the specifications applicable at the time of sale in accordance with TI's standard warranty. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by government requirements, testing of all parameters of each product is not necessarily performed.

TI assumes no liability for applications assistance or customer product design. Customers are responsible for their products and applications using TI components. To minimize the risks associated with customer products and applications, customers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any TI patent right, copyright, mask work right, or other TI intellectual property right relating to any combination, machine, or process in which TI products or services are used. Information published by TI regarding third-party products or services does not constitute a license from TI to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. Reproduction of this information with alteration is an unfair and deceptive business practice. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI products or services with statements different from or beyond the parameters stated by TI for that product or service voids all express and any implied warranties for the associated TI product or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

TI products are not authorized for use in safety-critical applications (such as life support) where a failure of the TI product would reasonably be expected to cause severe personal injury or death, unless officers of the parties have executed an agreement specifically governing such use. Buyers represent that they have all necessary expertise in the safety and regulatory ramifications of their applications, and acknowledge and agree that they are solely responsible for all legal, regulatory and safety-related requirements concerning their products and any use of TI products in such safety-critical applications, notwithstanding any applications-related information or support that may be provided by TI. Further, Buyers must fully indemnify TI and its representatives against any damages arising out of the use of TI products in such safety-critical applications.

TI products are neither designed nor intended for use in military/aerospace applications or environments unless the TI products are specifically designated by TI as military-grade or "enhanced plastic." Only products designated by TI as military-grade meet military specifications. Buyers acknowledge and agree that any such use of TI products which TI has not designated as military-grade is solely at the Buyer's risk, and that they are solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI products are neither designed nor intended for use in automotive applications or environments unless the specific TI products are designated by TI as compliant with ISO/TS 16949 requirements. Buyers acknowledge and agree that, if they use any non-designated products in automotive applications, TI will not be responsible for any failure to meet such requirements.
