

AM35x ARM Microprocessor

Technical Reference Manual

Literature Number: SPRUGR0B
October 2009–Revised July 2010

| | |
|---|------------|
| Preface | 127 |
| 1 Introduction | 137 |
| 1.1 Overview | 138 |
| 1.2 Environment | 139 |
| 1.3 Description | 140 |
| 1.3.1 MPU Subsystem | 141 |
| 1.3.2 On-Chip Memory | 141 |
| 1.3.3 External Memory Interfaces | 141 |
| 1.3.4 DMA Controllers | 141 |
| 1.3.5 Multimedia Accelerators | 142 |
| 1.3.6 Security (HS Devices Only) | 143 |
| 1.3.7 Comprehensive Power Management | 143 |
| 1.3.8 Peripherals | 144 |
| 1.4 Device Family | 146 |
| 1.4.1 Device Features | 146 |
| 1.4.2 Device Identification | 147 |
| 1.4.3 General Recommendations Relative to Unavailable Features/Modules | 148 |
| 1.5 Revision History | 149 |
| 2 Memory Mapping | 151 |
| 2.1 Introduction | 152 |
| 2.2 Global Memory Space Mapping | 154 |
| 2.3 L3 and L4 Memory Space Mapping | 157 |
| 2.3.1 L3 Memory Space Mapping | 157 |
| 2.3.2 L4 Memory Space Mapping | 158 |
| 2.3.2.1 L4-Core Memory Space Mapping | 158 |
| 2.3.2.2 L4-Wakeup Memory Space Mapping | 161 |
| 2.3.2.3 L4-Peripheral Memory Space Mapping | 162 |
| 2.3.2.4 L4-Emulation Memory Space Mapping | 163 |
| 2.3.3 Register Access Restrictions | 165 |
| 2.4 IPSS Memory Space Mapping | 166 |
| 2.4.1 L3 Interconnect View of the IPSS Memory Space | 166 |
| 3 MPU Subsystem | 167 |
| 3.1 MPU Subsystem Overview | 168 |
| 3.1.1 Introduction | 168 |
| 3.1.2 Features | 169 |
| 3.2 MPU Subsystem Integration | 170 |
| 3.2.1 MPU Subsystem Clock and Reset Distribution | 172 |
| 3.2.1.1 Clock Distribution | 172 |
| 3.2.1.2 Reset Distribution | 173 |
| 3.2.2 ARM Subchip | 174 |
| 3.2.2.1 ARM Overview | 174 |
| 3.2.2.2 ARM Description | 174 |
| 3.2.2.2.1 Public ARM Cortex-A8 Instruction, Data, and Private Peripheral Port | 174 |
| 3.2.2.2.2 MPU Subsystem Features | 174 |
| 3.2.2.3 Clock, Reset, and Power Management | 175 |

| | | |
|-----------|--|------------|
| 3.2.2.3.1 | Clocks | 175 |
| 3.2.2.3.2 | Reset | 175 |
| 3.2.2.3.3 | Power Management | 175 |
| 3.2.3 | AXI2OCP and I2Async Bridges | 175 |
| 3.2.3.1 | Bridges Overview | 175 |
| 3.2.3.2 | AXI2OCP Description | 176 |
| 3.2.3.3 | Clocks, Reset, and Power Management | 177 |
| 3.2.3.3.1 | Clocks | 177 |
| 3.2.3.3.2 | Reset | 177 |
| 3.2.3.3.3 | Power Management | 177 |
| 3.2.4 | Interrupt Controller | 177 |
| 3.2.4.1 | Clocks | 177 |
| 3.2.4.2 | Reset | 177 |
| 3.2.4.3 | Power Management | 177 |
| 3.3 | MPU Subsystem Functional Description | 178 |
| 3.3.1 | Interrupts | 178 |
| 3.3.2 | Power Management | 178 |
| 3.3.2.1 | Power Domains | 178 |
| 3.3.2.2 | Power States | 179 |
| 3.3.2.3 | Power Modes | 179 |
| 3.3.2.4 | Transitions | 183 |
| 3.4 | MPU Subsystem Basic Programming Model | 184 |
| 3.4.1 | Clock Control | 184 |
| 3.4.2 | MPU Power Mode Transitions | 184 |
| 3.4.2.1 | Basic Power-On Reset | 184 |
| 3.4.2.2 | MPU to Standby Mode | 184 |
| 3.4.2.3 | MPU Out of Standby Mode | 184 |
| 3.4.2.4 | MPU Power-On from a Powered-Off State | 184 |
| 3.4.3 | Neon Power Mode Transition | 185 |
| 3.4.4 | ARM Programming Model | 185 |
| 4 | Power, Reset, and Clock Management | 187 |
| 4.1 | PRCM Introduction to Power Management | 188 |
| 4.1.1 | Goal of Power Management | 188 |
| 4.1.2 | Architectural Blocks for Power Management | 188 |
| 4.1.2.1 | Clock Domain | 188 |
| 4.1.2.2 | Power Domain | 189 |
| 4.1.2.3 | Voltage Domain | 189 |
| 4.1.3 | Device Power-Management Architecture | 189 |
| 4.1.3.1 | Module Interface and Functional Clocks | 189 |
| 4.1.3.2 | Autoidle Clock Control | 190 |
| 4.2 | PRCM Overview | 192 |
| 4.2.1 | Introduction | 192 |
| 4.2.2 | PRCM Features | 194 |
| 4.3 | PRCM Environment | 195 |
| 4.3.1 | External Clock Signals | 196 |
| 4.3.2 | External Reset Signals | 197 |
| 4.4 | PRCM Integration | 198 |
| 4.4.1 | Power-Management Scheme, Reset, and Interrupt Requests | 200 |
| 4.4.1.1 | Resets | 200 |
| 4.4.1.2 | Interrupt Requests | 201 |
| 4.5 | PRCM Reset Manager Functional Description | 202 |
| 4.5.1 | Overview | 202 |
| 4.5.2 | General Characteristics of Reset Signals | 203 |

| | | |
|-----------|---|-----|
| 4.5.2.1 | Scope | 203 |
| 4.5.2.2 | Occurrence | 203 |
| 4.5.2.3 | Source Type | 203 |
| 4.5.3 | Reset Sources | 203 |
| 4.5.3.1 | Global Reset Sources | 204 |
| 4.5.3.2 | Local Reset Sources | 205 |
| 4.5.4 | Reset Distribution | 206 |
| 4.5.5 | Domain Reset Descriptions | 207 |
| 4.5.5.1 | MPU Domain | 207 |
| 4.5.5.2 | NEON Domain | 207 |
| 4.5.5.3 | CORE Domain | 207 |
| 4.5.5.4 | DSS Domain | 208 |
| 4.5.5.5 | USBHOST Domain | 208 |
| 4.5.5.6 | SGX Domain | 208 |
| 4.5.5.7 | WKUP Domain | 208 |
| 4.5.5.8 | PER Domain | 208 |
| 4.5.5.9 | DPLL Domains | 209 |
| 4.5.5.10 | EFUSE Domain | 209 |
| 4.5.5.11 | BANDGAP Logic | 209 |
| 4.5.5.12 | Other Module Resets | 209 |
| 4.5.5.13 | External Warm Reset Assertion | 211 |
| 4.5.6 | Reset Logging | 211 |
| 4.5.6.1 | PRCM Reset Logging Mechanism | 211 |
| 4.5.6.2 | SCM Reset Logging | 211 |
| 4.5.7 | Reset Management Overview | 213 |
| 4.5.8 | Reset Summary | 217 |
| 4.5.9 | Reset Sequences | 220 |
| 4.5.9.1 | Power-Up Sequence | 220 |
| 4.5.9.2 | CPEFUSE Reset Sequence | 220 |
| 4.6 | PRCM Power Manager Functional Description | 220 |
| 4.6.1 | Overview | 220 |
| 4.6.1.1 | Device Partitioning | 220 |
| 4.6.1.2 | Domain State Transitions | 221 |
| 4.6.1.3 | Device Power Modes | 221 |
| 4.6.2 | Domain Implementation | 222 |
| 4.6.2.1 | Domain Dependencies | 222 |
| 4.6.2.2 | Domain Software Controls | 222 |
| 4.7 | PRCM Clock Manager Functional Description | 223 |
| 4.7.1 | Overview | 223 |
| 4.7.1.1 | Interface and Functional Clocks | 224 |
| 4.7.2 | External Clock I/Os | 224 |
| 4.7.2.1 | External Clock Inputs | 224 |
| 4.7.2.1.1 | 32-kHz Always-On Clock | 224 |
| 4.7.2.1.2 | High-Frequency System Clock | 225 |
| 4.7.2.1.3 | Alternate Clock | 225 |
| 4.7.2.2 | External Clock Outputs | 225 |
| 4.7.2.3 | Summary | 225 |
| 4.7.3 | Internal Clock Generation | 226 |
| 4.7.3.1 | PRM | 227 |
| 4.7.3.2 | CM | 229 |
| 4.7.3.3 | DPLLs | 232 |
| 4.7.3.3.1 | DPLL1 (MPU) | 233 |
| 4.7.3.3.2 | DPLL3 (CORE) | 233 |

| | | |
|------------|--|-----|
| 4.7.3.3.3 | DPLL4 (Peripherals) | 234 |
| 4.7.3.3.4 | DPLL5 (Peripherals) | 235 |
| 4.7.3.3.5 | DPLL Clock Summary | 237 |
| 4.7.3.4 | 32-kHz Oscillator | 237 |
| 4.7.3.5 | Summary | 237 |
| 4.7.4 | Clock Distribution | 238 |
| 4.7.4.1 | Domain Clock Distribution | 238 |
| 4.7.4.1.1 | MPU Domain | 238 |
| 4.7.4.1.2 | SGX Domain | 238 |
| 4.7.4.1.3 | CORE Domain | 239 |
| 4.7.4.1.4 | IPSS Domain | 242 |
| 4.7.4.1.5 | EFUSE Domain | 243 |
| 4.7.4.1.6 | DSS Domain | 244 |
| 4.7.4.1.7 | USBHOST Domain | 244 |
| 4.7.4.1.8 | WKUP Domain | 245 |
| 4.7.4.1.9 | PER Domain | 246 |
| 4.7.4.1.10 | DPLL Domains | 247 |
| 4.7.4.2 | Clock Distribution Summary | 249 |
| 4.7.4.2.1 | Domain Source Clocks | 249 |
| 4.7.4.2.2 | Peripheral Module Clocks | 250 |
| 4.7.5 | External Clock Controls | 251 |
| 4.7.5.1 | Clock Request (sys_clkreq) Control | 251 |
| 4.7.5.2 | System Clock Oscillator Control | 252 |
| 4.7.5.3 | External Output Clock1 (sys_clkout1) Control | 254 |
| 4.7.5.4 | External Output Clock2 (sys_clkout2) Control | 254 |
| 4.7.6 | DPLL Control | 255 |
| 4.7.6.1 | DPLL Multiplier and Divider Factors | 255 |
| 4.7.6.2 | DPLL Jitter Correction | 255 |
| 4.7.6.3 | DPLL Frequency Ramp-Up Delay | 256 |
| 4.7.6.4 | DPLL Modes | 256 |
| 4.7.6.5 | DPLL Low-Power Mode | 258 |
| 4.7.6.6 | DPLL Clock Path Power Down | 258 |
| 4.7.6.7 | Latencies | 259 |
| 4.7.6.8 | Recalibration | 259 |
| 4.7.6.9 | DPLL Programming Sequence | 260 |
| 4.7.7 | Internal Clock Controls | 261 |
| 4.7.7.1 | PRM Source-Clock Controls | 261 |
| 4.7.7.2 | CM Source-Clock Controls | 263 |
| 4.7.7.3 | Common Interface Clock Controls | 264 |
| 4.7.7.4 | DPLL Source-Clock Controls | 265 |
| 4.7.7.5 | SGX Domain Clock Controls | 265 |
| 4.7.7.6 | CORE Domain Clock Controls | 267 |
| 4.7.7.7 | EFUSE Domain Clock Controls | 270 |
| 4.7.7.8 | DSS Domain Clock Controls | 270 |
| 4.7.7.9 | USBHOST Domain Clock Controls | 271 |
| 4.7.7.10 | WKUP Domain Clock Controls | 272 |
| 4.7.7.11 | PER Domain Clock Controls | 273 |
| 4.7.7.12 | Other Modules Clocks | 275 |
| 4.7.8 | Clock Configurations | 276 |
| 4.7.8.1 | Processor Clock Configurations | 276 |
| 4.7.8.2 | Interface and Peripheral Functional Clock Configurations | 276 |
| 4.8 | PRCM Idle and Wake-Up Management | 278 |
| 4.8.1 | Overview | 278 |

| | | |
|-------------|--|-----|
| 4.8.2 | Sleep Transition | 279 |
| 4.8.3 | Wakeup | 280 |
| 4.8.4 | Device Wake-Up Events | 280 |
| 4.8.5 | Sleep and Wake-Up Dependencies | 284 |
| 4.8.5.1 | Sleep Dependencies | 284 |
| 4.8.5.2 | Wake-Up Dependencies | 286 |
| 4.8.6 | Other Modules Idle/Wakeup Management | 288 |
| 4.9 | PRCM Interrupts | 289 |
| 4.10 | PRCM Voltage Management Functional Description | 290 |
| 4.11 | PRCM Basic Programming Model | 291 |
| 4.11.1 | Global Registers | 291 |
| 4.11.1.1 | Revision Information Registers | 291 |
| 4.11.1.2 | PRCM Configuration Registers | 291 |
| 4.11.1.3 | Interrupt Configuration Registers | 291 |
| 4.11.1.3.1 | MPU Interrupt Event Sources | 291 |
| 4.11.1.3.2 | MPU Interrupt Registers | 292 |
| 4.11.1.4 | Event Generator Control Registers | 292 |
| 4.11.1.5 | Output Signal Polarity Control Registers | 292 |
| 4.11.1.5.1 | CM_POLCTRL (CM Polarity Control Register) | 292 |
| 4.11.1.5.2 | PRM_POLCTRL (PRM Polarity Control Register) | 293 |
| 4.11.2 | Clock Management Registers | 293 |
| 4.11.2.1 | System Clock Control Registers | 293 |
| 4.11.2.1.1 | PRM_CLKSRC_CTRL (Clock Source Control Register) | 293 |
| 4.11.2.1.2 | PRM_CLKSETUP (Source-Clock Setup Register) | 294 |
| 4.11.2.1.3 | PRM_CLKSEL (Source-Clock Selection Register) | 294 |
| 4.11.2.2 | External Clock Output Control Registers | 295 |
| 4.11.2.2.1 | PRM_CLKOUT_CTRL (Clock Out Control Register) | 295 |
| 4.11.2.2.2 | CM_CLKOUT_CTRL (Clock Out Control Register) | 295 |
| 4.11.2.3 | DPLL Clock Control Registers | 295 |
| 4.11.2.3.1 | CM_CLKSELn_PLL_<processor_name> (Processor DPLL Clock Selection Register) | 295 |
| 4.11.2.3.2 | CM_CLKSELn_PLL (DPLL Clock Selection Register) | 296 |
| 4.11.2.3.3 | CM_CLKEN_PLL_<processor_name> (Processor DPLL Clock Enable Register) | 296 |
| 4.11.2.3.4 | CM_CLKEN_PLL (DPLL Enable Register) | 297 |
| 4.11.2.3.5 | CM_AUTOIDLE_PLL_<processor_name> (Processor DPLL Autoidle Register) | 297 |
| 4.11.2.3.6 | CM_AUTOIDLE_PLL (DPLL Autoidle Register) | 297 |
| 4.11.2.3.7 | CM_AUTOIDLE1_PLL (DPLL5 Autoidle Register) | 297 |
| 4.11.2.3.8 | CM_IDLEST_CKGEN (Source-Clock Idle-Status Register) | 298 |
| 4.11.2.3.9 | CM_IDLEST2_CKGEN (DPLL5 Source-Clock Idle-Status Register) | 298 |
| 4.11.2.3.10 | CM_IDLEST_PLL_<processor_name> (Processor DPLL Idle-Status Register) | 298 |
| 4.11.2.4 | Power-Domain Clock Control Registers | 298 |
| 4.11.2.4.1 | CM_CLKSEL_<domain_name> (Clock Select Register) | 299 |
| 4.11.2.4.2 | CM_FCLKEN_<domain_name> (Functional Clock Enable Register) | 300 |
| 4.11.2.4.3 | CM_ICLKEN_<domain_name> (Interface Clock Enable Register) | 300 |
| 4.11.2.4.4 | CM_AUTOIDLE_<domain_name> (Autoidle Register) | 301 |
| 4.11.2.4.5 | CM_IDLEST_<domain_name> (Idle-Status Register) | 301 |
| 4.11.2.4.6 | CM_CLKSTCTRL_<domain_name>(Clock State Control Register) | 302 |
| 4.11.2.4.7 | CM_CLKSTST_<domain_name> (Clock State Status Register) | 303 |
| 4.11.2.4.8 | CM_SLEEPDEP_<domain_name> (Sleep Dependency Control Register) | 303 |
| 4.11.2.5 | Domain Wake-Up Control Registers | 303 |
| 4.11.2.5.1 | PM_WKEN_<domain_name> (Wake-Up Enable Register) | 304 |
| 4.11.2.5.2 | PM_WKST_<domain_name> (Wake-Up Status Register) | 304 |
| 4.11.2.5.3 | PM_WKDEP_<domain_name> (Wake-Up Dependency Register) | 305 |
| 4.11.2.5.4 | PM_<processor_name>GRPSEL_<domain_name> (Processor Group Selection Register) | 306 |
| | | 306 |

| | | |
|-------------|---|-----|
| 4.11.3 | Reset Management Registers | 306 |
| 4.11.3.1 | Reset Control | 306 |
| 4.11.3.1.1 | PRM_RSTTIME (Reset Time Register) | 306 |
| 4.11.3.1.2 | RM_RSTCTRL_<domain_name> (Reset Control Register) | 306 |
| 4.11.3.1.3 | RM_RSTST_<domain_name> (Reset Status Register) | 306 |
| 4.11.4 | Power Management Registers | 308 |
| 4.11.4.1 | PM_PWSTST_<domain_name> (Power State Status Register) | 308 |
| 4.11.5 | Generic Programming Examples | 308 |
| 4.11.5.1 | Clock Control | 308 |
| 4.11.5.1.1 | Enabling and Disabling the Functional Clocks | 308 |
| 4.11.5.1.2 | Enabling and Disabling the Interface Clocks | 310 |
| 4.11.5.1.3 | Enabling and Disabling the INACTIVE State | 311 |
| 4.11.5.1.4 | Processor Clock Control | 312 |
| 4.11.5.2 | Reset Management | 315 |
| 4.11.5.3 | Wake-Up Control | 315 |
| 4.11.5.4 | Event Generator Programming Examples | 316 |
| 4.12 | PRCM Registers | 318 |
| 4.12.1 | CM Module Registers | 318 |
| 4.12.1.1 | CM Module Registers Mapping Summary | 318 |
| 4.12.1.2 | OCP_System_Reg_CM Register Descriptions | 322 |
| 4.12.1.2.1 | CM_REVISION | 322 |
| 4.12.1.2.2 | CM_SYSCONFIG | 322 |
| 4.12.1.3 | MPU_CM Register Descriptions | 323 |
| 4.12.1.3.1 | CM_CLKEN_PLL_MPU | 323 |
| 4.12.1.3.2 | CM_IDLEST_MPU | 325 |
| 4.12.1.3.3 | CM_IDLEST_PLL_MPU | 325 |
| 4.12.1.3.4 | CM_AUTOIDLE_PLL_MPU | 326 |
| 4.12.1.3.5 | CM_CLKSEL1_PLL_MPU | 327 |
| 4.12.1.3.6 | CM_CLKSEL2_PLL_MPU | 328 |
| 4.12.1.3.7 | CM_CLKSTCTRL_MPU | 329 |
| 4.12.1.3.8 | CM_CLKSTST_MPU | 330 |
| 4.12.1.4 | CORE_CM Register Descriptions | 331 |
| 4.12.1.4.1 | CM_FCLKEN1_CORE | 331 |
| 4.12.1.4.2 | CM_FCLKEN3_CORE | 333 |
| 4.12.1.4.3 | CM_ICLKEN1_CORE | 334 |
| 4.12.1.4.4 | CM_ICLKEN2_CORE | 336 |
| 4.12.1.4.5 | CM_ICLKEN3_CORE | 337 |
| 4.12.1.4.6 | CM_IDLEST1_CORE | 338 |
| 4.12.1.4.7 | CM_IDLEST2_CORE | 341 |
| 4.12.1.4.8 | CM_IDLEST3_CORE | 342 |
| 4.12.1.4.9 | CM_AUTOIDLE1_CORE | 343 |
| 4.12.1.4.10 | CM_AUTOIDLE2_CORE | 346 |
| 4.12.1.4.11 | CM_AUTOIDLE3_CORE | 347 |

Survey

Help us meet your expectations:

We are always looking at ways to develop our service and improve our quality to fit your needs. Please take a few minutes to complete our short questionnaire by:

- Providing general suggestions
or
- Rating a document and describing its critical points

<http://www.ti.com/csdocsurvey> (password: 123survey)

Thank you.

About This Manual

FCC Warning

This equipment is intended for use in a laboratory test environment only. It generates, uses, and can radiate radio frequency energy and has not been tested for compliance with the limits of computing devices pursuant to subpart J of part 15 of FCC rules, which are designed to provide reasonable protection against radio frequency interference. Operation of this equipment in other environments may cause interference with radio communications, in which case the user at his own expense will be required to take whatever measures may be required to correct this interference.

Information About Cautions and Warnings

This book may contain cautions and warnings.

CAUTION

This is an example of a caution statement.

A caution statement describes a situation that could potentially damage your software or equipment.

WARNING

This is an example of a warning statement.

A warning statement describes a situation that could potentially cause harm to you.

The information in a caution or a warning is provided for your protection. Please read each caution and warning carefully.

Register, Field, and Bit Calls

The naming convention applied for a call consists of:

- For a register call: *<Module name>.<Register name>*; for example: UART.UASR
- For a bit field call:
 - *<Module name>.<Register name>[End:Start] <Field name> field*; for example, UART.UASR[4:0] SPEED bit field
 - *<Field name> field <Module name>.<Register name>[End:Start]*; for example, SPEED bit field UART.UASR[4:0]
- For a bit call:
 - *<Module name>.<Register name>[pos] <Bit name> bit*, for example, UART.UASR[5] BIT_BY_CHAR bit
 - *<Bit name> bit <Module name>.<Register name>[pos]*; for example, BIT_BY_CHAR bit UART.UASR[5]

To help the reader navigate the document, each register call is hyperlinked to its register description in the register manual section. After each register description, a table summarizes all hyperlinked register calls.

To navigate in the PDF documents, see [Acrobat Reader Tips](#).

Coding Rules

The programming models or code listings follow the rules:

| Type | Definition | Example |
|-------------|--|---|
| File | Starts with the module name | PRCM_test1.c MCBSP1_init.h |
| Variable | Global variables are prefixed by "g_" Pointers are prefixed by "p" Global pointers are prefixed by "g_p" | g_SDMA_LogicalChan pAddrCounter g_pSDMA_LogicalChan |
| Function | Starts with the module name | PRCM_SetupClocks() ArmIntC_MaskInterrupts() |
| Typedef | Ends with "_t" | PRCM_Struct_t |
| Definition | Starts with the module name and is followed by the register name | #define SMS_ERR_TYPE *((volatile Uint32*)0x680080F4) #define MCBSP2_RCR1_REG *((volatile Uint32*)0x4807401C) |
| Enumeration | Starts with the module name | Typedef enum DMA_Mode_Label { INPUT_MODE OUTPUT_MODE } DMA_Mode_t; |

Flow Chart Rules

Flow charts follow the following rules:

| Shape | Name | Definition |
|---|-----------------------------------|---|
|  | Process | Any computational steps or processing function of a program; defined operation(s) causing change in value, form, or location of information |
|  | Decision | A decision or switching type operation that determines which of a number of alternate paths is followed |
|  | Predefined process or sub-process | One or more named operations or program steps specified in a subroutine or another set of flow charts |
|  | Data or I/O | General I/O function; information available for processing (input) or recording of processed information (output) |
|  | Terminator | Terminal point in a flow chart: start, stop, halt, delay, or interrupt; may show exit from a closed subroutine |
|  | Annotation | Additional descriptive clarification, comment |
|  | On page connector (reference) | Exit to, or entry from, another part of chart in the same page |
|  | Off page connector (reference) | The flow continues on a different page. |
|  | Summing Junction | Logical AND |
|  | Or | Logical OR |
|  | Parallel mode (ISO) | Beginning or end of two or more simultaneous operations |
|  | Flow Line | Lines indicate the sequence of steps and the direction of flow. |

Acrobat Reader Tips

Acrobat includes two methods to search for words in a PDF:

- The Find toolbar provides a basic set of options to locate a word in the current PDF.
- The Search window lists words or partial words that match your text in the current PDF.

These guidelines apply to Acrobat Reader 5.x, 6.0, and 7.0.

For more information on Acrobat Reader search features, see the Adobe Reader Help.

To search for words in a document using the Find dialog box:

1. Open the document.
2. To display the Find toolbar, right-click in the toolbar area and select Find.
3. In the Find box, type the word, words, or partial words for which you want to search.
4. From the Find Options menu, select options as desired.
5. To view each search result, click the Find toolbar, the Find Previous button, or the Find Next button to go backward or forward through the document.

To search for words in a document using the Search PDF window:

1. Open the document.
2. Click the Search button on the File toolbar or right-click on your document and select Search.
3. Type the word, words, or part of a word for which you want to search.
4. Click Search.
5. The results appear in page order and, if applicable, show a few words of context. Each result displays an icon to identify the type of occurrence. All other searchable areas display the Search Result icon.
6. To display the page that contains a search result, click an item in the Results list. The occurrence is highlighted.
7. To navigate to the next result, choose Edit > Search Results > Next Result (or Ctrl+G).
8. To navigate to the previous result, choose Edit > Search Results > Previous Result (or Shift+Ctrl+G).

Navigate through your previous view

To retrace your path within an Adobe PDF document:

- For the previous view: Choose View > Go To > Previous View or Alt+Left Arrow.
- For the next view: Choose View > Go To > Next View or Alt+Right Arrow. The Next View command is available only if you have chosen Previous View.

If you view the PDF document in a browser, use options on the Navigation toolbar to move between views.

- Right-click the toolbar area, and then choose *Navigation*.
- Click the Go To Previous View button or the Go To Next View button.

NOTE: This navigation tip is useful to return to your previous view after clicking on a register call hyperlink.

OMAP34xx Disclaimer

All programming models and use cases presented in this manual are provided for educative purposes only and may differ from or be optimized for your applications.

All OMAP peripheral devices presented in this manual are provided for illustration purposes and may be different from those in your system.

Trademarks

History

The following table summarizes the AM35x TRM versions.

| Version | Literature Number | Date | Notes |
|---------|-------------------|--------------|--------------------|
| * | SPRUGR0 | October 2009 | See ⁽¹⁾ |
| A | SPRUGR0 | June 2010 | See ⁽²⁾ |
| B | SPRUGR0 | July 2010 | See ⁽³⁾ |

⁽¹⁾ AM35x ARM Microprocessor Technical Reference Manual - * version (SPRUGR0) initial release.

⁽²⁾ AM35x ARM Microprocessor Technical Reference Manual - version A (SPRUGR0).

- Chapter 7: DMA
- Chapter 12: Display Subsystem
- Chapter 14: UART/IrDA/CIR
- Chapter 16: Multichannel SPI
- Chapter 17: Multichannel Buffered Serial Port

⁽³⁾ AM35x ARM Microprocessor Technical Reference Manual - version B (SPRUGR0).

- Chapter 8: Interrupt Controller
- Chapter 14: UART/IrDA/CIR

Introduction

This chapter introduces the features, supporting subsystems, and architecture of the AM35x ARM Microprocessors.

| Topic | Page |

| 1.1 Overview | 138 |
| 1.2 Environment | 139 |
| 1.3 Description | 140 |
| 1.4 Device Family | 146 |
| 1.5 Revision History | 149 |

1.1 Overview

The AM35x ARM Microprocessors are integrated on TI's advanced 65-nm process technology.

NOTE: This technical reference manual describes all available features. Some features may not be available or supported on your particular device. For more information, see your device-specific data manual and [Section 1.4, Device Family](#).

These devices are designed to provide maximum flexibility for ARM based applications including, but not limited to, Industrial Automation/Control, Single Board Computers, and Human Machine Interface.

These devices also feature M-Shield™ mobile security technology to enable secure e-commerce applications and the replay of copyright-protected digital media content.

Security features integrated on these devices support applications designed for:

- Protection against malicious attacks
- M-commerce
- Content protection for recordable media (CPRM)
- Digital rights management (DRM)

High-security (HS) devices rely on a security scheme based on hardware mechanisms and secure read-only memory (ROM) code, ensuring that only trusted code can access secure resources. These resources are in specific regions of memory as well as in peripherals, hardware cryptographic accelerators, and eFuse keys.

NOTE: To determine if a high-security (HS) version of your device is available and for more information on HS devices, see your device-specific data manual and [Section 1.4, Device Family](#).

The device supports high-level operating systems such as:

- Windows CE
- Linux

Multiple RTOS are also supported.

These devices also include state-of-the-art power-management techniques required for high-performance mobile products.

The following subsystems are part of the device:

- Microprocessor unit (MPU) subsystem based on the ARM® Cortex™-A8 microprocessor
- SGX subsystem for 3D graphics acceleration to support display and gaming effects

NOTE: SGX is not available on all devices. For more information see your device-specific data manual and [Section 1.4, Device Family](#).

- Camera image signal processor (VPFE) that supports multiple formats and interfacing options connected to a wide variety of image sensors
- Display subsystem with a wide variety of features for multiple concurrent image manipulation, and a programmable interface supporting a wide variety of displays. The display subsystem also supports NTSC/PAL video out.
- Level 3 (L3) and level 4 (L4) interconnects that provide high-bandwidth data transfers for multiple initiators to the internal and external memory controllers and to on-chip peripherals

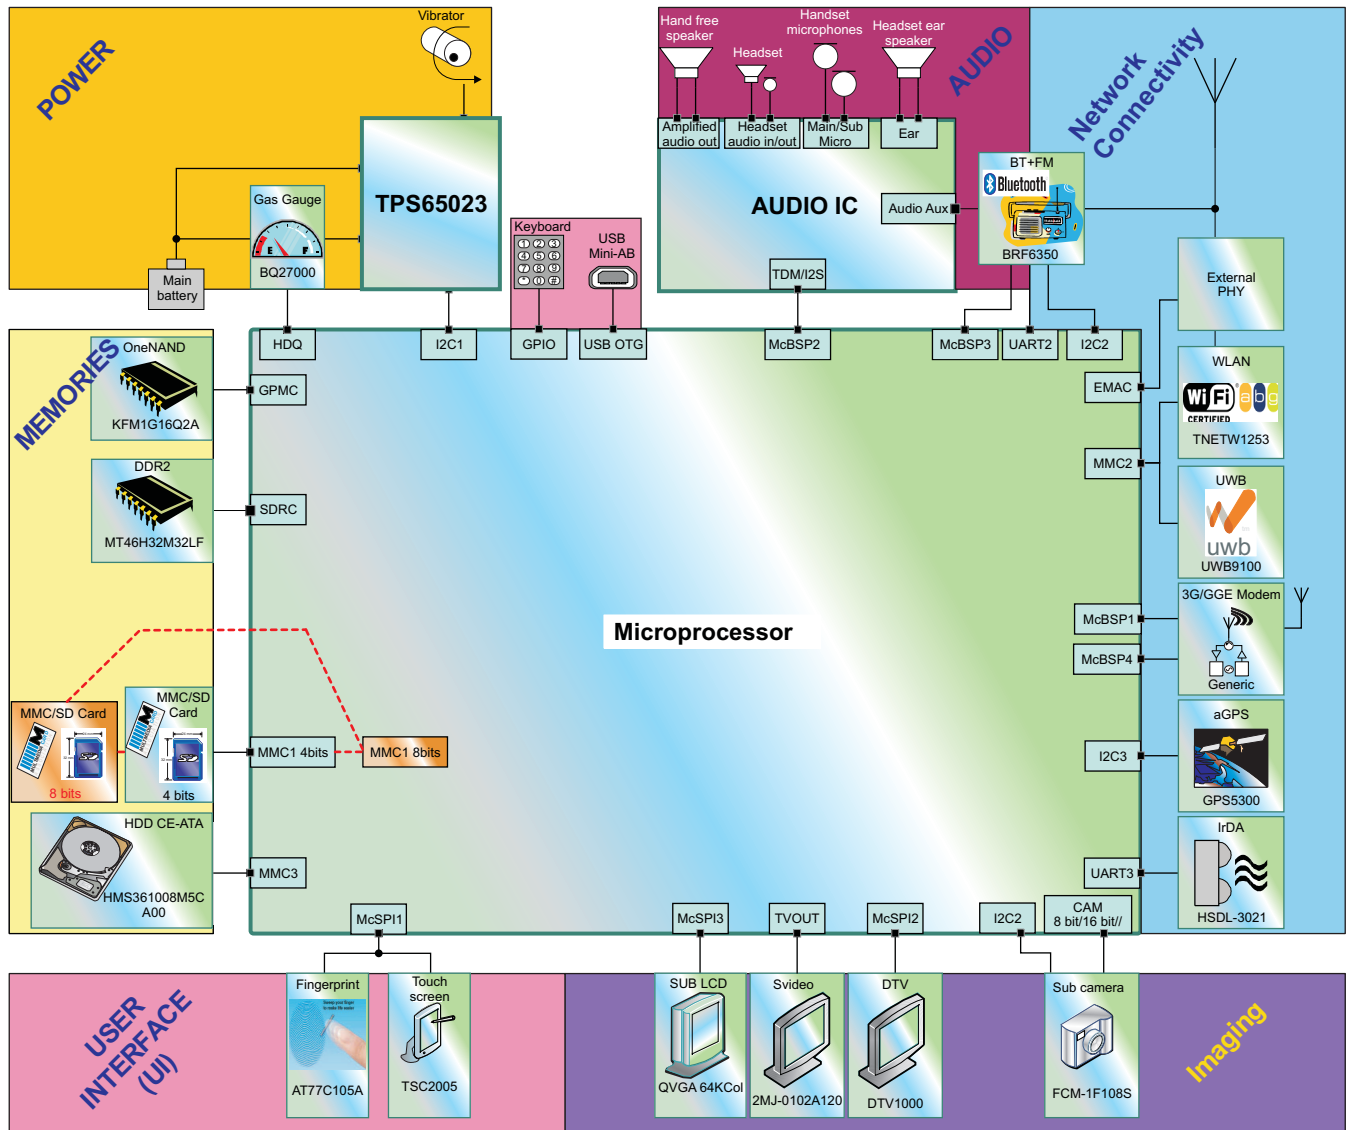

These devices also offer a comprehensive power and clock-management scheme that enables high-performance and low-power operation.

1.2 Environment

This section provides an overview of the device when integrated with the TPS65023 power integrated circuit (IC). For more information on the TPS65023 device, contact your TI representative.

Figure 1-1 provides an overview of a nonexhaustive environment for the high-tier device.

Figure 1-1. Environment Using TPS65023

108-001

NOTE: Some features are not available on all devices. For more information, see your device-specific data manual and [Section 1.4, Device Family](#).

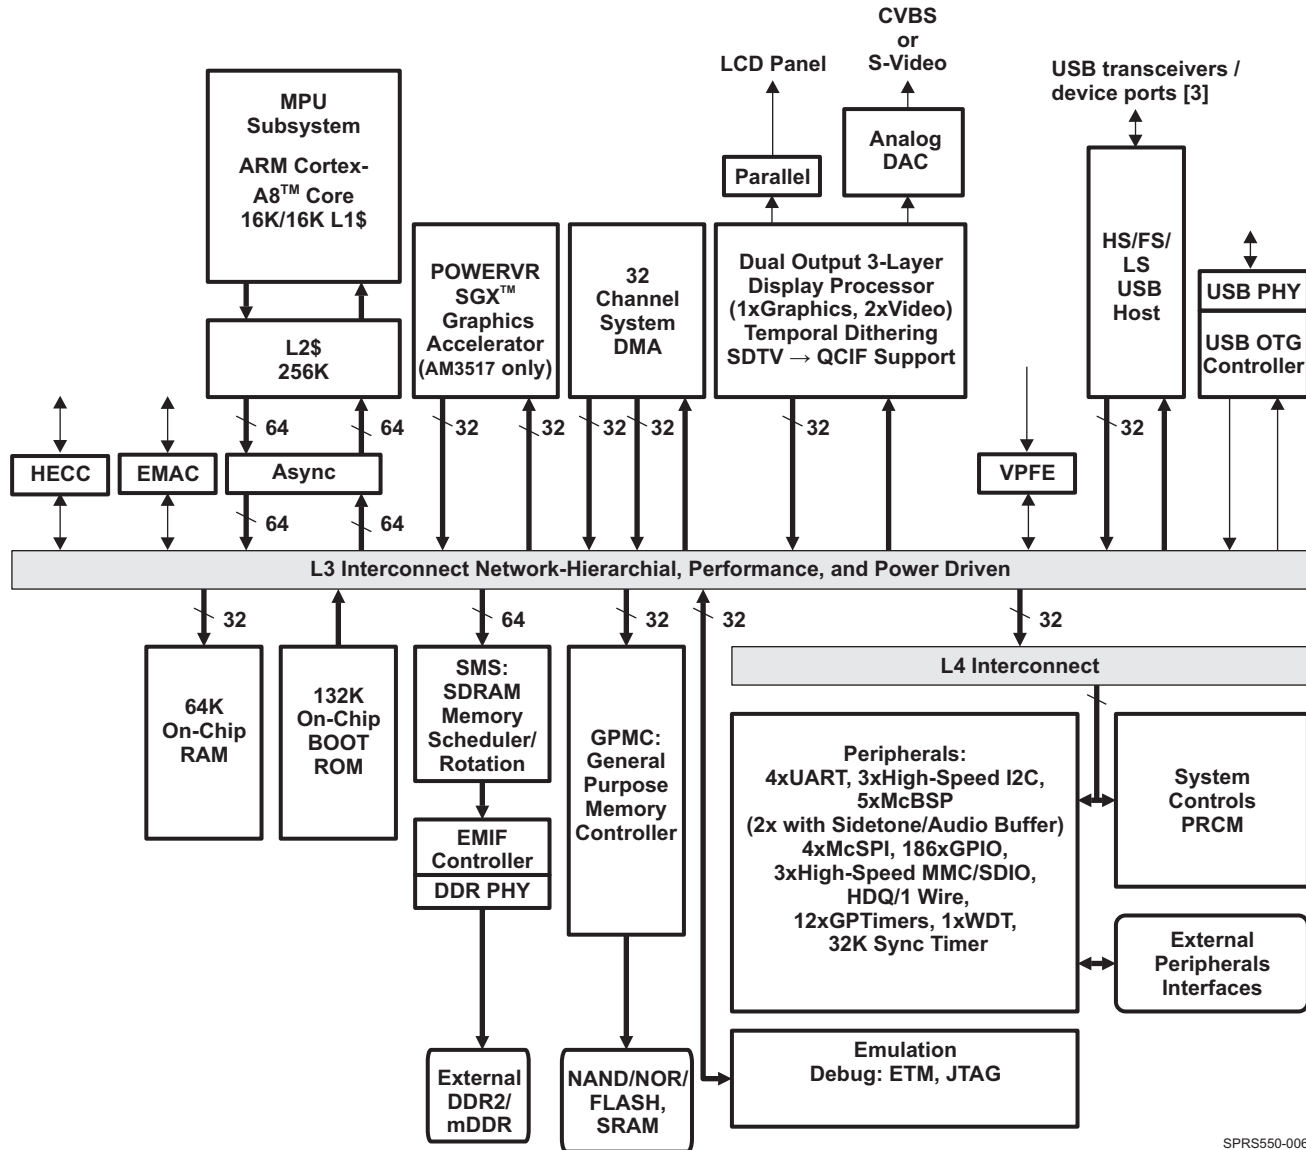

1.3 Description

These devices are offered in the following package:

- ZCN package: 491-pin BGA (17x17, 0.65mm pitch)
- ZER package: 484-pin PBGA (23x23, 1mm pitch)

Figure 1-2 shows the block diagram.

Figure 1-2. Block Diagram

SPRS550-006

NOTE: Some features are not available on all devices. For more information, see your device-specific data manual and [Section 1.4, Device Family](#).

1.3.1 MPU Subsystem

The MPU subsystem integrates the following modules

- ARM subchip
 - ARM® Cortex™-A8 core
 - ARM Version 7™ ISA: Standard ARM instruction set + Thumb®-2, Jazelle® RCT Java accelerator, and media extensions
 - NEON™ SIMD coprocessor (VFP lite + media streaming instructions)
 - Cache memories
 - Level 1: 16KB instruction and 16KB data—4-way set associative cache, 64 bytes/line
 - Level 2: see [Section 1.4](#), *Device Family*
- Interrupt controller (MPU INTC) of 96 synchronous interrupt lines
- Asynchronous interface with core logic
- Debug, trace, and emulation features: ICE-Crusher, ETM, ETB modules

1.3.2 On-Chip Memory

On-chip memory configuration offers memory resources for program and data storage:

- 112KB ROM
- 64KB single-access static random access memory (SRAM)

1.3.3 External Memory Interfaces

The device includes two external memory interfaces:

- General-purpose memory controller (GPMC)
 - NOR flash, NAND flash (with ECC Hamming code calculation), SRAM and Pseudo-SRAM asynchronous and synchronous protocols
 - Flexible asynchronous protocol control for external ASIC or peripheral interfacing
 - 16-bit data, up to 8 chip-selects (CSs)
 - 128M-byte addressable per chip-select, 1G-byte total address space
 - Nonmultiplexed device with limited address (2K bytes)
- SDRAM Controller (SDRC)
 - Double data rate (DDR2 and LPDDR) SDRAM
 - 16-bit or 32-bit data, 2 chip-selects, configurations for a maximum of 1 G-byte address space per chip-select
 - Work in conjunction with the SDRAM memory scheduler (SMS) companion module

1.3.4 DMA Controllers

The device embeds one generic DMA controller, the system DMA (sDMA) controller, used for memory-to-memory, memory-to-peripheral, and peripheral-to-memory transfers:

- One read port, one write port
- 32 prioritizable logical channels
- 96 hardware requests
- 256 x 32-bit FIFO dynamically allocable between active channels

The device also embeds two dedicated DMA controllers: display DMA and USB HS DMA.

1.3.5 Multimedia Accelerators

The device uses the following multimedia accelerators for display and gaming effects as well as high-end imaging and video applications:

- 3D graphics accelerator (SGX)
 - 3D graphics and video codecs supported on common hardware
 - Tile-based architecture
 - Universal scalable shader engine (USSE™) multithreaded engine incorporating pixel and vertex shader functionality reducing die area
 - Advanced shader feature set in excess of Microsoft VS3.0, PS3.0, and OGL2.0
 - Industry standard API supports OGL-ES 1.1 and 2.0, OpenVG 1.0, and OpenMax
 - Fine-grained task switching, load balancing, and power management
 - Programmable high-quality image anti-aliasing
 - Advanced geometry DMA driven operation for minimum CPU interaction
 - Fully virtualized memory addressing for OS operation in a unified memory architecture
 - Advanced and standard 2D operations (that is, vector graphics, BLTs, ROPs, etc.)
- Video Processing Front End (VPFE)
 - Supports most of the raw and smart image sensors available in the market
 - 16-bit parallel interface supported
 - Pixel clock up to 75 MHz

CAUTION

Clock configurations depend on the core voltage and maximum clock frequencies. Values in this document might not apply to production devices. Refer to your device-specific data manual for supported values for production devices.

- Display interface
 - Display controller
 - Color and monochrome displays up to 2048 x 2048 x 24-bpp resolution
 - 256 x 24-bit entries palette in red, green, blue (RGB)
 - 3,375 colors, 15 grayscales
 - Picture-in-picture (overlay), color-space conversion, rotation, color-phase rotation, and resizing support
 - Remote frame buffer interface
 - Liquid-crystal display (LCD) pixel interfaces (MIPI DPI 1.0) and LCD bus interfaces (MIPI DBI 1.0) supported
 - NTSC/PAL video encoder outputs with integrated digital-to-analog converters (DACs) output are supported on CVBS and S-video TV analog output signals
 - Embedded DMA controller

1.3.6 Security (HS Devices Only)

The secure firmware resides in a secure version of the ROM and includes hardware security features that enable HS devices and encryption/decryption accelerators. The following encryption/decryption accelerators are only available in HS devices:

- RNG
- 2 x DES/3DES
- SHA1/MD5
- SHA2/MD5
- 2 x AES with counter mode
- Fast PKA

The customer programmable fuse ROM (CPFROM) module is only available on high-security (HS) devices.

NOTE: To determine if a high-security (HS) version of your device is available and for more information on HS devices, see your device-specific data manual and [Section 1.4, Device Family](#).

1.3.7 Comprehensive Power Management

The device includes the following power management features:

- Clock and reset generation and distribution
- Auto clock gating to save active power by gating clock when peripheral is not active

1.3.8 Peripherals

The device supports a comprehensive set of peripherals to provide flexible and high-speed interfacing and on-chip programming resources. [Table 1-1](#) provides a list and description of the peripherals that are available.

Table 1-1. Device Peripherals

| Type | Name | Number | Description |
|---|---|------------------|---|
| Serial Communication | Multi-channel Buffered Serial Ports (McBSPs) | 5 | The McBSPs provide a full-duplex direct serial interface between the device and other devices in a system such as audio and voice codecs and other application chips. McBSP1, McBSP2, and McBSP3 serve as general purpose serial ports while McBSP2 and McBSP3 include additional audio-loopback capability. |
| | Multi-channel Serial Port Interface (McSPI) | 4 | The McSPIs provide a master/slave interface to SPI devices. |
| | High-speed Multi-port USB Host Controller | 1 | High-speed USB2.0 host controller with three host ports each offering high-speed data transactions (up to 480 Mbps) or full-speed/low-speed data transactions (12 and 1.5 Mbps, respectively). In high-speed mode, the USB host controller ports interface to external USB PHYs using a 12-pin or 8-pin UTMI low pin interface (ULPI). In full-speed and low-speed mode, the ports interface to external USB PHYs using a 6-/4-/3-pin serial interface. |
| | High-speed USB OTG Controller | 1 | High-speed USB2.0 OTG controller that offers high-speed data transactions (up to 480 Mbps) on a USB port with embedded DMA controller. The high speed USB OTG controller includes integrated PHY, thus eliminating need of external PHY. |
| | HDQ/1-Wire® | 1 | The HDQ/1-Wire interface supports the Benchmark HDQ protocol and the Dallas Semiconductor 1-Wire protocol. |
| | Universal Asynchronous Receiver/Transmitter (UART) | 4 | Serial communication interfaces compatible to the industry standard TL16C550 asynchronous communications element. UART1 and UART 2 are general serial communication interfaces. UART3 provides additional support for infrared data association (IrDA) and consumer infrared (CIR) communications. |
| | High-speed (HS) Inter-integrated Circuit (I2C) Controllers | 3 | Master/slave I2C high-speed standard interfaces with support for standard mode (up to 100K bits/s), fast mode (up to 400K bits/s), and high-speed mode (up to 3.4M bits/s). |
| | HECC | 1 | Interface used to connect to vehicle bus in automotive. |
| Removable Media | Multimedia Card/Secure Digital/Secure Digital I/O (MMC/SDIO) Card Interface | 3 | MMC memory card, SD memory card, or SDIO cards interface. |
| Miscellaneous | GP timers | 12 | Twelve general-purpose timers |
| | Watchdog timers (WDTs) | 1 | Three watchdog timers |
| | 32-kHz synchronization timer | 1 | 32-kHz clock timer |
| | General-purpose input/output (GPIO) | Package-specific | General-purpose input/output pins controlled by six GPIO controllers. |
| | EMAC | 1 | 10/100 Mbit Ethernet MAC operation with CPPI4.0 compliant & RMI interface. Interface used to connect to vehicle |
| | Control module | 1 | I/O multiplexing and chip-configuration control. |
| Security Modules (High-security Devices Only) | | | RNG, Fast PKA, 2xDES/3DES, SHA1/MD5, SHA2/MD5, 2xAES, and Secure Watchdog Timer. |

1.4 Device Family

1.4.1 Device Features

Devices are configured with different sets of features on different devices. This technical reference manual details all available features. Some features may not be available or supported in your particular device. Features supported across different devices are shown in [Table 1-2](#) (ZCN package). For more information on the ZCN package, refer to your device-specific data manual.

Table 1-2. Subsystem, Co-Processor, and Peripheral Support Matrix on the (ZCN Package)

| Subsystem/Co-Processor/Peripheral | Chapter | AM3517 | AM3505 |
|---|---------|--------|--------|
| POWERVR SGX™ 3D Graphics Accelerator | 11 | x | |
| Cortex-A8 Neon Co-Processor | 3 | x | x |
| SDRAM Controller | 9 | x | x |
| General-Purpose Memory Controller | 9 | x | x |
| VPFE | 10 | x | x |
| Display Subsystem | 12 | x | x |
| LCD DPI, LCD RFBI and TV Output Interface | | x | x |
| LCD DSI and LCD SDI | | | |
| McBSP1/2/3/4/5 | 17 | x | x |
| McSPI1/2/3/4 | 16 | x | x |
| High-Speed USB OTG Controller | 20 | x | x |
| High-Speed USB Host Controller | 20 | x | x |
| HDQ/1-Wire | 18 | x | x |
| UART1/2 | 14 | x | x |
| UART3/IrDA/CIR | 14 | x | x |
| I2C1/2/3 | 15 | x | x |
| EMAC | 22 | x | x |
| HECC | 23 | x | x |
| MMC/SD/SDIO1/2/3 | 19 | x | x |
| GP Timer (x12) | 13 | x | x |
| Watchdog Timer | 13 | x | x |
| 32-kHz Sync Timer | 13 | x | x |
| GPIO | 21 | x | x |
| Secure ROM | 1 | | |
| RNG | 1 | | |
| DES/3DES | 1 | | |
| SHA1/MD5 | 1 | | |
| SHA2/MD5 | 1 | | |
| AES | 1 | | |
| Fast PKA | 1 | | |
| Secure Watchdog Timer | 1 | | |
| High-security Device | 1 | | |
| General-purpose Device | 1 | x | x |

1.4.2 Device Identification

The identification registers include the CONTROL_IDCODE and CONTROL_DIE_ID data registers. These registers are accessible through the L4 interconnect port starting at physical address 0x4830 A204 and 0x4830 A218, respectively. See the Memory Mapping chapter for more information about the L4 memory space mapping. [Table 1-3](#) describes the identification registers.

The silicon type can be read in the HAWKEYE bit field value of the CONTROL.CONTROL_IDCODE register. The silicon revision can be read in the VERSION bit field value of the CONTROL.CONTROL_IDCODE register.

Table 1-3. Device Identification Registers

| Register Name | Address | Size |
|-------------------------------|-------------|------|
| CONTROL.CONTROL_IDCODE[31:0] | 0x4830 A204 | 32 |
| CONTROL.CONTROL_DIE_ID[127:0] | 0x4830 A218 | 128 |

To retrieve chip identification, see [Table 1-4](#). This register helps software identify the chip derivative.

Table 1-4. Chip Identification

| Scalable Resource | Name | Bit | Value | Description | AM3517 | AM3505 |
|---|----------------------|-------|-------|--|--------|--------|
| SGX | SGX_scalable_control | 14:13 | 00 | Full use. | 00 | 10 |
| | | | 01 | Core clock restricted in HW to /6 from L3. | | |
| | | | 10 | HW not present. | | |
| | | | 11 | Reserved. | | |
| Reserved | Reserved | 12 | 0 | Reserved. Not available for use. | 0 | 0 |
| MPU L2 Cache Size | MPU_L2_cache_size | 11:10 | 00 | 0 KB. | 11 | 11 |
| | | | 01 | 64 KB. | | |
| | | | 10 | 128 KB. | | |
| | | | 11 | Full use (256 KB). | | |
| MPU Frequency | ARM_MHz | 9:8 | 00 | 500 MHz. | 00 | 00 |
| | | | 01 | 400 MHz. | | |
| | | | 10 | 266 MHz. | | |
| | | | 11 | Reserved. | | |
| Reserved | Reserved | 7:5 | 1 | Reserved. Not available for use. | 0 | 0 |
| NEON & VFP | NEON_VFP Lite | 4 | 0 | Full use. | 0 | 0 |
| | | | 1 | Not available for use. | | |
| Reserved | Reserved | 3:2 | 1 | Reserved. Not available for use. | 0 | 0 |
| MMC1 Width | 4_8_bit_mmc | 1 | 0 | Full use (8-bit width at 3.0v IO) | 0 | 0 |
| | | | 1 | Restricted use (4-bit width at 3.0v IO) | | |
| TV Out | TO_OUT | 0 | 0 | Full use. | 0 | 0 |
| | | | 1 | Not available for use. | | |
| Control Device Status Register 15:0 (Address 0x4800 244C) | | | | | 0x0C00 | 0x4C00 |

Table 1-5. CONTROL_IDCODE Register Definition

| Field | Bits | Value | Comment |
|--------------------------------|---------|---------------------------------|----------------------------|
| CONTROL.CONTROL_IDCODE [31:28] | VERSION | | Revision number |
| CONTROL.CONTROL_IDCODE [27:12] | HAWKEYE | See Table 1-6 . | Hawkeye number |
| CONTROL.CONTROL_IDCODE [11:1] | TI_IDM | 0x13 | Manufacturer identity (TI) |
| CONTROL.CONTROL_IDCODE [0] | -- | 0x1 | Always set to 1. |

The Hawkeye number is hardcoded in the design. [Table 1-6](#) lists the Hawkeye number values.

Table 1-6. Hawkeye Number Value

| Silicon Type | Field | Value |
|--------------|-------------------------------|--------|
| ES1.0 | CONTROL.CONTROL_IDCODE[27:12] | 0xB868 |

- The CONTROL.CONTROL_DIE_ID register is the 128 bits single identifier of the device.

Table 1-7. CONTROL_DIE_ID

| Field | Bits | Value |
|---------------|----------|-------------------|
| DIE_ID[127:0] | RESERVED | Single identifier |

1.4.3 General Recommendations Relative to Unavailable Features/Modules

As explained in the previous section, some features are not available in all devices. For unavailable features, use the following recommendations:

- Memory mapping: Memory area of unavailable modules and features are RESERVED, read is undefined, and write can lead to unpredictable behavior.
- Interrupt controllers: Ensure that interrupts of unavailable modules and features are masked in the MPU subsystem.
- DMA: Ensure that DMA requests of unavailable modules and features are masked in DMA subsystems.
- System Control Module (SCM): Unavailable modules and feature pins are not functional and should not be used.
- Power, Reset, and Clock Management Module (PRCM): For power management and power-saving consideration, ensure that power domains of unavailable features/modules are switched off and clocks are cut off.
- Interconnect: To flag potential interconnect outstanding commands, the time-out of target agents attached to unavailable modules can be enabled with the lowest setting.

1.5 Revision History

Table 1-8 lists the changes made since the previous version of this document.

Table 1-8. Document Revision History

| Reference | Additions/Modifications/Deletions |
|-----------|--|
| | Changed second paragraph. |
| | Updated figure. |
| | Changed 1st bullet. |
| | Changed figure. |
| | Changed 1st sentence, 2nd bullet and 1st subbullet under 2nd bullet. |
| | Changed Camera Interface to Video Processing Front End (VPFE) |
| | Change watchdog timers number to 1. |
| | Changed 2D/3D Graphics Accelerator to POWERVR SGX™ 3D Graphics Accelerator |

Memory Mapping

This chapter describes memory mapping.

NOTE: This chapter gives information about all modules and features in the high-tier device. To check availability of modules and features, see Chapter 1, *Device Family*. The memory area of unavailable modules and features is RESERVED, read is undefined, and write can lead to unpredictable behavior.

| Topic | Page |
|---|------------|
| 2.1 Introduction | 152 |
| 2.2 Global Memory Space Mapping | 154 |
| 2.3 L3 and L4 Memory Space Mapping | 157 |
| 2.4 IPSS Memory Space Mapping | 166 |

2.1 Introduction

The microprocessor unit (MPU) has a 32-bit address port, allowing it to handle a 4Gbytes space divided into several regions, depending on the target type.

The memory map is composed of a memory space (general-purpose memory controller [GPMC], external memory interface [EMIF4], etc.), register space (L3 and L4 interconnects), and dedicated spaces (SGX, etc.), all of which are shared among the initiators (for example, the MPU subsystem or the display subsystem).

The GPMC and EMIF4 are dedicated to memory connection. The GPMC is used for NOR/NAND flash and PSRAM memories. The EMIF4 is used for DDR2. For more information, see the *Memory Subsystem* chapter.

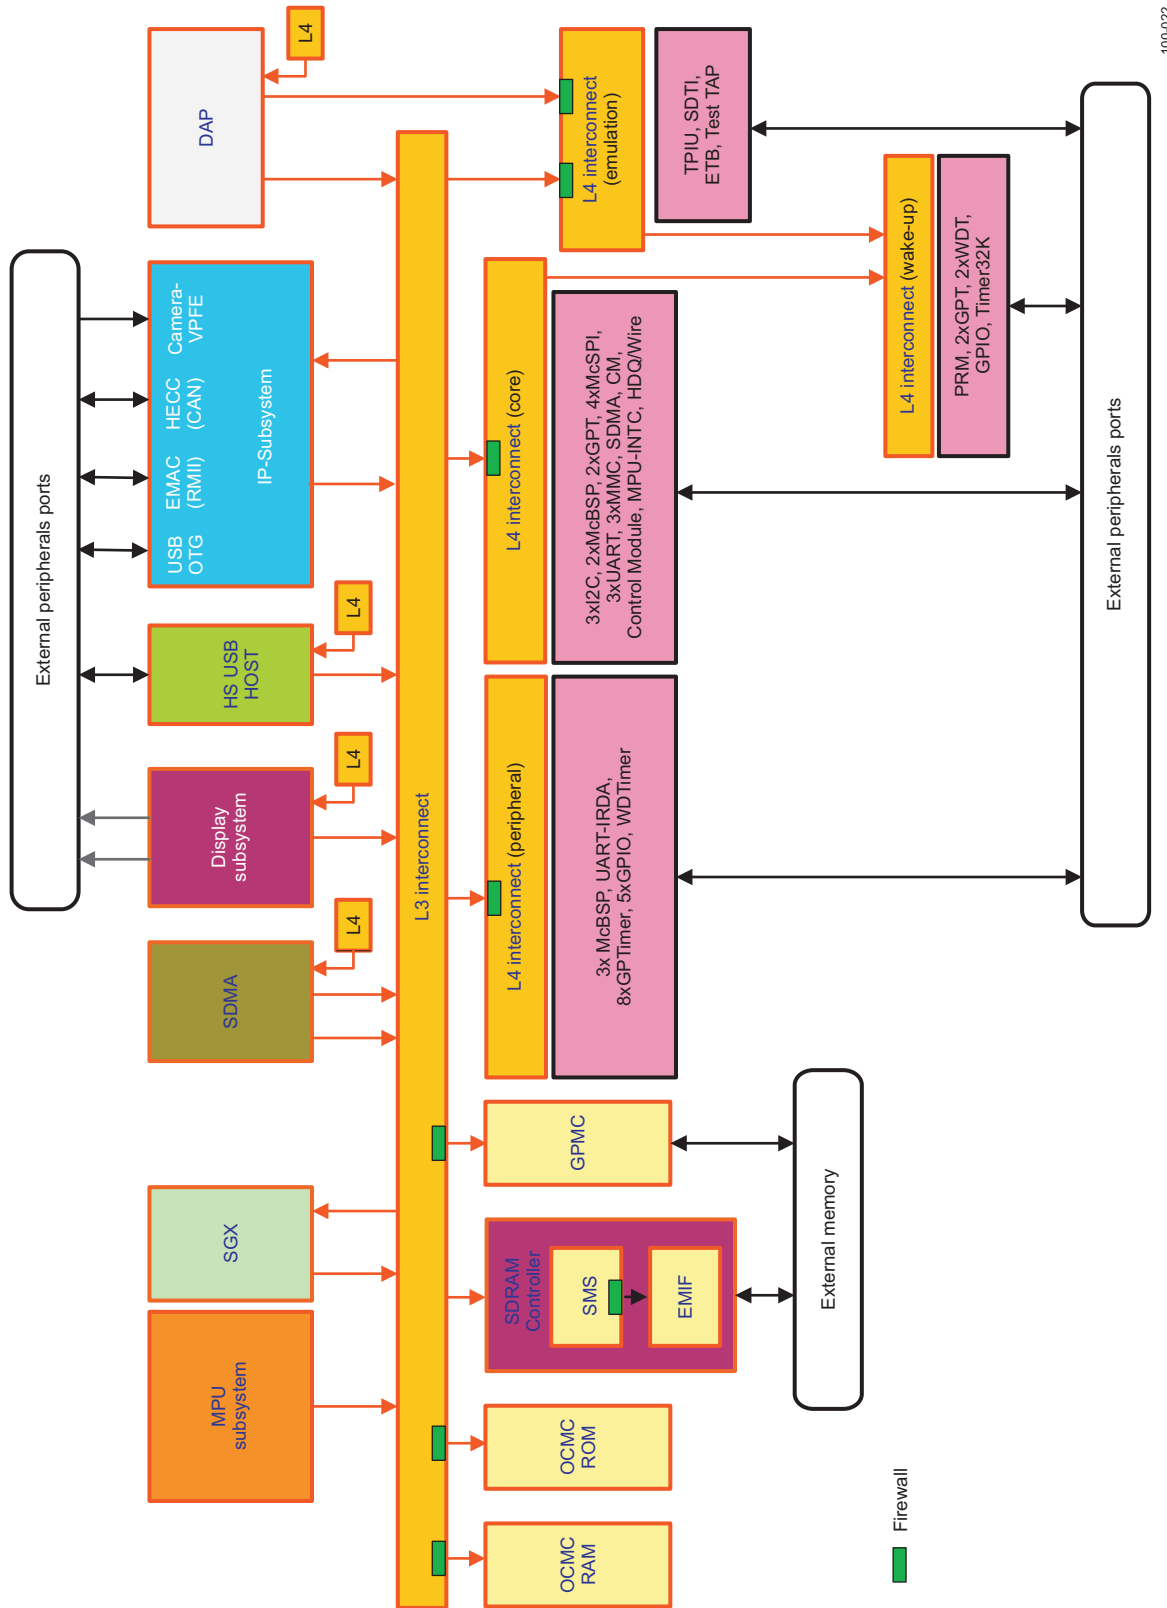

The L3 interconnect allows the sharing of resources, such as peripherals and external or on-chip memories, between all the initiators of the platform. The L4 interconnects control access to the peripherals.

Transfers between initiators and targets across the platform are physically conditioned by the chip interconnect and can be logically conditioned by firewalls. For more information about the intercommunication (L3 and L4 interconnects) and protection mechanisms implemented in the device, see the *Interconnect*.

NOTE: Some features may not be available or supported in your particular device. For more information, see Chapter 1, *Device Family*, and your device-specific data manual.

Figure 2-1 shows the interconnect of the device and the main modules and subsystems in the platform.

Figure 2-1. Interconnect Overview

100-022

2.2 Global Memory Space Mapping

This section provides a global view of the memory mapping and details the boot, GPMC, EMIF4, and virtual rotated frame buffer (VRFB) memory spaces.

The system memory mapping is flexible, with two levels of granularity for target address space allocation:

- Level 1: Four quarters are labeled Q0, Q1, Q2, and Q3. Each quarter corresponds to a 1Gbyte address space (total address space is 4Gbytes).
- Level 2: Each quarter is divided into eight blocks of 128Mbytes, with target spaces mapped inside the blocks.

This organization allows all target spaces to be decoded based on the five most significant bits (MSBs) of the 32-bit address ([31:27]).

- **Boot space**

The system has a 1Mbyte boot space either in the on-chip boot ROM or on the GPMC memory space. When booting from the on-chip ROM with the appropriate external `sys_boot5` pin configuration, the 1Mbyte memory space is redirected to the on-chip boot ROM memory address space [0x4000 0000 – 0x400F FFFF].

When booting from the GPMC with the appropriate external `sys_boot5` pin configuration, the memory space is part of the GPMC memory space.

For more information on `sys_boot5` pin configuration, see the *Memory Subsystem* and *Initialization* chapters.

- **GPMC space**

Eight independent GPMC chip-selects (`gpmc_ncs0` to `gpmc_ncs7`) are available in the first quarter (Q0) of the addressing space to access NOR/NAND flash and PSRAM memories. The chip-selects have a programmable start address and programmable size (16Mbytes, 32Mbytes, 64Mbytes, or 128Mbytes) in a total memory space of 1Gbyte.

- **EMIF4 space**

Two EMIF4 chip-selects (`emif4_ncs0` and `emif4_ncs1`) are available on the third quarter (Q2) of the addressing space to access SDRAM memories. The base address of EMIF4 space starts at 0x8000 0000. For more information on EMIF please refer to MemorySubsystem Chapter.

- **VRFB space**

The EMIF4-SMS virtual memory space is a different memory space used to access a subset of the EMIF4 memory space through the rotation engine. The virtual address space size is 768Mbytes split into two parts: The first 256M-byte part is in the second quarter (Q1) of the memory; the second 512Mbytes part is in the fourth quarter (Q3) of the memory.

For more information on GPMC, EMIF4, and VRFB, see the *Memory Subsystem* chapter.

This section gives information about all modules and features in the high-tier device. To check availability of modules and features, see Chapter 1, *Device Family*. The memory area of unavailable modules and features is RESERVED, read is undefined, and write can lead to unpredictable behavior.

[Table 2-1](#) describes the global memory space mapping.

Table 2-1. Global Memory Space Mapping

| QUARTER | Device Name | Start Address (HEX) | End Address (HEX) | Size | Description |

2.3 L3 and L4 Memory Space Mapping

The memory space system is defined from a hierarchical view: L1, L2, L3, and L4.

L1 memory includes the MPU subsystem.

The chip-level interconnect, which is made of one L3 and four L4s, enables communication between all modules and subsystems.

L3 handles many types of data transfers and, in particular, the data exchange with system on-chip/external memories.

The four L4s that handle transfers with peripherals are: the L4-Core, L4-Wakeup, L4-Per, and L4-Emu interconnects.

For more information about the interconnect, see the *Interconnect* chapter.

The following sections describe the register mapping of the L3 and L4 interconnects. The software configures these registers.

2.3.1 L3 Memory Space Mapping

The L3 interconnect control registers are mapped in a 16Mbytes space and allow the configuration of the L3 interconnect parameters.

The L3 default settings are fully functional and enable all possible functional data paths. However, the interconnect parameters can be changed to accommodate expectations.

Accesses to the L3 interconnect can be configured on a per-module basis using the internal L3 registers, which are grouped into five register block types:

- IA: initiator agent configuration registers
- TA: target agent configuration registers
- RT: register target (global configuration registers)
- PM: protection mechanism (firewalls) configuration registers
- SI: global sideband signal configuration registers

For more information, see the *Interconnect* chapter.

This section gives information about all modules and features in the high-tier device. To check availability of modules and features, see Chapter 1, *Device Family*. The memory area of unavailable modules and features is RESERVED, read is undefined, and write can lead to unpredictable behavior.

[Table 2-2](#) describes the mapping of the L3 interconnect control registers.

Table 2-2. L3 Control Register Mapping

| Device Name | Start Address (HEX) | End Address (HEX) | Size | Description |
|-------------|---------------------|-------------------|------|--|
| L3 RT | 0x6800 0000 | 0x6800 03FF | 1KB | L3 configuration registers |

2.3.2 L4 Memory Space Mapping

The device contains four L4 interconnects: the L4-Core, L4-Wakeup, L4-Per, and L4-Emu interconnects.

As with the L3 interconnect, the L4 interconnects can be configured to tune the access depending on the characteristics of each module.

For more information on the L4 interconnect, see the *Interconnect* chapter.

2.3.2.1 L4-Core Memory Space Mapping

The L4-Core interconnect is a 16Mbytes space composed of the L4-Core interconnect configuration registers and the module registers.

[Table 2-3](#) describes the mapping of the registers for the L4-Core interconnect.

NOTE: All memory spaces described as modules provide direct access to module registers outside the L4-Core interconnect. All other accesses are internal to the L4-Core interconnect.

This section gives information about all modules and features in the high-tier device. To check availability of modules and features, see Chapter 1, *Device Family*. The memory area of unavailable modules and features is RESERVED, read is undefined, and write can lead to unpredictable behavior.

Table 2-3. L4-Core Memory Space Mapping

2.3.2.4 L4-Emulation Memory Space Mapping

The L4-Emu interconnect is an 8Mbytes space composed of the L4-Emu interconnect configuration registers and module registers.

Table 2-6 describes the mapping of the registers for the L4-Emu interconnect.

NOTE: All memory spaces described as modules provide direct access to the module registers outside the L4-Emu interconnect. All other accesses are internal to the L4-Emu interconnect

2.3.3 Register Access Restrictions

This section gives information about all modules and features in the high-tier device. To check availability of modules and features, see Chapter 1, *Device Family*. The memory area of unavailable modules and features is RESERVED, read is undefined, and write can lead to unpredictable behavior.

Table 2-7 gives the supported data access widths per module.

Table 2-7. Register Access Restrictions

| Module | Allowed Access |

MPU Subsystem

This chapter describes the microprocessor unit (MPU) subsystem.

NOTE: Some features may not be available or supported in your particular device. For more information, see Chapter 1, the Device Family section, and your device-specific data manual.

| Topic | Page |
|---|------|
| 3.1 MPU Subsystem Overview | 168 |
| 3.2 MPU Subsystem Integration | 170 |
| 3.3 MPU Subsystem Functional Description | 178 |
| 3.4 MPU Subsystem Basic Programming Model | 184 |

3.1 MPU Subsystem Overview

3.1.1 Introduction

The MPU subsystem of the device handles transactions among the ARM core, the L3 interconnect, and the interrupt controller (INTC).

The MPU subsystem is a hard macro that integrates the ARM subchip with additional logic for protocol conversion, emulation, interrupt handling, and debug enhancements. Figure 3-1 is a high-level block diagram of the MPU subsystem.

Figure 3-1. MPU Subsystem Overview

mpuss-001

3.1.2 Features

The MPU subsystem integrates the following:

- ARM subchip
 - Public ARM Cortex™-A8 core
 - ARM version 7 ISA: Standard ARM instruction set + Thumb-2™, Jazelle® RCT Java accelerator, and media extensions
 - Neon single instruction, multiple data (SIMD) coprocessor (VFP light + media streaming instructions)
 - Cache memories
 - Level 1: 16-KB instruction and 16-KB data caches – 4-way associative, 64 bytes/line
 - Level 2: See [Section 1.4](#), *OMAP35xx Family*.
 - Emulation/debug
- INTC of 96 synchronous level-sensitive interrupt lines (For details, see [Chapter 8](#), *Interrupt Controller*.)
- AXI2OCP bridge between ARM AXI bus, L3 master open-core protocol (OCP) bus, and INTC master OCP bus
- MPU clock generator: Clock generation module that generate clocks, power modes, and idle and active acknowledge signals
- Debug, trace, and emulation features: ICECrusher™, embedded trace macrocell (ETM), advanced peripheral bus (APB) modules. Cortex-A8 MPU implements an APB slave interface that allows access to ETM, ICECrusher, and debug registers.

3.2 MPU Subsystem Integration

The MPU subsystem integrates the following group of submodules:

- Public ARM Cortex-A8 MPU: Provides a high processing capability, including the Neon technology for mobile multimedia acceleration. The ARM communicates through an AXI bus with the AXI2OCP bridge and receives interrupts from the MPU INTC.
- INTC: Handles module interrupts (for details, see [Chapter 8, Interrupt Controller](#)).
- AXI2OCP bridge: Allows communication among the ARM (AXI), the INTC (OCP), and the modules (OCP L3).
- I2Async bridge: An asynchronous bridge interface providing an asynchronous OCP-to-OCP interface. This interface is between the AXI2OCP bridge in the MPU subsystem and the T2Async bridge external to the MPU subsystem. The T2Async bridge connects to OCP L3.
- MPU clock generator: Provides clocks to internal modules of the MPU subsystem; fed by the MPU digital phase-locked loop (DPLL) of the power, reset, and clock management (PRCM) module of the device. The MPU DPLL generates the clock for the ARM Cortex-A8 CPU and the Cortex-A8 MPU subsystem logic. The power, reset, and MPU DPLL source clock are generated from the device PRCM module.

[Figure 3-2](#) shows the signals that interface with the external modules.

Figure 3-2. MPU Subsystem Integration Overview

mpuss-002

NOTE: Some debug, trace, and emulation features are implemented in the MPU subsystem. This chapter includes only clock/reset inputs and power-management aspects for these features.

3.2.1 MPU Subsystem Clock and Reset Distribution

3.2.1.1 Clock Distribution

The MPU subsystem includes a clock generator block that supplies clocks for the modules in the MPU subsystem. It is fed by the MPU_CLK clock from the PRCM module.

All major modules in the MPU subsystem are clocked at half the frequency of the ARM core. The divider of the output clock can be programmed with the PRCM.CM_CLKSEL2_PLL_MPU[4:0] MPU_DPPLL_CLKOUT_DIV bit field; the frequency is relative to the ARM core. For details see , *Power, Reset, and Clock Management (PRCM) module* . The clock generator generates the following functional clocks:

- **ARM (ARM_FCLK):** This is the core clock. It is the base fast clock that is routed internally to the ARM logic and internal RAMs, including Neon, L2 cache, the ETM core (emulation), and the ARM core. It runs at one half the frequency of the MPU_CLK when DPPLL1 is locked, and runs at the same frequency as the MPU_CLK when DPPLL1 is bypassed.
- **AXI2OCP clock (AXI_FCLK):** This clock is half the frequency of the ARM clock (ARM_FCLK). The OCP interface thus performs at one half the frequency of ARM.
- **INTC functional clock (MPU_INTC_FCLK):** This clock, which is part of the INTC module, is half the frequency of the ARM clock (ARM_FCLK).
- **ICE-Crusher functional clock (ICECRUSHER_FCLK):** ICECrusher clocking operates on the APB interface, using the ARM core clocking.
- **I2Async clock (I2ASYNC_FCLK):** This clock is half the frequency of the ARM clock (ARM_FCLK). It matches the OCP interface of the AXI2OCP bridge.

NOTE: The second half of the asynchronous bridge (T2ASYNC) is clocked directly by the PRCM module with the core clock. T2ASYNC is not part of the MPU subsystem.

Emulation clocking: Except for the ICECrusher functional clock, which is provided by the MPU DLL, the emulation modules in the MPU subsystem are not generated by the MPU subsystem DPPLL, but by an EMU DPPLL. These clocks (EMU_CLOCKS) are distributed by the PRCM module, are asynchronous with the ARM core clock (ARM_FCLK) and can run at a maximum of 1/3 the ARM core clock.

Figure 3-3 shows the MPU subsystem clocking scheme.

Figure 3-3. MPU Subsystem Clocking Scheme

Table 3-1 lists the clocks generated in the MPU subsystem by the MPU clock generator.

Table 3-1. MPU Clock Generator Clock Signals

| Signal Name | I/O | Interface | Comments |
|-----------------|-----|-------------|-----------------------------|
| MPU_CLK | I | PRCM | MPU DPLL clock out |
| ARM_FCLK | O | ARM | ARM functional clock |
| MPU_INTC_FCLK | O | MPU INTC | MPU INTC functional clock |
| I2ASYNC_FCLK | O | I2Async | I2Async functional clock |
| AXI_FCLK | O | AXI2OCP | AXI2OCP functional clock |
| ICECRUSHER_FCLK | O | ICE-Crusher | ICECrusher functional clock |

3.2.1.2 Reset Distribution

Resets to the MPU subsystem are provided by the PRCM module and controlled by the clock generator module. There are as many reset signals as power domains. For details about power domains, see [Section 3.3.2.1](#). [Figure 3-4](#) shows the reset scheme of the MPU subsystem.

Figure 3-4. MPU Subsystem Reset Scheme

Table 3-2. MPU Subsystem Reset Signals

| Signal Name | I/O | Interface | Comments |
|--------------|-----|-----------|--|
| MPU_RST | I | PRCM | MPU power domain reset |
| Neon_RST | I | PRCM | Neon power domain reset |
| CORE_RST | I | PRCM | CORE power domain reset |
| MPU_RSTPWRON | I | PRCM | ICECrusher reset. It is active only on cold reset. |
| EMU_RST | I | PRCM | Emulation interconnect reset |
| EMU_RSTPWRON | I | PRCM | Emulation modules reset |

For details about clocks, resets, and power domains, see , *Power, Reset, and Clock Management*.

3.2.2 ARM Subchip

3.2.2.1 ARM Overview

The public ARM Cortex-A8 processor incorporates the technologies available in the ARM7 architecture. These technologies include Neon for media and signal processing and Jazelle RCT for acceleration of realtime compilers, Thumb-2 technology for code density and the VFPv3 floating-point architecture.

For details, see the public ARM Cortex-A8 Technical Reference Manual.

3.2.2.2 ARM Description

3.2.2.2.1 Public ARM Cortex-A8 Instruction, Data, and Private Peripheral Port

The AXI bus interface is the main interface to the ARM system bus. It performs L2 cache fills and noncacheable accesses for instructions and data. The AXI interface supports 64-bit wide input and output data buses. It supports multiple outstanding requests on the AXI bus and a wide range of bus clock-to-core clock ratios. The bus clock is synchronous with the core clock.

See the public ARM Cortex-A8 Technical Reference Manual for a complete programming model of the transaction rules (ordering, posting, and pipeline synchronization) that are applied depending on the memory region attribute associated with the transaction destination address.

3.2.2.2.2 MPU Subsystem Features

Table 3-3 is a list of main functionalities of the ARM core supported in the MPU subsystem for the device. The MPU subsystem implements the ARM7™ instruction set architecture.

Table 3-3. ARM Core Key Features

| Feature | Comment |
|------------------------------------|---|
| ARM version 7 ISA | Standard ARM instruction set + Thumb-2, Jazelle RCT Java accelerator, and media extensions. Backward-compatible with previous ARM ISA versions. |
| L1 Icache and Dcache | 16KB, 4-way, 64-byte cache line, and 128-bit interface. Note: L1 memories cannot be put in retention mode. |
| L2 Cache | The L2 cache and cache controller are embedded in the ARM core. For size, see Section 1.4, OMAP35xx Family . |
| TLB | Fully associative and separate ITLB with 32 entries and DTLB with 32 entries |
| CoreSight ETM | The CoreSight ETM is embedded in the ARM core. The 4KB buffer (ETB) exists at the device level. |
| Branch target address cache | 512 entries |
| Enhanced Memory Management Unit | Mapping sizes are 4KB, 64KB, 1MB, and 16MB. ARM MMU adds extended physical address ranges. |
| Neon | Enhances throughput for media workloads and VFP-Lite support |
| Tightly coupled memory | Not present |
| AXI Bus | Separate 64-bit input and 64-bit output data buses. The public ARM Cortex-A8 has a single AXI bus interface. The AXI interface is shared by instruction fetches, data accesses, peripheral accesses and PLE (on-chip preload engine, previously known as DMA) accesses. DMA is available. |
| Low interrupt latency | Interrupt request (IRQ) and fast interrupt request (FIQ) are directly connected to ARM and INTC is before L3. |
| Vectored Interrupt Controller Port | Not used |
| JTAG based debug | Supported through debug access port (DAP) |
| Trace support | Supported through trace port interface unit (TPIU) |
| External coprocessor | Not supported |

For more information, see the public *ARM Cortex-A8 Technical Reference Manual*.

3.2.2.3 Clock, Reset, and Power Management

3.2.2.3.1 Clocks

[Table 3-4](#) shows the ARM functional clock. For configuration, see [Power, Reset, and Clock Management](#).

Table 3-4. MPU Subsystem Clock Signal

| Signal Name | I/O | Interface | Comments |
|-------------|-----|---------------------|------------------|
| ARM_FCLK | I | MPU Clock Generator | Functional clock |

3.2.2.3.2 Reset

[Table 3-5](#) lists the resets for the ARM. They include the power domain reset, Neon_RST, which resets the Neon module of the ARM subchip only, and MPU_RST, which resets the rest of the ARM subchip and the AXI2OCP and I2Async bridges.

Table 3-5. ARM Reset Signals

| Signal Name | I/O | Interface | Comments |
|-------------|-----|-----------|------------------------------|
| MPU_RST | I | PRCM | MPU power domain reset |
| Neon_RST | I | PRCM | Reset Neon only |
| EMU_RST | I | PRCM | Emulation interconnect reset |
| EMU_RSTPWON | I | PRCM | Emulation modules reset |

3.2.2.3.3 Power Management

For details, see [Section 3.3.2](#).

3.2.3 AXI2OCP and I2Async Bridges

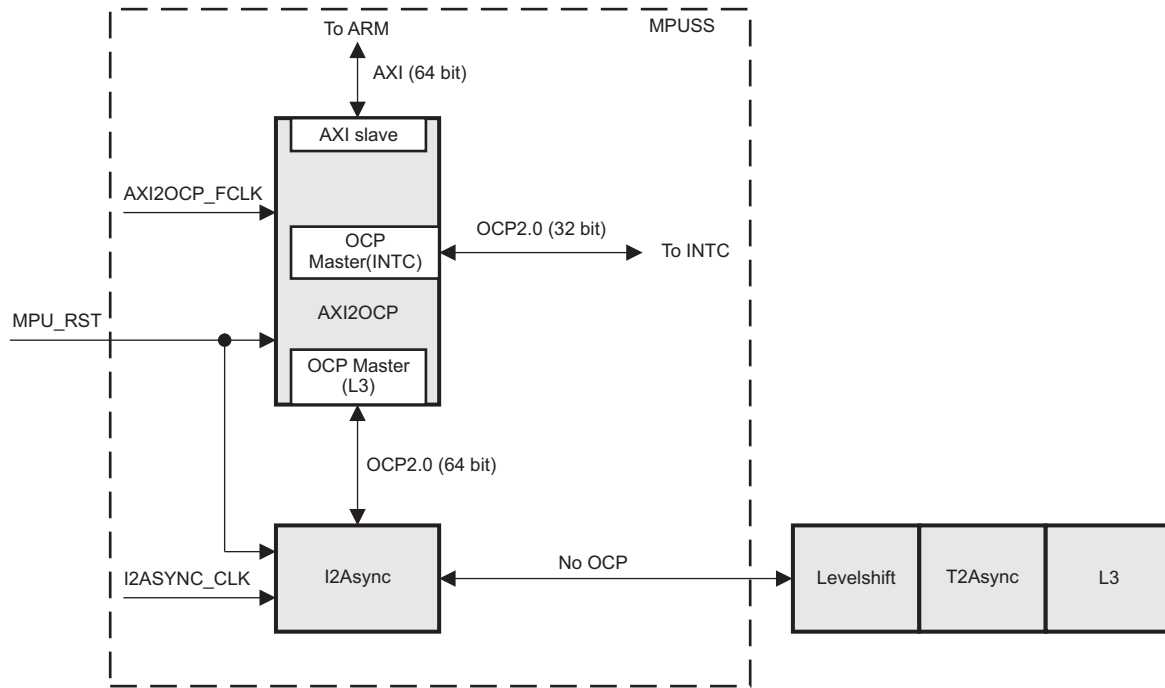

3.2.3.1 Bridges Overview

The AXI2OCP bridge connects the AXI bus on the ARM MPU to the OCP native L3 interconnect and INTC. It converts between AXI and OCP protocols and maintains a mapping of AXI tags to the OCP thread ID. This bridge is responsible for some minimal address decoding to determine where to forward requests between L3 and INTC.

Bridging to the L3 is accomplished through an asynchronous interface involving the I2Async and T2Async modules. The I2Async module in the MPU subsystem has an OCP port that is asynchronously transferred to the T2Async module and routed to the L3. T2Async is outside the MPU subsystem.

NOTE: The interface between I2Async and T2Async is not an OCP protocol.

[Figure 3-5](#) is an overview of the AXI2OCP and the L3 bridges.

Figure 3-5. Bridges Overview

mpuss-006

3.2.3.2 AXI2OCP Description

The AXI2OCP bridge key features are:

- Connection to the L3 interconnect through a 64-bit OCP port. Address bus is 32-bit.
- Connection to the INTC through a 32-bit OCP port (only single transactions are supported)
- Support of single-request-multiple-data (data handshaking) burst mode to pipeline requests to L3. Bursts with width less than 64 bits are converted as single requests on L3. This can affect system performance. The INTC does not support burst transfers
- Support of multiple outstanding requests
- Remapping of the AXI tags to five OCP threads:
 - Instruction fetch (Thread_IR)
 - Cacheable data read (Thread_CR)
 - Cacheable data write (Thread_CW)
 - Noncacheable data read (Thread_DR)
 - Noncacheable data write (Thread_DW)
- Interface to the L3 through the asynchronous bridge (I2Async)
- Emulation and support of boot-mode translation
- Translation of exclusive accesses to nonexclusive read/write in the bridge
- Boot mode address translation
- Force write nonposted support
- Debug related: Ready fail, force ready
- Interconnect attach neutralizer
- Narrow burst support
- Time-out counter for nonresponsive slaves on OCP

3.2.3.3 Clocks, Reset, and Power Management

3.2.3.3.1 Clocks

Table 3-6 lists the bridge functional clocks.

Table 3-6. Bridge Clock Signals

| Signal Name | I/O | Interface | Comments |
|--------------|-----|---------------------|--------------------------|
| AXI2OCP_FCLK | I | MPU Clock Generator | AXI2OCP functional clock |
| I2ASYNC_FCLK | I | MPU Clock Generator | I2Async functional clock |

3.2.3.3.2 Reset

Table 3-7 lists the bridge reset. It is a power domain reset that also resets the ARM.

Table 3-7. MPU Subsystem Reset Signal

| Signal Name | I/O | Interface | Comments |
|-------------|-----|-----------|------------------------|
| MPU_RST | I | PRCM | MPU power domain reset |

3.2.3.3.3 Power Management

For details, see [Section 3.3.2](#).

3.2.4 Interrupt Controller

For information, see [Chapter 8, Interrupt Controllers](#).

3.2.4.1 Clocks

Table 3-8 lists the INTC clocks.

Table 3-8. Bridge Clock Signals

| Signal Name | I/O | Interface | Comments |
|---------------|-----|---------------------|-----------------------|
| MPU_INTC_FCLK | I | MPU Clock Generator | INTC functional clock |
| MPU_INTC_ICLK | I | OCP Clock | INTC interface clock |

3.2.4.2 Reset

Table 3-9 lists the reset of the INTC. It is a power domain reset that resets the entire CORE power domain. For details, see [Chapter 8, Interrupt Controller](#) and [Power, Reset, and Clock Management](#).

Table 3-9. MPU Subsystem Reset Signal

| Signal Name | I/O | Interface | Comments |
|-------------|-----|-----------|-------------------------|
| CORE_RST | I | PRCM | CORE power domain reset |

3.2.4.3 Power Management

See [Chapter 8, Interrupt Controller](#), and [Power, Reset, and Clock Management](#).

3.3 MPU Subsystem Functional Description

3.3.1 Interrupts

The MPU INTC is connected to the MPU through the AXI2OCP bridge. It runs at half-processor speed. The INTC prioritizes all service requests from the system peripherals and generates an IRQ or an FIQ to the MPU, depending on the INTC programming. The INTC handles only interrupts directed to the MPU subsystem. A maximum of 96 requests can be steered/prioritized as MPU FIQ or IRQ interrupt requests. For details, see [Chapter 8, Interrupt Controller](#).

3.3.2 Power Management

3.3.2.1 Power Domains

The MPU subsystem is divided into five power domains controlled by the PRCM module, as shown in [Figure 3-6](#). The EMU and CORE power domains are not fully embedded in the MPU subsystem.

Figure 3-6. MPU Subsystem Power Domain Overview

Power-management requirements at the device level govern power domains for the MPU subsystem.

The device-level power domains are directly aligned with voltage domains and thus can be represented as a cross reference to the different voltage domains. [Table 3-10](#) shows the power domains of the MPU subsystem and the modules inside it.

Table 3-10. Overview of the MPU Subsystem Power Domain

| Functional Power Domain | Physical Power Domain per System/Module |
|-------------------------|--|
| MPU subsystem domain | ARM, AXI2OCP, I2Asynch Bridge, ARM L1 and L2 periphery logic and array, ICECrusher, ETM, APB modules |

Table 3-10. Overview of the MPU Subsystem Power Domain (continued)

| Functional Power Domain | Physical Power Domain per System/Module |
|-------------------------|---|
| MPU Neon domain | ARM Neon accelerator |
| CORE domain | MPU INTC |
| EMU domain | EMU (ETB, DAP) |

NOTE: L1 and L2 array memories have separate control signals to the MPU subsystem; thus are directly controlled by the PRCM module.

For information about the physical power domains and the voltage domains, see , *Power, Reset, and Clock Management*.

3.3.2.2 Power States

Each power domain can be driven by the PRCM module in four power states, depending on the functional mode required by the user.

Table 3-11. MPU Power States

| Power State | Logic Power | Memory Power | Clocks | Memory State Retention |
|-------------|-------------|--------------|-------------------------|------------------------|
| ACTIVE | On | On or Off | On (at least one clock) | All |
| INACTIVE | On | On or Off | Off | All |
| RETENTION | On or Off | On or Off | Off (all clocks) | All or part |
| OFF | Off | Off | Off (all clocks) | None |

For each power domain, the PRCM module manages all transitions by controlling domain clocks, domain resets, domain logic power switches, memory power switches, and memory retention. The MPU DPLL internally synchronizes the internal clocks, resets, and switches.

3.3.2.3 Power Modes

MPU DPLL power modes:

The PRCM.CM_AUTOIDLE_PLL_MPU[2:0] AUTO_MPU_DPLL bit field lets the MPU DPLL be put in an auto-idle mode when set to 0x1. In this mode, the MPU DPLL is automatically put in low power stop mode when the MPU clock is not required. It is also restarted automatically. [Table 3-12](#) describes the power modes of the MPU DPLL in auto-idle or manual mode. The manual modes (locked and low-power bypass) can be configured by the PRCM.CM_CLKEN_PLL_MPU[2:0] EN_MPU_DPLL bit field. The status of the MPU DPLL clock activity can be checked with the PRCM.CM_IDLEST_PLL_MPU[0] ST_MPU_CLK bit.

Table 3-12. MPU DPLL Power Modes

| Mode | System Input Clock | Clock Output | DPLL Power State | Condition |
|------------------|--------------------|--------------|------------------|---|
| Locked | ON | ON | ON | Software request (manual) or MPU wakes up (auto) |
| Low-power bypass | ON | ON | ON | Software request (manual) or on global reset release (auto) |
| Stop low power | OFF | OFF | ON | MPU is RET or OFF (auto). |
| OFF | OFF | OFF | OFF | Device is OFF (auto). |

The MPU DPLL power domain is switched off automatically by the PRCM module only when the device enters OFF mode.

MPU subsystem power modes:

The major part of the MPU subsystem belongs to the MPU power domain. Modules in this power domain can be off when the ARM processor is in OFF or standby mode. IDLE/WAKEUP control is managed by the clock generator block, but initiated by the PRCM module. The MPU standby status can be checked with the PRCM.CM_IDLEST_MPU[0] ST_MPU bit.

For the MPU to be on, the core (referred to here as the device core) power must be on.

Device power management does not allow INTC to go to OFF state when the MPU domain is on (active or one of the retention modes).

The Neon core is in independent power off mode when not in use. Enabling and disabling of Neon can be controlled by software.

CAUTION

The MPU L1 cache memory does not support retention mode, and its array switch is controlled with the MPU logic. For compliance, the L1 retention control signals exist at the PRCM boundary, but are not used. The ARM L2 can be put into retention independently of the other domains.

MPU retention modes are:

- Open switch retention (OSwR)
- Closed switch retention (CSwR)

These modes are described in [Table 3-13](#).

Table 3-13. MPU Retention Modes

| Name | Mode | ARM Logic | L1 | L2 |
|---------|------|-----------|-----|-----|
| Dormant | OSwR | OFF | OFF | RET |
| RET | CSwR | ON | ON | RET |

[Table 3-14](#) lists the supported operational power modes. All other combinations are illegal. The ARM L2, Neon, and ETM/debug can be powered up/down independently. The APB/ATB ETM/Debug column refers to all three features: ARM emulation, trace, and debug.

Table 3-14. MPU Subsystem Operation Power Modes

| Mode | MPU and ARM Core Logic | ARM L2 RAM | Neon | OMAP Core INTC | APB/ATB ETM/Debug | Comments |
|------|------------------------|------------|--------|----------------|---------------------|---|
| 1 | Active | Active | Active | Active | Disabled or enabled | Functional active run mode (ETM enabled mode when emulation/debug required. Production devices should have ETM disabled). |
| 2 | Active | Active | OFF | Active | Disabled or enabled | Functional active run mode. Neon disabled through software; Neon is internally clock-gated. |
| 3 | Active | RET | Active | Active | Disabled or enabled | Do not use; see ⁽¹⁾ . |
| 4 | Active | RET | OFF | Active | Disabled or enabled | Do not use; see ⁽¹⁾ . |

⁽¹⁾ The L2 can be put in retention mode regardless of other voltage domain states. The combination of Cortex Logic active and L2 in retention mode (modes 3 and 4) is legal, but results in incorrect execution of instructions with referencing data from L2. This combination must not be used.

Table 3-14. MPU Subsystem Operation Power Modes (continued)

| Mode | MPU and ARM Core Logic | ARM L2 RAM | Neon | OMAP Core INTC | APB/ATB ETM/Debug | Comments |
|------|------------------------|------------|---------|----------------|---------------------|--|
| 5 | Active | OFF | Active | Active | Disabled or enabled | Active mode; L2 is off. Controlled through software to the PRCM module. L2 context save and restore required or L2 flush. |
| 6 | Active | OFF | OFF | Active | Disabled or enabled | Active mode; L2 is off. Controlled through software to the PRCM module. L2 context save and restore required or L2 flush. |
| 7 | OFF | RET | OFF | OFF | Disabled or enabled | Lowest power sleep mode (dormant mode); L2 is in retention. Controlled through software to the PRCM module. ARM core and L1 context save and restore required or L1 flush. |
| 8 | Standby | Active | Standby | Active | Disabled or enabled | Standby mode. StandbyWFI (wait for interrupt) controlled to put into standby and wakeup through interrupt. |
| 9 | Standby | Active | OFF | Active | Disabled or enabled | Standby mode. StandbyWFI controlled to put into standby and wakeup through interrupt when Neon is off. |
| 10 | Standby | RET | Standby | Active | Disabled or enabled | Standby mode (retention mode). StandbyWFI controlled to put into standby and wakeup through interrupt when L2 is in retention. |
| 11 | Standby | RET | OFF | Active | Disabled or enabled | Standby mode (retention mode). StandbyWFI controlled to put into standby and wakeup through interrupt when L2 is in retention and Neon is off. |
| 12 | Standby | OFF | Standby | Active | Disabled or enabled | Standby mode. StandbyWFI controlled to put into standby and wakeup through interrupt when L2 is off. |

Table 3-14. MPU Subsystem Operation Power Modes (continued)

| Mode | MPU and ARM Core Logic | ARM L2 RAM | Neon | OMAP Core INTC | APB/ATB ETM/Debug | Comments |
|------|------------------------|------------|------|----------------|---------------------|---|
| 13 | Standby | OFF | OFF | Active | Disabled or enabled | Standby mode. Standby/WFI controlled to put into standby and wakeup through interrupt when L2 and Neon are off. |
| 14 | OFF | OFF | OFF | OFF | Disabled or enabled | Power-down mode |

In any mode where the MPU or Neon power domains are active, the MPU DPLL clocks must be active (modes 1, 3, and 5 require active clocks from the DPLL, while modes 7 and 8 do not).

Thus, the MPU DPLL must be in one of the following states:

- Locked
- Low-power bypass: inclk = on, clkout = on, power = on

When the MPU DPLL is not providing clocks, the MPU subsystem must be in a power mode where the MPU power domain, Neon power domain, debug power domain, and INTC power domain are in standby, RETENTION, or OFF state. The states of the MPU DPLL can be:

- Locked
- STOP low power
- OFF

CAUTION

The L2 can be put into retention mode regardless of other voltage domain states. The combination of ARM Logic active and L2 in retention mode (modes 3 and 4) is legal, but results in incorrect execution of instructions with referencing data from L2. This combination must not be used.

3.3.2.4 Transitions

Table 3-15 describes allowable transitions from power modes described in Table 3-14. For example, a transition from mode 13 to mode 4 is allowed, but the reverse is not true, because the L2 RET to OFF is illegal.

Any mode change that requires state saving or flush must be serialized. For example, L2 RET does not require state saving, so it can happen at the same time as power-down Neon. L2 off and Neon off cannot happen at the same time, because L2 flush and Neon state saving must be serialized. Standby mode can enter from active mode only by executing the WFI instruction.

Table 3-15. Power Mode Allowable Transitions

| From | To Power Mode | | | | | | | | | | | | | |
|------|---------------|---|---|---|---|---|---|---|---|----|----|----|----|----|
| | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 |
| 1 | Y | Y | Y | Y | Y | | | Y | | | | | | Y |
| 2 | Y | Y | Y | Y | | Y | | | Y | | Y | | | Y |
| 3 | Y | Y | Y | Y | | | Y | | | Y | | | | |
| 4 | Y | Y | Y | Y | | | Y | | | | Y | | | |
| 5 | Y | | Y | Y | Y | Y | Y | | | Y | | Y | | Y |
| 6 | | Y | Y | Y | Y | Y | Y | | | | Y | | Y | Y |
| 7 | Y | Y | Y | Y | | | Y | | | | | | | |
| 8 | Y | | Y | | | | | Y | | Y | | | | |
| 9 | Y | Y | Y | Y | | | | | Y | | Y | | | |
| 10 | Y | | Y | | | | | Y | | Y | | | | |
| 11 | Y | Y | Y | Y | | | | | Y | | Y | | | |
| 12 | Y | | Y | | Y | | | | | | | Y | | |
| 13 | Y | Y | Y | Y | Y | Y | | | Y | | Y | | Y | |
| 14 | Y | Y | Y | Y | Y | Y | Y | | | | | | | Y |

For more information about clocks, reset, power management, and wake-up events for the MPU subsystem, see , *Power, Reset, and Clock Management*.

3.4 MPU Subsystem Basic Programming Model

For detailed descriptions of registers used for MPU configuration, see , *Power, Reset, and Clock Management*, and [Chapter 8, Interrupt Controller](#).

3.4.1 Clock Control

For clock configuration settings, see , *Power, Reset, and Clock Management*.

3.4.2 MPU Power Mode Transitions

The following subsections describe transitions of different power modes for the MPU power domain:

- Basic power on reset
- MPU to standby mode
- MPU out of standby mode
- MPU power on from a powered-off state

3.4.2.1 Basic Power-On Reset

The following power-on reset (POR) sequence applies to initial power-up and wakeup from device off mode:

1. Reset DPLL, supply reference clock, program the MPU DPLL in applicable DPLL mode to generate clocks for MPU subsystem modules. This is controlled solely by the PRCM module.
2. Reset the INTC (CORE_RST) and the MPU subsystem modules (MPU_RST). The clocks must be active during MPU reset and CORE reset.

3.4.2.2 MPU to Standby Mode

The following MPU to standby mode sequence applies to initial power-up and wakeup from device off mode:

1. The ARM core initiates entering standby through software only (CP15 - WFI).
2. MPU modules requested internally by MPU subsystem to enter idle, after ARM core standby detected.
3. MPU is in standby output asserted for the PRCM module (all outputs ensured to be at reset values).
4. The PRCM module requests the INTC to enter idle mode. Acknowledge from INTC goes to the PRCM module.
5. The PRCM module starts to shut down clocks through DPLL programming.

NOTE: The INTC SWAKEUP output is a pure hardware signal to the PRCM module for the status of its IDLE request and IDLE acknowledge handshake.

NOTE: In debug mode, ICECrusher can prevent the MPU subsystem from entering IDLE mode.

3.4.2.3 MPU Out of Standby Mode

The following MPU out of standby mode sequence of operation applies to initial power-up and wakeup from device off mode:

1. PRCM must start clocks through DPLL programming.
2. Detect active clocking through status output of DPLL.
3. Initiate an interrupt through the INTC to wake up the ARM core from STANDBYWFI mode.

3.4.2.4 MPU Power-On from a Powered-Off State

1. To minimize the peaking of current during power up, DPLL power on, MPU power on, Neon power on, and Core power on (INTC) should follow the ordered sequence per power switch daisy chain.

NOTE: Before the MPU can be reset, the CORE power domain must be on, and reset, with the DPLL clocks on.

2. Follow the reset sequence as described in [Section 3.4.2.1](#), *Basic Power-On Reset*.

3.4.3 Neon Power Mode Transition

Because of the hardware sleep dependency between Neon and the MPU domain, when the Neon power domain transition is configured to automatic hardware-supervised mode (the CM_CLKSTCTRL_Neon[1:0] CLKTRCTRL_Neon bit field is set to 0x3), it cannot transition to idle mode unless the MPU goes to standby mode. The MPU domain must also be configured in automatic hardware-supervised mode (the CM_CLKSTCTRL_MPU[1:0] CLKTRCTRL_MPU bit field must be set to 0x3) for the Neon power domain transition to occur.

3.4.4 ARM Programming Model

For the complete programming model, see the public *ARM Cortex-A8 Technical Reference Manual*.

Power, Reset, and Clock Management

This chapter describes power, reset, and clock management.

4.1 PRCM Introduction to Power Management

This introduction contains the following information:

- Requirement and goal of power management in mobile devices
- State-of-the-art power-management techniques for maximizing battery life for mobile devices
- Essential architectural building blocks for power management
- Overview of the device power-management architecture

NOTE: Some features may not be available or supported in your particular device. For more information, see Chapter 1, the *Device Family* section, and your device-specific data manual.

4.1.1 Goal of Power Management

Power management (efficient use of the available limited battery resources of a mobile device) is one of the most important design aspects of any mobile system. It imposes strong control over limited available power resources to ensure they function for the longest possible amount of time.

The device architecture ensures maximum performance for user satisfaction (audio/video support) while offering versatile power-management techniques for maximum design flexibility, depending on application requirements.

4.1.2 Architectural Blocks for Power Management

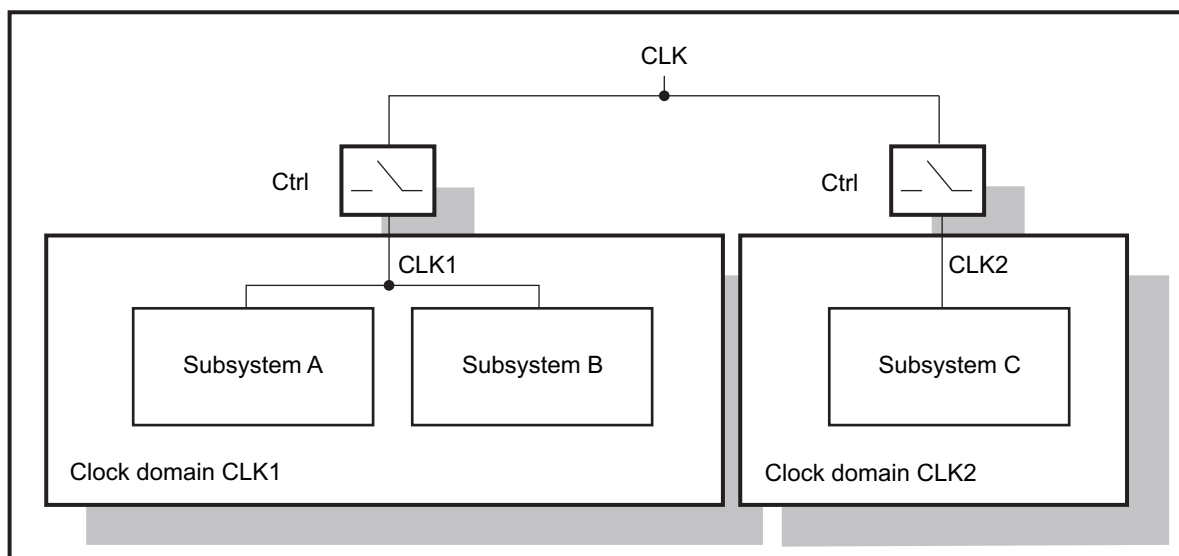

The processor does not support Voltage and Power domains. As a result, there is one voltage supply to the device processors and peripherals. There is also no support for switching power on or off to individual power domains. Although the power domain terminology is retained, the state of power to all domains is either ON when the device is supplied with external power, or OFF when the external power source to the device is off.

The device does support dynamic clock gating for power management through clock domains. A clock domain is a group of modules or subsections of the device that share a common clock.

4.1.2.1 Clock Domain

A clock domain is a group of modules fed with the same gated clock signal (see [Figure 4-1](#)). By gating the clock to each domain, it is possible to cut a clock to a group of inactive modules to lower their active power consumption. Thus, a clock domain allows control of dynamic power consumption by the device.

Figure 4-1. Generic Clock Domain

prcm-005

Table 4-1 lists the two possible states of the clock domain.

Table 4-1. States of a Clock Domain

| State | Description |
|--------|---------------------------------------|
| Active | The domain clock is running. |
| Idle | The domain clock is stopped or gated. |

4.1.2.2 Power Domain

Some members of the device family support independent control of power to subsections of the device (called Power Domains) via independent power switches. While retaining some of the Power Domain terminology, this device does not support independent Power Domain control. The state of all Power Domains in the device is either ON when the device is externally supplied with power or OFF when the device is completely powered down. In effect, the entire device is a single power domain.

4.1.2.3 Voltage Domain

Whereas some members of the device family have subsystems grouped into voltage domains that can be supplied by independently scalable voltage regulators, the device has its core subsystems all in a single voltage domain. Therefore, the voltage domain concept does not apply to this device.

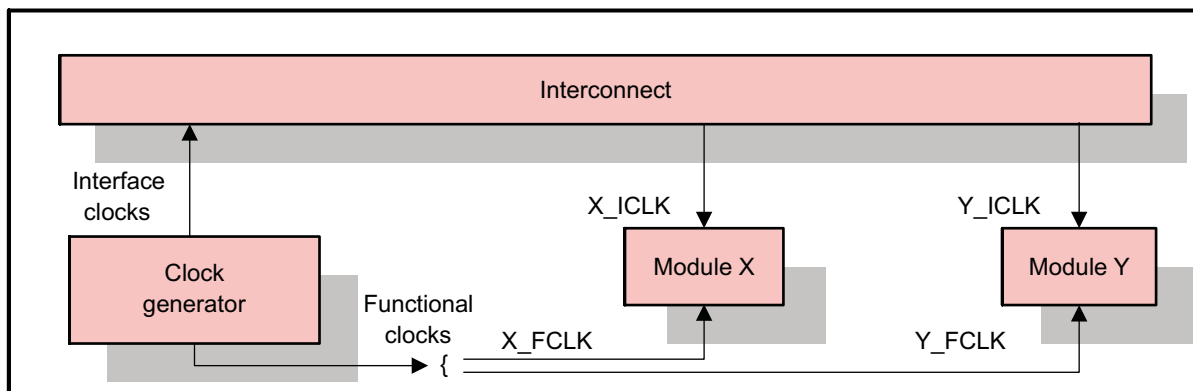

4.1.3 Device Power-Management Architecture

The device supports a clock distribution and control architecture, which is described in the following sections.

4.1.3.1 Module Interface and Functional Clocks

The clocks delivered to the modules in the device are divided into two categories: interface clocks and functional clocks (see Figure 4-2).

Figure 4-2. Functional and Interface Clocks

prcm-009

Interface clocks have the following characteristics:

- They ensure proper communication between any module/subsystem and the interconnect.
- In most cases, they supply the module interface and registers.
- A typical module has one interface clock, but it can have several.
- They are synchronous across the entire device, because the interconnect fabric is itself fully synchronous.
- Interface clock management is done at the device level.
- From the standpoint of the power, reset, and clock management (PRCM) module, an interface clock is distributed through the device interconnect and is identified with an _ICLK suffix.

Functional clocks have the following characteristics:

- They supply the functional part of a module or a subsystem.
- Each module can have several functional clocks, or none at all. A module may or may not require its functional clocks to be active (nonidle).
- Several modules can share the same functional clock signals, but the branches of the clock tree are not balanced between the modules.
- From the PRCM standpoint, a functional clock is directly distributed to the related modules through a dedicated clock tree. It is identified with an `_FCLK` suffix.

NOTE: At the module level, the interface clocks are always fed by the interface clock outputs of the PRCM. The functional clocks are fed either by a PRCM functional clock output or a PRCM interface clock output. In the latter case, the functional and interface clocks of the module inherit capabilities (autoidle features) from the PRCM interface clock (see [Section 4.7, Clock Manager Functional Description](#)).

4.1.3.2 Autoidle Clock Control

The device supports an autoidle clock control scheme for the module interface clocks. With this control scheme, PRCM can automatically activate and deactivate the interface clock of any device module, depending on its operating mode. This scheme executes under hardware control and is transparent to the software. This scheme identifies two module types in the device: the target and the initiator modules, or subsystems.

NOTE: The functional clocks do not have the autoidle clock scheme, and the software must gate the functional clock of each module when it is not needed.

Initiator

An initiator can generate bus transactions (read, write, etc.) toward targets. It is considered to be active when it generates transactions. If it enters standby mode, it stops generating transactions. Because most initiators also support a target port for configuration purposes, they are both targets and initiators. Some examples of initiators are processors, direct memory access (DMA), and memory management unit (MMU).

Target

A target is a passive module that can process bus transactions (that is, it reads/writes to memory-mapped registers). It is considered to be active when its interface clocks and some or all of its functional clocks are available so it can accept incoming transactions. A target can be put in idle mode by the PRCM, and in this mode its interface clock can be gated at any time. An idle module can still receive its functional clocks and generate interrupts and DMA requests. It can also generate asynchronous wake-up requests, if it is wakeup-capable.

Active, Idle, and Standby Modes

The PRCM module handles automatic clock control differently for initiator and target modules.

For the initiator module, the following hardware handshake scheme is employed:

1. The initiator, when switching from active to idle mode, signals its status to the PRCM.
2. The PRCM cuts off the interface clock to the initiator module.
3. When the initiator module must reactivate, it signals the PRCM, which reactivates its functional and interface clocks.

For the target module, the following hardware handshake scheme is employed:

1. When the PRCM confirms that the target module satisfies the idle conditions, it signals the target module.
2. The target module acknowledges the idle request of the PRCM, depending on its idle mode internal settings (for details about idle mode settings, see the chapter in the technical reference manual for the corresponding device module):
 - If the module is set to smart-idle mode, it terminates its current operations, and then acknowledges

- the idle request to the PRCM.
- If the module is set to force-idle mode, it acknowledges immediately, regardless of its current state. Because pending transfers, interrupts, and DMA requests can potentially be lost, special software care must be taken.
 - If the module is set to no-idle mode, it does not acknowledge the idle request. This forces the PRCM to maintain the clock active.
3. The PRCM cuts off the module clocks.
 4. The target module can be wakened by the PRCM when its wake-up conditions are satisfied (wake-up event). It activates the module clocks, and then signals the wakeup.
 5. The target module acknowledges the wake-up request.
 6. Some target modules can support wake-up capability. They can explicitly request the PRCM to activate their clock.

This automatic clock control ensures reduced dynamic power consumption of the device without any associated software overhead.

4.2 PRCM Overview

This section gives information about all modules and features in the high-tier device. See Chapter 1, *Device Family* section, to check availability of modules and features. For power saving considerations, ensure that clocks for unavailable or unused modules are gated.

4.2.1 Introduction

The power-management framework of the device significantly reduces dynamic power consumption to extend the life of the battery in the end-product. This framework incorporates support for state-of-the-art power-management techniques. It ensures optimal device operation with significantly reduced power consumption. The PRCM module, which is the enhanced power-management subsystem of the device, is the central control module for the clock, reset, and power-management signals in the device.

The device has the following features to support the different power-management techniques:

- Clock tree with selective clock-gating conditions
- Hardware-controlled reset sequencing management
- Support for hardware-controlled autogating of module clocks
- Support for low-power device standby mode

The PRCM module is the centralized management module for the power, reset, and clock control signals. It interfaces with all the components on the device for power, clock, and reset management through power-control signals. It integrates enhanced features to allow the device to adapt energy consumption dynamically according to changing application and performance requirements.

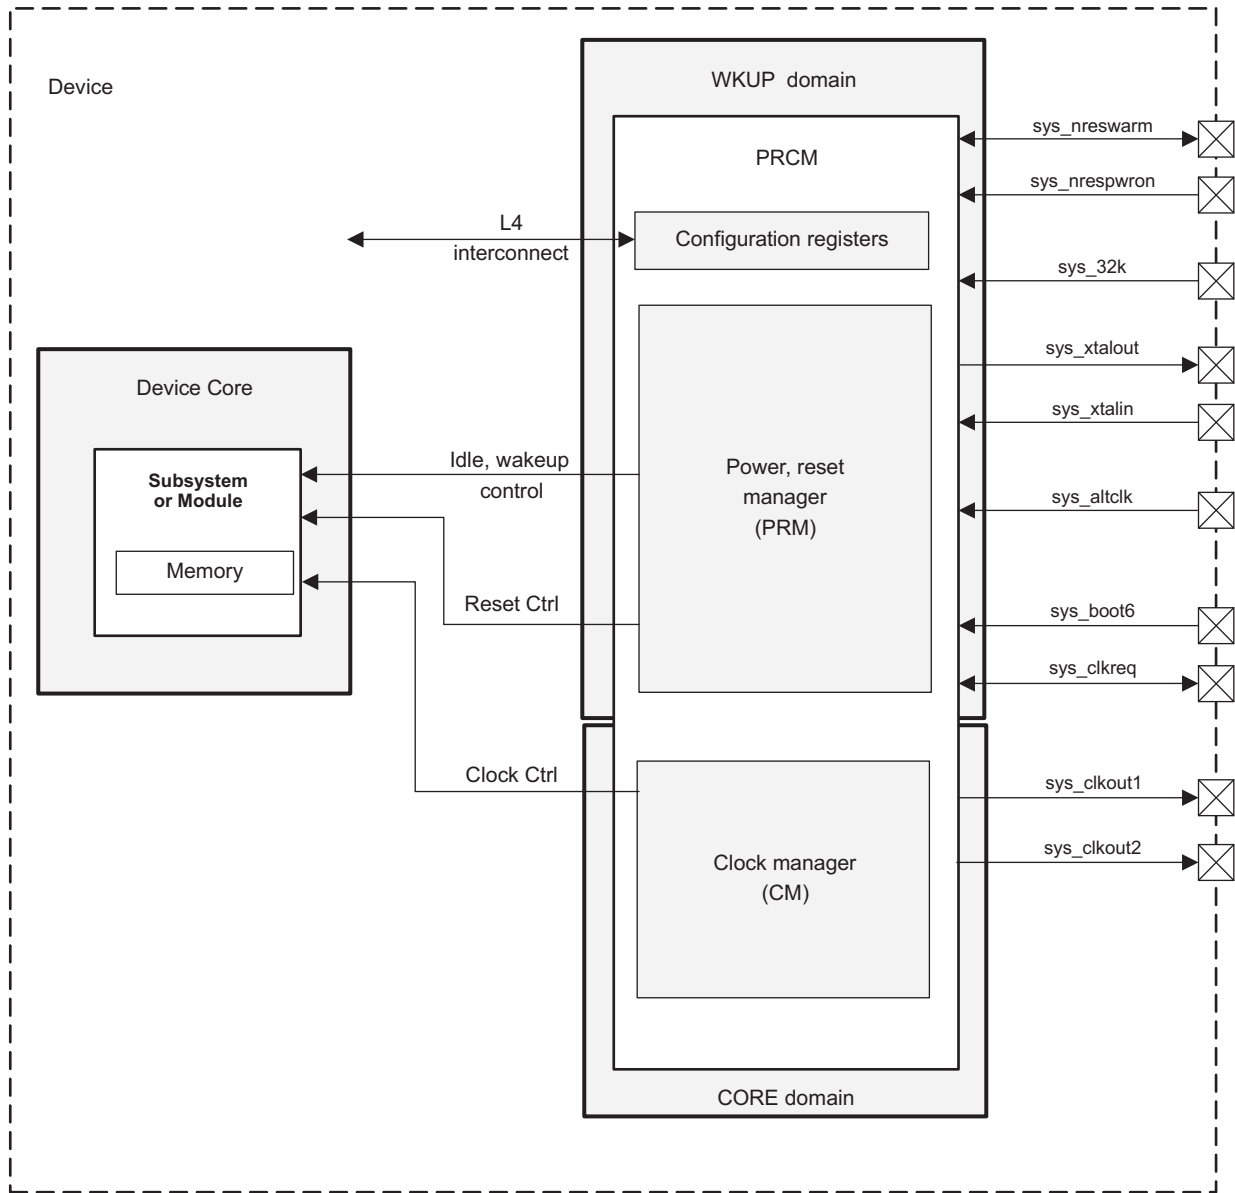

The PRCM module is composed of two main entities:

- Power reset manager (PRM): Handles the power, reset, wake-up management, and system clock source control (oscillator)
- Clock manager (CM): Handles the clock generation, distribution, and management

The PRCM is fully configurable through its L4 interface port.

[Figure 4-3](#) is an overview of the PRCM module and its internal connections with a generic power domain (a group of modules with related functionality).

Figure 4-3. PRCM Overview

prcm-010

4.2.2 PRCM Features

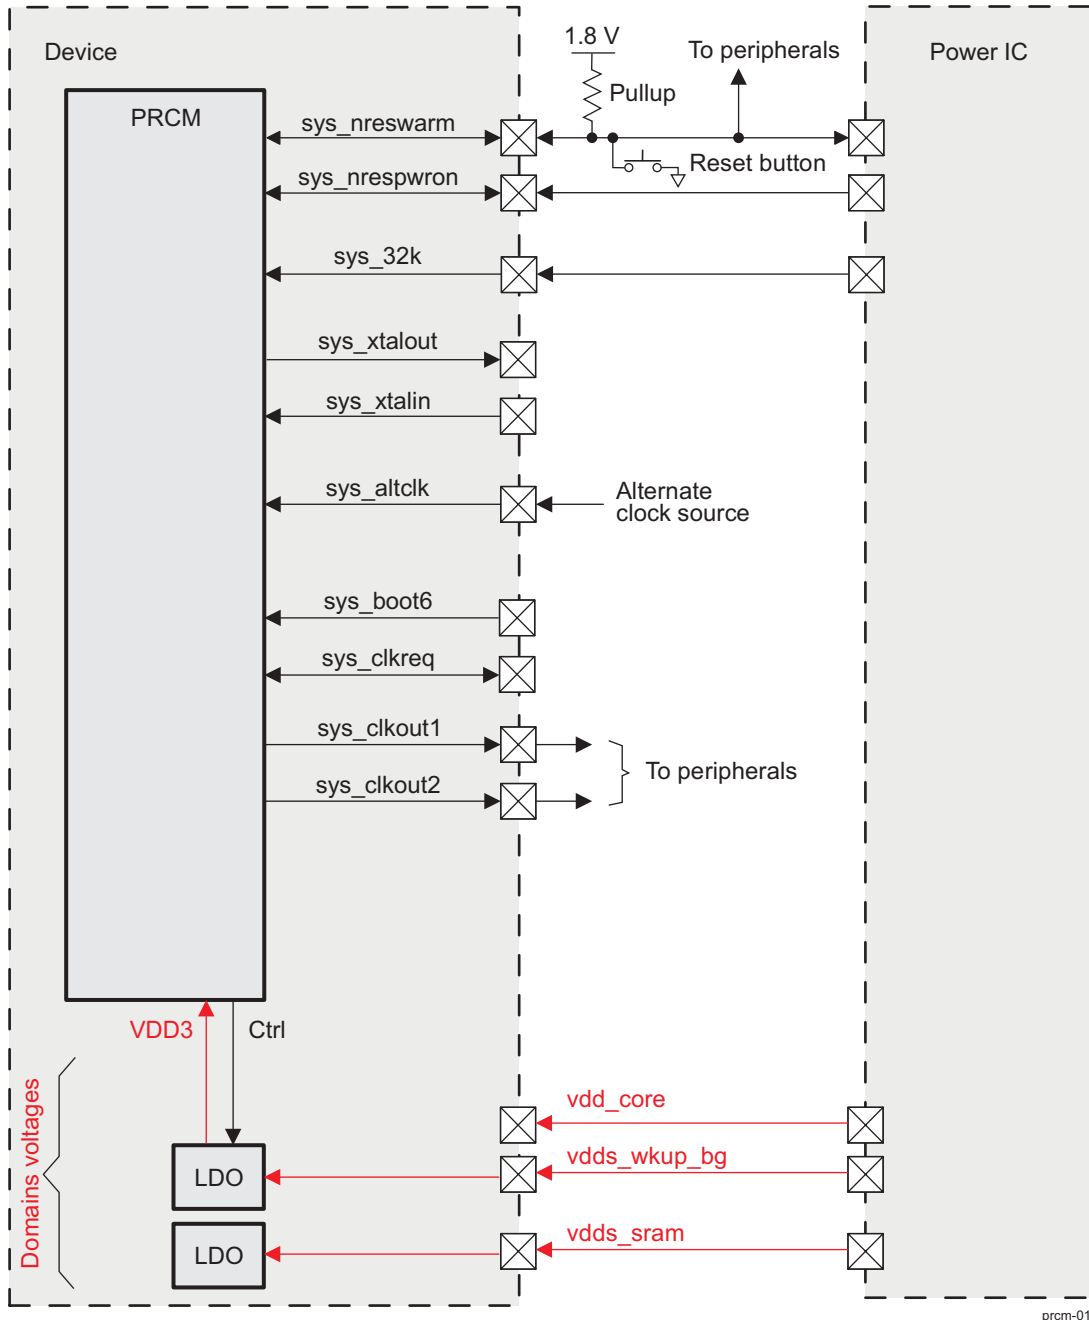

The PRCM module includes the following features:

- Handling proper idle/wake-up procedures
- Allowing both software and partial hardware control
- Monitoring and handling wake-up events
- Controlling system clock/reset input sources
- Managing and distributing clocks and resets with high granularity
- Handling power-up sequences
- Debug and emulation features

4.3 PRCM Environment

The PRCM module receives the external reset, clock, and power signals. Figure 4-4 shows the interface of the PRCM with external reset, clock, and power sources.

Figure 4-4. PRCM Functional External Interface (Detailed View)

NOTE: In the remainder of this chapter, the term "power IC" refers to a peripheral power source IC that is interfaced with the device.

The following sections describe the interfaces for the external clock, reset, and power sources.

4.3.1 External Clock Signals

The device has three external clock inputs: low frequency (sys_32k), high frequency (sys_xtalin), and an optional clock (sys_altclk). The device has two configurable clock outputs: sys_clkout1 and sys_clkout2. Figure 4-5 shows the external clock signals of the PRCM module. Table 4-2 lists the external clock signals, I/Os, and module reset values.

Figure 4-5. External Clock Interface

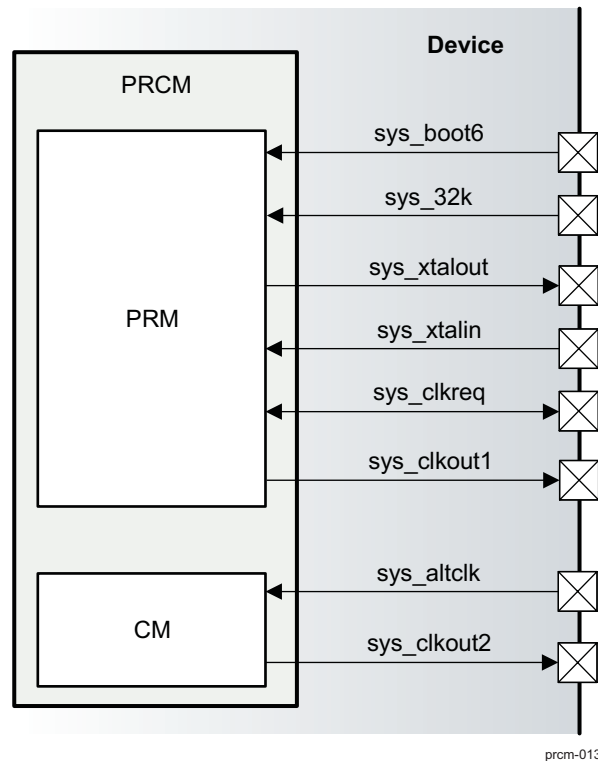

Table 4-2. External Clock Signal Descriptions

| Signal Name | I/O ⁽¹⁾ | Description | Module Reset Value |
|-------------|--------------------|--|--------------------|
| sys_boot6 | I | Boot oscillator mode control | Unknown |
| sys_32k | I | 32-kHz clock input | Unknown |
| sys_xtalout | O | Output of oscillator | 0 |
| sys_xtalin | I | Main input clock. Crystal oscillator clock (only at 26 MHz) or CMOS digital clock (at 26 MHz). | Unknown |
| sys_clkreq | I/O | Clock request to/ from device for system clock | 1 |
| sys_clkout1 | O | Configurable output clock 1 | 0 |
| sys_altclk | I | Alternate clock source selectable for USB (48 MHz) or NTSC/PAL (54 MHz) | Unknown |
| sys_clkout2 | O | Configurable output clock 2 | 0 |

⁽¹⁾ I = Input, O = Output

Figure 4-6 shows the PRCM external clock sources.

Figure 4-6. PRCM External Clock Sources

The system clock source can be either of the following:

- Internal oscillator with crystal connected between sys_xtalin and sys_xtalout
- A CMOS digital clock that arrives at the sys_xtalin pin

In the first option, the sys_clkreq signal is used in input mode to control sys_clkout1 and the internal clock oscillator. In the second option, the signal is used in output mode to request the external system clock.

An external pulldown or pullup tied on sys_boot6 determines whether the internal oscillator is used or an external clock source is supplied, respectively.

CAUTION
Only one clock source option can be used at a time.

An alternate clock input (sys_altclk) provides a precise clock source for 54 MHz, 48 MHz, or other frequencies (for example, 59 MHz or 49.04 MHz for VDAC).

For more information about external clock signals, see [Section 4.7.5](#), *External Clock Controls*.

4.3.2 External Reset Signals

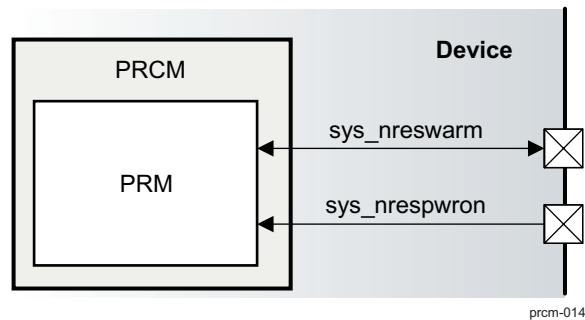

The device supports two reset signals: power-on (sys_nrespwron) and warm reset (sys_nreswarm).

sys_nrespwron is asserted at power up to reset the full logic in the device. sys_nreswarm can be activated at any time by an external device or an external reset push-button action (see [Figure 4-4](#)) to cause a global warm reset event.

Because sys_nreswarm is bidirectional, it can also be used to drive a reset of external devices. Any global warm reset source (for example, a push-button) causes sys_nreswarm to be driven out and maintained for a limited length of time at the boundary of the device. In this way, the device and its related peripherals are properly reset together.

The sys_nrespwron assertion also causes the sys_nreswarm assertion.

[Figure 4-7](#) shows the external reset signals. [Table 4-3](#) lists the external reset signals, I/Os, and module reset values.

Figure 4-7. External Reset Signals

prcm-014

Table 4-3. External Reset Signals Description

| Signal Name | I/O ⁽¹⁾ | Description | Module Reset Value |
|----------------------------|--------------------|-----------------|--------------------|
| <code>sys_nreswarm</code> | I/O | Warm-boot reset | 1 |
| <code>sys_nrespwron</code> | I | Power-on reset | Unknown |

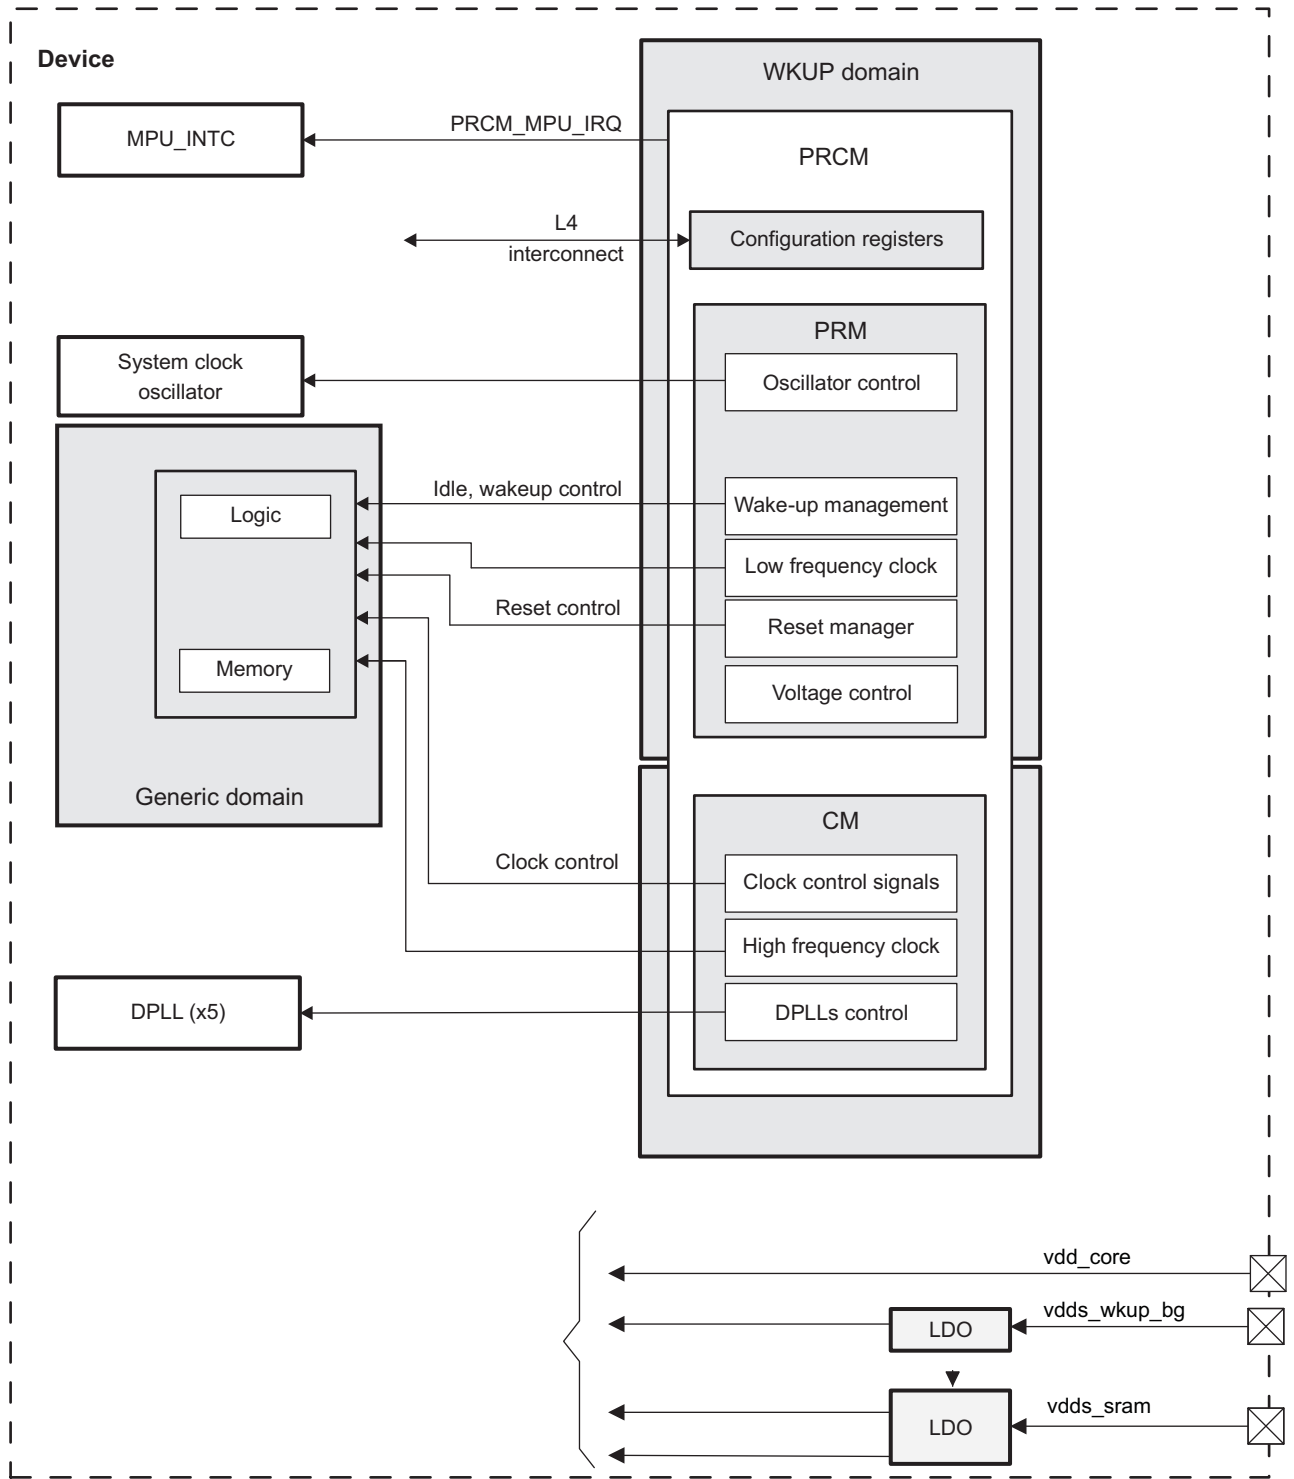

⁽¹⁾ I = Input, O = Output

4.4 PRCM Integration

The PRCM internal registers can be accessed for configuration and controlled through the WKUP L4 interconnect. In addition to the L4 interconnect, the PRCM internal module interface contains the following:

- A set of signals for idle/wake-up control for each module
- Clocks and reset signals
- Interrupt to the MPU subsystem interrupt controller (INTC)
- Digital phase-locked loop (DPLL) control commands for recalibration and bypass
- System clock oscillator control for device-level sleep/wake-up transitions

Figure 4-8. PRCM Integration

prcm-016

4.4.1 Power-Management Scheme, Reset, and Interrupt Requests

4.4.1.1 Resets

The PRM and CM modules are reset by independent reset signals (see [Table 4-4](#)).

Table 4-4. PRCM Reset Signals

| PRCM Subsystem | Reset Signal |
|----------------|----------------|
| PRM | PRM_RSTPWON |
| CM | CM_RSTPWON_RET |

The PRM module is reset by the cold reset signal PRM_RSTPWON. The CM module is reset by assertion of the CM_RSTPWON_RET signal.

The CM logic is reset on:

- Any global cold reset

The PRM logic is reset on:

- Any global cold reset

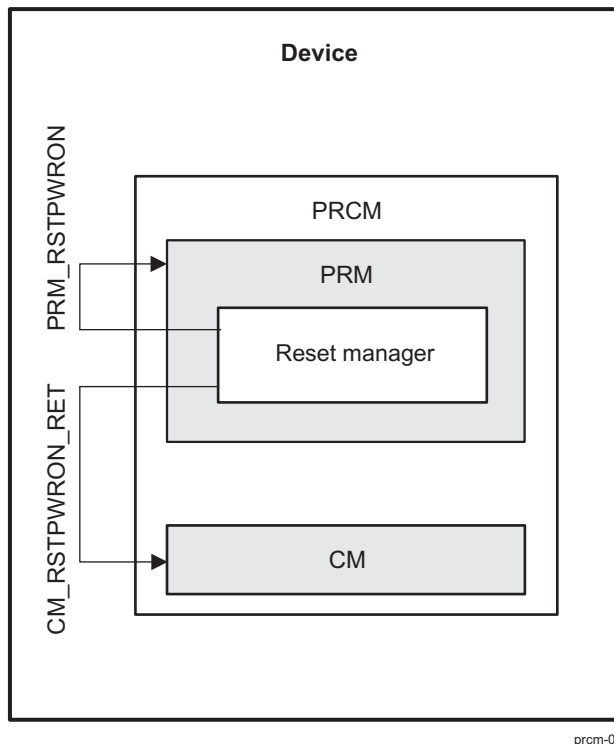

CM and PRM registers that are sensitive to a warm reset are also reset when a global warm reset occurs. However, the CM and PRM logic is not reset.

NOTE: At global cold reset:

- Only the device finite state-machine (FSM) in the PRM is operating on the 32-kHz clock, and it is released from reset on the release of the global reset.
- PRM logic operates on the system clock and is released from reset on release of the reset PRM_RSTPWON.

[Figure 4-9](#) shows the PRCM reset signals.

Figure 4-9. PRCM Reset Signals

4.4.1.2 Interrupt Requests

The PRCM module can generate an interrupt to the MPU interrupt controller module:

- PRCM_MPU_IRQ: Mapped to the MPU INTC module (M_IRQ_11 interrupt line)

4.5 PRCM Reset Manager Functional Description

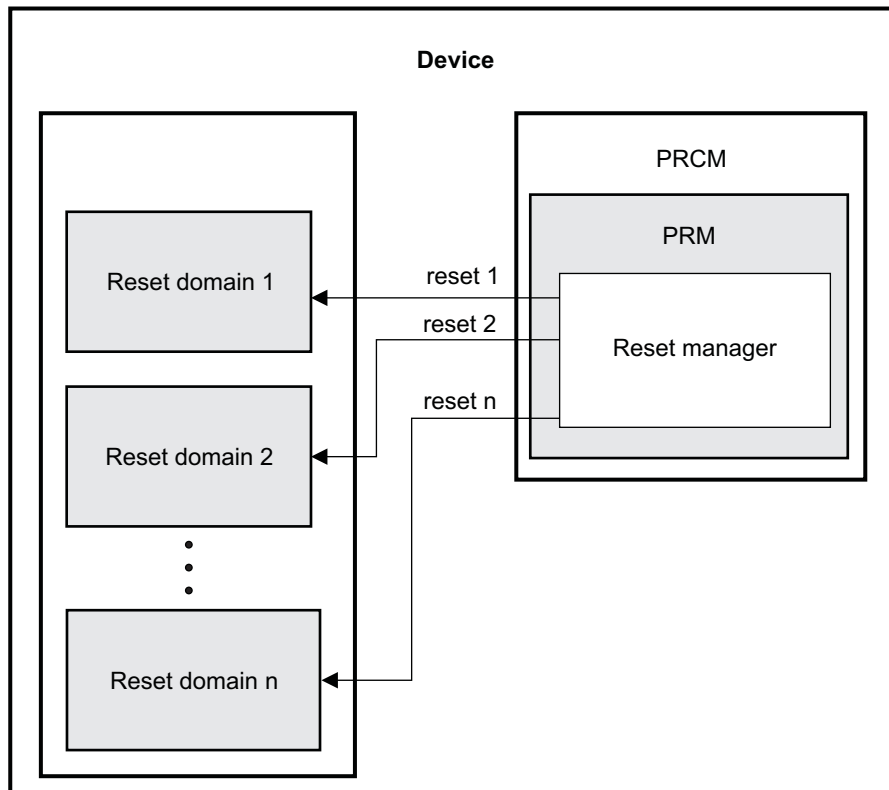

4.5.1 Overview

The PRCM manages the reset of all the modules in the device, including DPLLs.

Several reset domains are defined. A reset domain is defined by a unique reset signal that originates from the reset manager and is connected to one or multiple modules of the device. All the connected modules of the reset domain are reset simultaneously when the reset signal is asserted.

Figure 4-10 is an overview of the reset manager interface with a generic domain in the device.

Figure 4-10. Reset Manager Interface

prcm-019

Resets can be generated either by hardware sources or software control. For modules that can be reset by software control, a software-reset bit is implemented in their <module name>_SYSCONFIG configuration register. Software reset has the same effect on the module logic as a hardware reset.

Special reset control is available when the device operates under emulation control to reset specific reset domains.

NOTE: All reset assertion is asynchronous, and all reset signals are active low, except for the DPLL reset signals.

4.5.2 General Characteristics of Reset Signals

Reset signals can be categorized based on three criteria:

- Scope
- Occurrence
- Source type

4.5.2.1 Scope

A reset signal can be categorized according to its scope (the area of the device affected by that reset):

- Global reset: Affects the entire device; all modules are reset. Generally, when the device powers up or an abnormal operation is detected (secure watchdog timer overflows, the eFuse bad device is detected, etc.).
- Local reset: Affects one reset domain. When a software-reset control bit for a domain is set, only the group of modules within that domain is affected.

4.5.2.2 Occurrence

A reset signal can also be categorized depending on when the reset occurs:

- Cold reset: Occurs only on device power up or in certain emulation modes. The cold reset is a global reset that affects every module on the device. It usually corresponds to the initial power-on reset.
- Warm reset: Occurs when the device is in normal operating state. The warm reset is also a global reset, but it does not affect all the modules on the device. Usually, the device does not require a complete reboot on a warm reset. Several reset sources are types of warm resets, such as the global software reset and the watchdog reset.

Modules that behave differently in cold reset and warm reset have two reset signals: RST and PWRON_RST. These reset signals reconstruct warm reset and cold reset in modules that require them.

For a global warm reset, the PRCM performs the following sequence:

1. It applies a warm reset on all the modules.
2. It drives the sys_nreswarm reset output low and holds it for a specified length of time (programmed in the PRCM.PRM_RSTTIME[7:0] RSTTIME1 bit field).

A global warm reset does not apply to the following modules of the device:

- SDRC
- System control module (SCM) (I/O control)
- Part of PRM and CM registers (see note below)
- 32-kHz synchronization timer
- DPPLL3 (refer to)
- Emulation modules
- eFuse farm

NOTE: For information on the PRCM registers affected by the global warm reset see the Registers Mapping Summary tables in [Section 4.12, PRCM Register Manual](#).

4.5.2.3 Source Type

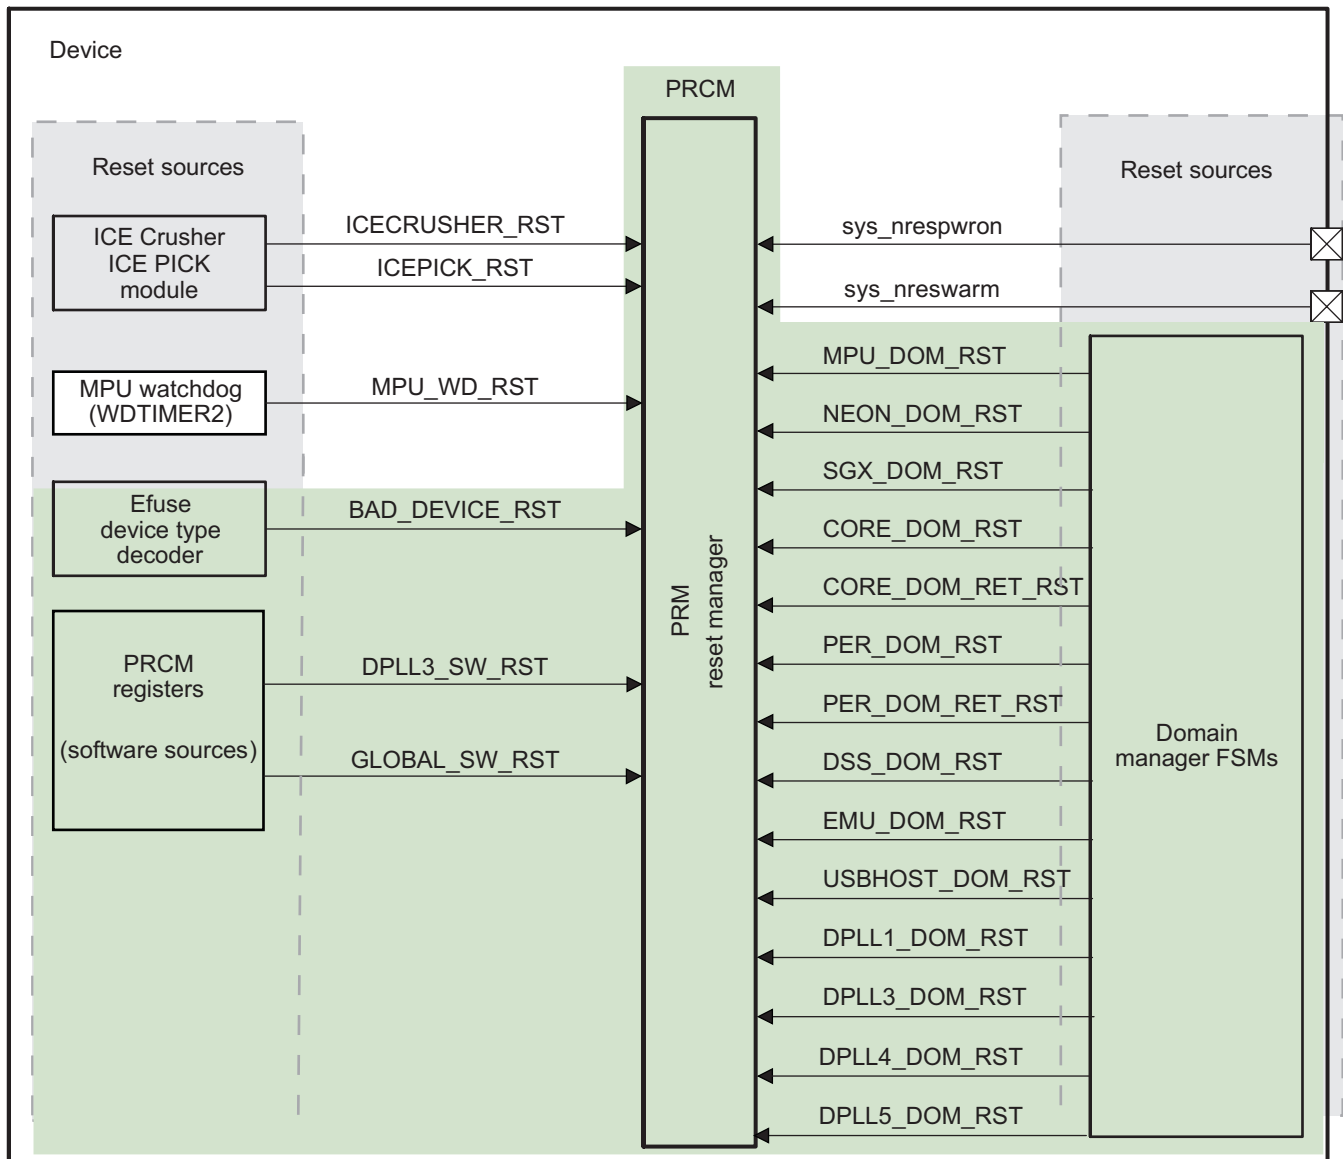

A reset can also be categorized depending on whether it is software-controlled or hardware-triggered:

- Software reset: Triggered by setting a bit in a configuration register of the PRCM module
- Hardware reset: Triggered by a signal from a hardware module inside or outside the PRCM module

4.5.3 Reset Sources

[Figure 4-11](#) is an overview of the reset sources.

Figure 4-11. Reset Sources Overview

*The green region in the figure represents the boundary of the PRCM.

prcm-020

4.5.3.1 Global Reset Sources

Table 4-5 lists the global reset sources of the device. The global reset source signals received by the reset manager trigger the reset of all the device modules. For all hardware reset signals, the source of the reset is identified; for the software reset signals, the reset triggering bit is identified.

Table 4-5. Global Reset Sources

| Type ⁽¹⁾ | Name | Source/Control | Description |
|---------------------|----------------|-------------------|---|
| H/C | sys_nrespwron | Input pin | The entire device is reset on power up. |
| H/C | BAD_DEVICE_RST | PRCM | Asserted when during the power-up sequence the device is identified as bad, after reading eFuses. |
| H/W | sys_nreswarm | Bidirectional pin | External hardware warm reset |

⁽¹⁾ H = Hardware reset, S = Software reset, C = Cold reset, W = Warm reset

Table 4-5. Global Reset Sources (continued)

| Type ⁽¹⁾ | Name | Source/Control | Description |
|---------------------|------------------|-------------------------------|---|
| H/W | SECURE_WD_RST | WDTIMER1 | Security watchdog timer overflow reset |
| H/W | MPU_WD_RST | WDTIMER2 | MPU watchdog timer overflow reset |
| H/W | MPU_SEC_VIOL_RST | Processor security FSM | Security violation reset request by the processor security FSM |
| S/W | GLOBAL_SW_RST | PRCM.PRM_RSTCTRL[1] RST_GS | Global software reset |
| S/W | DPLL3_SW_RST | PRCM.PRM_RSTCTRL[2] RST_DPLL3 | Local cold reset for DPLL3 and a global cold reset to the device. |
| H/W | ICEPICK_RST | ICEPick module | Global warm reset from ICEPick emulation module. |

4.5.3.2 Local Reset Sources

Table 4-6 lists the local reset sources of the device. A local reset source signal received by the reset manager resets only some of the device modules.

Table 4-6. Local Reset Sources

| Type ⁽¹⁾ | Name | Source/Control | Description |
|---------------------|------------------|----------------|---|
| H/C | CORE_DOM_RET_RST | PRCM | Asserted only for a domain transition from OFF to ACTIVE state as in the case of the device power-up. See note below for further clarification. |
| H/C | USB_DOM_RET_RST | PRCM | |
| H/C | PER_DOM_RET_RST | PRCM | |
| H/C | MPU_DOM_RST | PRCM | Asserted only for a domain transition from OFF to ACTIVE state as in the case of the device power-up. See note below for further clarification. |
| H/C | NEON_DOM_RST | PRCM | |
| H/C | SGX_DOM_RST | PRCM | |
| H/C | CORE_DOM_RST | PRCM | |
| H/C | PER_DOM_RST | PRCM | |
| H/C | DSS_DOM_RST | PRCM | |
| H/C | DPLL1_DOM_RST | PRCM | |
| H/C | DPLL3_DOM_RST | PRCM | |
| H/C | DPLL4_DOM_RST | PRCM | |
| H/C | DPLL5_DOM_RST | PRCM | |

⁽¹⁾ H = Hardware reset, S = Software reset, C = Cold reset, W = Warm reset

NOTE: For domains with <domain name>_DOM_RST and <domain name>_DOM_RET_RST, the reset sources are asserted together when the device transitions from OFF to ON power state, whereas only <domain name>_DOM_RET_RST is asserted on a global or local warm reset.

4.5.4 Reset Distribution

Each domain can contain one power-on reset (RSTPWRON) and one or more reset (RST) signals. These signals behave as follows:

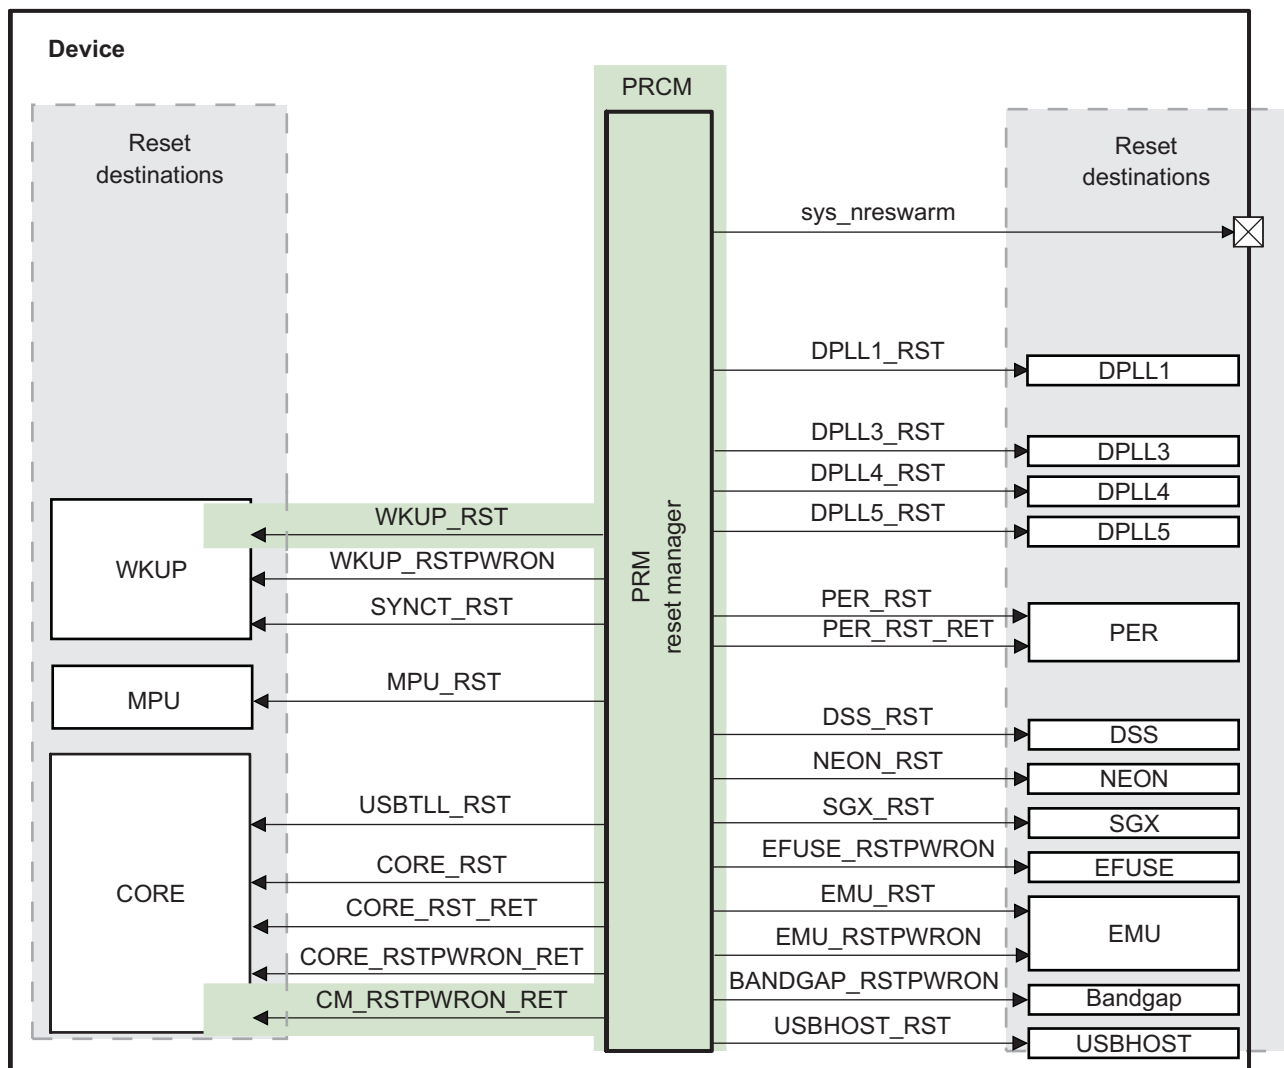

- On any global or local cold reset, both RST and RSTPWRON are asserted.
- On any global or local warm reset, only RST is asserted.

The CORE domain receives two additional legacy reset signals: retention reset (RST_RET) and power-on retention reset (RSTPWRON_RET). These signals behave as follows:

- On any global cold reset, both RST_RET and RSTPWRON_RET are asserted.
- On any global warm reset, only RST_RET is asserted.

Figure 4-12 shows the reset distribution among the domains.

Figure 4-12. Reset Destinations Overview

* The green region in the figure represents the boundary of the PRCM

prcm-021

4.5.5 Domain Reset Descriptions

4.5.5.1 MPU Domain

The MPU domain has one input and one output reset signal (see [Table 4-7](#)).

Table 4-7. MPU Domain Reset Signals

| Name | I/O ⁽¹⁾ | Source/Destination ⁽²⁾ | Reset Domain |
|------------------|--------------------|-----------------------------------|--|
| MPU_RST | I | PRM | Resets the MPU processor core and the asynchronous bridge in the MPU domain. |
| MPU_SEC_VIOL_RST | O | PRM | Global cold reset source to reset manager. Generated by the security FSM in the MPU subsystem. |

⁽¹⁾ I = Input, O = Output

⁽²⁾ Source for an input signal and destination for an output signal.

NOTE: The MPU_CLK is divided by 2 inside the MPU subsystem to generate the ARM_FCLK. This divider is only active when the DPLL is locked. (Refer to MPU Subsystem for information on ARM_FCLK).

4.5.5.2 NEON Domain

The NEON domain has one reset input signal (see [Table 4-8](#)).

Table 4-8. NEON Domain Reset Signal

| Name | I/O ⁽¹⁾ | Source | Reset Domain |
|----------|--------------------|--------|-----------------------------|
| NEON_RST | I | PRM | Resets the NEON coprocessor |

⁽¹⁾ I = Input, O = Output

4.5.5.3 CORE Domain

The CORE domain has eight input reset signals. (See [Table 4-9](#)).

Table 4-9. CORE Domain Reset Signals

| Name | I/O ⁽¹⁾ | Source/Destination ⁽²⁾ | Reset Domain |
|------------------|--------------------|-----------------------------------|---|
| CORE_RST | I | PRM | Resets parts of the three asynchronous bridges, MPU INTC, interconnects, GPMC, OCM, UART[1,2], HDQ, and HS USB, I2C[1..3], McBSP 1 and 5, McSPI [1..3], MMC[1..3], GPTIMER[10,11], D3D[1,2], SHAM1, RNG, AES[1..2], PKA, and SHAM2 |
| CORE_RST_RET | I | PRM | Resets part of the SDRC, SDMA, SMS, and MPU INTC |
| CORE_RSTPWON_RET | I | PRM | Resets part of the SDRC and SCM |
| CM_RSTPWON_RET | I | PRM | Resets the clock manager |
| CPEFUSE_RST | I | PRM | Reset the Customer Programmable EFUSE controller. Asserted under the same condition as that of CORE_RST. The CPEFUSE functional clock must be active to release the reset. This clock is enabled by default following a power-on reset. (For the reset sequence, see Section 4.5.9.2 .) |
| USBTLL_RST | I | PRM | Resets the USB TLL asynchronously |

⁽¹⁾ I = Input, O = Output

⁽²⁾ Source for an input signal and destination for an output signal

The CM logic is reset on:

- Any global cold reset

Because the CM logic is not reset in this case, the CM registers that are sensitive to a warm reset must also be reset synchronously with the L4 clock when a global warm reset occurs.

4.5.5.4 DSS Domain

The DSS domain has one reset input signal (see [Table 4-10](#)).

Table 4-10. DSS Domain Reset Signal

| Name | I/O ⁽¹⁾ | Source | Reset Domain |
|---------|--------------------|--------|-------------------------------------|
| DSS_RST | I | PRM | Resets the entire display subsystem |

⁽¹⁾ I = Input, O = Output

4.5.5.5 USBHOST Domain

The USBHOST domain has one reset input signal (see [Table 4-11](#)).

Table 4-11. USBHOST Domain Reset Signal

| Name | I/O ⁽¹⁾ | Source | Reset Domain |
|-------------|--------------------|--------|---|
| USBHOST_RST | I | PRM | Resets the entire HS USB Host subsystem |

⁽¹⁾ I = Input, O = Output

4.5.5.6 SGX Domain

The SGX domain has one reset input signal (see [Table 4-12](#)).

Table 4-12. SGX Domain Reset Signal

| Name | I/O ⁽¹⁾ | Source | Reset Domain |
|---------|--------------------|--------|---------------------------------|
| SGX_RST | I | PRM | Resets the entire SGX subsystem |

⁽¹⁾ I = Input, O = Output

4.5.5.7 WKUP Domain

The WKUP domain has three reset input signals and two reset output signals (see [Table 4-13](#)).

Table 4-13. WKUP Domain Reset Signals

| Name | I/O ⁽¹⁾ | Source/Destination ⁽²⁾ | Reset Domain |
|---------------|--------------------|-----------------------------------|--|
| WKUP_RST | I | PRM | Resets the GPTIMER[1,12], WDTIMER2, GPIO 1 and USIMOCP |
| WKUP_RSTPWON | I | PRM | Reset the wake-up control module and WDTIMER1 |
| SYNCT_RST | I | PRM | Resets the 32-kHz sync timer. This reset is directly connected to the sys_nrespwron global reset source. |
| SECURE_WD_RST | O | PRM | Global warm reset for PRM. Generated by WDTIMER1. |
| MPU_WD_RST | O | PRM | Global warm reset for PRM. Generated by WDTIMER2. |

⁽¹⁾ I = Input, O = Output

⁽²⁾ Source for an input signal and destination for an output signal

The PRM logic is reset on any global cold reset. Because the PRM logic is not reset in this case, the PRM registers that are sensitive to a warm reset must also be reset synchronously with the system clock when a global warm reset occurs.

4.5.5.8 PER Domain

The PER domain has two reset input signals (see [Table 4-14](#)).

Table 4-14. PER Domain Reset Signal

| Name | I/O ⁽¹⁾ | Source | Reset Domain |
|-------------|--------------------|--------|--|
| PER_RST | I | PRCM | Resets the UART3, McBSP[2,3,4], GPTIMER[2,...,9], WDTIMER3 modules |
| PER_RST_RET | I | PRCM | Resets the GPIO [2,...,6] modules |

⁽¹⁾ I = Input, O = Output

4.5.5.9 DPLL Domains

The DPLL domains for DPLL1, DPLL3, DPLL4 and DPLL5 each have one reset input signal.

Table 4-15. DPLL Domain Reset Signals

| Name | I/O ⁽¹⁾ | Source | Reset Domain |
|----------------|--------------------|--------|-------------------------|
| DPLL1_RSTPWRON | I | PRCM | Resets the DPLL1 module |
| DPLL3_RSTPWRON | I | PRCM | Resets the DPLL3 module |
| DPLL4_RSTPWRON | I | PRCM | Resets the DPLL4 module |
| DPLL5_RSTPWRON | I | PRCM | Resets the DPLL5 module |

⁽¹⁾ I = Input, O = Output

They are asserted for any type of global cold reset.

4.5.5.10 EFUSE Domain

The EFUSE domain has one reset input signal (see [Table 4-16](#)).

Table 4-16. EFUSE Domain Reset Signal

| Name | I/O ⁽¹⁾ | Source | Reset Domain |
|----------------|--------------------|--------|-----------------------------|
| EFUSE_RSTPWRON | I | PRCM | Resets the eFuse controller |

⁽¹⁾ I = Input, O = Output

This signal is asserted for any type of global cold reset.

4.5.5.11 BANDGAP Logic

The BANDGAP logic has one reset input signal (see [Table 4-17](#)).

Table 4-17. BANDGAP Logic Reset Signal

| Name | I/O ⁽¹⁾ | Source | Reset Domain |
|------------------|--------------------|--------|--------------------------|
| BANDGAP_RSTPWRON | I | PRCM | Resets the BANDGAP logic |

⁽¹⁾ I = Input, O = Output

This signal is asserted for any type of global cold reset.

4.5.5.12 Other Module Resets

Both [Figure 4-13](#) and [Figure 4-14](#) show the reset connectivity of the remaining modules. The CBASS, USBOTG subsystem, CPGMAC subsystem, VPFE, HECC, EMIF subsystem, and VBUS-to-OCF bridges are connected to the Warm Reset output of the PRM as shown in the [Figure 4-13](#).

Additionally, a software reset register is present in the system control module to allow software to reset these modules. Note that SW Reset is not self-clearing. Software needs to write '1' to put these modules in reset and write '0' to bring it out of reset. Please refer to the *System Control Module* chapter for more details on the software reset register.

Figure 4-13. Other Module Reset Distributions Overview

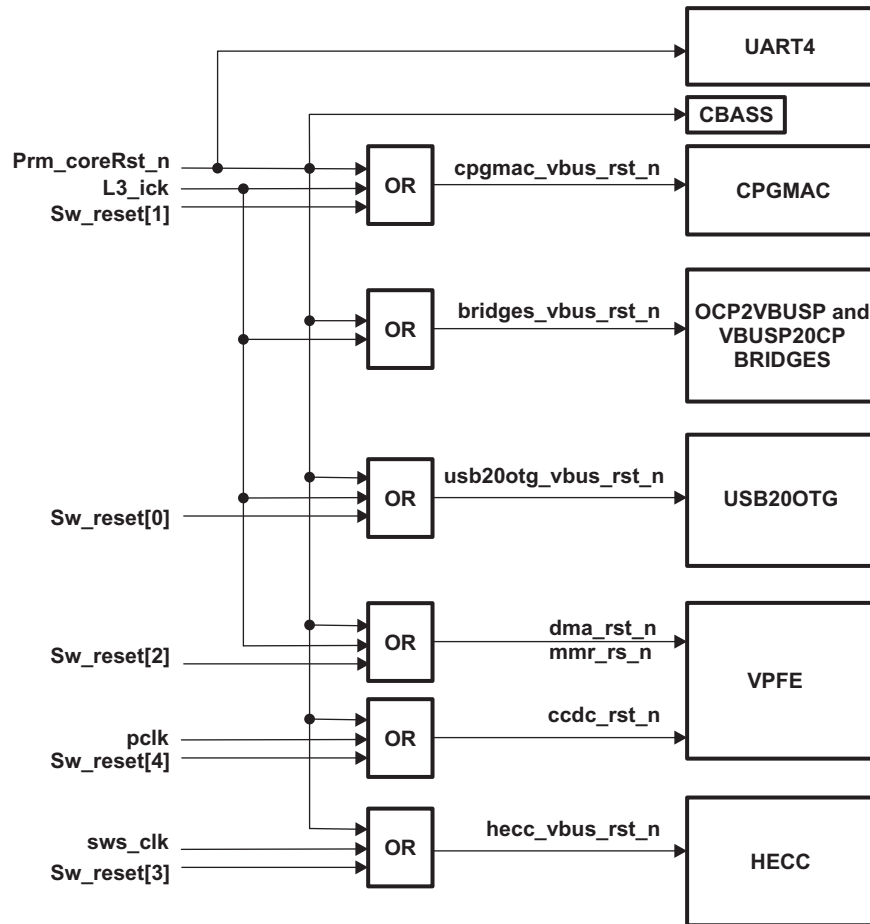

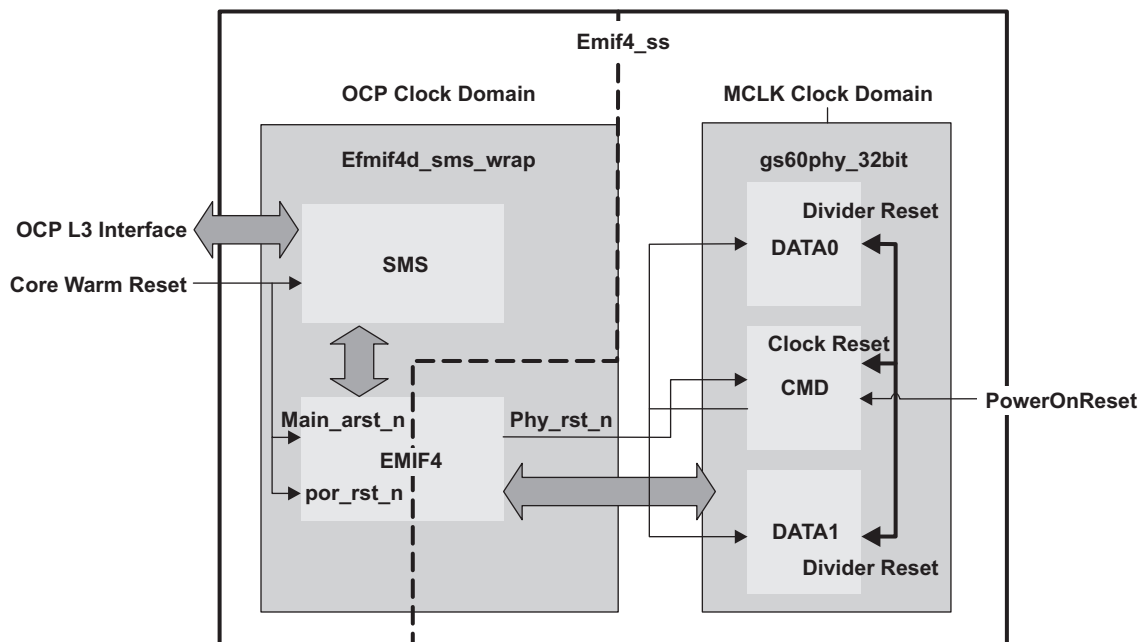

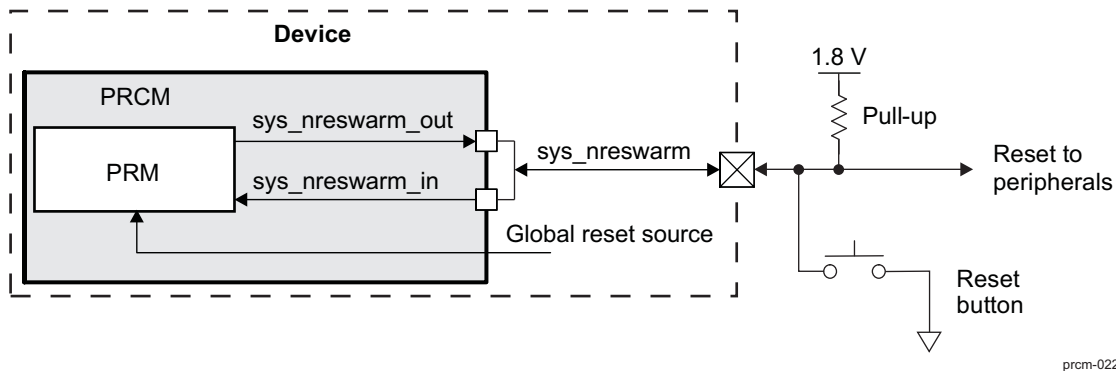

Figure 4-14. EMIF4 Reset Distributions Overview

4.5.5.13 External Warm Reset Assertion

Figure 4-15 shows the external warm reset interface.

Figure 4-15. External Warm Reset Interface

Any global reset source (internal or external) causes `sys_nreswarm_out` to be driven and maintained at the boundary of the device for at least the amount of time configured in the `PRCM.PRM_RSTTIME[7:0]` `RSTTIME1` bit field. This ensures that the device and its related peripherals are properly reset together.

NOTE: Because the system warm-reset output is implemented on a bidirectional pad, any input pulse on `sys_nreswarm` causes a global warm reset.

4.5.6 Reset Logging

The reset in the device is logged in two ways. First, dedicated registers in the PRCM (that is, the `RM_RSTST_<power domain>` and `PRM_RSTST` registers) log the reset source. Second, the SCM also logs the device reset activity in dedicated registers, for security purposes.

4.5.6.1 PRCM Reset Logging Mechanism

The reset status registers (`RM_RSTST_<power domain>` and `PRM_RSTST`) are reset asynchronously on assertion of a global cold reset. However, a reset status bit is always logged when the reset is released to the domain.

For this reason, after the assertion of a global cold reset, the reset status register is cleared to 0. When the domain reset is released, the register bit to log the global cold reset (that is, the `RM_RSTST_<power domain> [0] GLOBALCOLD_RST` bit) is updated to 1. For the same reason, the reset status register of domains released from reset by software is updated only when software releases the domain reset.

The assertion of a global cold reset prevents logging any other source of reset until after the release of the domain reset. This is valid in the following situations:

- A source of reset other than global cold reset is asserted before, during, or after the active period of a global cold source of reset and before the release of the domain reset signal.
- A source of reset other than global cold reset was asserted and then released, but a global cold reset source was asserted before the release of the domain reset signal.

4.5.6.2 SCM Reset Logging

The PRM exports reset the activity status signals to the SCM. For security purposes, the SCM uses these signals to log a reset status in the `SCM.CONTROL_SEC_STATUS` register. The reset activity status signal is asserted high when any source of reset to the domain is active.

It also provides reset status for the following global reset signals:

- Global cold reset
- Global warm reset
- Global warm secure watchdog reset (`SECURE_WD_RST`)

- Global warm security violation reset (MPU_SEC_VIOL_RST)

There is one reset activity status signal for each of the following domains:

- CORE
- DSS
- EMU
- SGX
- MPU
- NEON
- PER
- USBHOST

These signals are asserted high on assertion of any source of reset on the domain and logged. For information about the SCM, see the *System Control Module* chapter.

4.5.7 Reset Management Overview

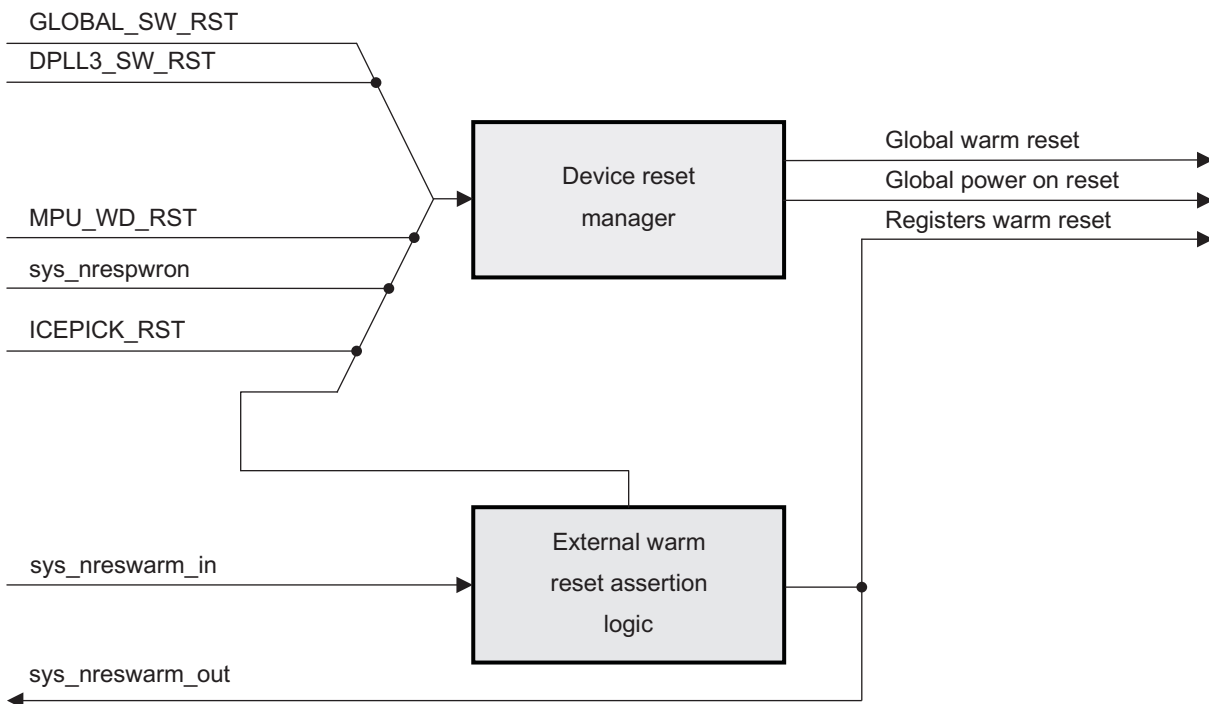

The reset management structure in the device can be considered as a 2-layered structure composed of multiple instances of the reset manager. In the first layer, a top-level reset manager, called the device reset manager, handles all the sources of global reset (cold and warm). It provides reset managers for the second layer, called local reset managers, and the global reset and global power-on reset signals.

Each domain has a minimum of one local reset manager. The local reset manager also receives resets, such as the software reset and domain power transition reset, from the local reset source for the domain.

Figure 4-16 through Figure 4-19 provide an overview of reset management in the device. They do not provide reset sequencing between the reset managers.

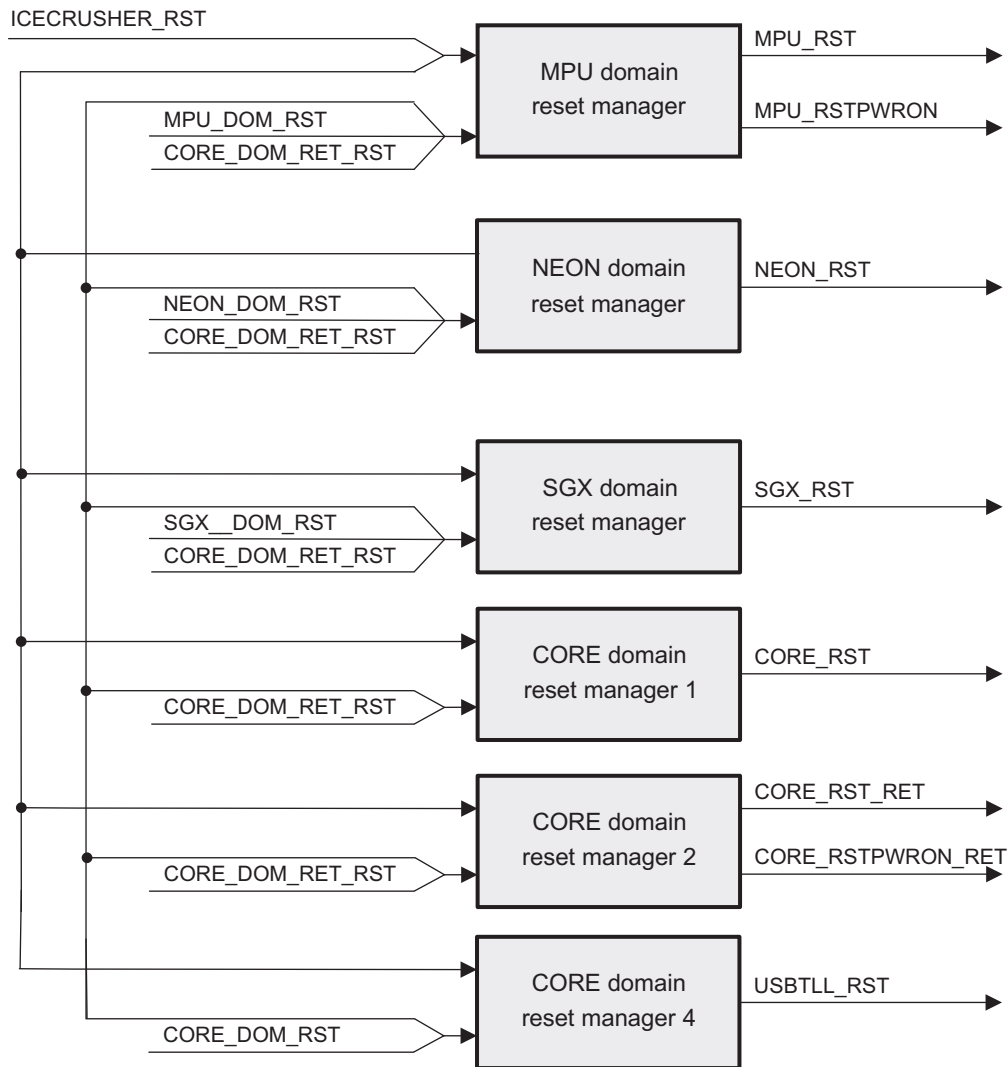

NOTE: The domain must be ready (that is, the domain clocks must be active) before its reset is released.

Figure 4-16. Device Reset Manager Overview

4.5.8 Reset Summary

[Table 4-18](#) and [Table 4-19](#) summarize the different sources of global and local resets and their actions on the reset signals.

Table 4-18. Global Reset Summary⁽¹⁾

| Power Domain | Domain Resets Signal | Reset Sources | | | | |
|---------------------|-------------------------|--------------------|------------------|---------------------|----------------|-------------------|
| | | Cold Reset | | Warm Reset | | |
| | | sys_nres pweron | DPLL3_ SW_RST | sys_nres warm_in | MPU_WD_ RST | GLOBAL_ SW_RST |
| MPU | MPU_RST | | | | | |
| NEON | NEON_RST | | | | | |
| SGX | SGX_RST | | | | | |
| CORE | CORE_RST | | | | | |
| | CORE_RSTPWRON | | | | | |
| | CORE_RST_RET | | | | | |
| | CORE_RSTPWRON_RET | | | | | |
| | CM_RSTPWRON_RET | | | | | |
| | USBTLL_RST | | | | | |
| WKUP | WKUP_RST | | | | | |
| | SYNCT_RST | | | | | |
| PER | PER_RST | | | | | |
| | PER_RST_RET | | | | | |
| DSS | DSS_RST | | | | | |
| USBHOST | USBHOST_RST | | | | | |
| EMU | EMU_RST | | | | | |
| | EMU_RSTPWRON | | | | | |
| | ICEPICK_RSTPWRON | | | | | |
| DPLL1 | DPLL1_RSTPWRON | | | | | |
| DPLL3 | DPLL3_RSTPWRON | | | | | |
| DPLL4 | DPLL4_RSTPWRON | | | | | |
| DPLL5 | DPLL5_RSTPWRON | | | | | |
| SR | SR_RST | | | | | |
| EFUSE | EFUSE_RSTPWRON | | | | | |
| BANDGAP | BANDGAP_RSTPWRON | | | | | |
| Device pad (output) | SYS_NRESWARM_OUT | | | | | |

⁽¹⁾ The shaded blocks identify the domain reset signals triggered as a result of the reset source signal (at the head of the column).

Table 4-19. Local Reset Summary⁽¹⁾

| Domain Resets | | Reset Sources | | | | |
|---------------------|-------------------|--------------------------|---------------------|------------------|--------------------------|--------------------|

⁽¹⁾ The shaded blocks identify the domain reset signals triggered as a result of the reset source signal (at the head of the column).

4.5.9 Reset Sequences

4.5.9.1 Power-Up Sequence

NOTE: Please reference the device-specific data manual for power-up sequencing.

4.5.9.2 CPEFUSE Reset Sequence

In the CPEFUSE reset sequence, Customer Programmable EFUSE is coupled with the SCM. Whenever the SCM is reset, the CPEFUSE cells are sensed. This sequence is initiated by the PRCM module and the SCM (hardware-controlled) after a device cold reset. Under these conditions, the CM part of the PRCM is released from reset, and, according to the configuration of the PRCM.CM_FCLKEN3_CORE[0] EN_CPEFUSE bit, the CPEFUSE functional clock is automatically restarted and the CPEFUSE_RST reset is released (de-asserted). The SCM completes the autoload sequence of the CPEFUSE. Software must poll the autoload completion status bit in the SCM before switching off the CPEFUSE functional clock.

Whenever the software must blow a CPEFUSE, it must ensure that the functional clock is enabled; it starts the autoload sequence by programming the SCM.

For information about the SCM, see the *System Control Module* chapter.

4.6 PRCM Power Manager Functional Description

4.6.1 Overview

4.6.1.1 Device Partitioning

Table 4-20 lists the device modules split over the domains.

4.6.1.2 Domain State Transitions

For each domain, the PRM manages state transitions, controlling domain clocks and resets.

Two types of power state transitions are possible:

- Sleep: Moving from a higher consumption power state (ACTIVE) to a lower consumption power state (INACTIVE).
- Wake-up: Moving directly from a lower consumption power state (INACTIVE) to the ACTIVE power state.

4.6.1.3 Device Power Modes

A device power mode is a specific functional combination of the states of all the domains of the device.

Unlike domain states, device power modes are not hardware-defined; they are defined by software as relevant combinations of the domain states.

There are two types of device power modes:

- Active: Any valid combination of domain states in which one or several domains are still active, regardless of whether any software is running.
- Standby: Any valid combination of domain states in which all the domains are in INACTIVE state.

4.6.2 Domain Implementation

4.6.2.1 Domain Dependencies

Besides the inner conditions to operate a state transition on a single domain, the device offers hardwired and software-programmable dependencies between the domains.

Two kinds of dependencies exist:

- Sleep dependencies: Used to start a sleep transition on a domain only if the related domains are in mute mode (not requesting any service from the linked domain)
- Wake-up dependencies: Used to initiate a wake-up transition on a domain as a consequence of a linked domain wake-up transition

Two dedicated sets of registers (PRCM.CM_SLEEPDEP_<domain> and PRCM.PM_WKDEP_<domain>) allow the setting of programmable dependencies.

[Section 4.8.5, Sleep and Wake-Up Dependencies](#), summarizes the possible dependency combinations between domains.

4.6.2.2 Domain Software Controls

If all conditions are met to initiate a domain state transition (that is, all the modules are idle/standby and the related clocks are shut down), the PRCM automatically manages the transition according to the following settings:

- Dependencies setting: The PRCM.CM_SLEEPDEP_<domain> registers and PRCM.PM_WKDEP_<domain> registers are used to set/clear programmable dependencies between domains.

Not all dependencies are programmable by software; some are hardwired and thus do not allow any control. For more information about the dependencies between domains, see [Section 4.8, Idle and Wake-Up Management](#), and [Section 4.11, Basic Programming Model](#).

- Event generator: Three registers (PRCM.PM_EVGENCTRL_MPU, PRCM.PM_EVGENONTIM_MPU, and PRCM.PM_EVGENOFFTIM_MPU) allow the MPU domain to be switched between on inactive mode. The PRCM.PM_EVGENONTIM_MPU and PRCM.PM_EVGENOFFTIM_MPU registers are used to set the durations of the on and inactive modes, respectively.

For details, see [Section 4.11, Basic Programming Model](#), and [Section 4.12, PRCM Registers Manual](#).

4.7 PRCM Clock Manager Functional Description

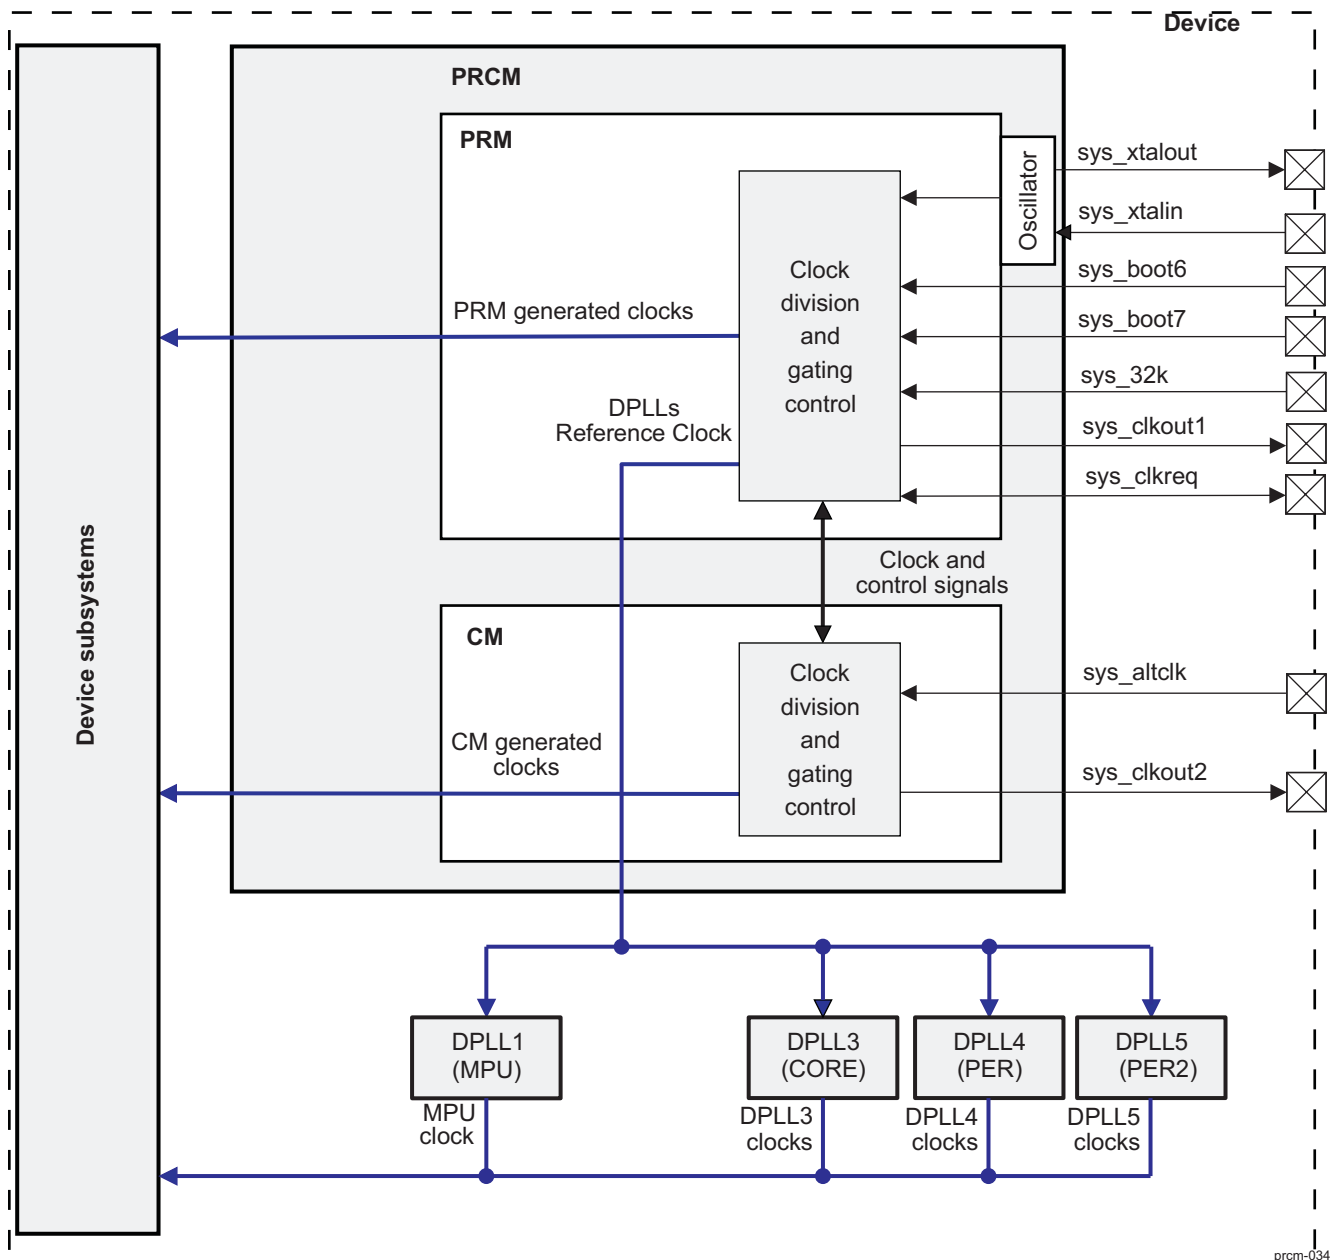

This section gives information about all modules and features in the high-tier device. See Chapter 1, *Device Family* section, to check availability of modules and features. For power saving considerations, ensure that clocks to unused domains and modules are properly gated.

4.7.1 Overview

The PRCM module provides control for clock generation, division, distribution, synchronization, and gating. It distributes the clock sources to all the modules in the device.

The device-level clock generation is handled by internal oscillators (the system clock oscillator and the 32-kHz oscillator for secure clock) and DPLLs; clock division and gating are handled by the PRM and the CM sections of the PRCM. Figure 4-20 shows the high-level clock-management scheme in the device.

Figure 4-20. PRCM Clock Manager Overview

prcm-034

4.7.1.1 Interface and Functional Clocks

The PRCM propagates two kinds of clocks:

- Interface clock: Ensures proper communication between any module and the system interconnects (L3 or L4). In most cases, the interface clock supplies the interface and registers of the module. For some modules, the interface clock is also used as the functional clock.
- Functional clock: Supplies the functional part of a module or subsystem. In some cases, a module or subsystem may require several functional clocks.

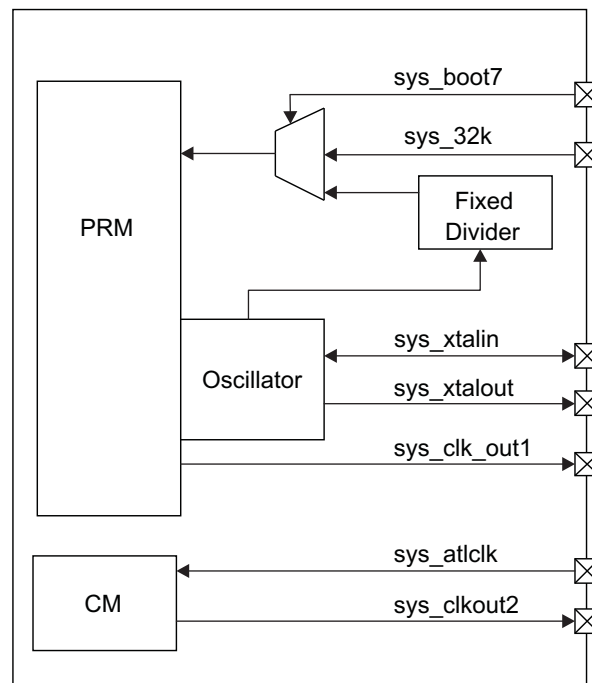

To be operational, a module requires functional clock(s); to communicate with other modules, it requires an interface clock. For example, the functional clock of a general-purpose timer (GPTIMER) must be active for it to run, but its interface clock can be turned off.

A module can use one or more optional functional clocks. Because an optional functional clock is used only for specific features of the module, it can be shut down without stopping the module activity (for example, 54 MHz for the DSS domain).

4.7.2 External Clock I/Os

Figure 4-21 shows the external clock I/Os of the device.

Figure 4-21. External Clock I/O

4.7.2.1 External Clock Inputs

4.7.2.1.1 32-kHz Always-On Clock

The 32-kHz clock is used for low-frequency operation (timers, denouncing, etc.). It also supplies the WKUP domain for operation in the lowest power standby mode. The device supports an external 32kHz clock signal or an internal 32kHz clock divided down from the external 26MHz high-frequency clock. The selection between external and internal 32kHz clock is done by sys_boot7 pin. The sys_32k input pin supplies the 32-kHz always-on clock (32K_FCLK clock) when the sys_boot7 pin is configured for external 32-kHz clock.

4.7.2.1.2 High-Frequency System Clock

The high-frequency system clock (SYS_CLK) is either supplied to the device from an external clock source through the sys_xtalin input pin or is generated internally by a local system clock crystal oscillator. In the latter case, a crystal is connected between the sys_xtalout and sys_xtalin device pins. The sys_boot[6] pin is used to set the oscillator operating mode (see [Figure 4-6](#)).

The source system clock can be 26 MHz and is internally divided by 2 to provide the standard frequencies (26 MHz becomes 13 MHz). It supplies the reference to the DPLLs and is also used by several modules. The system clock is activated in the device after the device power-on reset is released by the reset manager in the PRCM module.

The source-clock selection register (PRCM.PRM_CKSEL [2:0] SYS_CLKIN_SEL bit field) is set by the software to identify the input frequency of the system clock.

[Table 4-21](#) provides the system clock input configurations.

Table 4-21. System Clock Input Configurations

| Input Source | Device Pin Mapping | Description |
|----------------------------------|---|----------------------------------|
| Quartz | sys_xtalin and sys_xtalout | Internal oscillator is enabled. |
| Square clock (1.8-V CMOS signal) | sys_xtalin (sys_xtalout is not connected) | Internal oscillator is bypassed. |

NOTE: An external pullup or pulldown tied on the sys_boot6 input pin of the device determines whether the internal oscillator is used (oscillator mode) or an external clock source is supplied to the sys_xtalin input pin (bypass mode).

4.7.2.1.3 Alternate Clock

The sys_altclk pin can be used to provide an alternate 54-MHz, 48-MHz, or any other frequency clock.

4.7.2.2 External Clock Outputs

The device can output two clocks externally:

- sys_clkout1 can output an oscillator clock (12, 13, 16.8, 19.2, 26, or 38.4 MHz) at any time. The output oscillator clock can be controlled either by software or externally using sys_clkreq control.
- sys_clkout2 can output sys_clk (12, 13, 16.8, 19.2, 26, or 38.4 MHz), core_clk (CORE DPLL output), or 96-MHz or 54-MHz clocks. It can be divided by 2, 4, 8, or 16. This output is active only when the CORE domain is ACTIVE. Also, the selected source clock must be enabled by software. Enabling sys_clkout2 does not automatically request the required source clock.

4.7.2.3 Summary

[Table 4-22](#) summarizes the external clock I/O.

Table 4-22. External Clock I/Os

| Name | I/O ⁽¹⁾ | Source/Destination | Description |
|-------------|--------------------|--------------------|--|
| sys_xtalin | I | Oscillator | Main input clock. Crystal oscillator clock (only at 26 MHz) or CMOS digital clock (at 26 MHz). |
| sys_xtalout | O | Oscillator | Output of oscillator |
| sys_clkout1 | O | PRCM | Configurable output clock 1 |
| sys_clkout2 | O | PRCM | Configurable output clock 2 |
| sys_32k | I | PRCM | 32-kHz clock input |
| sys_altclk | I | PRCM | Alternate selectable clock source for UARTs or NTSC/PAL. It can be 54 MHz, 48 MHz, or any frequency. |

⁽¹⁾ I = Input, O = Output

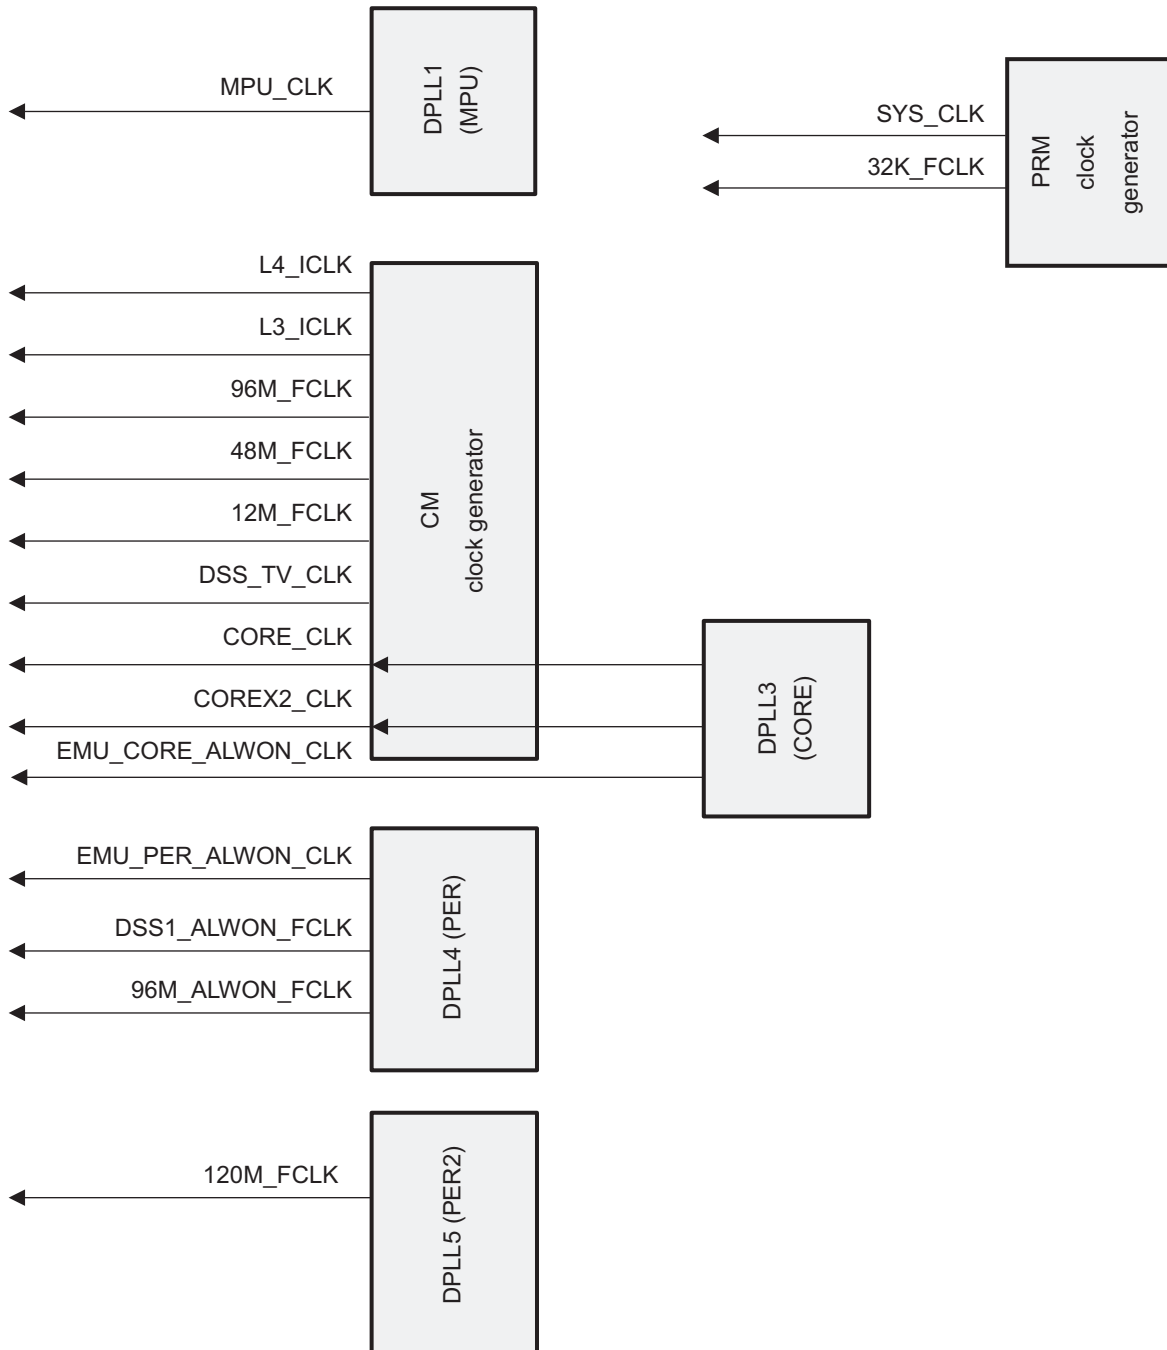

4.7.3 Internal Clock Generation

The device generates internal clocks from four sources:

- PRM
- CM
- DPLLs
- 32-kHz oscillator

Figure 4-22 shows the internal clock generation scheme of the device.

Figure 4-22. Internal Clock Sources

prcm-036

4.7.3.1 PRM

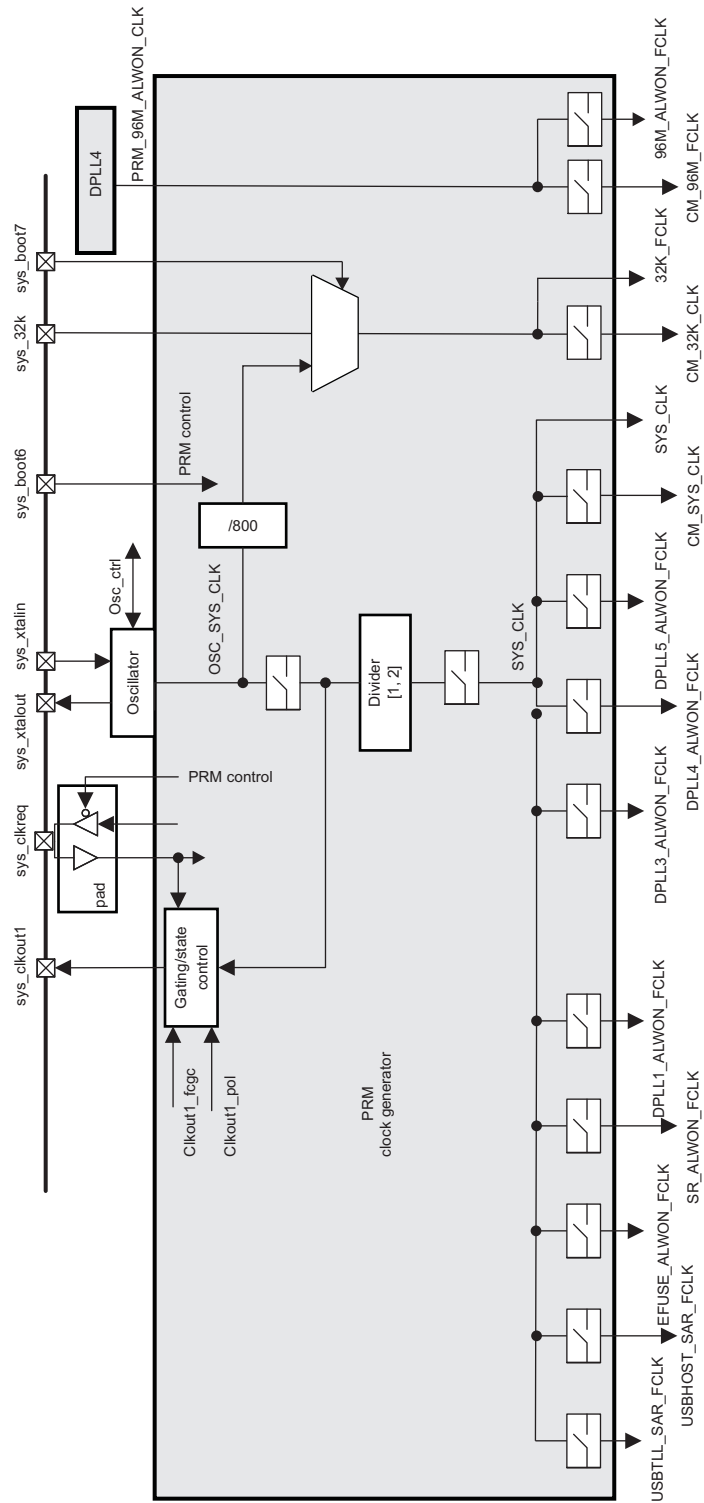

The PRM resides in the WKUP domain. It handles the generation of the 32-kHz low-frequency clocks and the high-frequency system clocks from the SYS_CLK. It also manages the clock oscillator and the external clock output sys_clkout1.

SYS_CLK is generated by the internal oscillator or supplied as the external clock signal on the sys_xtalin pin. It supplies most of the clocks in the device. SYS_CLK is also the source of the WKUP domain interface clocks.

It also handles the gating and distribution of the 96-MHz clock from DPLL4 to the CM and the PER domain modules.

[Figure 4-23](#) is the functional overview of the PRM. The other clocks in the figure are explained in the following sections.

Figure 4-23. PRCM Clock Generator

prcm-037

4.7.3.2 CM

The CM clock generator generates interface clocks and peripheral functional clocks for most of the modules. It also controls DPLL3, DPLL4, and the external peripheral clock output sys_clkout2 (see [Figure 4-24](#)).

The CM is in the CORE domain.

DPLL3 receives SYS_CLK from the PRM and generates CORE_CLK through the CM. CORE_CLK is the source for the interface clocks (L3 and L4) and the functional clock. The L3 and L4 interface clocks supply the device interconnects and all module interface clocks. The L4 clock is divided to supply the reset managers (PRM) in the WKUP domain. The clocks derived from CORE_CLK are fully balanced over the device.

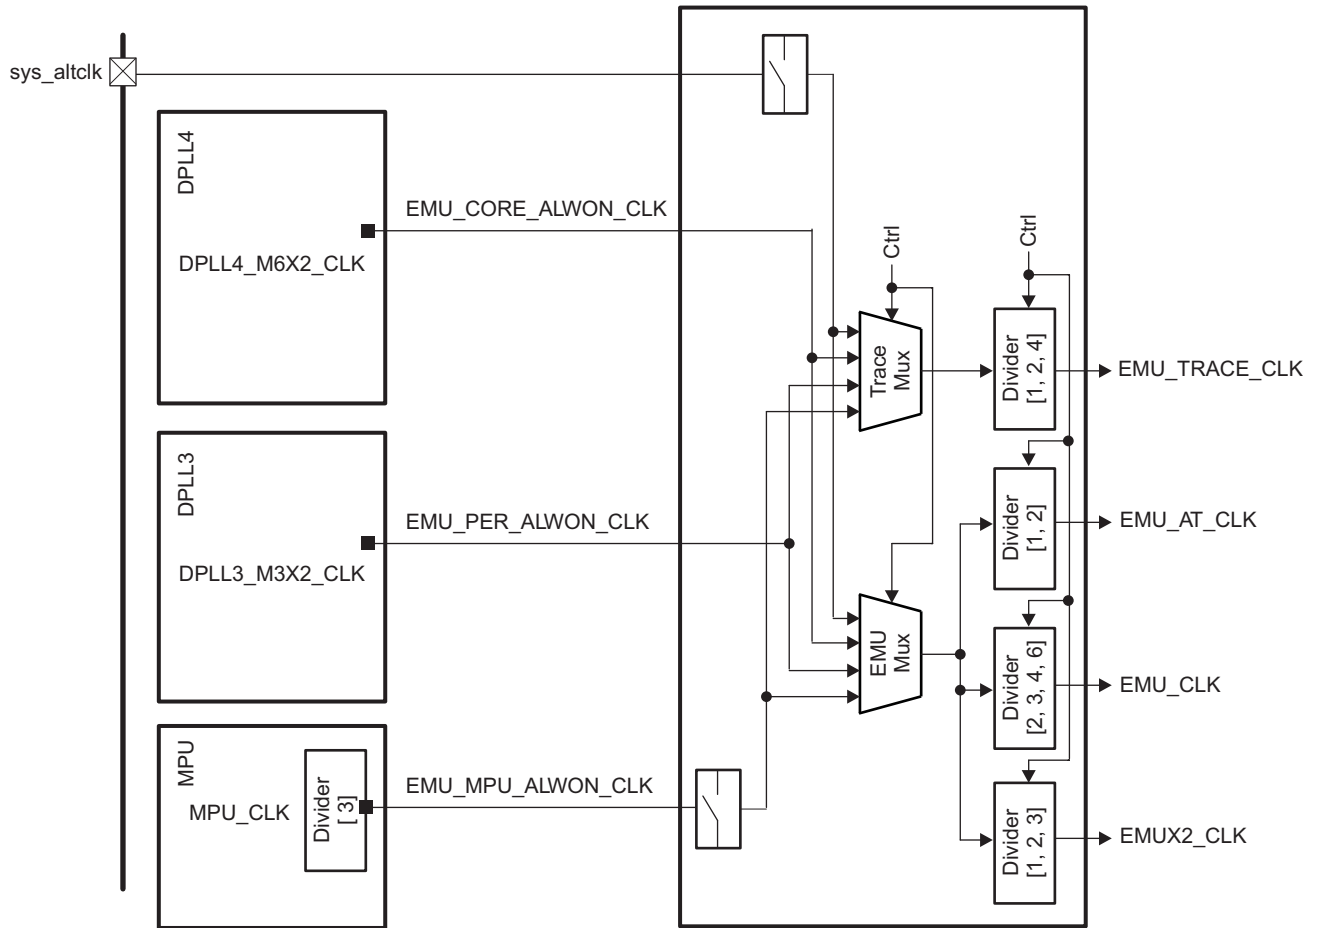

The 96M_FCLK, 48M_FCLK, and 12M_FCLK clocks are functional unbalanced clocks for a number of modules in the CORE and PER domains.

The functional 96-MHz clock path can be bypassed with SYS_CLK to allow a peripheral such as I²C to be functional while the DPLL4 is not yet enabled. The default configuration after initial power-on is bypassed with the system clock. Software must switch to the DPLL-generated clock after programming the proper system settings.

The 96-MHz clock input from PRM to the CM (that is, CM_96M_FCLK) is internally gated by the CM.

[Figure 4-24](#) shows the functional overview of the CM.

Figure 4-25. CM Emulation Clock Generator Functional Overview

prcm-100

4.7.3.3 DPLLs

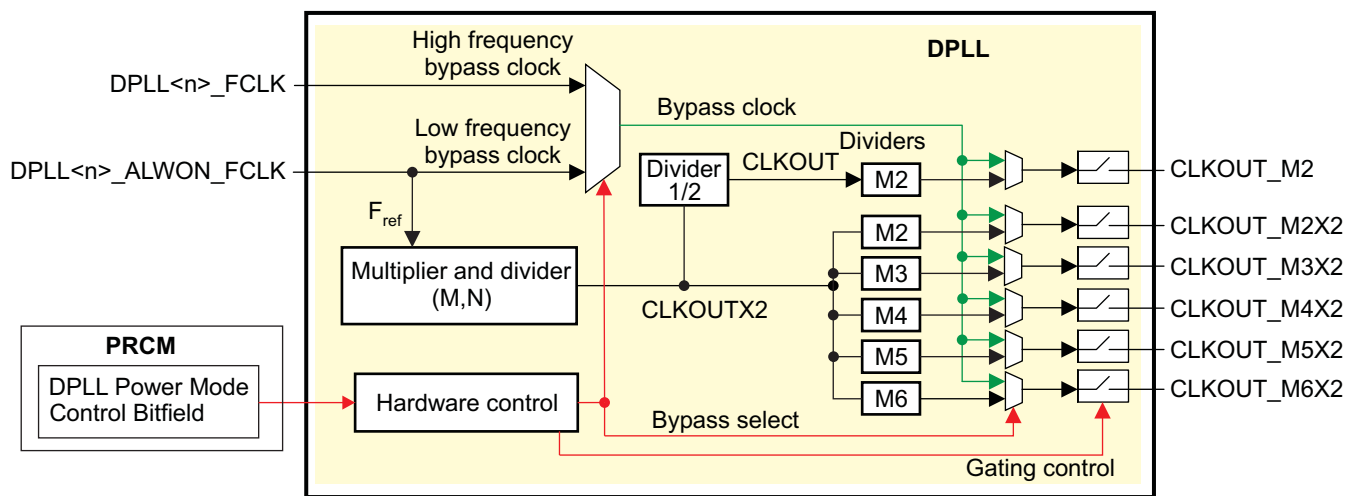

To generate high-frequency clocks, the device supports five on-chip DPLLs controlled directly by the PRCM:

- DPLL1 (MPU)
- DPLL3 (CORE)
- DPLL4 (PER)
- DPLL5 (PER2)

NOTE: This chapter discusses only DPLL1 to DPLL5, because they are directly controlled by the PRCM module. The *Display Interface Subsystem* chapter discusses the DPLLs in the DSS.

Figure 4-26 shows the functional architecture of a generic DPLL.

Figure 4-26. Generic DPLL Functional Diagram

prcm-039

Depending on its hardware configuration, the DPLL may receive one or two clock inputs.

When the DPLL has two clock inputs, it uses one as the reference clock (F_{ref}) to generate the high-frequency clock; the second one serves as the bypass clock when the DPLL is in bypass mode (that is, not locked and generating the high-frequency clock). For example, DPLL1 receives the high-frequency bypass clock from the DPLL3 output, and the reference clock from the PRM.

When the DPLL has only one clock input, it uses that clock input as the reference clock and bypass clock. For example, DPLL3, DPLL4, and DPLL5 receive only one input clock from PRM, and it is used as both the reference and the bypass clock.

It internally generates two main clocks according to the following equations:

- $CLKOUTX2 = (F_{ref} \times 2 \times M) / (N+1)$
- $CLKOUT = CLKOUTX2/2$

where M is an 11-bit multiplier and N is a 7-bit divider.

NOTE: When M is set to 0 or 1, the DPLL is forced into bypass mode.

The internal clocks (CLKOUT and CLKOUTX2) of the DPLL may then be used to generate six independent output clocks:

- $CLKOUT_M2 = CLKOUT / M2$
- $CLKOUT_M2X2 = CLKOUTX2 / M2$
- $CLKOUT_M3X2 = CLKOUTX2 / M3$

- $\text{CLKOUT_M4X2} = \text{CLKOUTX2} / \text{M4}$
- $\text{CLKOUT_M5X2} = \text{CLKOUTX2} / \text{M5}$
- $\text{CLKOUT_M6X2} = \text{CLKOUTX2} / \text{M6}$

where M2, M3, M4, M5, and M6 are additional dividers for the DPLL-synthesized clock.

The output clock frequencies defined by these equations are generated by the DPLL only when it is locked. When the DPLL is in bypass mode, however, all clock outputs run at the bypass clock frequency. The bypass clock can either be a high-frequency bypass clock (only for DPLL1) or the low-frequency reference clock.

The DPLL also provides an independent clock-gating signal for each of the six output clocks. The PRCM provides the DPLL with a clock-gating control signal, and the DPLL returns a clock activity status signal indicating whether the output clock is effectively gated or running.

For an explanation of the DPLL multiplier, divider settings, and gating controls, see [Section 4.7.6, DPLL Control](#).

Each clock-generating DPLL of the device has the following features:

- Independent domain
- Control by the CM
- Fed by always-on SYS_CLK with independent gating control for the SYS_CLK
- Analog part supplied by a dedicated power supply and an embedded LDO to eliminate 1-MHz noise
- Up to six independent output dividers for simultaneous generation of multiple output clocks with different frequencies

4.7.3.3.1 DPLL1 (MPU)

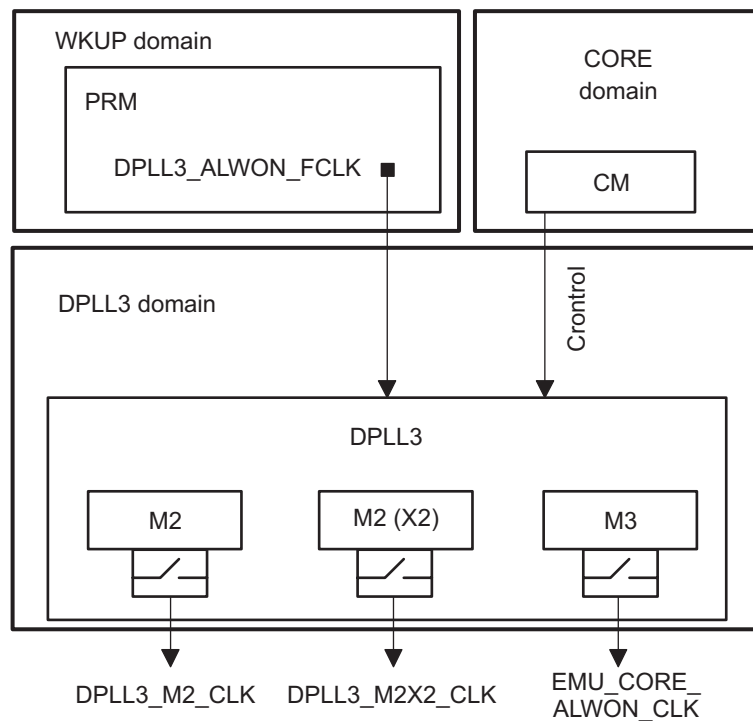

DPLL1 is in the MPU subsystem. It supplies clocks to this subsystem that are used as the source clocks for internally generating all subsystem clocks.

DPLL1 uses a reference clock to produce its synthesized clock. It receives the reference clock (DPLL1_ALWON_FCLK) from the PRM and its high-frequency bypass clock (DPLL1_FCLK) from the CM. The reference clock is SYS_CLK and the high-frequency bypass clock is CORE_CLK.

To save on DPLL power consumption by the processor, the high-frequency bypass input clock from DPLL3 (CORE) is used when the DPLL is set to bypass mode (either statically, or dynamically during relock time) or when the processor is not required to run faster than at L3 clock speed. This use of the high-frequency bypass input clock also optimizes the performance of the DPLLs during frequency scaling.

4.7.3.3.2 DPLL3 (CORE)

[Figure 4-27](#) is the block diagram of DPLL3.

Figure 4-27. DPLL3 Clocks

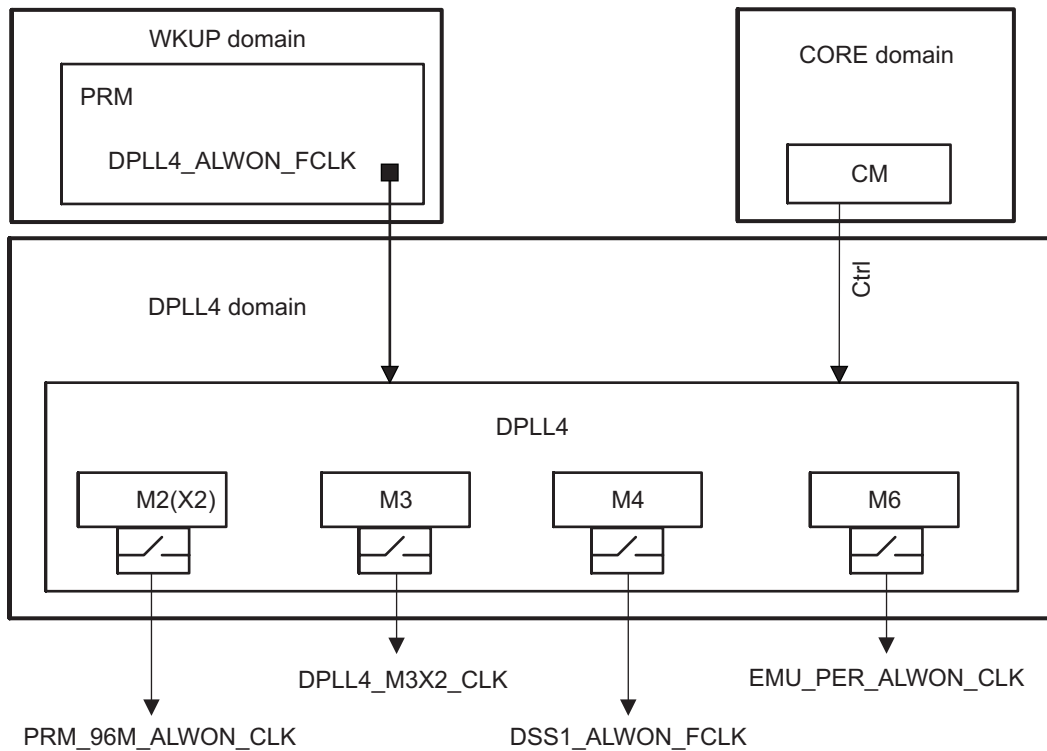

prcm-040

DPLL3 receives its reference clock (DPLL3_ALWON_FCLK), which is the SYS_CLK, from the PRM. DPLL3 does not receive a high-frequency bypass clock, and it uses the reference clock as the low-frequency bypass clock. DPLL3 supplies the source clock for all interfaces and a few functional clocks for the device modules. It also serves as the source of the emulation trace clock. While the CORE domain is on, the output of DPLL3 can be used as HS bypass clock input to DPLL1.

4.7.3.3.3 DPLL4 (Peripherals)

Figure 4-28 is the block diagram of DPLL4.

Figure 4-28. DPLL4 Clocks

prcm-041

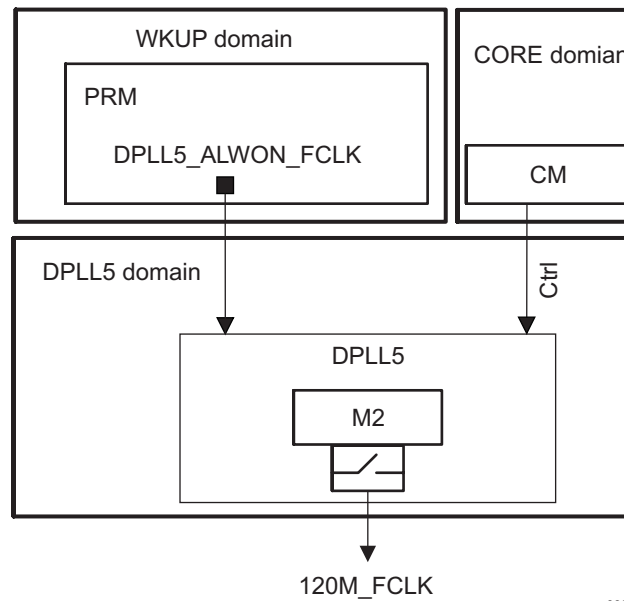

DPLL4 receives its reference clock (DPLL4_ALWON_FCLK), which is the SYS_CLK, from the PRM. DPLL4 does not receive a high-frequency bypass clock, and it uses the reference clock as the low-frequency bypass clock. DPLL4 generates clocks for the peripherals, supplying five clock sources:

- 96-MHz always-on source clock for the PRM
- 54-MHz to TV DAC
- Display functional clock
- Emulation trace clock

The clock outputs to the DSS, PER, and EMU domains are always on.

4.7.3.3.4 DPLL5 (Peripherals)

Figure 4-29 is the block diagram of DPLL5.

Figure 4-29. DPLL5 Clocks

DPLL5 receives its reference clock (DPLL5_ALWON_FCLK), which is the SYS_CLK, from the PRM. DPLL5 does not receive a high-frequency bypass clock, and it uses the reference clock as the low-frequency bypass clock. DPLL5 generates clocks for the peripherals, supplying five clock sources:

- 120-MHz functional clock to the peripheral domain modules.
- USIM source clock for the functional clock of the USIM open-core protocol (OCP) in the WKUP domain.

4.7.3.3.5 DPLL Clock Summary

Table 4-23 summarizes the use of the divided output clocks of the five DPLLs in the device.

Table 4-23. DPLL Output Clocks

| | CLKOUT_M2 | CLKOUT_M2X2 | CLKOUT_M3X2 | CLKOUT_M4X2 | CLKOUT_M5X2 | CLKOUT_M6X2 |
|-------|-----------|------------------|-------------|-------------|-------------|-------------|
| DPLL1 | | X ⁽¹⁾ | | | | |
| DPLL3 | X | X | X | | | |
| DPLL4 | | X | X | X | X | X |
| DPLL5 | X | | | | | |

⁽¹⁾ X represents the DPLL clock output used.

4.7.3.4 32-kHz Oscillator

An internal 32-kHz always-on oscillator feeds the secure watchdog timer (WDTIMER1) and the secure timer (GPTIMER12). It is not software-controllable. The oscillator ensures protection for these timers against clock stoppage caused by an external attack.

4.7.3.5 Summary

Table 4-24 summarizes the source clocks in the device.

Table 4-24. Source-Clock Summary

| Clock Name | External/Internal Source | Clock Generator | Description |
|-----------------|------------------------------|-------------------|--|
| 32K_FCLK | sys_32k (input pin) | PRM | |
| SYS_CLK | Oscillator | PRM | System clock. Serves as primary source clock of the device. Also used as functional and interface clock for PRM. |
| DSS_TV_CLK | DPLL4/sys_altclk (input pin) | CM | DSS TV clock |
| 120M_FCLK | DPLL5 | CM | |
| 96M_FCLK | DPLL4 | CM | |
| 48M_FCLK | DPLL4/sys_altclk (input pin) | CM | |
| 12M_FCLK | DPLL4/sys_altclk (input pin) | CM | |
| 96M_ALWON_CLK | | DPLL4 | Direct from DPLL4 |
| CORE_CLK | DPLL3 | CM | DPLL3 clock output frequency |
| COREX2_CLK | DPLL3 | CM | DPLL3 clock output frequency x 2 |
| L3_ICLK | DPLL3 | CM | L3 interconnect interface clock |
| L4_ICLK | DPLL3 | CM | L4 interconnect interface clock |
| MPU_CLK | | DPLL1 | MPU subsystem source clock |
| SECURE_32K_FCLK | | 32-kHz oscillator | Generated internally by an RC oscillator. It is always active. |

4.7.4 Clock Distribution

4.7.4.1 Domain Clock Distribution

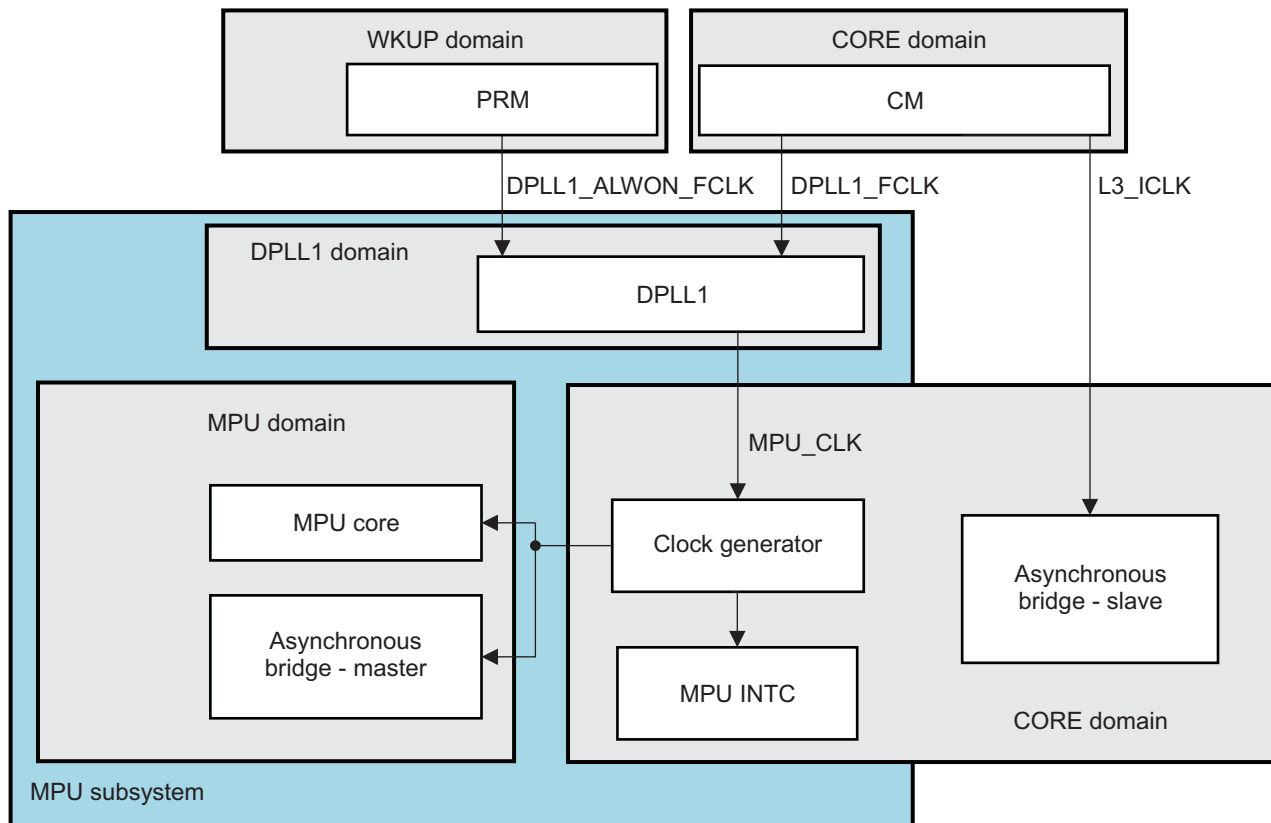

This section describes the PRCM clock distribution over device domains:

4.7.4.1.1 MPU Domain

The PRCM does not directly provide any clock to the MPU domain. It feeds only DPLL1, which generates MPU_CLK. All clocks are then locally generated by the clock generator in the MPU subsystem.

Figure 4-30 shows the clocking scheme in the MPU domain.

Figure 4-30. MPU Domain Clocking Scheme

prcm-042

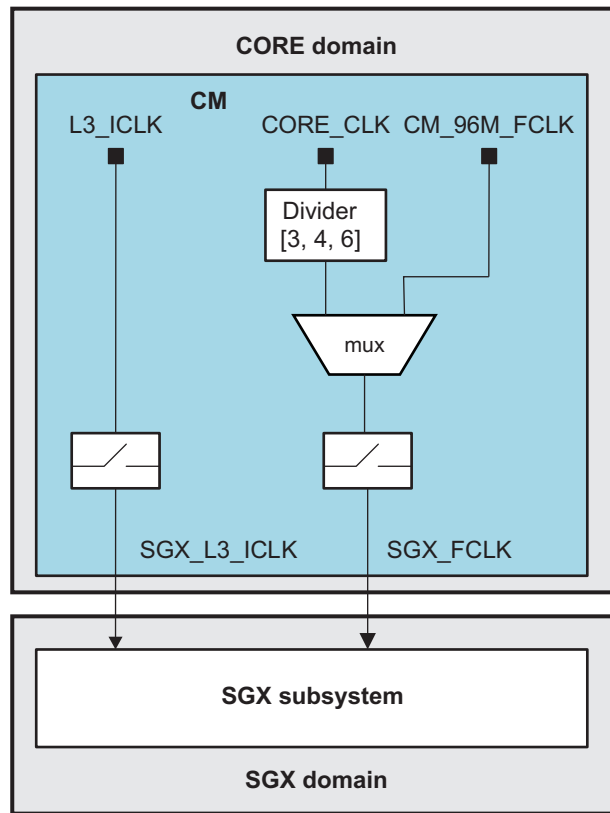

4.7.4.1.2 SGX Domain

This section gives information about all modules and features in the high-tier device. See Chapter 1, *Device Family* section, to check availability of modules and features. For power savings considerations, ensure that clocks to unused modules are properly cut off.

The SGX subsystem interface clock is sourced by the L3 clock, whereas the functional clock source can be selected between CORE_CLK and CM_96M_FCLK. When the functional clock source is CORE_CLK, its frequency can be divided (by 3, 4, or 6).

Figure 4-31 shows the clocking scheme in the SGX domain.

Figure 4-31. SGX Domain Clocking Scheme

prcm-044

4.7.4.1.3 CORE Domain

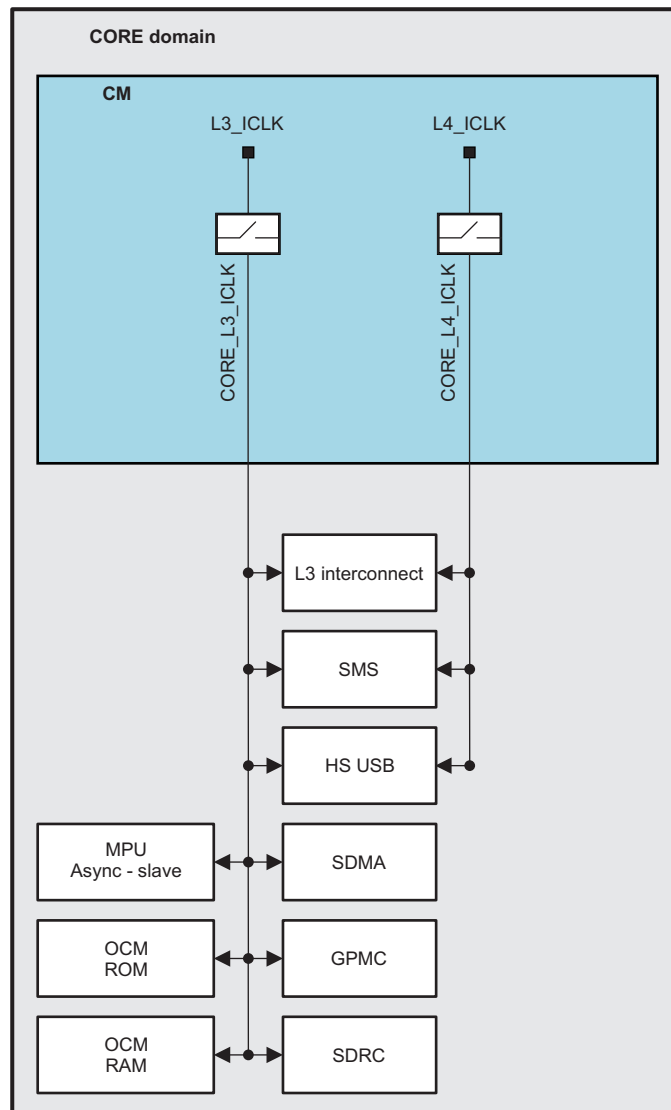

The CORE domain has both L3- and L4-derived clock domains.

The CORE domain receives several functional clocks (12-, 48-, 96-MHz, system, and 32-kHz) that feed its peripherals and modules, with an exception:

- The McBSP 1 and McBSP 5 modules can be clocked either by CORE_96M_FCLK from the CM or from an external clock, MCBSP_CLKS. The SCM manages the selection between the two sources. For more information about the SCM, see *System Control Module* chapter.

Figure 4-32 through Figure 4-34 show the clock signals and their relationships in the CORE domain.

Figure 4-32. CORE Clock Signals: Part 1

prcm-045

Figure 4-33. CORE Clock Signals: Part 2

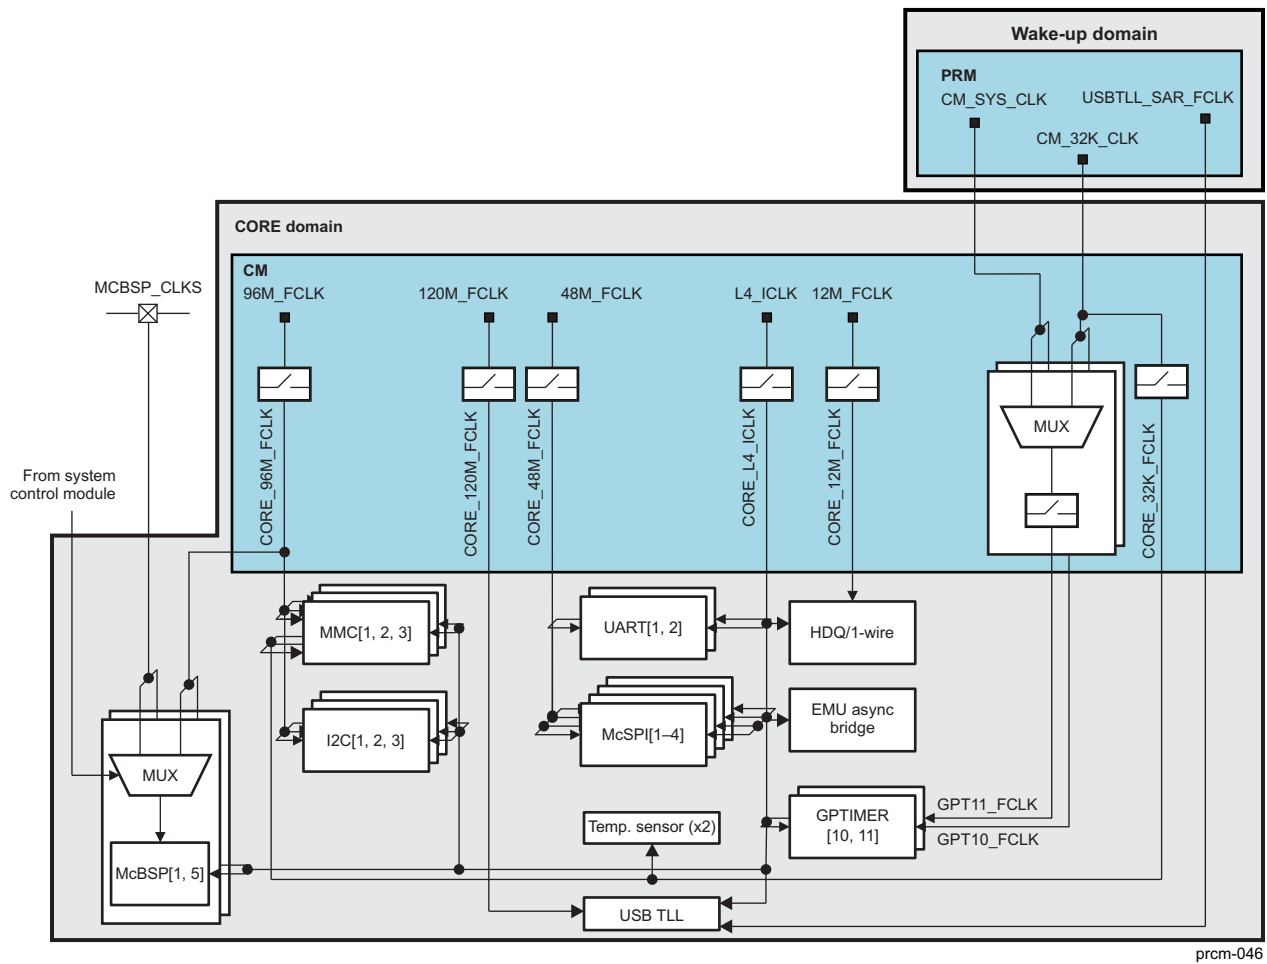

Figure 4-34. CORE Clock Signals: Part 3

prcm-047

4.7.4.1.4 IPSS Domain

The IPSS domain receives following clocks from the system:

- **L3_ICLK:** interface clock that feeds VBUS, VBUS2OCP and OCP2VBUS architecture of IPSS. This clock is used as interface clock for all the IPSS modules.
- **SYS_CLK:** used as functional clock for HECC module and as source clock for USBOTG SS.

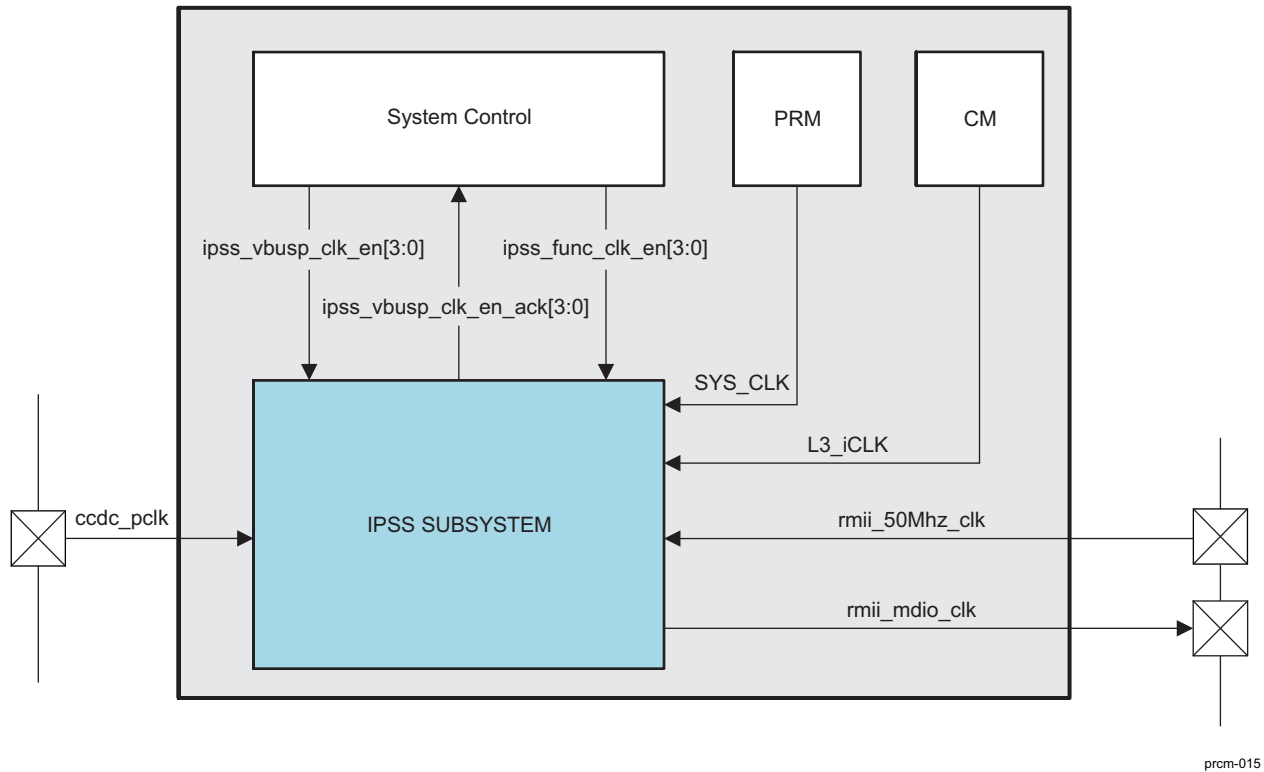

External clocks include:

- **rmii_50mhz_clk:** This clock feeds EMAC module for RMII functionality. (Refer to the EMAC chapter for more information on EMAC and RMII clocks.)
- **rmii_mdio_clk:** This is the output clock coming from EMAC which is used for external PHY.
- **ccdc_pclk:** This is the VPFE pixel clock input from the external sensor. (Refer to the VPFE chapter for more information on ccdc_pclk.)

The CONTROL_IPSS_CLK_CTRL register controls the clocking for IPSS. The field `ipss_vbusp_clk_en` has the gating control for interface clock and `ipss_func_clk_en` field will switch ON the functional clock for the IPSS modules (VPFE, USBOTG, HECC and EMAC). Few of the modules use their interface clock as functional clock, for more details refer to corresponding modules chapter.

Software can program `ipss_vbusp_clk_en` register bits to put corresponding modules in IDLE mode. It needs to read `ipss_vbusp_clk_en_ack` bits to make sure that these module clocks are gated. (Refer to the System Control Module chapter for more details.)

Figure 4-35. IPSS Domain

4.7.4.1.5 EFUSE Domain

Figure 4-36 shows the clock signals and their relationships in the EFUSE domain.

Figure 4-36. EFUSE Clock Signals

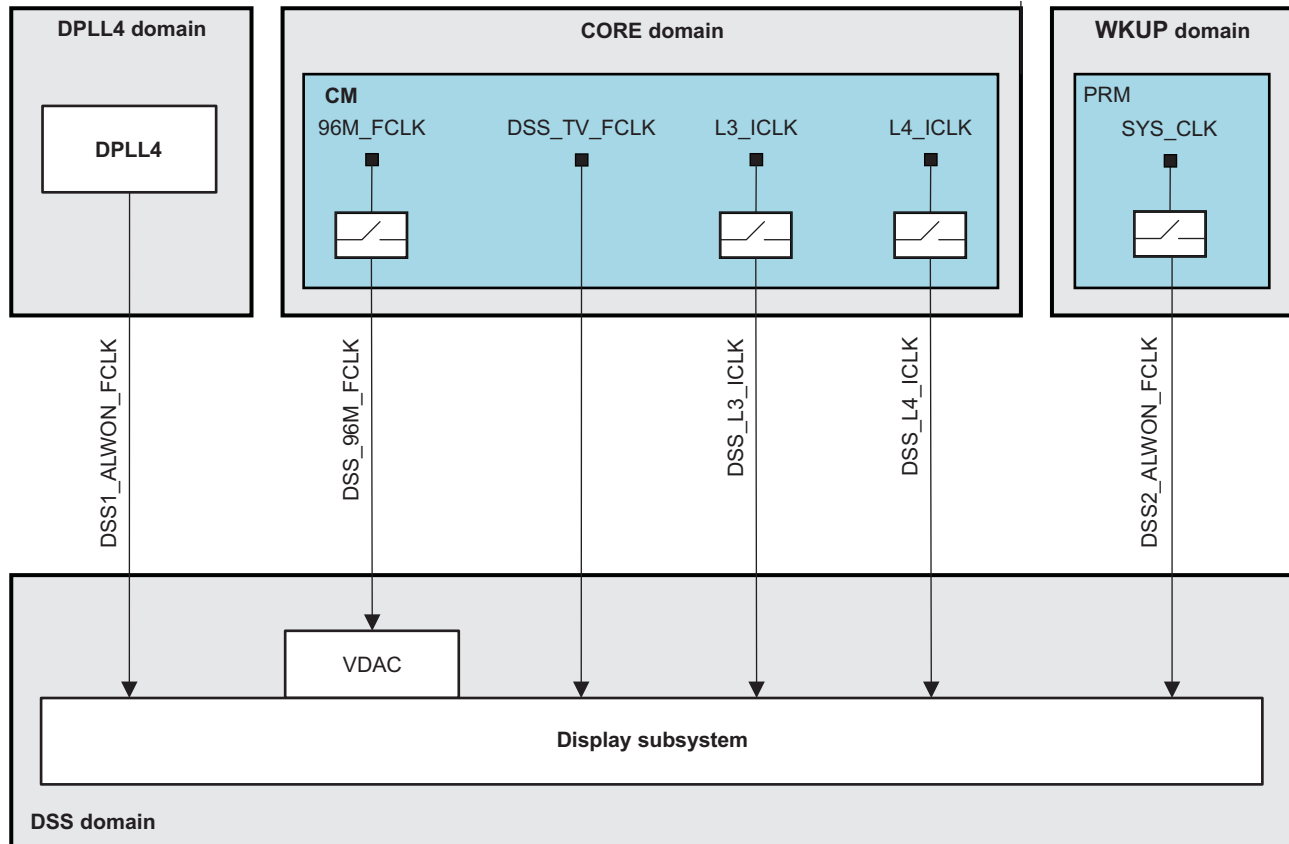

The EFUSE sense procedure is performed at device power up. During this procedure, the PRM enables the EFUSE_ALWON_FCLK clock.

4.7.4.1.6 DSS Domain

This section gives information about all modules and features in the high-tier device. See Chapter 1, *Device Family* section, to check availability of modules and features. For power savings considerations, ensure that clocks to unused modules are properly cut off.

Figure 4-37 shows the clock signals and their relationships in the DSS domain.

Figure 4-37. DSS Clock Signals

prcm-049

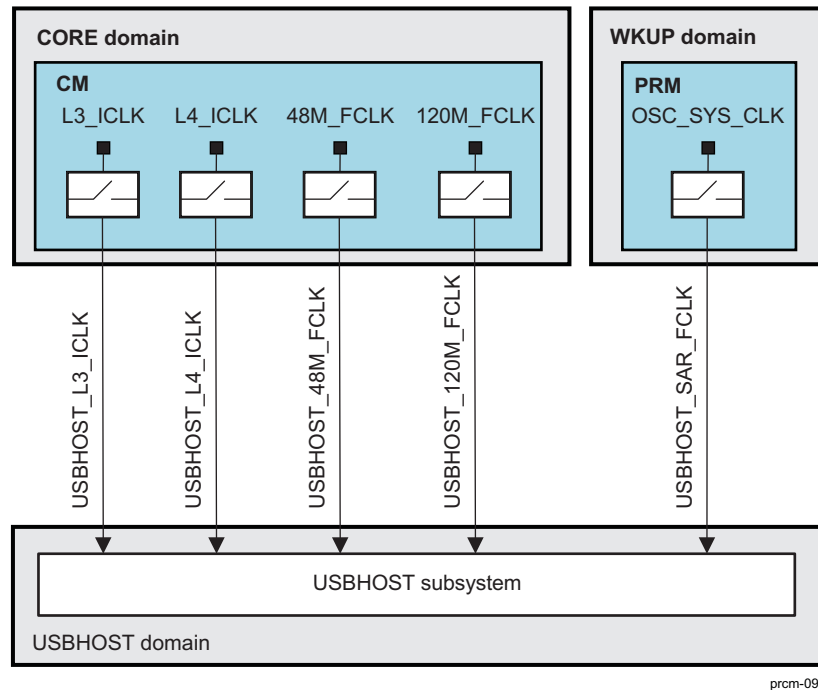

The DSS subsystem interface is clocked with the L3 and L4 clocks. It receives four functional clocks:

- DSS1_ALWON_FCLK: Issued from DPLL4. Its frequency can be a division by 1 to 16 of the frequency of the DPLL4 synthesized clock.
- DSS2_ALWON_FCLK: The gated SYS_CLK. Used mainly for display in low-power refresh modes.
- DSS_96M_FCLK: Required when TV output is activated
- DSS_TV_FCLK: Required when TV output is activated

4.7.4.1.7 USBHOST Domain

Figure 4-38 shows the clock signals and their relationships in the USBHOST domain.

Figure 4-38. USBHOST Clock Signals

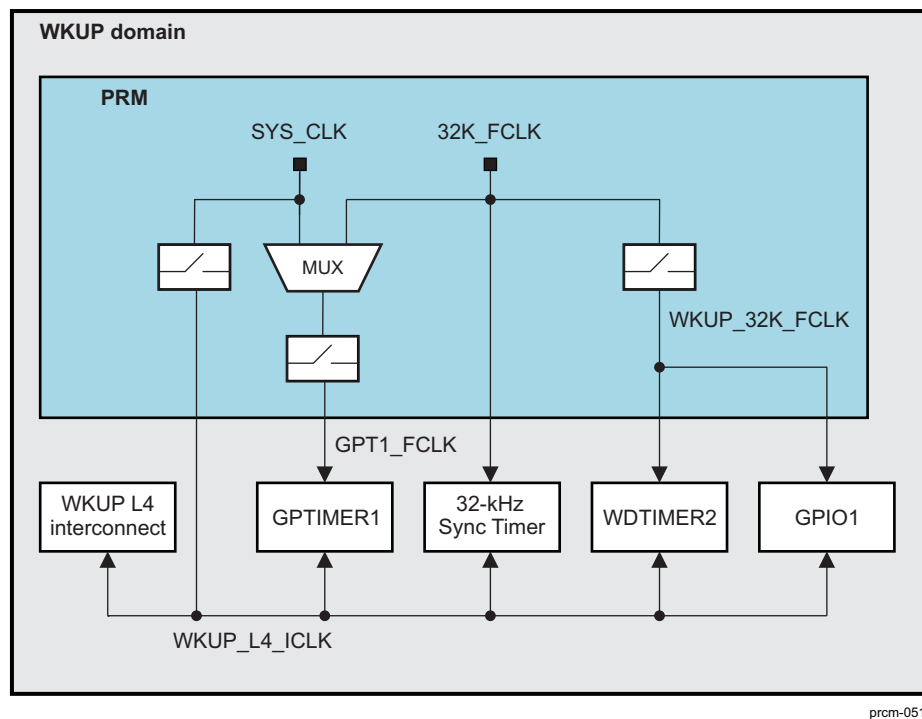

The HS USB Host subsystem interface is clocked with the L3 and L4 clocks (USBHOST_L3_ICLK and USBHOST_L4_ICLK, respectively).

The HS USB Host subsystem requires two functional clocks (USBHOST_120M_FCLK and USBHOST_48M_FCLK) that may or may not be requested simultaneously. Therefore, they are gated independently based on the configuration of the CM_FCLKEN_USBHOST[0] EN_USBHOST1 and CM_FCLKEN_USBHOST[1] EN_USBHOST2 bits.

The HS USB Host subsystem gets an additional functional clock from the PRM (USBHOST_SAR_FCLK). It is dedicated to the save-and-restore mechanism and is automatically gated/enabled by the PRM, based on the HS USB Host save-and-restore bit configuration (that is, the PM_PWSTCTRL_USBHOST[4] SAVEANDRESTORE bit) and on the USBHOST domain state transitions.

4.7.4.1.8 WKUP Domain

Figure 4-39 shows the clock signals and their relationships in the WKUP domain.

Figure 4-39. WKUP Clock Signals

All clocks in the WKUP domain are generated by the PRM, except for the functional clock for the secure timers (WDTIMER1 and GPTIMER12). This clock is supplied directly by the internal 32-kHz oscillator (SECURE_32K_FCLK). The functional clock GPT1_FCLK of GPTIMER1 can be selected as either SYS_CLK or 32K_FCLK. The 32-kHz sync timer, WDTIMER2, and GPIO1 receive 32K_FCLK as their functional clock. This is the low-frequency always-on clock.

The PRM receives SYS_CLK as the L4 interface clock. For all other modules of the WKUP domain, the L4 interface clock WKUP_L4_ICLK is derived from SYS_CLK. Communication between the WKUP domain and CORE L4 interconnects is asynchronous.

The USIM OCP module receives the functional clocks (USIM_FCLK and 32K_FCLK) and the L4 interface clock (WKUP_L4_ICLK) from the PRM.

4.7.4.1.9 PER Domain

Figure 4-40 shows the clock signals and their relationships in the PER domain.

Figure 4-40. PER Clock Signals

prcm-052

The PER domain receives several functional clocks (48M_FCLK, 96M_ALWON_FCLK, SYS_CLK, and 32K_FCLK) that feed its peripherals and modules. All the functional clocks (except 48M_FCLK) are permanently supplied so that the peripherals can be used during low-power scenarios. Figure 4-40 shows the clock distribution scheme in the PER domain.

The McBSP 2, 3, and 4 modules can be clocked either by a clock from PRM (PER_96M_FCLK) or from an external clock (MCBSP_CLKS). This clock must be permanently buffered from the pad to the PER domain. The device SCM manages the selection between the two (see System Control Module chapter).

4.7.4.1.10 DPLL Domains

The PRCM provides clock sources for the DPLLs, as shown in Figure 4-41

Figure 4-41. DPLL Clock Signals

The PRCM also manages clock-gating control for these DPLL outputs.

The MPU uses clock outputs locally in the subsystem. The CM uses the DPLL3 clock outputs to generate all interface clocks and some functional clocks. The CM uses two of the five clocks generated by DPLL4 and one clock output of DPLL5 to generate functional clocks for the peripheral domain modules. The remaining three clocks of DPLL4 are propagated to their corresponding modules.

4.7.4.2 Clock Distribution Summary

4.7.4.2.1 Domain Source Clocks

Table 4-25 summarizes clock distribution for each domain.

Table 4-25. Clock Distribution

| Power Domain | Clock | Generator | Destination |
|-----------------|--------------------|---|---|
| MPU | MPU_CLK | DPLL1 | MPU subsystem |
| NEON | | | NEON |
| SGX | SGX_FCLK | CM | SGX subsystem |
| | SGX_L3_ICLK | CM | |
| CORE | CORE_120M_FCLK | CM | USB TLL |
| | CORE_96M_FCLK | CM | McBSP[1,5], MMC[1,2,3], I2C[1,2,3] |
| | CORE_48M_FCLK | CM | UART[1,2], McSPI[1..4] |
| | CORE_12M_FCLK | CM | HDQ |
| | GPT10_FCLK | CM | GPTIMER10 |
| | GPT11_FCLK | CM | GPTIMER11 |
| | CPEFUSE_FCLK | CM | CPEFUSE |
| | USBTLL_SAR_FCLK | PRM | USB TLL |
| | CM_32K_CLK | PRM | Temperature sensor (x2), MMC[1,2,3] |
| | CORE_L3_ICLK | CM | L3 interconnect, SDMA, MPU Async Bridge(Slave), USB20OTGSS, SMS, GPMC, OCM ROM, SDRC, OCM RAM, CORE L3 interconnect |
| CORE_L4_ICLK | CM | L3 interconnect, SDMA, McBSP[1,5], MMC[1,2], I2C[1..3], GPTIMER [10,11], UART[1,2], McSPI[1..4], HDQ, CORE L4 interconnect, SCM | |
| DSS | DSS_TV_FCLK | CM | DSS, VDAC |
| | DSS_96M_FCLK | CM | |
| | DSS1_ALWON_FCLK | DPLL4 | |
| | DSS2_ALWON_FCLK | PRM | |
| | DSS_L3_ICLK | CM | |
| | DSS_L4_ICLK | CM | |
| PER | 96M_ALWON_FCLK | PRM | McBSP[2..4] |
| | PER_48M_FCLK | CM | UART3 |
| | PER_32K_ALWON_FCLK | CM | WDTIMER3, GPIO[2..6], |
| | GPT2_ALWON_FCLK | PRM | GPTIMER2 |
| | GPT3_ALWON_FCLK | PRM | GPTIMER3 |
| | GPT4_ALWON_FCLK | PRM | GPTIMER4 |
| | GPT5_ALWON_FCLK | PRM | GPTIMER5 |
| | GPT6_ALWON_FCLK | PRM | GPTIMER6 |
| | GPT7_ALWON_FCLK | PRM | GPTIMER7 |
| | GPT8_ALWON_FCLK | PRM | GPTIMER8 |
| GPT9_ALWON_FCLK | PRM | GPTIMER9 | |

Table 4-25. Clock Distribution (continued)

| Power Domain | Clock | Generator | Destination |
|--------------|------------------|-------------------|---|
| | PER_L4_ICLK | CM | UART3, PER L4 interconnect, WDTIMER3, GPIO[2..6], GPTIMER[2..9], McBSP[2..4] |
| WKUP | WKUP_32K_FCLK | PRM | WDTIMER2, GPIO1 |
| | SECURE_32K_FCLK | 32-kHz oscillator | WDTIMER1, GPTIMER12 |
| | 32K_FCLK | PRM | 32-kHz sync timer, USIM OCP |
| | GPT1_FCLK | PRM | GPTIMER1 |
| | USIM_FCLK | CM | USIM OCP |
| | WKUP_L4_ICLK | PRM | WKUP L4 interconnect, GPTIMER[1,12], 32-kHz sync timer, GPIO1, WDTIMER[1,2], USIM OCP |
| EFUSE | EFUSE_ALWON_FCLK | PRM | eFuse farm |
| DPLL1 | DPLL1_ALWON_FCLK | PRM | DPLL1 |
| | DPLL1_FCLK | CM | |
| DPLL3 | DPLL3_ALWON_FCLK | PRM | DPLL3 |
| DPLL4 | DPLL4_ALWON_FCLK | PRM | DPLL4 |
| DPLL5 | DPLL5_ALWON_FCLK | PRM | DPLL5 |

NOTE:

- Modules supplied by the L3 interface clock only:
 - MPU asynchronous bridge
 - All memory controllers (OCM ROM, OCM RAM, SDRC, SMS, and GPMC)
- Modules that require both L3 and L4 clocks:
 - SDMA
 - HS USB
 - All security modules (FPKA, AES, RNG, SHAM, and D3D)
- Modules fed by the L4 clock:
 - SCM
 - All peripherals (McBSP1, McBSP5, MMC1, MMC2, I2C1, I2C2, I2C3, McSPI1, McSPI2, McSPI3, McSPI4, UART1, UART2, HDQ, GPTIMER10, and GPTIMER11)

4.7.4.2.2 Peripheral Module Clocks

Table 4-26 lists the peripherals and DSS functional clock frequency requirements.

Table 4-26. Peripheral Module Functional Clock Frequencies

| Module | Functional Clock | Frequency |
|-------------------|------------------|----------------------------|
| MMC-SDIO[1,2,3] | 96M_FCLK | 96 MHz |
| McBSP[1, 5] | 96M_FCLK | 96 MHz |
| McSPI[1..4] | CORE_48M_FCLK | 48 MHz |
| UART[1..3] | | |
| Display subsystem | DSS1_ALWON_FCLK | Up to 173 MHz |
| | DSS2_ALWON_FCLK | System clock |
| | DSS_96M_FCLK | 96 MHz |
| | DSS_TV_FCLK | 54 MHz |
| I2C[1..3] | CORE_96M_FCLK | 96 MHz |
| HDQ | CORE_12M_FCLK | 12 MHz |
| GPTIMER1 | GPT1_FCLK | 32-kHz (p) or system clock |
| GPTIMER[2..9] | GPTn_ALWON_FCLK | 32-kHz (p) or system clock |

Table 4-26. Peripheral Module Functional Clock Frequencies (continued)

| Module | Functional Clock | Frequency |
|---------------------|--------------------|------------------------|
| GPTIMER[10, 11] | GPTn_FCLK | 32-kHz or system clock |
| GPTIMER12 | SECURE_32K_FCLK | 32 kHz (p) (s) |
| FPKA1 | SECURITY_L3_ICLK | L3_ICLK |
| AES 1 | SECURITY_L4_ICLK2 | L4_ICLK |
| D3D 1 | | |
| SHAM 1 | | |
| RNG1 | | |
| AES 2 | | |
| SHAM 2 | CORE_L4_ICLK | L4_ICLK |
| D3D 2 | | |
| WDTIMER1 | | |
| WDTIMER2 | SECURE_32K_FCLK | 32 kHz (p) (s) |
| WDTIMER3 | WKUP_32K_FCLK | 32 kHz |
| WDTIMER3 | PER_32K_ALWON_FCLK | 32 kHz |
| GPIO1 | WKUP_32K_FCLK | 32 kHz |
| GPIO[2-6] | PER_32K_ALWON_FCLK | 32 kHz |
| 32-kHz sync timer | 32K_FCLK | 32 kHz (p) |
| Bandgap/temp sensor | 32K_FCLK | 32 kHz (p) |
| System control | CORE_L4_ICLK | L4_ICLK |

4.7.5 External Clock Controls

Because the use of `sys_32k` and `sys_altclk` was discussed previously (see [Section 4.7.3.1, PRM](#), and [Section 4.7.3.2, CM](#)), these clock signals are not discussed here. This section discusses the remaining external clock signals.

4.7.5.1 Clock Request (`sys_clkreq`) Control

The system clock request signal `sys_clkreq` is bidirectional. In bypass mode in the system clock oscillator (see [Section 4.7.5.2](#)), it is an output signal driven by the device to request an external clock. In this case, the output buffer is driven as long as the system clock is requested by the device; otherwise, it remains in high impedance. In this way, other external peripherals can share the same clock request signal with the device.

If `PRM_POLCTRL.CLKREQ_POL = 1`, the software must configure the SCM to select the internal pulldown on the `sys_clkreq` pad, or an external pulldown is connected to the pad. If `PRM_POLCTRL.CLKREQ_POL = 0`, the internal pull-up on the `sys_clkreq` pad, or an external pull-up is connected to the pad.

In master mode in the system clock oscillator (see [Section 4.7.5.2](#)), `sys_clkreq` is an input. If `PRM_POLCTRL.CLKREQ_POL = 1`, the software must configure the SCM to select the internal pulldown on the `sys_clkreq` pad, or an external pulldown is connected to the pad. If `PRM_POLCTRL.CLKREQ_POL = 0`, the internal pull-up on the `sys_clkreq` pad, or an external pull-up is connected to the pad.

The `PRCM.PRM_POLCTRL[1] CLKREQ_POL` bit allows software control over the polarity of `sys_clkreq`. This software setting takes effect when the clock is requested by the device and also when the clock request is driven externally. The output buffer is directly driven by this register when the clock request comes from the device.

[Table 4-27](#) shows the bidirectional control of the `sys_clkreq` Pad:

Table 4-27. sys_clkreq Pad Direction Control

| | | | | Sys_clkreq Direction | Description |
|-----------------|-----------|---|---|---|---|
| Oscillator Mode | Sys_boot6 | Internal Clock request (always active high) | External Clock request (Note: polarity depends on CLKREQ_POL) | | |
| Master Mode | 0 | 0 | 0 ⁽¹⁾ | Input (Output buffer in Hi-Z) Note: (Input is not driven from outside of the device in that case) | The clock is neither requested internally nor externally (external device/peripheral) |
| | 0 | 0 | 1 ⁽¹⁾ | Input (Output buffer in Hi-Z) | The clock is requested externally |
| | 0 | 1 | 0 ⁽¹⁾ | Output | The clock is requested internally |
| | 0 | 1 | 1 ⁽¹⁾ | Output Note: (The pad is driven both by the device and from outside of the device in that case.) | The clock is requested both internally and externally |
| Bypass Mode | 1 | 0 | 0 ⁽¹⁾ | Input (Output buffer in Hi-Z) Note: (Input is not driven from outside of the device in that case.) | The clock is neither requested internally nor externally |
| | 1 | 0 | 1 ⁽²⁾ | Input (output buffer in Hi-Z) | The clock is requested externally |
| | 1 | 1 | 0 ⁽²⁾ | Output | The clock is requested internally |
| | 1 | 1 | 1 ⁽²⁾ | Output Note: (Input is not driven from outside of the device in that case.) | The clock is requested both internally and externally |

⁽¹⁾ Case when PRM_POLCTRL.CLKREQ_POL = 1 (sys_clkreq active high). These values would be inverted in the table above, in case PRM_POLCTRL.CLKREQ_POL = 0 (sys_clkreq active low).

⁽²⁾ Case when PRM_POLCTRL.CLKREQ_POL = 1 (sys_clkreq active high). These values would be inverted in the table above, in case PRM_POLCTRL.CLKREQ_POL = 0 (sys_clkreq active low).

4.7.5.2 System Clock Oscillator Control

Depending on the hardware configuration, the device can receive the system clock from an external source or generate it locally using the internal system clock crystal oscillator. Thus, the device oscillator has two possible operating modes:

- Master (oscillator enable) mode: The oscillator is enabled and connected to an external quartz. It provides the system clock to the device. The oscillator is activated on a device wake-up or on an external clock request.
- Bypass (oscillator inactive) mode: The system clock is supplied by an external device and the oscillator is always set in bypass mode. The oscillator is insensitive to the external system clock request on the sys_clkreq pin.

NOTE: An external pullup or pulldown tied on the sys_boot6 input pin of the device determines whether the oscillator is in master or bypass mode. See [Section 4.3.1, External Clock Signals](#).

When operating in master mode, the device receives an external clock request (sys_clkreq) and provides the system clock to external peripherals through the sys_clkout1 pin; in bypass mode, the device generates a clock request to the external clock source to request the system clock.

The selected mode of the oscillator can be read from the PRCM.PRM_CLKSRC_CTRL[1:0] SYSCLKSEL bit field.

Whatever the oscillator mode, the oscillator can be powered down when the device enters inactive mode, unless an external system clock request is active (from the sys_clkreq pin). Note that this option can only be used if the 32kHz clock is not derived from the high frequency sysclk, as the 32kHz clock is required for autonomous wakeup capability. This setting is configured in the PRCM.PRM_CLKSRC_CTRL[4:3] AUTOEXTCLKMODE bit field. Table 4-29 lists the four possible operation modes of the system clock.

Table 4-28. System Clock Operation Modes

| AUTOEXTCLKMODE | System Clock Mode | Oscillator Mode | Description |
|----------------|-----------------------------------|-----------------|--|
| 0x0 | Always-active mode | Master | The oscillator is kept active even when the clock is neither requested by the device internally (all device clocks are inactive) nor externally (that is, the sysclkreq input signal is not asserted). |
| | | Bypass | The sys_clkreq output signal is permanently asserted by the device, regardless of its internal clocks state (active or inactive). |
| 0x1 | Off when device in INACTIVE state | Master | The oscillator is switched off when the device is in INACTIVE mode and the sys_clkreq input signal is not asserted. |
| | | Bypass | The sys_clkreq output signal is de-asserted when the device is in idle mode. |

To exit power-down mode, the oscillator requires a device wakeup or an external clock request.

The device allows configuring of the system clock stabilization time to ensure a stable system clock in the device. This delay is configured in the PRCM.PRM_CLKSETUP[15:0] SETUP_TIME bit field.

Figure 4-42 shows the system clock oscillator controls in the device.

Figure 4-42. System Clock Oscillator Controls

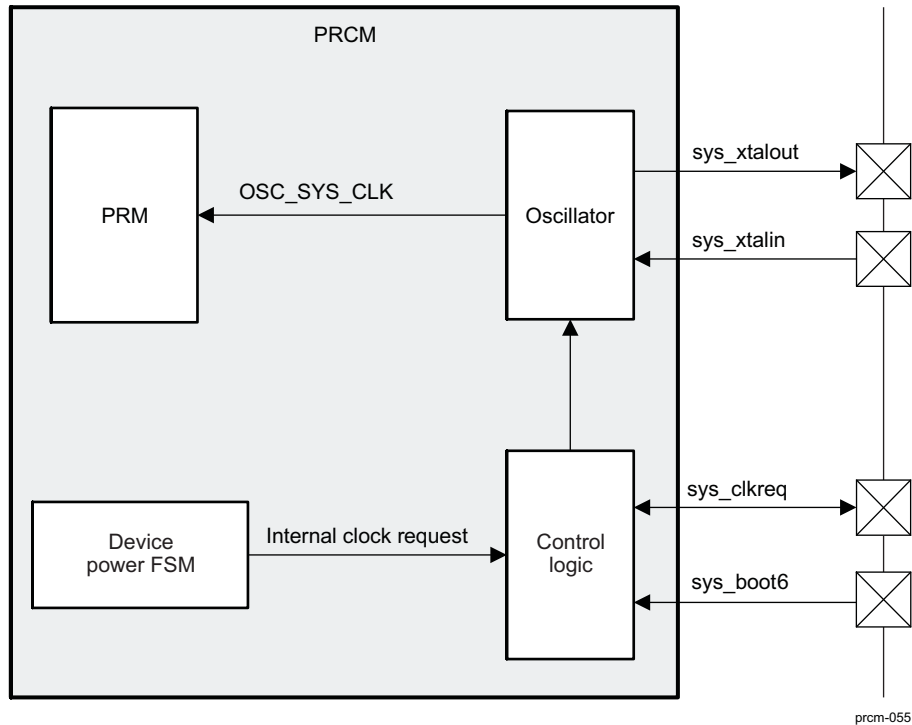

Table 4-29 lists the oscillator controls.

Table 4-29. Oscillator Controls

| Oscillator Mode | Internal Clock Request ⁽¹⁾ | External Clock Request ⁽¹⁾ | Oscillator State | sys_clkreq Pad Direction | sys_clkreq ⁽¹⁾ | Description |
|-----------------|---------------------------------------|---------------------------------------|------------------|--|------------------------------|---|
| Master | Not asserted | Not asserted | Off | Both input and output | Not asserted | System clock not requested internally (within the device) and externally (by an external device or peripheral). |
| | Not asserted | Asserted | Active | Input | Asserted | System clock is requested externally only. |
| | Asserted | Not asserted | Active | Output | Asserted | System clock is requested internally only. |
| | Asserted | Asserted | Active | Both input and output (that is, driven internally by device and externally by peripheral) | Asserted | System clock is requested internally and externally. |
| Bypass | Not asserted | x ⁽²⁾ | Bypass | Both input and output (when external request is not asserted) or input (when external request is asserted) | External clock request state | System clock is not requested internally (sys_clkreq input has no effect). |
| | Asserted | x ⁽²⁾ | Bypass | Output (when only internal request is asserted) or both input and output (when external and internal request are asserted) | Asserted | System clock is requested internally (sys_clkreq input has no effect). |

⁽¹⁾

- If the PRCM.PRM_POLCTRL[1] CLKREQ_POL is set to active high (that is, 0x1), Asserted = 1, and Not asserted = 0.
- If the PRCM.PRM_POLCTRL[1] CLKREQ_POL is set to active low (that is, 0x0), Asserted = 0, and Not asserted = 1.

⁽²⁾ x indicates that the signal may be asserted or not asserted.

4.7.5.3 External Output Clock1 (sys_clkout1) Control

The sys_clkout1 clock is active if the oscillator clock (OSC_SYS_CLK) is active (stable) and an external system clock request is active. It can be gated by programming the PRCM.PRM_CLKOUT_CTRL[7] CLKOUT_EN bit. The polarity of the sys_clkout1 signal, when the clock is gated, is controllable by programming the PRCM.PRM_POLCTRL[2] CLKOUT_POL bit.

When the device is in standby mode, both SYS_CLK and sys_clkout1 are disabled. In that case, reactivation of sys_clkout1 depends on the oscillator mode:

- Oscillator in active mode (sys_boot6 is 0): The sys_clkout1 clock can be reactivated (after oscillator stabilization), provided its gating was previously enabled by programming the PRCM.PRM_CLKOUT_CTRL[7] CLKOUT_EN bit and asserting an external clock request. This activation does not generate a device wake-up event; an external clock request activates only the internal SYS_CLK oscillator and sys_clkout1.
- Oscillator in bypass mode (sys_boot6 is 1): The sys_clkout1 clock can be reactivated only after the device wakes up (on any wake-up event) and SYS_CLK is active. When the device is active, SYS_CLK is running and sys_clkout1 is enabled as soon as requested by software.

4.7.5.4 External Output Clock2 (sys_clkout2) Control

A second output clock, sys_clkout2, is generated with a frequency that can be the source-clock frequency divided by 1, 2, 4, 8, or 16. Its source clock can be CORE_CLK, CM_SYS_CLK, 96 MHz, or 54 MHz. The selected source clock must be enabled by software. Enabling sys_clkout2 does not automatically request the required source clock. The polarity of the sys_clkout2 signal, when the clock is gated, is controllable by programming the PRCM.CM_POLCTRL[0] CLKOUT2_POL bit.

4.7.6 DPLL Control

The PRCM allows the configuration of the output clock frequencies of the DPLLs by setting their respective multipliers and dividers. It also allows control of the operating mode of the DPLLs and automatic recalibration mode.

4.7.6.1 DPLL Multiplier and Divider Factors

DPLL clock outputs are set by programming the corresponding multiplier and divider factors M, N, M2, M3, M4, M5, and M6. [Table 4-30](#) lists the register bit fields for configuration of the multiplier and divider factors for the DPLLs.

Table 4-30. DPLL Multiplier and Divider Factors

| | DPLL1 | DPLL3 | DPLL4 | DPLL5 |
|----|--|---|--|---|
| M | PRCM.CM_CLKSEL1_PLL_MPU[18:8] MPU_DPLL_MULT | PRCM.CM_CLKSEL1_PLL[26:16] CORE_DPLL_MULT | PRCM.CM_CLKSEL2_PLL[18:8] PERIPH_DPLL_MULT | PRCM.CM_CLKSEL4_PLL[18:8] PERIPH2_DPLL_MULT |
| N | PRCM.CM_CLKSEL1_PLL_MPU[6:0] MPU_DPLL_DIV | PRCM.CM_CLKSEL1_PLL[14:8] CORE_DPLL_DIV | PRCM.CM_CLKSEL2_PLL[6:0] PERIPH_DPLL_DIV | PRCM.CM_CLKSEL4_PLL[6:0] PERIPH2_DPLL_DIV |
| M2 | PRCM.CM_CLKSEL2_PLL_MPU[4:0] MPU_DPLL_CLKOUT_DIV | PRCM.CM_CLKSEL1_PLL[31:27] CORE_DPLL_CLKOUT_DIV | PRCM.CM_CLKSEL3_PLL[4:0] DIV_96M | PRCM.CM_CLKSEL5_PLL[4:0] DIV_120M |
| M3 | Not used | PRCM.CM_CLKSEL1_EMU[20:16] DIV_DPLL3 | PRCM.CM_CLKSEL_DSS[12:8] CLKSEL_TV | Not used |
| M4 | Not used | Not used | PRCM.CM_CLKSEL_DSS[4:0] CLKSEL_DSS1 | Not used |
| M5 | Not used | Not used | PRCM.CM_CLKSEL_ | Not used |
| M6 | Not used | Not used | PRCM.CM_CLKSEL1_EMU[28:24] DIV_DPLL4 | Not used |

4.7.6.2 DPLL Jitter Correction

To satisfy the jitter specification of the DPLL at a specific internal clock frequency, set the corresponding `CM_CLKEN_PLL_processor_name>[7:4]processor_name>_DPLL_FREQSEL`, `CM_CLKEN_PLL[23:20]PERIPH_DPLL_FREQSEL`, `CM_CLKEN_PLL[7:4]CORE_DPLL_FREQSEL`, `CM_CLKEN2_PLL[7:4]PERIPH2_DPLL_FREQSEL` bit field. [Table 4-31](#) lists the possible values for the bit field and the corresponding internal clock frequency ranges.

NOTE: The internal clock frequency is the frequency of the internal interface clock F_{int} , with $F_{int} = \text{CLKINP}/(N + 1)$.

Table 4-31. Internal Clock Frequency

| Bit Field Values | Clock Frequency Ranges |
|---------------------------|------------------------|
| 0x3 | 0.75 MHz—1.0 MHz |
| 0x4 | 1.0 MHz—1.25 MHz |
| 0x5 | 1.25 MHz—1.5 MHz |
| 0x6 | 1.5 MHz—1.75 MHz |
| 0x7 | 1.75 MHz—2.1 MHz |
| 0xB | 7.5 MHz—10 MHz |
| 0xC | 10 MHz—12.5 MHz |
| 0xD | 12.5 MHz—15 MHz |
| 0xE | 15 MHz—17.5 MHz |
| 0xF | 17.5 MHz—21 MHz |
| Other cases are reserved. | |

NOTE: In the DPLL programming sequence, the DPLL_FREQSEL must be programmed before the new Multiplier factor M and the Divider factor N are programmed so that the new value is taken into account during current DPLL relock.

4.7.6.3 DPLL Frequency Ramp-Up Delay

When the DPLL switches from bypass mode to lock mode, the clock output frequency changes from bypass clock frequency to normal operating frequency. The frequency ramp-up feature allows the DPLL output frequency to switch gradually (in steps) from the bypass to locked frequency. Before reaching the locked frequency, the DPLL output switches to four intermediate frequencies:

1. $F_{out}/8$
2. $F_{out}/4$
3. $F_{out}/2$
4. F_{out}

The time delay in passing from the bypass clock frequency to normal frequency is the ramp-up delay. The ramp-up delay is configured by setting the `CM_CLKEN_PLL_processor_name>[9:8]processor_name>_DPLL_RAMPTIME`, `CM_CLKEN_PLL[25:24]PERIPH_DPLL_RAMPTIME`, `CM_CLKEN_PLL[9:8]CORE_DPLL_RAMPTIME`, `CM_CLKEN2_PLL[9:8]PERIPH2_DPLL_RAMPTIME` bit field.

There are three possible values for the bit field and the corresponding ramp-up delays:

- 0x0: Disables the frequency ramping feature.
- 0x1: Ramp step size range is 2–40 Fint cycles.
- 0x2: Ramp step size range is 4–80 Fint cycles.
- 0x3: Ramp step size range is 12–240 Fint cycles.

NOTE: If the ramp-up time configured for the DPLL is less than the DPLL lock time, the last frequency step, $F_{out}/2$ to F_{out} , gets stretched to the DPLL lock time.

4.7.6.4 DPLL Modes

DPLL supports several power modes (see [Table 4-32](#)). Each mode results in a tradeoff between power savings and relock time.

Table 4-32. DPLL Power Modes

| Mode | Clock Input | Clock Output | DPLL Power State | Power Consumption | Latency |
|--------------------|-------------|------------------|------------------|-------------------|----------------------------|
| Locked | On | Lock frequency | ON | Maximum | N/A |
| Low-power bypass | On | Bypass frequency | ON | Less than locked | Same as low-power stop |
| Fast-relock bypass | On | Bypass frequency | ON | Less than locked | Less than low-power bypass |
| Low-power stop | On | Bypass frequency | ON | Less than locked | Same as low-power bypass |
| MN bypass | On | Bypass frequency | ON | Less than locked | Maximum |
| Off | Off | Off | OFF | Minimum | Maximum |

A DPLL power mode can be achieved on a software request (manual) and/or automatically (automatic), depending on the specific hardware conditions. After a device power-on reset, the DPLL can be kept in either low-power stop mode (DPLL4 and DPLL5) or MN bypass mode (DPLL1 and DPLL3).

A DPLL can switch from one mode to the other as a result of the following:

- Software-programmed transition only (manual): The software configures a dedicated register for the next desired DPLL mode. It must ensure that the transition can be performed based on the activity on the device.
- Combined software-programmed and hardware-conditions-based transition (automatic): The PRCM triggers the transition when the software requests it (by configuring the registers) and the hardware conditions are satisfied. When the hardware conditions are no longer met, the PRCM triggers the return transition.

For automatic transition, automatic mode must be enabled by programming the PRCM.CM_AUTOIDLE_PLL or the PRCM.CM_AUTOIDLE_PLLprocessor_name> registers.

Table 4-33 describes the manual and automatic control of the DPLL power modes by the PRCM.

Table 4-33. DPLL Power Modes Support

| Mode | DPLL1 | DPLL3 | DPLL4 | DPLL5 |
|--------------------|--|--|---|---|
| Locked | Software request (manual) or MPU wakes up (automatic). | Software request (manual) or CORE wakes up (automatic). | Software request (manual) or at least one peripheral clock is used (automatic). | Software request (manual) or at least one peripheral clock is used (automatic). |
| Low-power bypass | Software request (manual) | Software request (manual) or all interface clocks are gated (automatic). | N/A | N/A |
| Fast-relock bypass | N/A | Software request (manual). | N/A | N/A |
| Low-power stop | MPU is idle (automatic). | Device is idle (automatic). | (Default state) Software request (manual) or all functional clocks from DPLL are unused or on global reset release (automatic). | (Default state) Software request (manual) or all functional clocks from DPLL (120-MHz clock) are unused or on global reset release (automatic). |
| MN bypass | Global reset (automatic) | Global reset (automatic). | N/A | N/A |
| Off | Device off (automatic) | Device off (automatic). | Device off (automatic) | Device off (automatic) |

NOTE: DPLL1 and DPLL3 cannot be manually forced to switch to Low-Power Stop mode from any other power mode. They must be in Locked state with automatic transition to Low-Power Stop mode configured and the hardware condition for the transition (identified in Table 4-33) must be satisfied, in order to switch to the Low-Power Stop mode.

Table 4-34 lists the bit fields that must be programmed for manual and automatic mode control of the four DPLLs.

Table 4-34. DPLL Power Mode Control

| Mode | Manual Control | Auto Control |
|-------|--|--|
| DPLL1 | PRCM.CM_CLKEN_PLL_MPU[2:0] EN_MPU_DPLL | PRCM.CM_AUTOIDLE_PLL_MPU[2:0] AUTO_MPU_DPLL |
| DPLL3 | PRCM.CM_CLKEN_PLL[2:0] EN_CORE_DPLL | PRCM.CM_AUTOIDLE_PLL[2:0] AUTO_CORE_DPLL |
| DPLL4 | PRCM.CM_CLKEN_PLL[18:16] EN_PERIPH_DPLL | PRCM.CM_AUTOIDLE_PLL[5:3] AUTO_PERIPH_DPLL |
| DPLL5 | PRCM.CM_CLKEN2_PLL[2:0] EN_PERIPH2_DPLL | PRCM.CM_AUTOIDLE2_PLL[2:0] AUTO_PERIPH2_DPLL |

NOTE: The DPLL automatically enters locked mode on a domain wakeup only if the DPLL is locked before the sleep transition and one of the automatic modes is enabled.

4.7.6.5 DPLL Low-Power Mode

The DPLL can operate in a low-power mode by reducing the operating frequency range. This in turn reduces the power consumption of the DPLL. In this mode, however, there is a period and phase jitter effect.

The DPLL can enter this mode only if the targeted lock frequency of the DPLL is less than 600 MHz. This implies locking or relocking the DPLL to a new targeted locked-frequency when entering or exiting low-power mode. Software must ensure that the DPLL lock-frequency does not exceed 600 MHz in low-power mode.

Software can enable/disable automatic switching of the DPLL between normal mode and low-power mode. The new mode is effective only after the DPLL is relocked. Low-power mode control is considered only during the following transitions:

- From bypass mode to lock
- From stop mode to lock
- From lock to relock

Table 4-35 lists the bit fields that must be programmed for manual control of the four DPLLs.

Table 4-35. LP Mode Control

| Mode | Manual Control |
|-------|---|
| DPLL1 | PRCM.CM_CLKEN_PLL_MPU[10] EN_MPU_DPLL_LPMODE |
| DPLL3 | PRCM.CM_CLKEN_PLL[10] EN_CORE_DPLL_LPMODE |
| DPLL4 | PRCM.CM_CLKEN_PLL[26] EN_PERIPH_DPLL_LPMODE |
| DPLL5 | PRCM.CM_CLKEN2_PLL[10] EN_PERIPH2_DPLL_LPMODE |

4.7.6.6 DPLL Clock Path Power Down

DPLL3 and DPLL4 can power down the CLKOUTX2 path. A small section of logic is powered down as the M2 post divider is also shared with the CLKOUT path, which remains functional.

The HSDIVIDER can power down each CLKOUTn path (with n in the range of 3 to 6) independently, therefore allowing further power savings. The clock output path is also powered down when the DPLL is in stop mode, regardless of the software setting.

Software must ensure the proper sequencing of the control. To avoid a glitch at the output, activate this control when the clock is no longer required, and when the output clock is gated. Conversely, ensure a delay between deactivation and reactivation of the clock by using the power-down control.

Table 4-36 lists the bit fields and the corresponding clock outputs of the DPLLs.

Table 4-36. Clock Path Power-Down Control

| DPLL | Control Bit Field | Clock Path |
|-------|--|---|
| DPLL4 | PRCM.CM_CLKEN_PLL[27] PWRDN_96M | 96-MHz clock output (DPLL4 output M2X2) |
| | PRCM.CM_CLKEN_PLL[28] PWRDN_TV | DSS TV clock output (DPLL4 output M3X2) |
| | PRCM.CM_CLKEN_PLL[29] PWRDN_DSS1 | DSS1 clock output (DPLL4 output M4X2) |
| | PRCM.CM_CLKEN_PLL[31] PWRDN_EMU_PERIPH | EMU_PERIPH clock output (DPLL4 output M6X2) |
| DPLL3 | PRCM.CM_CLKEN_PLL[12] PWRDN_EMU_CORE | EMU_CORE clock output (DPLL3 output M3X2) |

4.7.6.7 Latencies

Lock mode for the DPLL is frequency lock.

Lock latencies depend on the internal reference frequency (F_{INT}) of the DPLL, calculated as:

$$F_{INT} = F_{ref} / (N+1)$$

where F_{ref} is the reference clock input to DPLL.

Table 4-37 lists the operating modes of the DPLL and the output clock frequency and associated lock latency.

FREQSEL[3] = 0 refers to the following bits:

- CM_CLKEN_PLL_MPU[7]
- CM_CLKEN_PLL[7]
- CM_CLKEN_PLL[23]
- CM_CLKEN2_PLL[7]

Table 4-37. DPLL Operating Mode and Latency

| Mode | CLKOUTX2 | Lock Time in FINT cycles (FREQSEL[3] = 0) | Lock Time in Fint Cycles (FREQSEL[3]= 1) |
|---------------------|-------------------------------------|--|---|
| OFF | Off | 150 | 780 |
| M, N reprogramming | bypass clock | 150 | 780 |
| Low-power stop mode | Off | 40 | 400 |
| Low-power bypass | bypass clock | 40 | 400 |
| Fast-relock bypass | bypass clock | 10 | 100 |
| Active (locked) | $CLKINP \times M/(N+1)/M2 \times 2$ | N/A | N/A |

The post-divider M2 supports change on the fly. The time required to switch from the clock with the old period to the clock with the new period depends on the old value of M2 (see Table 4-38).

Table 4-38. Time Required to Switch Clocks

| Old Value of M2 | Time for Switching |
|-----------------|-------------------------|
| 1 | 4 REFCLKs + 8 CLKOUTX2s |
| Even | 4 REFCLKs + 2 CLKOUTX2s |
| Odd & > 1 | 4 REFCLKs + 4 CLKOUTX2s |

4.7.6.8 Recalibration

A lock sequence occurs during an initial lock or during a relock following a new multiplier or divider value. Each time the DPLL is reset or performs a lock sequence, it performs a recalibration of the output frequency, based on the voltage and temperature conditions. By compensating for voltage and temperature changes within a certain range, the calibration allows the lock frequency to remain steady. If the voltage or temperature drifts outside the acceptable range, the DPLL asserts a recalibration flag.

For example, a large temperature drift can cause the DPLL to lose its lock and require recalibration. When the DPLL locks at a temperature within the 080 degrees Celsius range, the maximum temperature drift is approximately 55 degrees Celsius. When DPLL starts at a negative temperature, the maximum temperature drift is higher.

If the DPLL locks at 30 degrees Celsius, the temperature can change by 60 degrees Celsius (from 30 to +90 degrees Celsius) and the DPLL will not lose the lock. However, for temperatures above the 60 degrees Celsius range, the DPLL may need to be relocked. A new relock sequence reinitializes the starting temperature.

This compensation mechanism is active only while the DPLL is locked. When the DPLL is in off or bypass mode (low-power or fast-relock), it does not assert the recalibration flag. If the voltage or temperature exceeds the drift limits while the DPLL is not locked, and then the DPLL tries to relock, the DPLL fails to lock within the normal delay and recalibrates automatically before eventually locking. The only difference from a standard relock is the delay.

The DPLL can automatically start recalibration when the recalibration flag is asserted, or recalibration can be managed by the software. The mode of operation is selected by configuring the corresponding registers in the PRCM (see [Table 4-39](#)). The software or manual control mode is selected by default.

NOTE: Automatic recalibration of the DPLL can start at any time. While relocking, the DPLL switches to bypass mode. For modules that are sensitive to frequency change while operating, this can introduce operational instability. For example, the SDRC is sensitive to a frequency change on DPLL3 because its embedded DLL relocks on a frequency change. Any access during this DLL relock period can be corrupted. It is important, therefore, to stall SDRC access during DPLL recalibration.

To allow the software to recalibrate the DPLL at the correct time depending on the device activity, the PRCM can generate a wake-up event on the MPU domain, followed by an interrupt on the MPU when the DPLL recalibration flag is asserted.

[Table 4-39](#) summarizes the software programming control over the DPLL recalibration feature.

Table 4-39. DPLL Recalibration Controls

| DPLL | Software Control | Description |
|--------------|--|---|
| DPLL1 (MPU) | PRCM.CM_CLKEN_PLL_MPU[3] MPU_DPLL_DRIFTGUARD | Enable/disable the MPU DPLL automatic recalibration feature. |
| | PRCM.PRM_IRQENABLE_MPU[7] MPU_DPLL_RECAL_EN | Enable/disable the MPU DPLL recalibration interrupt to MPU. |
| | PRCM.PRM_IRQSTATUS_MPU[7] MPU_DPLL_ST | Status of the MPU DPLL recalibration interrupt |
| DPLL3 (CORE) | PRCM.CM_CLKEN_PLL[3] EN_CORE_DPLL_DRIFTGUARD | Enable/disable the CORE DPLL automatic recalibration feature. |
| | PRCM.PRM_IRQENABLE_MPU[5] CORE_DPLL_RECAL | Enable/disable the CORE DPLL recalibration interrupt to MPU. |
| | PRCM.PRM_IRQSTATUS_MPU[5] CORE_DPLL_ST | Status of the CORE DPLL recalibration interrupt |
| DPLL4 (PER) | PRCM.CM_CLKEN_PLL[19] EN_PERIPH_DPLL_DRIFTGUARD | Enable/disable the PER DPLL automatic recalibration feature. |
| | PRCM.PRM_IRQENABLE_MPU[6] PERIPH_DPLL_RECAL | Enable/disable the PER DPLL recalibration interrupt to MPU. |
| | PRCM.PRM_IRQSTATUS_MPU[6] PERIPH_DPLL_ST | Status of the PER DPLL recalibration interrupt |
| DPLL5 (PER2) | PRCM.CM_CLKEN2_PLL[3] EN_PERIPH2_DPLL_DRIFTGUARD | Enable/disable the PER DPLL2 automatic recalibration feature. |
| | PRCM.PRM_IRQENABLE_MPU[25] SND_PERIPH_DPLL_RECAL_EN | Enable/disable the PER DPLL2 recalibration interrupt to MPU. |
| | PRCM.PRM_IRQSTATUS_MPU[25] SND_PERIPH_DPLL_ST | Status of the PER DPLL2 recalibration interrupt |

NOTE: DPLL recalibration is not necessary in real use (specified operating voltage and temperature range).

4.7.6.9 DPLL Programming Sequence

The DPLL programming sequence follows:

1. Set the multiplier (M) and divider (N) values for the desired CLKOUT frequency (see [Section 4.7.6.1](#)).
2. Set the corresponding output dividers (M2, M3, M4, M5, and M6) (see [Section 4.7.6.1](#)).
3. Set the corresponding FREQSEL bit field to satisfy the jitter specification (see [Section 4.7.6.2](#)).
4. Set the corresponding ramp-up delay (see [Section 4.7.6.3](#)).
5. Enable/disable the auto-recalibration feature (see [Section 4.7.6.8](#)).
6. Enable/disable the autoidle feature (see [Section 4.7.6.4](#)).
7. Mask/unmask the interrupt to the MPU (see [Section 4.7.6.8](#)).
8. Enable the DPLL lock mode (see [Section 4.7.6.4](#)).

4.7.7 Internal Clock Controls

This section describes the software and hardware controls of the internal source clocks. [Figure 4-43](#) through list the clock controls. The *Source selection/division* column lists the PRCM register bits used to select or divide the clocks. The *Software control* column lists the PRCM register bits used to enable/disable the clocks. The *Hardware control* column lists the hardware conditions required to effectively gate the clocks.

In the *Hardware control* column, the boxes labeled CL, GS, GC, and HC indicate specific information about the hardware clock controls:

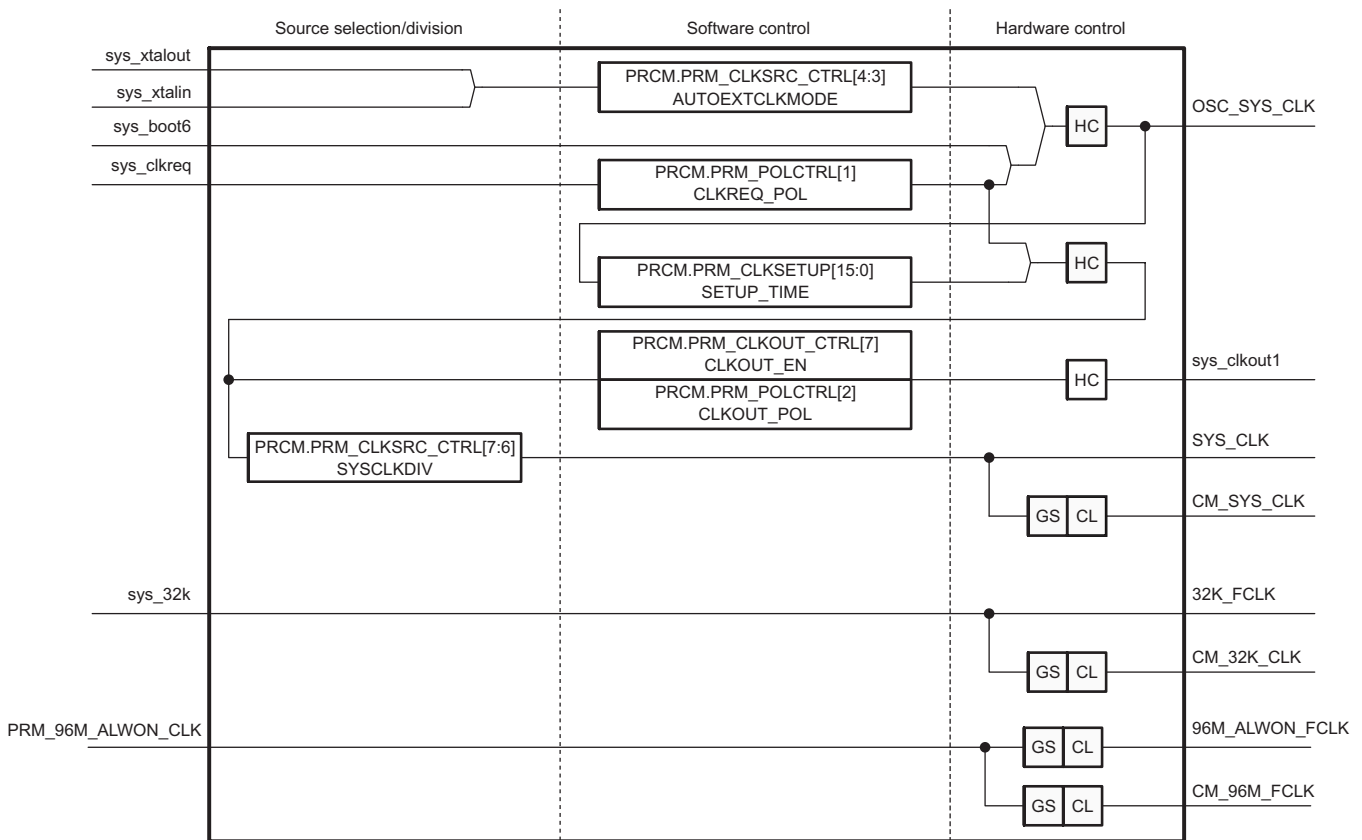

- CL (combinational logic): The functional or interface clock is required by more than one module across more than one domain. The gating control is the OR combination of all the domain clock requests. If any module of this clock domain requests the clock, the clock is not gated.
- GS (gating selection): The clock is selectable among several possible source clocks for a module. The gating control depends on the software programming of the CM_CLKSEL_<domain_name> type of register. The clock request of the module or domain must be set by the CM_CLKSEL bit.
- GC (gating control): The functional/interface clock is required by a single module across the domain. The gating control depends only on the software programming of the FCLKEN/ICLKEN bit. For the interface clock, the enable bit is effective only if autoidle mode is not used. If autoidle mode is used, the gating control also depends on the state of the domain.
- HC (hardware control): A specific rule not covered by CL, GS, or GC.

NOTE: Because the PRCM must receive hardware acknowledgement from the different modules before it can gate the clock, the clock is not gated immediately after the software requests clock-gating conditions.

4.7.7.1 PRM Source-Clock Controls

[Figure 4-43](#) shows the common source-clock controls for the PRM.

Figure 4-43. Common PRM Source-Clock Controls

prcm-056

Table 4-40 shows the common source-clock gating controls for the PRM.

Table 4-40. Common PRM Source-Clock Gating Controls

| Clock Name | Reset | Clock-Gating Control | Gating Description |
|----------------|---------|---|---|
| OSC_SYS_CLK | Running | PRCM.PRM_CLKSRC_CTRL[4:3] AUTOEXTCLKMODE and device power state and sys_clkreq | Gated when the oscillator is programmed to power down with the device sleep/retention/off transition. |
| sys_clkout1 | Running | PRCM.PRM_CLKOUT_CTRL[7] CLKOUT_EN and PRCM.PRM_POLCTRL[2] CLKOUT_POL and sys_clkreq | Active when OSC_SYS_CLK is active, sys_clkout1 is enabled, and sys_clkreq is asserted. |
| SYS_CLK | Running | Activated after clksetup_count_overflow | Active when OSC_SYS_CLK is active and the SYS_CLK setup time is up. |
| CM_SYS_CLK | Running | PRCM.CM_CLKSEL_CORE[6] CLKSEL_GPT10, PRCM.CM_CLKSEL_CORE[7] CLKSEL_GPT11, and depends on the clock-gating conditions of GPT10_FCLK and GPT11_FCLK | Active if it is the source clock of the GPT10_FCLK or GPT11_FCLK and the functional clock is active. |
| 32K_FCLK | Running | None | Always-active clock from sys_32k input pin |
| CM_32K_CLK | Running | PRCM.CM_CLKSEL_CORE[6] CLKSEL_GPT10, PRCM.CM_CLKSEL_CORE[7] CLKSEL_GPT11, and depends on the clock-gating conditions of GPT10_FCLK and GPT11_FCLK | Active if it is the source clock of the GPT10_FCLK or GPT11_FCLK and the functional clock is active. |
| CM_96M_FCLK | Gated | CM_CLKSEL1_PLL[3] SOURCE_48M bit cleared, and depends on the clock-gating condition of 96M_FCLK, 48M_FCLK, and 12M_FCLK | Active if the derived clocks (96M_FCLK, 48M_FCLK, and 12M_FCLK) are active. |
| 96M_ALWON_FCLK | Gated | CM_FCLKEN_PER[0] EN_MCBSP2, CM_FCLKEN_PER[1] EN_MCBSP3, and CM_FCLKEN_PER[2] EN_MCBSP4 | Gated when none of the three McBSPs [2..4] have their functional clock enable requested. |

The oscillator output clock (OSC_SYS_CLK) is gated whenever the PRCM.PRM_CLKSRC_CTRL[4:3] AUTOEXTCLKMODE bit field is programmed to power down the oscillator when the device enters retention. In this condition, all the clock trees in the device must be gated, and the four DPLLs (DPLL1, DPLL3, and DPLL4) must enter stop mode before this transition can occur.

SYS_CLK is gated under the same conditions as the oscillator output clock, but it is enabled only after the oscillator stabilizes. Oscillator stabilization is determined by a counter overflow configured in the PRCM.PRM_CLKSETUP[15:0] SETUP_TIME bit field.

The sys_clkreq active condition is described in Section 4.7.5, External Clock Control.

4.7.7.2 CM Source-Clock Controls

Figure 4-44 shows the common source-clock controls for the CM.

Figure 4-44. Common CM Source-Clock Controls

prcm-057

Table 4-41 shows the common source-clock gating controls for the CM.

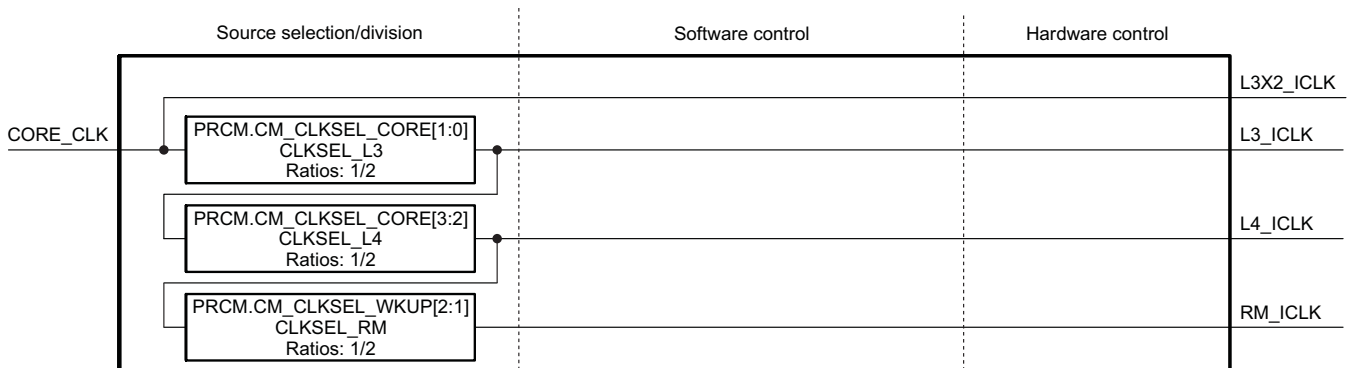

Table 4-41. Common CM Source-Clock Gating Controls

| Clock Name | Reset | Clock-Gating Control | Gating Description |
|--------------|---------|--|---|
| CORE_CLK | Running | Depends on the clock-gating conditions of: L3_ICLK and L4_ICLK | Gated when all interface clocks of the different modules of the device are gated |
| 96M_FCLK | Stopped | Depends on the clock-gating conditions of: CORE_96M_FCLK and DSS_96M_FCLK | If the dependent clocks are active, the clock is active. |
| 48M_FCLK | Stopped | Depends on the clock-gating conditions of CORE_12M_FCLK, PER_48M_FCLK and USBHOST_48M_FCLK | If the dependent clocks are active, the clock is active. |
| 12M_FCLK | Stopped | Depends on the clock-gating conditions of CORE_12M_FCLK | If the dependent clock is active, the clock is active. |
| sys_clkout2 | Stopped | PRCM.CM_CLKOUT_CTRL[7] CLKOUT2_EN | Active if enabled |
| DPLL4_M2_CLK | Stopped | Depends on the clock-gating conditions of: 96M_FCLK | If the dependent clocks are active, the clock is active. |
| DPLL4_M3_CLK | Stopped | CM_CLKSEL1_PLL.SOURCE_54M and depends on the clock-gating conditions of: DPLL4_M2_CLK and DSS_TV_CLK | If the dependent clocks are active, the clock is active. DSS_TV_CLK is a dependent clock if set by the register configuration. |
| 120M_FCLK | Stopped | CM_FCLKEN_USBHOST[1] EN_USBHOST2, CM_FCLKEN3_CORE[2] EN_USBTLL, CM_FCLKEN_WKUP[9] EN_USIMOCP, CM_CLKSEL_WKUP[6:3] CLKSEL_USIMOCP | If any of the dependent clocks (that is, USIM_FCLK, CORE_120M_FCLK, or USBHOST_12M_FCLK) is active, the clock is active. The USIM_FCLK is a dependent clock if set by the register configuration. |

4.7.7.3 Common Interface Clock Controls

Figure 4-45 shows the clock controls for the common interface.

Figure 4-45. Common Interface Clock Controls

prcm-058

Table 4-42 shows the clock-gating controls for the common interface.

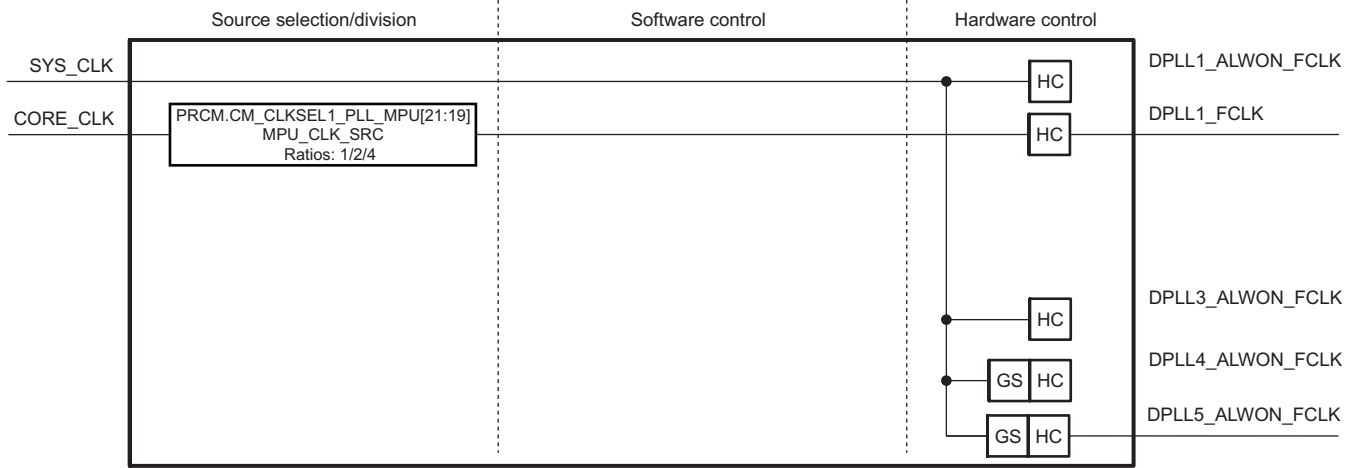

Table 4-42. Common Interface Clock-Gating Controls

| Clock Name | Reset | Clock-Gating Control | Gating Description |
|------------|---------|--|---|
| L3X2_ICLK | Running | CORE_CLK gating conditions | Depends on the gating conditions of the CORE_CLK |
| L3_ICLK | Running | Depends on the clock-gating conditions of: SGX_L3_ICLK, CORE_L3_ICLK, SECURITY_L3_ICLK | Gated when all L3 interface clocks of the different modules of the device are gated |
| L4_ICLK | Running | Depends on the clock-gating conditions of CORE_L4_ICLK, SECURITY_L4_ICLK, DSS_L4_ICLK, PER_L4_ICLK, SR_L4_ICLK, and WKUP_L4_ICLK | Gated when all L4 interface clocks of the different modules of the device are gated |
| RM_ICLK | Running | None | Gated with source clock (CORE_CLK) |

4.7.7.4 DPLL Source-Clock Controls

Figure 4-46 shows the clock controls for the DPLL domain.

Figure 4-46. DPLL Domain Clock Controls

prcm-059

Table 4-43 shows the clock-gating controls for the DPLL domain.

Table 4-43. DPLL Domain Clock-Gating Controls

| Clock Name | Reset | Clock-Gating Control | Gating Description |
|------------------|---------|--|---|
| DPLL1_ALWON_FCLK | Running | PRCM.CM_AUTOIDLE_PLL_MPU[2:0] AUTO_MPU_DPLL, PRCM.CM_CLKEN_PLL_MPU[2:0] EN_MPU_DPLL, and MPU domain power state | Gated if the DPLL is set to automatic active control and enabled in lock mode while the MPU domain goes into retention or off mode. It is also gated if DPLL is set to low-power bypass mode. |
| DPLL1_FCLK | Stopped | | |
| DPLL3_ALWON_FCLK | Running | PRCM.CM_AUTOIDLE_PLL[2:0] AUTO_CORE_DPLL, PRCM.CM_CLKEN_PLL[2:0] EN_CORE_DPLL, and CORE domain power clocks state | Gated if the DPLL is set to automatic active control and enabled in lock mode while the CORE domain is idle. It is also gated if DPLL is set to low-power or fast-relock bypass mode. |
| DPLL4_ALWON_FCLK | Stopped | PRCM.CM_AUTOIDLE_PLL[5:3] AUTO_PERIPH_DPLL, PRCM.CM_CLKEN_PLL[18:16] EN_PERIPH_DPLL, and depends on the clock-gating conditions of DPLL4_M2_CLK | Gated if the DPLL is set to automatic active control and enabled in lock mode while its dependent clock is inactive. It is also gated if DPLL is set to low-power stop mode. |
| DPLL5_ALWON_FCLK | Stopped | PRCM.CM_AUTOIDLE2_PLL[2:0] AUTO_PERIPH2_DPLL, PRCM.CM_CLKEN2_PLL[2:0] EN_PERIPH2_DPLL, and depends on the clock-gating conditions of DPLL5_M2_CLK | Gated if the DPLL is set to automatic active control and enabled in lock mode while its dependent clock is inactive. It is also gated if DPLL is set to low-power stop mode. |

4.7.7.5 SGX Domain Clock Controls

This section gives information about all modules and features in the high-tier device. See Chapter 1, *Device Family* section, to check availability of modules and features. For power savings considerations, ensure that clocks to unused modules are cut off.

Figure 4-47 shows the clock controls for the SGX domain.

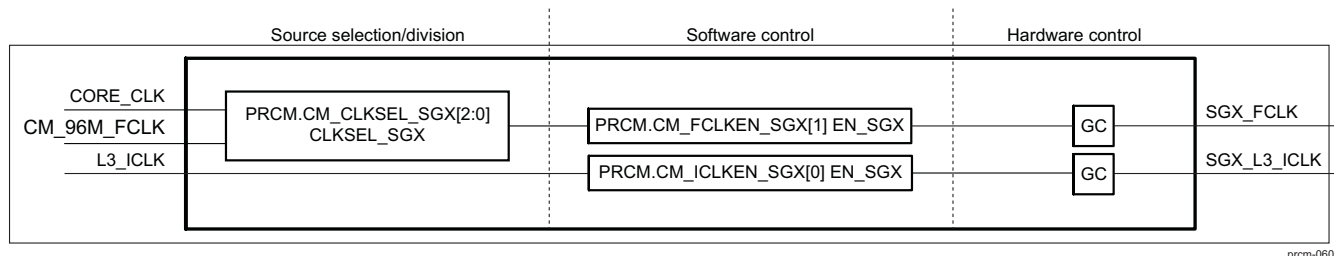

Figure 4-47. SGX Domain Clock Controls

Table 4-44 lists the clock-gating controls for the SGX domain.

Table 4-44. SGX Domain Clock-Gating Controls

| Clock Name | Reset | Clock-Gating Control | Gating Description |
|------------|---------|------------------------------|---------------------------------------|
| SGX_FCLK | Stopped | PRCM.CM_FCLKEN_SGX[1] EN_SGX | Gated when the enable bit is set to 0 |
| SGX_ICLK | Stopped | PRCM.CM_ICLKEN_SGX[1] EN_SGX | Gated when the enable bit is set to 0 |

4.7.7.6 CORE Domain Clock Controls

Figure 4-48 through Figure 4-50 show the clock controls for the CORE domain.

Figure 4-48. CORE Domain Clock Controls: Part 1

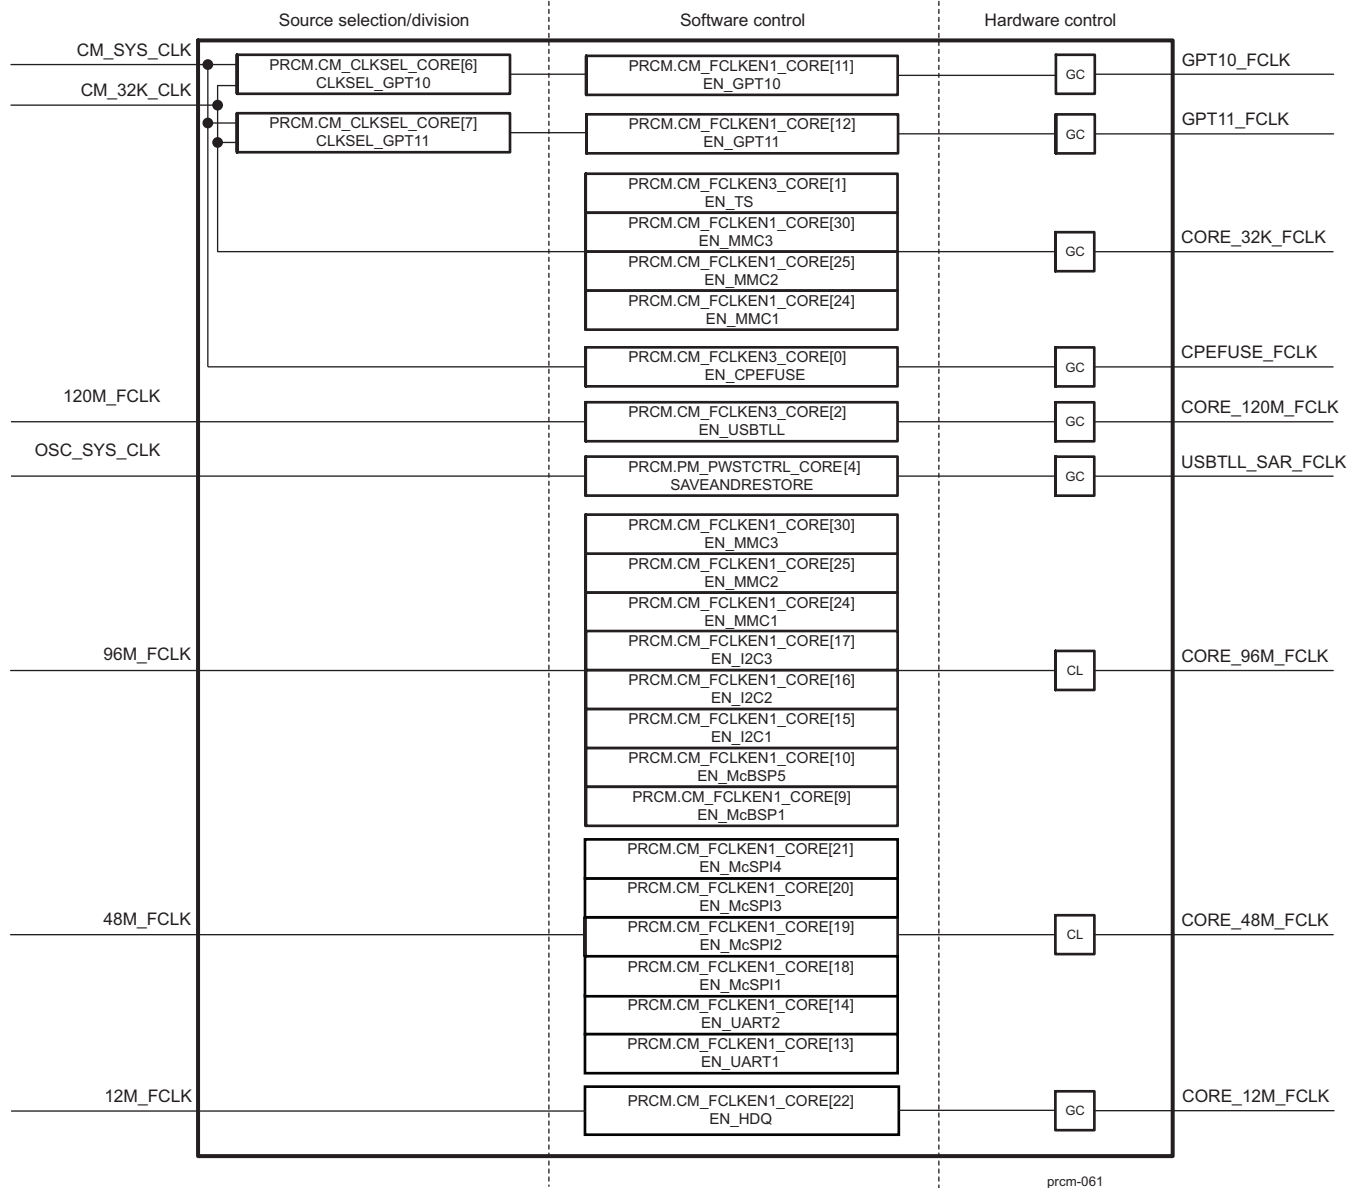

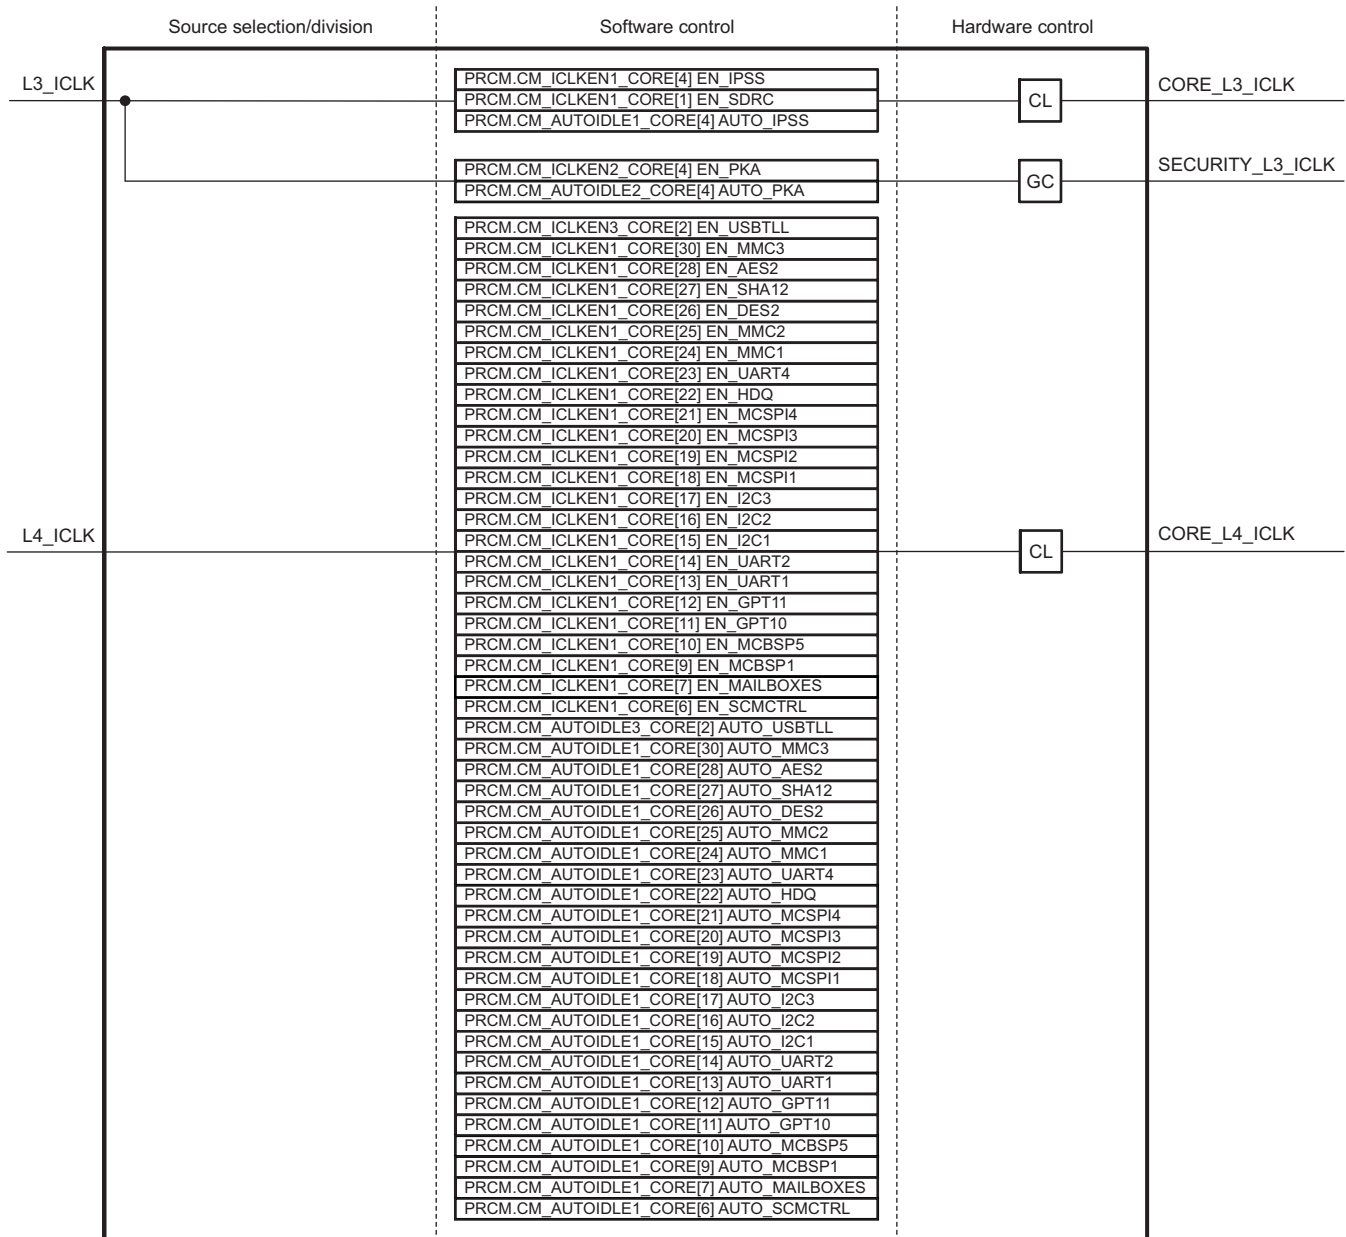

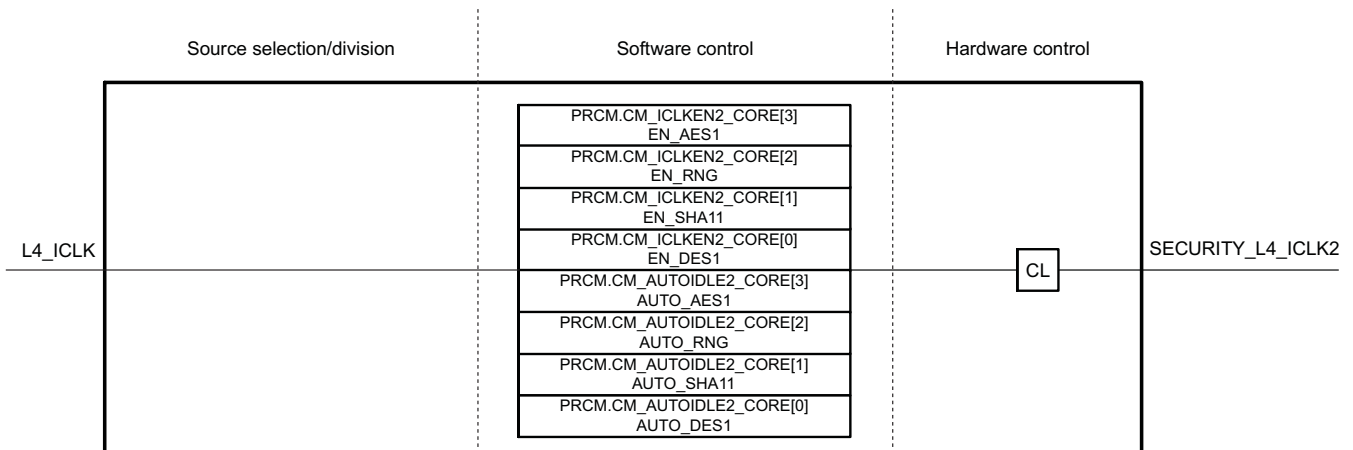

Figure 4-49. CORE Domain Clock Controls: Part 2

prcm-062

Figure 4-50. CORE Domain Clock Controls: Part 3

prcm-063

Table 4-45 lists the clock-gating controls for the CORE domain.

Table 4-45. CORE Domain Clock-Gating Controls

| Clock Name | Reset | Clock-Gating Control | Gating Description |
|-----------------|---------|---|---|
| GPT10_FCLK | Stopped | PRCM.CM_FCLKEN1_CORE[11] EN_GPT10 | Gated when the enable bit is set to 0 |
| GPT11_FCLK | Stopped | PRCM.CM_FCLKEN1_CORE[12] EN_GPT11 | Gated when the enable bit is set to 0 |
| CORE_96M_FCLK | Stopped | McBSP[1..5] input clock source select (in SCM) and PRCM.CM_FCLKEN1_CORE (MMC[1-2], McBSP[1, 5], I2C[1-3]) | Gated when the enable bits of the module functional clock are set to 0. (The McBSPs can have MCBSP_CLKS as an alternate functional clock.) |
| CORE_48M_FCLK | Stopped | PRCM.CM_FCLKEN1_CORE (UART[1-2], McSPI[1-4]) | Gated when the functional clock enable bits of the module are set to 0 |
| CORE_12M_FCLK | Stopped | PRCM.CM_FCLKEN1_CORE[22] EN_HDQ | Gated when the enable bit is set to 0 |
| CORE_L3_ICLK | Running | PRCM.CM_ICLKEN1_CORE EN_(SDRC, IPSS), PRCM.CM_AUTOIDLE1_CORE4] AUTO_IPSS | Gated when: 1. All enable bits are set to 0. 2. The enable-autoidle bit pair is set to 1, the remaining enable bits are set to 0, and the clock is not requested by any module. |
| CORE_L4_ICLK | Running | PRCM.CM_ICLKEN1_CORE (AES2, SHAM2, D3D2, MMC[1..2], HDQ, MCSP[1-4], I2C[1-3], UART[1,2], GPT[10,11], MCBSP[1,5], SCMCTRL) and PRCM.CM_AUTOIDLE1_CORE (AES2, SHAM2, D3D2, MMC[1..2], HDQ, MCSP[1-4], I2C[1-3], UART[1,2], GPT[10,11], MCBSP[1,5], SCMCTRL) | Gated when: 1. All enable bits are set to 0. 2. All enable-autoidle bit pairs are set to 1, and the clock is not requested by any module. |
| CORE_32K_FCLK | Stopped | CM_FCLKEN1_CORE[24] EN_MMC1, CM_FCLKEN1_CORE[25] EN_MMC2, CM_FCLKEN1_CORE[30] EN_MMC3, CM_FCLKEN3_CORE[1] EN_TS | Gated when: 1. All enable bits are set to 0. |
| CPEFUSE_FCLK | Stopped | CM_FCLKEN3_CORE[0] EN_CPEFUSE | Gated when CPEFUSE autoloading sequence is performed, and the enable bit is set to 0 |
| CM_USIM_CLK | Stopped | CM_FCLKEN_WKUP[9] EN_USIMOCP | Gated when the enable bit is set to 0 |
| USBTLL_SAR_FCLK | Stopped | CORE domain power state and PM_PWSTCTRL_CORE[4] SAVEANDRESTORE | Gated when the save-restore bit is set to 0 after the restore operation completes. |
| CORE_120M_FCLK | Stopped | CM_FCLKEN3_CORE[0] EN_USBTLL and DPLL5 operating mode | Gated when the enable bit is set to 0, or the DPLL5 is in stop or bypass mode |

4.7.7.7 EFUSE Domain Clock Controls

Figure 4-51 shows the clock controls for the EFUSE domain. Table 4-46 lists the clock-gating control for the EFUSE domain.

Figure 4-51. EFUSE Domain Clock Controls

Table 4-46. EFUSE Domain Clock-Gating Control

| Clock Name | Reset | Clock-Gating Control | Gating Description |
|------------------|---------|----------------------|---|
| EFUSE_ALWON_FCLK | Running | None | Active when VDD_CORE is ramped up to power on the device and the eFuse-ready hardware signal is released. |

4.7.7.8 DSS Domain Clock Controls

This section gives information about all modules and features in the high-tier device. See Chapter 1, *Device Family* section, to check availability of modules and features. For power savings considerations, ensure that clocks to unused modules are cut off.

Figure 4-52 shows the clock controls for the DSS domain. Table 4-47 lists the clock-gating controls for the DSS domain.

Figure 4-52. DSS Domain Clock Controls

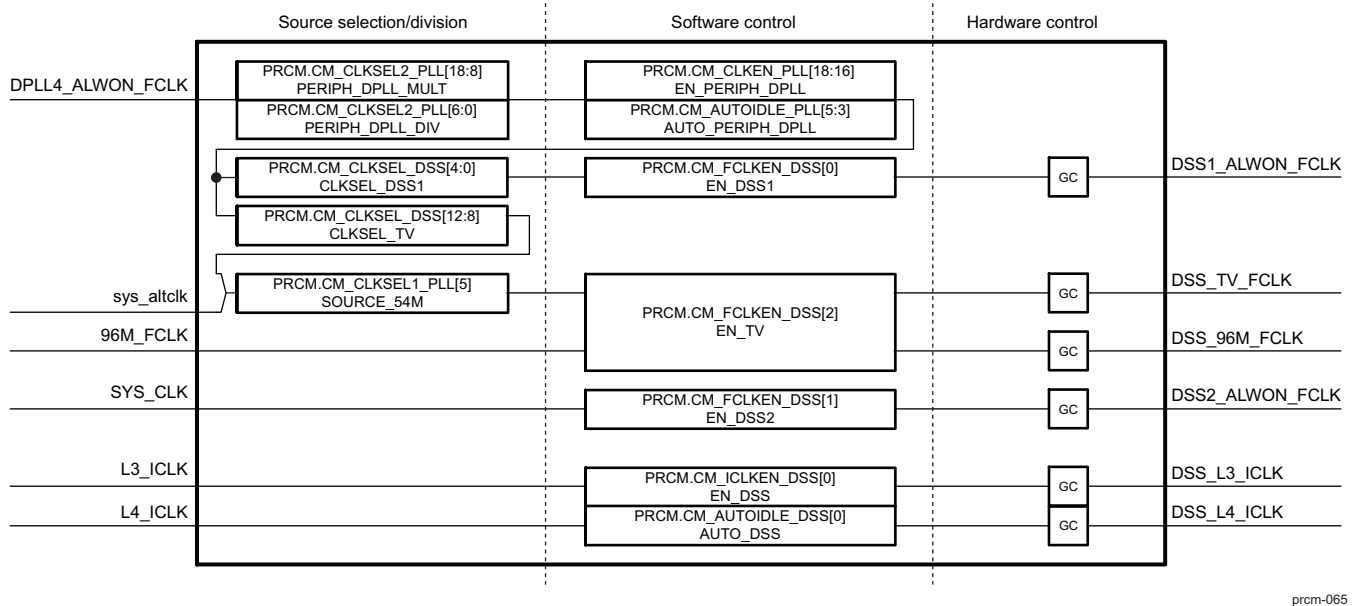

Table 4-47. DSS Domain Clock-Gating Controls

| Clock Name | Reset | Clock-Gating Control | Gating Description |
|-----------------|---------|-------------------------------|---------------------------------------|
| DSS1_ALWON_FCLK | Stopped | PRCM.CM_FCLKEN_DSS[0] EN_DSS1 | Gated when the enable bit is set to 0 |
| DSS2_ALWON_FCLK | Stopped | PRCM.CM_FCLKEN_DSS[1] EN_DSS2 | Gated when the enable bit is set to 0 |
| DSS_TV_FCLK | Stopped | PRCM.CM_FCLKEN_DSS[2] EN_TV | Gated when the enable bit is set to 0 |
| DSS_96M_FCLK | Stopped | | |

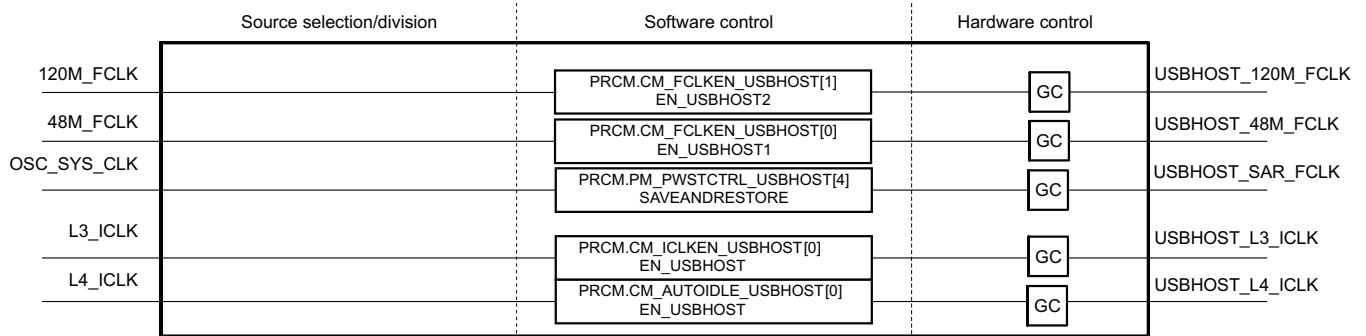

Table 4-47. DSS Domain Clock-Gating Controls (continued)

| Clock Name | Reset | Clock-Gating Control | Gating Description |
|-------------|---------|--|---|
| DSS_L3_ICLK | Stopped | PRCM.CM_ICLKEN_DSS[0] EN_DSS, PRCM.CM_AUTOIDLE_DSS[0] AUTO_DSS | Gated when: 1. Enable bit is set to 0. 2. Enable-autoidle bit pair is set to 1, and the clock is not requested by any module. |
| DSS_L4_ICLK | Stopped | | |

4.7.7.9 USBHOST Domain Clock Controls

Figure 4-53 shows the clock controls for the USBHOST domain. Table 4-48 lists the clock-gating controls for the USBHOST domain.

Figure 4-53. USBHOST Domain Clock Controls

prcm-091

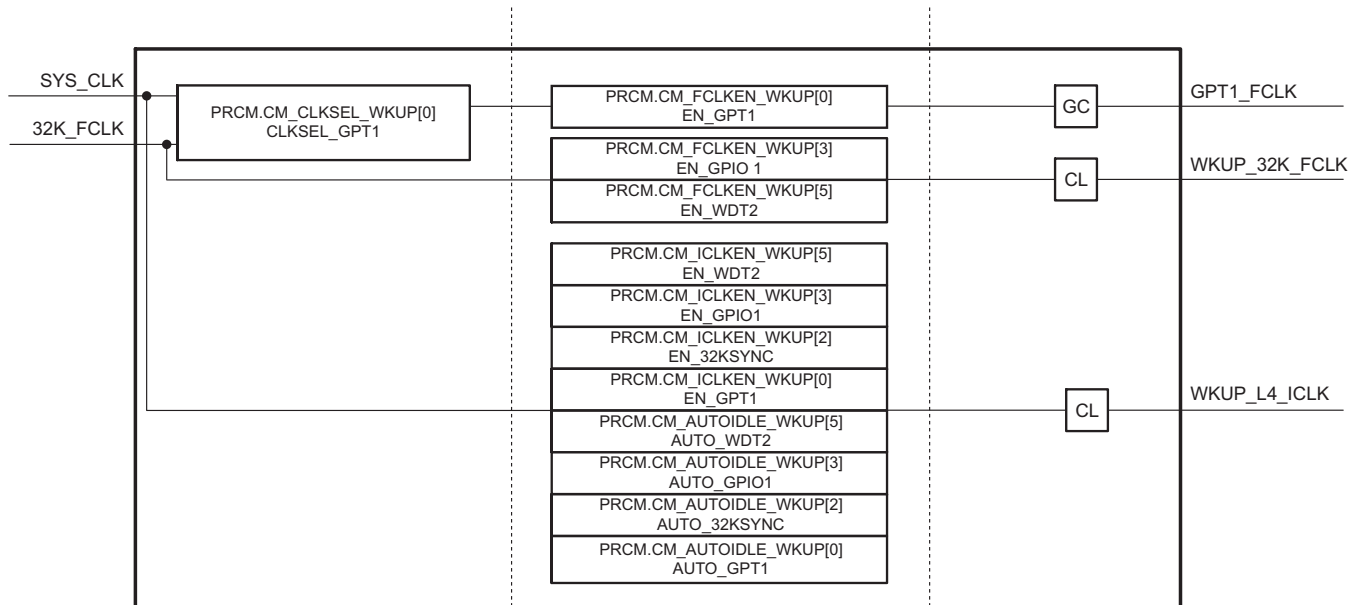

Table 4-48. USBHOST Domain Clock-Gating Controls

| Clock Name | Reset | Clock-Gating Control | Gating Description |
|-------------------|---------|--|--|
| USBHOST_48M_FCLK | Stopped | PRCM.CM_FCLKEN_USBHOST[0] EN_USBHOST1 | Gated when the enable bit is set to 0 |
| USBHOST_120M_FCLK | Stopped | PRCM.CM_FCLKEN_USBHOST[1] EN_USBHOST2 | Gated when the enable bit is set to 0 |
| USBHOST_L3_ICLK | Stopped | PRCM.CM_ICLKEN_USBHOST[0] EN_USBHOST, PRCM.CM_AUTOIDLE_USBHOST[0] AUTO_USBHOST | Gated when: 1. Enable bit is set to 0. 2. Enable-autoidle bit pair is set to 1, and the clock is not requested by subsystem. |
| USBHOST_L4_ICLK | Stopped | | |
| USBHOST_SAR_FCLK | Stopped | PRCM.PM_PWSTCTRL_USBHOST[4] SAVEANDRESTORE | Gated when the save-restore bit is set to 0, or when the domain is in OFF state after the save operation completes or in ON state after the restore operation completes. |

4.7.7.10 WKUP Domain Clock Controls

Figure 4-54 shows the clock controls for the WKUP domain. Table 4-49 lists the clock-gating controls for the WKUP domain.

Figure 4-54. WKUP Domain Clock Controls

| GPT8_ALWON_FCLK | Stopped | PRCM.CM_FCLKEN_PER[9] EN_GPT8 | Gated when the enable bit is set to 0 |
| GPT9_ALWON_FCLK | Stopped | PRCM.CM_FCLKEN_PER[10] EN_GPT9 | Gated when the enable bit is set to 0 |
| PER_L4_ICLK | Stopped | PRCM.CM_ICLKEN_PER EN_(GPIO[2..6], WDT3, UART3, GPT[2..9], MCBSP[2..4]) and PRCM.CM_AUTOIDLE_PER AUTO_(GPIO[2..6], WDT3, UART3, GPT[2..9], and MCBSP[2..4]) | Gated when: 1. All enable bits are set to 0. 2. All enable-autoidle bit pairs are set to 1, and the clock is not requested by any module. |
| 96M_ALWON_FCLK | Stopped | None | Always-on clock |

For audio applications, the McBSP functional clocks are provided externally by the MCBSP_CLKS pin. This clock must be permanently supplied to allow McBSPs to function. If the external clock input is selected as the functional clock, the PER domain sleep transition is prevented.

4.7.7.12 Other Modules Clocks

Device IPs get their clocks from existing clock sources or externally from an IO. Figure 4-57 shows the clock connections for the HECC, VPFE, CPGMACSS_R, USB20TGSS, EMIF4A, SMS, DDR PHY and Bridges/SCR.

Figure 4-57. Clock Sources for Other Modules

4.7.8 Clock Configurations

The device supports several clock configurations. A clock configuration is a consistent set of divider ratios programmed into PRCM to obtain a certain combination of clock speed to match the performance requirement.

In the device, the MPU is connected to the interconnects through asynchronous bridges. The functional frequency of the processor can be configured independently of its interface clock frequency.

4.7.8.1 Processor Clock Configurations

Generic processor operating performance points may be defined as:

- DPLL1 (MPU DPLL) synthesized clock frequency (CLKOUTX2) configured by setting the M and N parameters of the DPLL
- DPLL1 (MPU DPLL) output clock frequency (MPU_CLK) configured by setting the M2 parameter of the DPLL

NOTE: The MPU_CLK is divided by 2 inside the MPU subsystem to generate the ARM_FCLK This divider is only active when the DPLL is locked. (Refer to MPU Subsystem for information on ARM_FCLK).

The frequency of the ARM processor clock (MPU_FCLK) can be configured. [Table 4-51](#) identifies the processor clock, the source clock and the configuration register bits fields.

Table 4-51. Processor Clock Configuration Controls

| Module | Clocks | Reference Clock | Multiplier (factors) | Divider (factors) | Configuration Bits |
|--------|------------------------|-----------------|----------------------|-------------------|---|
| DPLL1 | CLKOUT X2 | SYS_CLK | M (0 ... 2047) | | PRCM.CM_CLKSEL1_PLL_MPU[18:8] MPU_DPLL_MULT |
| | | | | N (0 ... 127) | PRCM.CM_CLKSEL1_PLL_MPU[6:0] MPU_DPLL_DIV |
| | MPU_CLK ⁽¹⁾ | CLKOUTX2 | | M2 | PRCM.CM_CLKSEL2_PLL_MPU[4:0] MPU_DPLL_CLKOUT_DIV |

⁽¹⁾ The MPU_CLK is divided by 2 inside the MPU subsystem to generate the ARM_FCLK This divider is only active when the DPLL is locked. (Refer to MPU Subsystem for information on ARM_FCLK).

Table 4-52. Processor Clock Configurations

| CLOCK | BYPASS | LOCKED |
|-------------------------------|--------------------------------------|----------------------------------|
| MPU_CLK | DPLL1_FCLK (Bypass Clock from DPLL3) | (SYS_CLK * M * 2) / ([N+1] * M2) |
| ARM_FCLK | MPU_CLK | MPU_CLK / 2 |
| MPUSS Internal Modules Clocks | ARM_FCLK / 2 | ARM_FCLK / 2 |

4.7.8.2 Interface and Peripheral Functional Clock Configurations

The DPLL3 (CORE DPLL) generates the CORE_CLK which serves as the source clock for the L3_ICLK and L4_ICLK interface clocks of the device. The CORE_CLOCK is also used by the DPLL1 as the bypass clock. The L3_ICLK is supplied to the SGX module as SGX_L3_ICLK and is used as its functional clock. The L4_ICLK is used by RM_L4_CLK as its source clock.

The interface and peripheral functional clocks frequencies can be configured according to the device performance requirements.

DPLL3 synthesized clock frequencies are configured as:

- $f_{CLKOUT} = (f_{SYS_CLK} \times M) / (N+1)$
- $f_{CLKOUTX2} = f_{CLKOUT} \times 2$

DPLL3 output clock frequencies are configured as:

- $f_{\text{CORE_CLK}} = f_{\text{CLKOUT}} / M2$
 - $f_{\text{COREX2_CLK}} = f_{\text{CLKOUTX2}} / M2$
- L3_ICLK, L4_ICLK and RM_L4_ICLK frequencies are configured as:
- $f_{\text{L3_ICLK}} = f_{\text{CORE_CLK}} / \text{DIV_L3}$
 - $f_{\text{L4_ICLK}} = f_{\text{L3_ICLK}} / \text{DIV_L4}$
 - $f_{\text{RM_L4_ICLK}} = f_{\text{L4_ICLK}} / \text{DIV_RM}$

Table 4-53 identifies the interface clocks, their reference clocks, and the control bits for configuration of the interface clock frequencies.

Table 4-53. Interface Clock Configuration Controls

| Module | Clock | Reference Clock | Multiplier (Factor) | Divider (Factor) | Configuration Bits |
|-----------------|------------|-----------------|---------------------|------------------|--|
| DPLL3 | CLKOUT | SYS_CLK | M (0 ... 2047) | | PRCM.CM_CLKSEL1_PLL[26:16] CORE_DPLL_MULT |
| | CLKOUTX2 | | | N (0 ... 127) | PRCM.CM_CLKSEL1_PLL[14:8] CORE_DPLL_DIV |
| CORE_CLK | CORE_CLK | CLKOUT | | M2 (1 ... 31) | PRCM.CM_CLKSEL1_PLL[31:27] CORE_DPLL_CLKOUT_DIV |
| | COREX2_CLK | CLKOUTX2 | | | |
| L3 interconnect | L3_ICLK | CORE_CLK | | DIV_L3 (1 ... 2) | PRCM.CM_CLKSEL_CORE[1:0] CLKSEL_L3 |
| L4 interconnect | L4_ICLK | L3_ICLK | | DIV_L4 (1 ... 2) | PRCM.CM_CLKSEL_CORE[3:2] CLKSEL_L4 |
| RM clock | RM_L4_ICLK | L4_ICLK | | DIV_RM (1 ... 2) | PRCM.CM_CLKSEL_WKUP[2:1] CLKSEL_RM |

SGX_FCLK and DPLL1_FCLK (bypass mode) frequencies are configured as:

- $f_{\text{SGX_FCLK}} = f_{\text{CORE_CLK}} / \text{DIV_SGX}$
- $f_{\text{SGX_FCLK}} = f_{\text{CM_96M_FCLK}}$
- $f_{\text{DPLL1_FCLK}} = f_{\text{CORE_CLK}} / \text{DIV_DPLL1}$

Table 4-54 identifies the functional clocks, their reference clocks and the control bits for configuration of the functional clock frequencies.

Table 4-54. Functional Clock Configuration Controls

| Module | Clock | Reference Clock | Divider (Factor) | Configuration Bits |
|---------------|------------|-------------------------|---------------------|--|
| SGX | SGX_FCLK | CORE_CLK CM_96M_FCLK | DIV_SGX (3, 4, 6) | PRCM.CM_CLKSEL_SGX[2:0] CLKSEL_SGX PRCM.CM_CLKSEL_SGX[2:0] CLKSEL_SGX |
| MPU HS bypass | DPLL1_FCLK | CORE_CLK | DIV_DPLL1 (1, 2, 4) | PRCM.CM_CLKSEL1_PLL_MPU[20:19] MPU_CLK_SRC |

The rest of the functional clocks are issued from DPLL4 and DPLL5 and remain invariable, regardless of the interface clock configuration. In all clock configurations, any divider ratio to generate functional clocks is applicable, provided it complies with the maximum frequency specification.

4.8 PRCM Idle and Wake-Up Management

4.8.1 Overview

When a group of modules belonging to a clock domain do not require a clock (interface or functional), the PRCM can be programmed to automatically cut the clock to those modules, thereby reducing their power consumption. When all clocks in a domain are cut, the domain is idle.

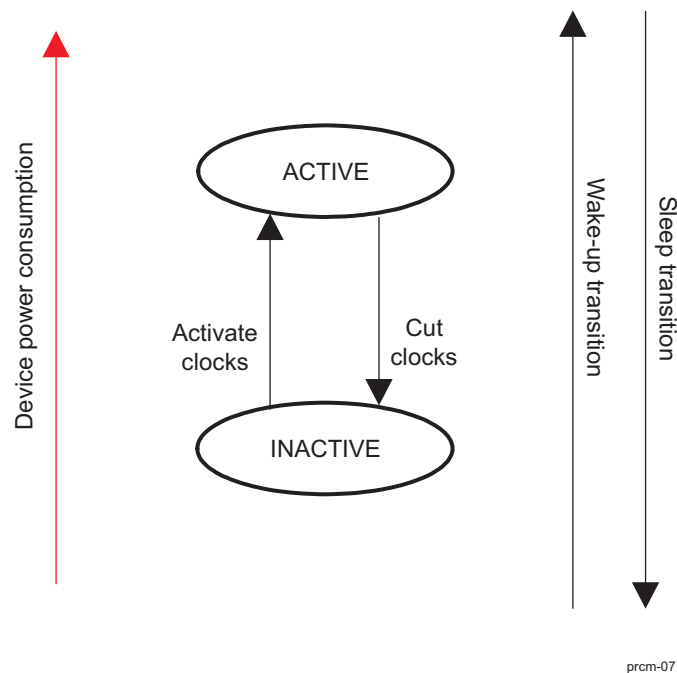

Similarly, when a module in low-power idle mode is required to switch to active mode, the PRCM activates the necessary clock signals to the module. This is a wake-up transition. Generally, a wake-up event triggers the wake-up transition.

A sleep/wake-up dependency can be defined between different domains. A sleep dependency ensures that a domain does not make a sleep transition unless all the dependent domains are in idle mode and do not require the domain. Similarly, a wake-up dependency ensures that a domain wakes up when any of its dependent domains wakes up.

The PRCM automatically handles the sequence clock-gating conditions for each domain, based on the configured dependencies between the domains and the clock-control bits of the modules.

Figure 4-58 shows the sleep/wake-up transition of the domains.

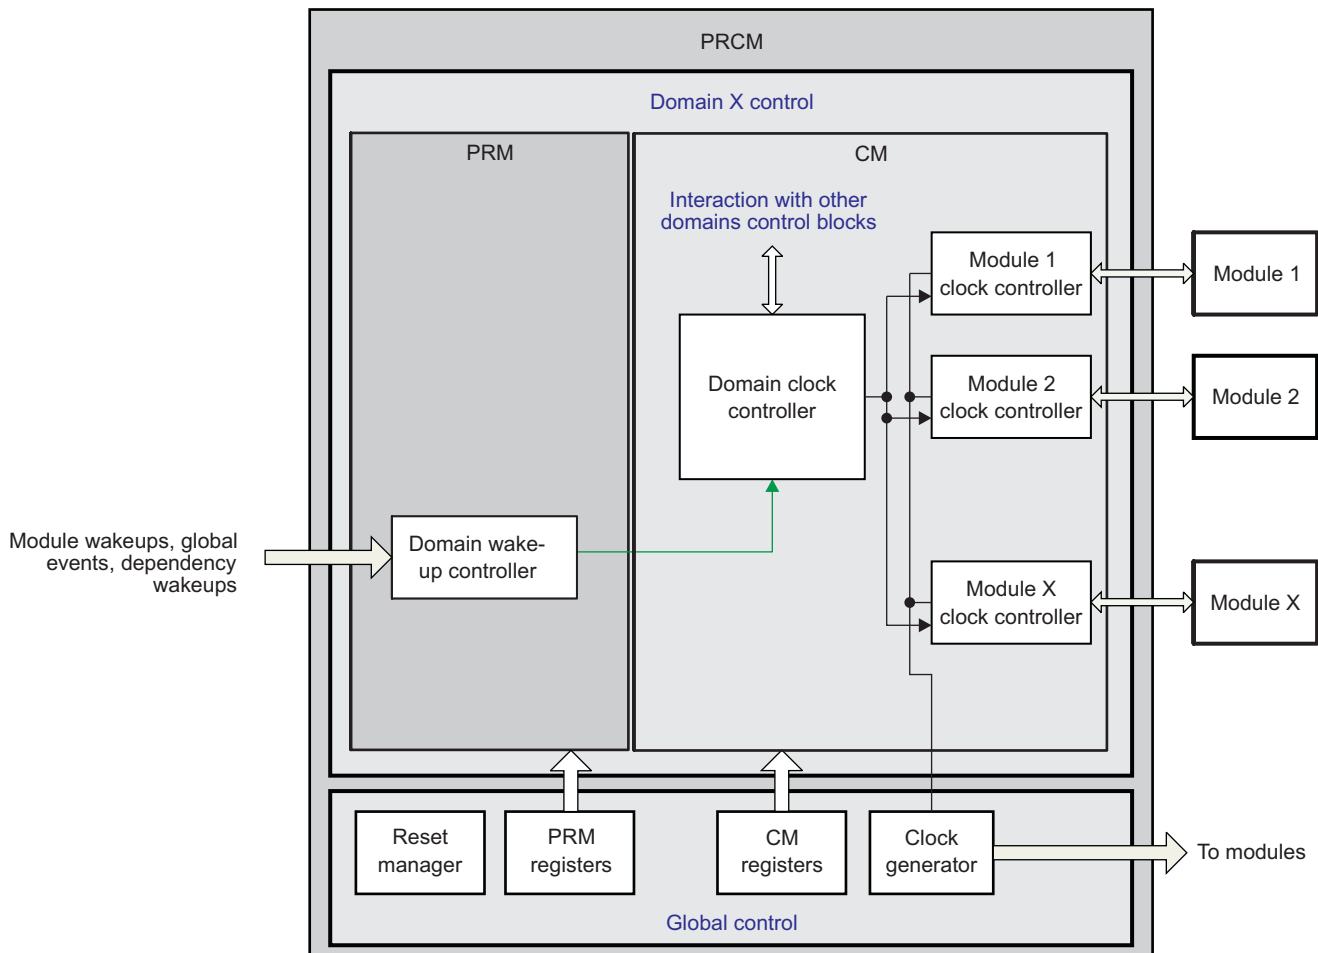

Figure 4-58. Domain Sleep/Wake-Up Transition

prcm-071

Functionally, the PRCM is composed of a single global control block and a power-control block for each domain. The domain power-control block handles wake-up events and clock-gating control for the domain. The domain power controllers communicate with each other for sleep dependencies and wake-up dependencies. All these blocks interact with the global control block that handles reset management, clock generation and distribution, and all PRCM registers.

Figure 4-59. Device Power Reset and Clock Controllers

prcm-072

Figure 4-59 details the functions within one domain control block:

- A module clock controller (for example, module X clock controller) uses a hardware handshake protocol to communicate directly with the module. It controls the idle transition of the target module and responds to the standby requests of the initiator module (for details, see [Section 4.1.3.2, Autoidle Clock Control](#)). Depending on the mode, the clock controller sends clock commands (enable/disable) to the clock generator. The registers that control the functional and interface clocks in the module are directly mapped to the module clock controller.
- The domain clock controller gathers information from the following:
 - All module clock controllers of the domain
 - The domain wake-up controller
 - The other domain control blocks
 On a wake-up event, the domain clock controller starts the module domain clocks.
- The domain wake-up controller gathers all events that can wake up the domain.
- The reset manager globally controls all resets in the device. It gathers information from all domain control blocks to sequence the clocks, and resets the activation of each domain.
- The clock generator generates and distributes clocks over the device, depending on requests from all module clock controllers and on other global conditions.

4.8.2 Sleep Transition

The PRCM can initiate a domain sleep transition on a domain only if the domain meets the following conditions:

- All initiator modules are idle (they have completed their activity and idled themselves through software requests).
- All target modules are idle (automatically when all initiators are in standby mode or on software request).
- All sleep dependencies with other domains are met (can be set by software).

The domain state transition can be set to automatic (hardware controlled) or software-controlled by setting the PRCM. CM_CLKSTCTRL_<domain> CLKTRCTRL_<domain> bit field.

4.8.3 Wakeup

There are three types of wake-up events:

- **Global:** Generated on a particular device event (device wakeup, DPLL recalibration, etc.). Used mainly to wake up the MPU domain
- **Module:** Functional wake-up event issued from a module, which wakes up the domain where the module resides. It can also directly wake up the MPU depending on software settings in the PRCM.PM_MPUGRPSEL_<domain>.
- **Dependency:** A domain can wake up on the wakeup of another domain. The dependency is software-controllable by configuring the PRCM.PM_WKDEP_<domain> register.

4.8.4 Device Wake-Up Events

This section summarizes the wake-up events for each domain. [Table 4-55](#) through [Table 4-63](#) list the wake-up events, related control registers, and MPU interrupts.

The register PRCM.PRM_IRQENABLE_MPU enables the MPU interrupts. In some cases it can also enable the wake-up feature associated with the interrupt (DPLL recalibration requests and device wake-up event).

NOTE:

- The PRCM can be configured to generate an interrupt to the MPU subsystem as a result of a wake-up event from the CORE, WKUP, and PER domain modules to the MPU. However, these modules may also directly interrupt the MPU subsystem. To avoid a double interrupt (from the PRCM and one of these modules) as the result of a single event (wakeup), one interrupt must be masked when the other is unmasked. For further information on its interrupt capability, see the chapter of the corresponding module.
 - The UART, GPIO, McSPI, and USIM OCP modules generate an asynchronous wake-up event (that is, their interface and functional clocks can be gated during the sleep period). However, because the GPTIMERS generate a synchronous wake-up event, they require their functional clock to be active during the sleep period; their interface clock can be gated. McBSP modules can generate a synchronous or asynchronous wake-up event, based on the mode configurations. For further information on its wake-up capability, see the chapter of the corresponding module.
 - The ability of a module to generate a wake-up event depends on the state of the domain in which the module resides. If the domain is inactive (that is, both the functional and interface clocks of the domain are gated), only the asynchronous wake-up modules can wake up the domain. If only the interface clocks in the domain are gated, both synchronous and asynchronous wake-up modules can generate a wake-up event to activate the interface clock.
-

Table 4-55. MPU Domain Wake-Up Events

| Internal Wake-Up Events | Source Module | PRCM Software Control | Wake-Up Event | Interrupt/Type | Interrupt to |

4.8.5 Sleep and Wake-Up Dependencies

4.8.5.1 Sleep Dependencies

The (clock activity) dependencies between domains are implemented to manage their sleep and wake-up transitions to ensure stable operation of the device.

A domain sleep transition is achieved when all its clock domains (that is, functional and interface) are gated. For the gating of a clock domain, the following conditions must be satisfied:

- All initiator modules in the clock domain are in standby mode, that is, they cannot initiate any new transitions.
- All target modules in the clock domain are in idle mode and have no pending transitions.
- If the domain depends on another domain (that is, has a sleep dependency), the clock domains of the other domain must be muted.

A clock domain is said to be muted when all its public initiator modules (that is, the initiator modules of the clock domain that can generate interconnect transactions towards targets outside the clock domain) are in standby mode, and the domain cannot initiate new interconnect transactions toward other domains.

Table 4-64 describes the mute conditions for the clock domains.

Table 4-64. Clock Domain Mute Conditions

| Clock Domain Name | Clock Domain Composition | Mute Conditions |
|-------------------|---|--------------------------------|
| MPU | MPU domain and MPU INTC in CORE domain | MPU in stand-by, MPU INTC idle |
| SGX | SGX domain | SGX in stand-by |
| DSS | DSS domain | DSS in stand-by |
| PER | PER domain | N/A (No public Initiator) |
| CORE_L3 | L3 interconnect, L3 targets/initiators in CORE domain | sDMA in standby |
| CORE_L4 | L4 interconnect, L4 targets in CORE domain | N/A (No public Initiator) |
| USBHOST | USBHOST domain | USBHOST in stand-by |
| WKUP | WKUP domain | N/A (No public Initiator) |

A sleep dependency prevents the PRCM from gating the clocks to a domain (for sleep transition to inactive from on state) if a dependent domain is active (i.e., its clocks are active). A domain may depend on several other domains.

A domain sleep dependency is programmed by setting the PRCM.CM_SLEEPDEP_<domain> register.

Example:

The PER domain has a programmable sleep dependency with the MPU domain, and a hardwired sleep dependency with the CORE domain. Therefore, if all software dependencies are enabled, the PER domain can go into idle mode only if the MPU and CORE-L3 clock domains are idle. If all software dependencies are disabled, the PER domain can go into idle mode, provided that the CORE-L3 clock domain is muted (no access to the PER domain can be pending).

[Table 4-65](#) summarizes the programmable and hardwired sleep dependencies among the domains.

Table 4-65. Sleep Dependencies

| Power Domain | Clock Domain | Sleep Dependency | | | | | | | | | |
|--------------|--------------|------------------|------|-----|-----|-----|---------|---------|---------|----------|------|
| | | MPU | NEON | SGX | DSS | PER | CORE_L3 | CORE_L4 | CORE_CM | USB HOST | WKUP |
| MPU | MPU | n/a | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| NEON | MPU | 1 | n/a | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| SGX | SGX | RW | 0 | n/a | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| DSS | DSS | RW | 0 | 0 | n/a | 0 | RW | 0 | 0 | 0 | 0 |
| PER | PER | RW | 0 | 0 | 0 | n/a | 1 | 0 | 0 | 0 | 0 |
| CORE | CORE_L3 | 1 | 0 | 1 | 1 | 1 | n/a | 1 | 0 | 1 | 1 |
| | CORE_L4 | 1 | 0 | 0 | 0 | 0 | 1 | n/a | 0 | 0 | 0 |
| | CORE_CM | 1 | 1 | 1 | 1 | 1 | 1 | 1 | n/a | 1 | 1 |
| USBHOST | USBHOST | RW | 0 | 0 | | 0 | 0 | 0 | 0 | n/a | 0 |
| WKUP | WKUP | 1 | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 0 | n/a |

Notes:

| | | |
|---|-----|--------------------|
| No software control (hardwired values): | 0 | Does not depend on |
| | 1 | Depends on |
| Software controllable | RW | Read and write |
| | n/a | Not applicable |

NOTE: The first row of the table identifies the dependent domains for a domain listed in the first column. Therefore, to identify the sleep dependency of domain X, identify domain X in the first column and its sleep dependency with domains (of the first row) is identified by its row.

4.8.5.2 Wake-Up Dependencies

A wake-up dependency allows a domain to wake up (from inactive to on state) when another domain wakes up (from off to on state). For example, domain one (PD1) provides a service to domain two (PD2), which creates a dependency between the two domains. When the dependent domain (PD2) wakes up, it signals PD1 with a broadcasted wake-up event, causing PD1 to wake up.

A broadcasted wake-up event can originate from one of two sources:

- PD2 internal wake-up event (typically, a peripheral wake-up event)
- Abortion of the mute mode (at least one initiator in the domain exits standby mode) of PD2 when both the sleep dependency and wake-up dependency with PD1 are enabled.

NOTE: The domain wake-up dependency is a nontransitive property.

If a domain PD1 has wake-up dependency with domain PD2, i.e., PRCM.PM_WKDEP_PD1.EN_PD2 bit is set to 1 and if PD2 has wake-up dependency with domain PD3, i.e., PRCM.PM_WKDEP_PD2.EN_PD3 bit is set to 1.

However, if PD1 does not have a direct wake-up dependency with PD3, i.e., PRCM.PM_WKDEP_PD1.EN_PD3 bit is set to 0. Then if the PD1 and PD2 are INACTIVE and PD3 is INACTIVE and is woken-up by a wake-up event, the PD2 is also woken-up but not the PD1.

Because a domain can depend on several other domains, it can broadcast the wake-up signal to each domain on which it depends.

A domain wake-up dependency can either be hardwired (set in the hardware) or programmable through software by configuring the PM_WKDEP_<domain> register for that domain. Continuing the example of PD2 as dependent on PD1, setting the PM_WKDEP_PD1.PD2 bit means that when PD2 wakes up, PD1 also wakes up.

The MPU domain can be wakened only by the DSS, USBHOST, PER, CORE-L3, CORE-L4, and WKUP domains. All wake-up dependencies of the MPU domain are software-configurable.

When the wake-up dependency with other domains is software-programmable (that is, with the USBHOST, PER, CORE, and WKUP domains), two registers may need be configured: PM_WKDEP_<domain> and PM_<processor>GROUPSEL_<domain>.

The PM_WKDEP_<domain> register serves only to enable/disable the global wake-up dependency of the processor domain on these three domains. The PM_<processor>GROUPSEL_<domain> register must be configured to enable the particular wake-up event in these domains that will wake up the processor domain. Thus, the global wake-up dependency for a dependent domain must be enabled so that a wake-up event can occur, if it has been enabled in the corresponding GROUPSEL register.

For example, if the wake-up dependency of the MPU domain is to be enabled for a wake-up event from the GPIO2 module of the PER domain, the following configuration is required:

- PRCM.PM_MPUGRPSEL_PER[13] GRPSEL_GPIO2
- PRCM.PM_WKDEP_MPU[7] EN_PER

Table 4-66 summarizes the programmable and hardwired wake-up dependencies among the domains.

Table 4-66. Wake-Up Dependencies

| Power Domain | Clock Domain | Wake-Up Dependency | | | | | | | | | |
|--------------|--------------|--------------------|------|-----|-----|----------|-----|---------|---------|---------|------|
| | | MPU | NEON | SGX | DSS | USB HOST | PER | CORE_L3 | CORE_L4 | CORE_CM | WKUP |
| MPU | MPU | n/a | 0 | 0 | RW | RW** | RW* | RW* | RW* | 0 | RW** |
| NEON | MPU | RW | n/a | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| SGX | SGX | RW | 0 | n/a | 0 | 0 | 0 | 0 | 0 | 0 | RW |
| DSS | DSS | RW | 0 | 0 | n/a | 0 | 0 | 0 | 0 | 0 | RW |
| USBHOST | USBHOST | RW | 0 | 0 | 0 | n/a | 0 | RW | 0 | 0 | RW |
| PER | PER | RW | 0 | 0 | 0 | 0 | n/a | RW | 0 | 0 | RW |

Table 4-66. Wake-Up Dependencies (continued)

| Power Domain | Clock Domain | Wake-Up Dependency | | | | | | | | | |
|--------------|--------------|--------------------|------|-----|-----|----------|-----|---------|---------|---------|------|
| | | MPU | NEON | SGX | DSS | USB HOST | PER | CORE_L3 | CORE_L4 | CORE_CM | WKUP |
| CORE | CORE_L3 | 1 | 0 | 0 | 1 | 1 | 1 | n/a | 1 | 0 | 1 |
| | CORE_L4 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | n/a | 0 | 1 |
| | CORE_CM | 1 | 0 | 0 | 1 | 1 | 1 | 1 | 1 | n/a | 1 |
| WKUP | WKUP | 1 | 0 | 0 | 0 | 1 | 1 | 1 | 1 | 0 | n/a |

Legend:

| | |
|------|---|
| RW | Software wakeup dependency: dependency by PM_WKDEP_<> register. |
| RW* | Software wakeup dependency: dependency by PM_WKDEP_<> and PM_<>GRPSEL_<> registers. |
| RW** | Software wakeup dependency: dependency by PM_<>GRPSEL_<> registers. |
| 1 | Hardware wakeup dependency: dependency always enabled. |
| 0 | No wakeup dependency applicable. |
| n/a | Not applicable |

4.8.6 Other Modules Idle/Wakeup Management

For the purposes of Idle and Wakeup Management in the device, a number of modules (HECC, CPGMAC, VPFE and USB200TG) are grouped together in a domain called the IP subsystem (IPSS). The IPSS has a single Idle req/ack interface to the CM. When CM asserts ipss_idle_req signal to IPSS, ipss_idle_ack will be returned if all IPSS modules (HECC, CPGMAC, VPFE and USB200TG) are clock gated. An MPU programmable register (IPSS_CLK_CTRL) is implemented in the system control module for gating the clocks to these modules.

To gate the VBUSP (interface) clock of a IPSS module, the MPU writes the <module>_vbusp_clk_en bit in IPSS_CLK_CTRL register. The MPU must poll the <module>_vbusp_clk_en_ack bit in IPSS_CLK_CTRL register to make sure that clock is gated. Due the clock gating procedure, the MPU must not send a VBUSP request to this module.

To exit clock gating mode for an IP, the MPU must clear <module>_vbusp_clk_en bit in IPSS_CLK_CTRL register. The <module>_vbusp_clk_en_ack bit will be updated to indicate when the clock is ungated.

The MPU can also gate the functional clock to a IPSS module by writing to the <module>_func_clk_en bit in the IPSS_CLK_CTRL register.

4.9 PRCM Interrupts

[Table 4-67](#) lists the interrupts from the PRCM to the MPU.

Table 4-67. Interrupt Descriptions

| Interrupt Name | Mapping | Description |
|----------------|----------|--|
| PRCM_MPU_IRQ | M_IRQ_11 | To MPU interrupt controller (MPU INTC) |

Table 4-68 summarizes the event flags (in the PRM_IRQSTATUS_MPU register) and mask (in the PRM_IRQENABLE_MPU register) related to the events generating PRCM interrupts to the MPU.

Table 4-68. MPU Interrupt Event Descriptions

| Event Flag | Event Mask | Map to | Automatic MPU Domain Wake-Up Event | Description |
|--|--|--------------|------------------------------------|--|
| PRM_IRQSTATUS_MPU[0] WKUP_ST | PRM_IRQENABLE_MPU[0] WKUP_EN | PRCM_MPU_IRQ | No | MPU peripheral group wakeup |
| PRM_IRQSTATUS_MPU[2] EVGENON_ST | PRM_IRQENABLE_MPU[2] EVGENON_EN | PRCM_MPU_IRQ | No | Event generator end of on time |
| PRM_IRQSTATUS_MPU[3] EVGENOFF_ST | PRM_IRQENABLE_MPU[3] EVGENOFF_EN | PRCM_MPU_IRQ | No | Event generator end of off time |
| PRM_IRQSTATUS_MPU[4] TRANSITION_ST | PRM_IRQENABLE_MPU[4] TRANSITION_EN | PRCM_MPU_IRQ | No | A sleep or wake-up transition completion event for NEON, SGX, DSS, PER, EMU, USBHOST domains |
| PRM_IRQSTATUS_MPU[5] CORE_DPLL_ST | PRM_IRQENABLE_MPU[5] CORE_DPLL_RECAL_EN | PRCM_MPU_IRQ | Yes | DPLL3 recalibration event |
| PRM_IRQSTATUS_MPU[6] PERIPH_DPLL_ST | PRM_IRQENABLE_MPU[6] PERIPH_DPLL_RECAL_EN | PRCM_MPU_IRQ | Yes | DPLL4 recalibration event |
| PRM_IRQSTATUS_MPU[7] MPU_DPLL_ST | PRM_IRQENABLE_MPU[7] MPU_DPLL_RECAL_EN | PRCM_MPU_IRQ | Yes | MPU DPLL recalibration event |
| PRM_IRQSTATUS_MPU[9] IO_ST | PRM_IRQENABLE_MPU[9] IO_EN | PRCM_MPU_IRQ | No | I/O pads wake-up event |
| PRM_IRQSTATUS_MPU[25] SND_PERIPH_DPLL_RECAL_ST | PRM_IRQENABLE_MPU[25] SND_PERIPH_DPLL_RECAL_EN | PRCM_MPU_IRQ | Yes | DPLL5 recalibration event |

NOTE: The software must first read the event flag to know the interrupt cause, and then write 1 to it to clear the flag.

4.10 PRCM Voltage Management Functional Description

This section describes the voltage control architecture. It also explains the interactions between the device and the external power IC.

NOTE: For more information regarding the device power pads connection, please refer to your device-specific data manual.

4.11 PRCM Basic Programming Model

The PRCM supports an extensive set of module-specific registers that allow programming control over numerous features of the clocks, resets, and power-management signals for each domain of the device.

These registers are fully programmable and accessible by the MPU subsystem.

Logically, the registers are grouped into five categories:

- Global
- Clock management
- Reset management
- Power management
- Voltage management

4.11.1 Global Registers

4.11.1.1 Revision Information Registers

- CM_REVISION: Indicates the CM module revision code; it is read-only
- PRM_REVISION: Indicates the PRM module revision code; it is read-only

4.11.1.2 PRCM Configuration Registers

- CM_SYSCONFIG: Holds an AUTOIDLE bit to control the CM internal clock autogating feature
- PRM_SYSCONFIG: Holds an AUTOIDLE bit to control the PRM internal clock autogating feature

4.11.1.3 Interrupt Configuration Registers

The PRM can interrupt the MPU as a result of several events:

- PRM internal event (event generator, sleep transition, wake-up transition)
- Peripheral wake-up event for a peripheral with interrupt capability (GPTIMER[1..12], GPIO[1..6], McBSP[1..5], UART[1..3], IPSS, I2C[1..3], McSPI[1..4], MMC[1,2])
- Module/device-level event not associated with any interrupt (DPLL recalibration, I/O wakeup)

The PRM interrupt is enabled by programming the PRM_IRQENABLE_<processor_name> register; the interrupt status can be read from the PRM_IRQSTATUS_<processor_name> register.

The device has the following processor interrupt registers:

- PRM_IRQSTATUS_MPU
- PRM_IRQENABLE_MPU

4.11.1.3.1 MPU Interrupt Event Sources

The MPU interrupt registers correspond to the interrupt sources connected to the interrupt line mapped to the MPU interrupt controller.

Multiple events can activate this interrupt line:

- MPU peripheral group wake-up event
- Event-generator module end-of-on time and end-of-off time events
- Sleep or wake-up transition (SGX, USBHOST, PER, DSS, NEON, EMU domains)
- DPLL1/DPLL3/DPLL4/DPLL5 recalibration request
- I/O pad wake-up event

The end-of-on time period and end-of-off time period events of the event generator module are sources of interrupts to the MPU processor (the corresponding bits in the PRM_IRQENABLE_MPU are set to 1). The end-of-OFF time period is the source of wake-up events on the MPU domain.

The MPU can force a sleep or wake-up transition on some domains (SGX, USBHOST, PER, DSS, NEON, EMU). The PRM triggers the MPU interrupt when the domain enters a power state. The software must clear the CM_CLKSTCTRL_<domain_name> register only after getting the interrupt. If the software clears this bit before getting the interrupt, the interrupt never occurs, regardless of whether the transition occurs.

An interrupt for a peripheral with wake-up capability is enabled when the wake-up enable bit (PM_WKEN_<domain_name> register type) and group select bit (PM_<processor_name>GRPSEL_<domain_name> type of register) are set to 1.

The PRM triggers the MPU interrupt as long as the DPLL recalibration flag is set and the corresponding interrupt enable bit in the PRM_IRQENABLE_<processor_name> register is set to 1. The recalibration flag is set by the DPLL and remains active if the DPLL is not reinitialized.

4.11.1.3.2 MPU Interrupt Registers

4.11.1.3.2.1 PRM_IRQENABLE_MPU (MPU Interrupt Enable Register)

The MPU interrupt enable register allows independent masking/unmasking of each MPU internal interrupt source.

NOTE: If the following interrupts are enabled and the MPU domain is idled, then when the event occurs, the PRCM sets the interrupt that wakes up the domain:

- DPLL1/DPLL3/DPLL4/DPLL5 recalibration event
-

4.11.1.3.2.2 PRM_IRQSTATUS_MPU (MPU Interrupt Status Register)

The MPU interrupt status register provides the status of all PRCM internal events that can generate an MPU interrupt. Software must read this register to identify the interrupt cause, and then clear the pending interrupt by setting the corresponding bit to 1.

4.11.1.4 Event Generator Control Registers

For details about the event generator module, see the public *ARM® Cortex™-A8 Technical Reference Manual*.

In the PRCM, three event generator registers allow configuration of the event generator module:

- PM_EVGENCTRL_MPU (event generator control register): Event-generator settings
- PM_EVGENONTIM_MPU (event generator on-time register): On-time duration setting
- PM_EVGENOFFTIM_MPU (event generator off-time register): Off-time duration setting

4.11.1.5 Output Signal Polarity Control Registers

4.11.1.5.1 CM_POLCTRL (CM Polarity Control Register)

The CM_POLCTRL register allows the setting of the polarity of sys_clkout2 when gated (disabled). sys_clkout2 can be gated to a low level or a high level, depending on the software programming of this register. [Figure 4-60](#) shows the normal behavior of sys_clkout2 when gated.

Figure 4-60. sys_clkout2 Gating Polarity Control

prcm-078

4.11.1.5.2 PRM_POLCTRL (PRM Polarity Control Register)

The PRM polarity control register allows the setting of the polarity of the external signals controlled by the PRM. It contains the following polarity control bits:

- CLKOUT_POL: Polarity of sys_clkout1
- CLKREQ_POL: Polarity of sys_clkreq
- EXTVOL_POL: Polarity of both sys_nvmode signals: sys_nvmode1 and sys_nvmode2

At device power up, CLKREQ_POL = 1. Depending on the system hardware implementation, these signals may or may not be used during device power up. For details about using these signals, see [Section 4.7, Clock Manager Functional Description](#),

4.11.2 Clock Management Registers

4.11.2.1 System Clock Control Registers

4.11.2.1.1 PRM_CLKSRC_CTRL (Clock Source Control Register)

The clock source control register is dedicated to the clock source controls of the device. It contains the following bit fields:

- SYSCLKSEL: Indicates the oscillator mode (oscillator/bypass) and is automatically updated at power up
- AUTOEXTCLKMODE: Enables autogating for the system clock, depending on the device power state. The clock can be configured to be automatically gated when all domains are in idle state. When the gating condition is satisfied, the internal oscillator is turned off, if it is used. Otherwise, sys_clkreq is asserted to notify the external clock source to turn off.

NOTE: Power consumption is reduced with the SYS_CLK off; however, wake-up latency is increased because of oscillator stabilization time after the clock is turned on again.

- SYSCLKDIV: Input divider (1, 2) of the system clock,

4.11.2.1.2 **PRM_CLKSETUP (Source-Clock Setup Register)**

The source-clock setup register allows the setting of the setup time of the oscillator system clock, based on the number of 32-kHz clock cycles. This duration corresponds to the time required by the oscillator to stabilize before propagating the system clock.

Because the reset lasts long enough for oscillator stabilization, this register is not used at power-on reset of the device. This is ensured either by the external reset source (power IC) or by the reset extension in the PRCM (RSTTIME0 timer). The PRM_CLKSETUP register is cleared on cold reset only.

4.11.2.1.3 **PRM_CLKSEL (Source-Clock Selection Register)**

The PRCM.PRM_CLKSEL[2:0] SYS_CLKIN_SEL bit field is used to select the input frequency of the system clock (12, 13, 16.8, 19.2, 26 or 38.4 MHz).

4.11.2.2 External Clock Output Control Registers

4.11.2.2.1 PRM_CLKOUT_CTRL (Clock Out Control Register)

The PRM clock out control register provides control to enable and disable the gating of the sys_clkout1 output clock.

4.11.2.2.2 CM_CLKOUT_CTRL (Clock Out Control Register)

The CM clock out control register provides control over the device output clock sys_clkout2, which can be used externally for functional or test purposes. The register allows the following:

- Selection of the source clock for sys_clkout2:
 - CORE_CLK
 - SYS_CLK
 - 96-MHz clock
 - 54-MHz clock
- Dividing-down the selected source clock by 1, 2, 4, 8, or 16
- Enabling/disabling of the gating of sys_clkout2

4.11.2.3 DPLL Clock Control Registers

A set of registers controls the clock features of the five DPLLs (DPLL1, DPLL3, DPLL4, and DPLL5):

- CM_CLKSELn_PLL_<processor_name>
- CM_CLKSELn_PLL
- CM_CLKEN_PLL_processor_name>
- CM_CLKEN_PLL
- CM_AUTOIDLE_PLL_processor_name>
- CM_AUTOIDLE_PLL
- CM_IDLEST_PLL_<processor_name>
- CM_IDLEST_CKGEN
- CM_IDLEST2_CKGEN

The following sections describe the purposes of these registers.

4.11.2.3.1 CM_CLKSELn_PLL_<processor_name> (Processor DPLL Clock Selection Register)

The processor DPLL clock selection register controls the clock configuration of DPLL1, including the following features:

- The multiplier (M) and divider (N) values of the DPLL
- Selection of the fast bypass clock (CORE_CLK or CORE_CLK/2) in bypass mode
- Configuration of DPLL output clock divider values (M2 factor)

The device has two DPLL clock selection registers for DPLL1:

- CM_CLKSEL1_PLL_MPU: DPLL1 multiplier, divider, and fast bypass clock selection
- CM_CLKSEL2_PLL_MPU: DPLL1 output clock divider selection

4.11.2.3.2 CM_CLKSELn_PLL (DPLL Clock Selection Register)

The DPLL clock selection register controls the clock configuration for DPLL3, DPLL4, and DPLL5, including the following features:

- The multiplier (M) and divider (N) values of the DPLL
- Configuration of DPLL output clock divider values

The device has following DPLL clock selection registers for DPLL3, DPLL4, and DPLL5:

- CM_CLKSEL1_PLL: DPLL3 multiplier, divider, and output clock division configuration. Source selection for the 54-MHz and 48-MHz clock (48M_FCLK) between DPLL4 output and sys_altclk.
- CM_CLKSEL2_PLL: DPLL4 multiplier and divider configuration
- CM_CLKSEL3_PLL: Divider configuration for 96-MHz clock (96M_FCLK)
- CM_CLKSEL4_PLL: DPLL5 multiplier and divider configuration
- CM_CLKSEL5_PLL: Divider configuration for 120-MHz clock (120M_FCLK)

4.11.2.3.3 CM_CLKEN_PLL_<processor_name> (Processor DPLL Clock Enable Register)

The processor DPLL clock enable register allows the enabling or disabling of DPLL1. It allows an immediate setting of the DPLL.

The device clock enable registers for DPLL1 is CM_CLKEN_PLL_MPU: DPLL1.

The CM_CLKEN_PLL_<processor_name> register allows programmable control of the following DPLL features:

- Low-power bypass mode/lock mode selection
- Automatic recalibration enable/disable
- Programmable internal frequency range of the DPLL
- Frequency ramping feature disabled and enabled with programmable step duration (4 s, 20 s, or 40 s)
- The DPLL LP mode can be enabled or disabled. However, switching between LP and normal mode is effective only when the DPLL has performed a recalibration; therefore, the DPLL must lock or relock. Also, the LP mode control is considered only during the following transitions:
 - From bypass to lock
 - From stop mode to lock
 - From lock to relock

NOTE: DPLL1 enters its internal power state (MNBYPASS) after being released from reset or when a multiplier value of 0 or 1 is loaded into the DPLL. Therefore, even if the CM_CLKEN_PLL_MPU[2:0] EN_MPU_DPLL bit field is reset to the low-power bypass mode, DPLL1 automatically transitions to MNBYPASS mode, because the multiplier value (the CM_CLKSEL1_PLL_MPU[18:8] MPU_DPLL_MULT bit field) resets to 0.

4.11.2.3.4 **CM_CLKEN_PLL (DPLL Enable Register)**

The DPLL enable register allows control of DPLL3 DPLL4, and DPLL5. It allows an immediate setting of the DPLLs. This register controls the following features of the two DPLLs:

- DPLL operation mode:
 - Low-power bypass, fast-relock bypass, and lock modes for DPLL3
 - Low-power bypass and lock modes for DPLL4
- Programmable automatic recalibration
- Programmable internal frequency range for the DPLL
- Frequency ramp-up feature disable/enable with programmable step duration
- The DPLL3 output M3X2 and the DPLL4 outputs M2X2, M3X2, M4X2, M5X2, and M6X2 clock paths can be powered down. However, the setting takes effect only when the output clock is gated. It is also powered down whenever the DPLL is in stop mode, regardless of the software settings.
- The DPLL LP mode can be enabled or disabled. However, switching between LP and normal mode is effective only when the DPLL has performed a recalibration; therefore, the DPLL must lock or relock. Also, the LP mode control is considered only during the following transition:
 - From bypass to lock
 - From stop mode to lock
 - From lock to relock

4.11.2.3.5 **CM_AUTOIDLE_PLL <processor_name> (Processor DPLL Autoidle Register)**

The processor DPLL autoidle register allows the enabling/disabling of the automatic processor DPLL activity control. In automatic mode, the DPLL automatically enters low-power stop mode when the DPLL clock is not required. It is also restarted automatically.

The following is the device DPLL auto-control register:

- CM_AUTOIDLE_PLL_MPU: DPLL1 autoidle mode control.

4.11.2.3.6 **CM_AUTOIDLE_PLL (DPLL Autoidle Register)**

The DPLL autoidle register allows the enabling/disabling of the automatic mode-switching control for DPLL3 and DPLL4. This automatic mode takes effect only when the DPLLs are locked.

DPLL3 can be configured to automatically switch to either low-power bypass mode or low-power stop mode when the CORE domain clock is not required.

DPLL4 can be configured to automatically switch to low-power stop mode when the PER domain clock is not required.

4.11.2.3.7 **CM_AUTOIDLE1_PLL (DPLL5 Autoidle Register)**

The DPLL5 autoidle register allows the enabling/disabling of the automatic mode-switching control. This automatic mode takes effect only when the DPLL is locked.

When enabled, DPLL5 is automatically switched to low-power stop mode whenever the 120-MHz output clock is gated.

4.11.2.3.8 **CM_IDLEST_CKGEN (Source-Clock Idle-Status Register)**

The source-clock idle-status register provides a status of DPLL3 and DPLL4 clock activity. It also provides the status of the functional clocks derived from DPLL4 output.

The activity status for DPLL3 and DPLL4 can be:

- DPLL is bypassed.
- DPLL is locked.

The activity status for the functional clocks can be:

- The functional 96-MHz clock is active, or not.
- The functional 48-MHz clock is active, or not.
- The functional 12-MHz clock is active, or not.
- The functional 54-MHz clock is active, or not.

The functional 96-MHz clock and all other functional clocks derived from it are active only when DPLL4 is locked and the clock is required.

The functional 48-MHz and 12-MHz clocks are qualified as active only if the clock is required and when the external alternate clock is selected as the source clock.

The functional 54-MHz clock (DSS_TV_CLK) is active only when DPLL4 is locked, selected as the source clock, and required.

4.11.2.3.9 **CM_IDLEST2_CKGEN (DPLL5 Source-Clock Idle-Status Register)**

The source-clock idle-status register provides the status of DPLL5 clock activity. It also provides the status of the functional clocks derived from DPLL5 output.

The activity status for DPLL5 can be:

- DPLL is bypassed.
- DPLL is locked.

The activity status for the functional clocks can be:

- The 120-MHz functional clock is active, or not.
- The output stage of the 120-MHz functional clock is active, or not.

4.11.2.3.10 **CM_IDLEST_PLL_<processor_name> (Processor DPLL Idle-Status Register)**

The processor DPLL idle-status register indicates the status of the processor DPLL: whether it is in locked or bypass mode.

The device DPLL idle-status register is:

- CM_IDLEST_PLL_MPU: DPLL1 activity status.

4.11.2.4 **Power-Domain Clock Control Registers**

An identical set of registers controls the clock features of the domains in the device:

- CM_CLKSEL_<domain_name>
- CM_FCLKEN_<domain_name>
- CM_ICLKEN_<domain_name>
- CM_AUTOIDLE_<domain_name>
- CM_IDLEST_<domain_name>
- CM_CLKSTCTRL_<domain_name>
- CM_CLKSTST_<domain_name>
- CM_SLEEPDEP_<domain_name>

The following sections describe the purposes of these registers.

4.11.2.4.1 CM_CLKSEL_<domain_name> (Clock Select Register)

The clock select register controls the selection of the module or subsystem input clock frequency (except for the processor modules). Therefore, it deals only with modules or subsystems for which the frequency is scalable or selectable (the others have fixed and nonprogrammable frequencies). Both functional and interface clocks can be scaled. In most cases, their value is a divided value from the DPLL3 (CORE) or the DPLL4 (PER) output clock.

The device includes the following clock select registers:

- CM_CLKSEL_CORE: L3 and L4 interconnects and GPTIMER10 and 11 functional clocks
- CM_CLKSEL_DSS: DSS functional clock 1 and TV functional clock
- CM_CLKSEL_PER: GPTIMER2, 3, 4, 5, 6, 7, 8, and 9 functional clocks
- CM_CLKSEL_SGX: SGX subsystem functional clock
- CM_CLKSEL_WKUP: GPTIMER1 functional clock and reset manager counter clock and USIMOCP functional clock

The functional clock of the GPTIMER1 is selectable between the always-on 32K_FCLK and the system clock (SYS_CLK), but it is used with the 32-kHz clock.

The CM_CLKSEL_SGX register controls the SGX functional clock divider ratio, which is divided from the L3_ICLK source clock. [Table 4-69](#) summarizes L3_ICLK ratio for different configurations of the register field.

Table 4-69. SGX Functional Clock Ratio Settings

| CM_CLKSEL_SGX.CLKSEL_SGX | SGX_L3_FCLK |
|--------------------------|-------------|
| 0x1 | L3_ICLK |
| 0x2 | L3_ICLK/2 |
| 0x3 | L3_ICLK/3 |
| 0x4 | L3_ICLK/4 |

4.11.2.4.2 CM_FCLKEN_<domain_name> (Functional Clock Enable Register)

The functional clock enable register allows control of the functional clock activity of each module or subsystem. All module functional clocks are controllable by software, except for the MPU, interconnect, and memory subsystems, for which the clocks are automatically controlled by the PRCM.

The device has the following functional clock control registers:

- CM_FCLKEN1_CORE and CM_FCLKEN3_CORE: CORE domain nonsecure peripherals set
- CM_FCLKEN_DSS: DSS subsystem
- CM_FCLKEN_PER: PER domain peripherals set
- CM_FCLKEN_SGX: SGX subsystem
- CM_FCLKEN_WKUP: WKUP domain peripherals set
- CM_FCLKEN_USBHOST: HS USB Host subsystem

The software effect is immediate and direct. The functional clock is turned on as soon as the bit is set, and turned off if the bit is cleared and the clock is not required by any module. On module wakeup, the functional clock can be automatically restarted.

NOTE: The functional clock supplies the functional part of a module or subsystem, which is not operational without its functional clock. In some cases, a module or a subsystem may require multiple functional clocks.

4.11.2.4.3 CM_ICLKEN_<domain_name> (Interface Clock Enable Register)

The interface clock enable register allows control of the interface clock activity of each module or subsystem. This register provides control over each module in the device.

The device has following interface clock control registers:

- CM_ICLKEN1_CORE, CM_ICLKEN2_CORE, and CM_ICLKEN3_CORE: CORE domain peripherals set
- CM_ICLKEN_DSS: DSS subsystem
- CM_ICLKEN_PER: PER domain peripherals set
- CM_ICLKEN_SGX: SGX subsystem
- CM_ICLKEN_WKUP: WKUP domain peripherals set
- CM_ICLKEN_USBHOST: HS USB Host subsystem

This register has an immediate effect, causing the source of the interface clock to be effectively cut (if the appropriate bit is cleared and no module requires this clock) or activated (if the appropriate bit is set).

Independent functional and interface clock control registers provide potential power savings for each module. For example, because the configuration port and interface of the module are still active, disabling a functional clock of a module while keeping its interface clock active (leaving the module inactive but allowing access to its registers) reduces power consumption.

When the interface clock is disabled, the module cannot communicate with the rest of the device; therefore, it is in idle mode. For example, the interface clock of a peripheral can be disabled while its functional clock is active; it is then idled, from the device standpoint, while it can detect any external event. This configuration typically allows a main part of the device to go into idle mode while keeping a peripheral active and ready to wake up from an external event.

Because a module may or may not be able to function without its functional or interface clocks, power-management strategies must be adapted accordingly. This relation is programmable and is defined in the CLOCKACTIVITY bits of the module SYSCONFIG register; therefore, it requires consistent programming of the CM_FCLKEN and CM_ICLKEN registers.

NOTE: The interface clock ensures proper communication between any module and the interconnect (L3 or L4), in most cases supplying the module interface and registers.

4.11.2.4.4 CM_AUTOIDLE_<domain_name> (Autoidle Register)

The autoidle register holds an AUTOIDLE bit per module that belongs to the related domain. Each AUTOIDLE bit enables/disables automatic (hardware) gating of a module interface clock.

When AUTOIDLE and ICLKEN are set for a module, the module interface clock is managed automatically (that is, by hardware control) according to the domain clock activity; for example, stopped before a domain sleep transition and reenabled on wakeup. Table 4-70 lists the possible autoidle settings for the interface clock.

Table 4-70. Interface Clock Autoidle Settings

| CM_AUTOIDLE.AUTO_<module> | CM_ICLKEN.EN_<module> | Interface Clock |
|---------------------------|-----------------------|------------------------------|
| 0 | 0 | Disabled |
| 0 | 1 | Enabled |
| 1 | 0 | Disabled |
| 1 | 1 | Automatic enabling/disabling |

The device has the following autoidle control registers:

- CM_AUTOIDLE1_CORE, CM_AUTOIDLE2_CORE, and CM_AUTOIDLE3_CORE: CORE domain peripherals set
- CM_AUTOIDLE_DSS: DSS subsystem
- CM_AUTOIDLE_PER: PER domain peripherals set
- CM_AUTOIDLE_WKUP: WKUP domain peripherals set
- CM_AUTOIDLE_USBHOST: HS USB Host subsystem

NOTE: For the SGX module, the automatic idle mode is always enabled, and is not software-controllable.

4.11.2.4.5 CM_IDLEST_<domain_name> (Idle-Status Register)

The idle-status register allows checking whether a target module is in idle mode or if an initiator module is in standby mode. The software should not access to a target module in idle mode. A target access, in this state, can lead to an error.

The idle mode of any module can depend on the configuration of the CM_FCLKEN_<domain_name> and CM_ICLKEN_<domain_name> registers, or may be controlled automatically by hardware, depending on the configuration of the CM_AUTOIDLE_<domain_name> registers.

The device has the following idle status registers:

- CM_IDLEST_MPU: MPU subsystem
- CM_IDLEST1_CORE, CM_IDLEST2_CORE, and CM_IDLEST3_CORE: CORE domain peripherals set
- CM_IDLEST_DSS: DSS
- CM_IDLEST_PER: Peripheral domain peripherals set
- CM_IDLEST_NEON: NEON subsystem
- CM_IDLEST_SGX SGX subsystem
- CM_IDLEST_WKUP: WKUP domain peripherals set
- CM_IDLEST_USBHOST: HS USB Host subsystem

4.11.2.4.6 CM_CLKSTCTRL_<domain_name>(Clock State Control Register)

The clock state control register holds a CLKTRCTRL_<clock domain> bit field for each clock domain in the domain. It controls the hardware- and software-supervised state transitions between active and inactive states. [Table 4-71](#) lists the clock state transition settings.

Table 4-71. Clock State Transition Settings

| CM_CLKSTCTRL_<pwr domain>. CLKTRCTRL_<clk domain> | Description |
|---|---|
| 0x0 | The automatic hardware-supervised mode is disabled. The clocks in a clock domain cannot be cut automatically. This prevents any power transition on the domain. |
| 0x1 | Starts software-supervised (forced) sleep transition on the domain. All clocks in the clock domain are automatically cut whenever the initiators in the modules are in standby mode. |
| 0x2 | Starts software-supervised (forced) wake-up transition on the domain. The clocks in the clock domain are restarted. |
| 0x3 | The automatic hardware-supervised mode is enabled, and the clocks in the clock domain are automatically cut whenever the modules and subsystem in the clock domain are in idle or standby mode and the domain dependencies are met. |

The hardware-supervised mode and the software-supervised (forced) sleep mode are mutually exclusive. It is a software decision to program one mode or another, and the software programs the PRCM accordingly.

The hardware-supervised mode is coupled to the sleep and wake-up dependencies programmed in the PRCM, whereas the software-supervised mode must be independent of those dependencies. Therefore, the sleep and wake-up dependencies must be disabled before the software forces a sleep transition on a domain; otherwise, the forced-domain will be wakened immediately because of the wake-up dependency.

The device has the following clock state control registers:

- CM_CLKSTCTRL_MPU: MPU subsystem clock domain
- CM_CLKSTCTRL_CORE: L3 and L4 clock domains
- CM_CLKSTCTRL_DSS: DSS clock domain
- CM_CLKSTCTRL_PER: Peripherals clock domain
- CM_CLKSTCTRL_NEON: NEON clock domain
- CM_CLKSTCTRL_SGX: Graphics clock domain
- CM_CLKSTCTRL_EMU: Emulation clock domain
- CM_CLKSTCTRL_USBHOST: HS USB Host clock domain

The CORE domain has three clock domains (L3 and L4); it does not have forced sleep and forced wake-up ability.

Although the sleep transition in the MPU domain cannot be initiated by software using this register, a software-initiated forced wake-up capability exists. This can be used to wake up the MPU domain if it does not wake up when the CORE domain wakes up (the MPU wake-up-dependency PM_WKDEP_MPU[0] EN_CORE bit is set to 0).

If the hardware-supervised mode is enabled, the following occur:

- The MPU domain clock is automatically cut if the MPU executes the wait-for-interrupt instruction.
- The L3 domain clock is automatically cut when all initiators are in standby mode and slave ports are idled.
- The L4 domain clock is automatically cut when all peripherals and slave ports are idled.
- The DSS interface clock is automatically cut when it stops fetching data from the frame buffer (provided the MPU is also in standby mode, if sleep dependency in the MPU domain is enabled). The display functional clock is controlled only by the CM_FCLKEN_DSS register.
- The PER domain clock is automatically cut when all initiators are in standby mode and all slave ports are in idle (provided the MPU is standby mode and the CORE domain is INACTIVE, if sleep dependency in their domains is enabled).
- Because of the hardwired sleep dependency between NEON and the MPU domain, NEON can go into idle only if the MPU goes into standby mode. The MPU domain must also be configured in automatic

hardware supervised mode for the NEON domain idle transition to occur.

- The USBHOST domain clock is automatically cut whenever the USBHOST is in standby mode (provided MPU is also in standby mode, if sleep dependency in the MPU domain is enabled).

NOTE: Hardware-supervised mode must not be used for the SGX domain when smart-standby is enabled.

4.11.2.4.7 **CM_CLKSTST_<domain_name> (Clock State Status Register)**

The clock state status register logs the activity status of the domain clock. This includes the activity of the interface clocks running only on the domain.

The device has following clock state status registers:

- CM_CLKSTST_MPU: MPU subsystem clock activity
- CM_CLKSTST_CORE: L3 clock domain activity and L4 clock domain activity
- CM_CLKSTST_DSS: DSS clock activity
- CM_CLKSTST_PER: PER clock domain activity
- CM_CLKSTST_SGX: Graphics subsystem clock activity
- CM_CLKSTST_EMU: Emulation clock activity
- CM_CLKSTST_USBHOST: USBHOST clock activity

4.11.2.4.8 **CM_SLEEPDEP_<domain_name> (Sleep Dependency Control Register)**

The sleep dependency control register allows the enabling or disabling of the sleep transition dependency of a domain with respect to other domains.

The device has following sleep dependency registers:

- CM_SLEEPDEP_DSS: Display domain sleep dependency with the MPU domain
- CM_SLEEPDEP_PER: PER domain sleep dependencies with the MPU and CORE domains
- CM_SLEEPDEP_SGX: SGX domain sleep dependency with the MPU domain
- CM_SLEEPDEP_USBHOST: USBHOST domain sleep dependency with the MPU domain

Although the CORE domain is composed of L3 and L4 clock domains, the sleep dependency with the L3 clock domain is always enabled (not programmable by software); there is no sleep dependency between the PER domain and the CORE_L4 clock domain.

The dependencies listed in [Table 4-72](#) can be enabled or disabled by software.

Table 4-72. Sleep Dependency Settings

| Dependent Domain | Parent Domain | MPU | CORE-L3 |
|------------------|---------------|---------------------|----------------|
| DSS | | Software controlled | |
| PER | | Software controlled | Always enabled |
| SGX | | Software controlled | |
| USBHOST | | Software controlled | |

4.11.2.5 **Domain Wake-Up Control Registers**

The following modules have programmable wake-up control:

- CORE domain:
 - USBTLL
 - McBSP 1 and 5
 - GPTIMER[10, 11]
 - UART[1,2]
 - I2C[1..3]
 - McSPI[1..4]

- MMC[1,2, 3]
- PER domain:
 - McBSP[2..4]
 - GPTIMER[2..9]
 - UART 3
 - WDTIMER3
 - GPIO[2..6]
- WKUP domain:
 - GPTIMER[1, 12]
 - GPIO1
 - I/O pad
 - USIM OCP
- DSS domain:
 - DSS subsystem
- USBHOST domain:
 - HS USB Host subsystem

The registers in the following sections control the wake-up settings.

4.11.2.5.1 *PM_WKEN_<domain_name> (Wake-Up Enable Register)*

The wake-up enable register applies only to modules that can generate wake-up events. It allows the enabling or disabling of the wakeup of the related domain on a module or subsystem wake-up event. Each EN_<module> bit in the register enables/disables the wake-up event from the module to the PRCM.

The device has the following wake-up enable registers:

- PM_WKEN1_CORE and PM_WKEN3_CORE: CORE domain modules wake-up control
- PM_WKEN_DSS: Display subsystem (DSS) wake-up control
- PM_WKEN_PER: Peripheral domain modules wake-up control
- PM_WKEN_WKUP: WKUP domain modules wake-up control
- PM_WKEN_USBHOST: HS USB Host subsystem wake-up control

NOTE:

- The wake-up capability of GPTIMER12 (the secure timer) is not programmable, but is always enabled.
 - The wake-up signals issued from the MPU INTC are nonmaskable in the PRCM. However, they cannot be generated if the corresponding interrupts are masked in the INTC.
-

4.11.2.5.2 *PM_WKST_<domain_name> (Wake-Up Status Register)*

The wake-up status register logs wake-up events from all modules. Each ST_<module> bit of this register logs a given module-generated wake-up event.

The device has the following wake-up status registers:

- PM_WKST1_CORE and PM_WKST3_CORE: CORE domain modules wake-up event status
- PM_WKST_PER: Peripheral domain modules wake-up event status
- PM_WKST_WKUP: WKUP domain modules wake-up event status
- PM_WKST_USBHOST: HS USB Host subsystem wake-up control

The functional clock of the module causing the wakeup automatically restarts on the wakeup, but the software must enable the functional clock (CM_FCLKEN_<domain_name> register) before clearing the wake-up status bit.

NOTE:

- Software must clear this register before a new sleep transition request; otherwise, the register prevents the sleep transition from occurring.
- If the PRM interrupt is enabled on a module wakeup, the PM_WKST_<domain_name> must be cleared before clearing the PRM_IRQSTATUS_<processor_name> interrupt status register.

4.11.2.5.3 PM_WKDEP_<domain_name> (Wake-Up Dependency Register)

The wake-up dependency register allows the enabling/disabling of a wake-up dependency between domains. When a domain wakes up, it can wake up another domain.

The device has the following wake-up dependency registers:

- PM_WKDEP_MPU: MPU domain wake-up dependency with the following domains:
 - CORE
 - WKUP
 - DSS
 - PER
- PM_WKDEP_DSS: DSS domain wake-up dependency with the following domains:
 - MPU
 - WKUP
- PM_WKDEP_PER: The PER domain has programmable wake-up dependency with the following domains:
 - MPU
 - WKUP
 - CORE

The PER domain can be wakened only by a wakeup of the L3 clock domain, not by an L4 clock domain.

- PM_WKDEP_NEON: The NEON domain has programmable wake-up dependency with the following domain:
 - MPU
- PM_WKDEP_SGX: The SGX domain has programmable wake-up dependency with the following domains:
 - MPU
 - WKUP
- PM_WKDEP_USBHOST: The USBHOST domain has programmable wake-up dependency with the following domains:
 - MPU
 - WKUP
 - CORE

There is no wake-up dependency control for the WKUP domain, because it is always on.

Because the CORE domain wake-up dependencies are not programmable, the CORE domain always wakes up on a wake-up event on the following domains:

- MPU
- WKUP
- DSS
- SGX
- PER
- USBHOST

4.11.2.5.4 **PM_<processor_name>GRPSEL_<domain_name> (Processor Group Selection Register)**

The processor group selection register allows defining the group of modules in the domain that can wake up the MPU domain. This bit is effective only if the module wake-up capability is enabled (PM_WKEN_<domain_name> register).

The device has the following processor group selection registers:

- PM_MPUGRPSEL1_CORE and PM_MPUGRPSEL3_CORE: CORE domain modules MPU wake-up control
- PM_MPUGRPSEL_PER: PER domain modules MPU wake-up control
- PM_MPUGRPSEL_WKUP: WKUP domain modules MPU wake-up control
- PM_MPUGRPSEL_USBHOST: HS USB Host subsystem MPU wake-up control

NOTE:

- The wake-up capability of GPTIMER12 (the secure timer) is always attached to the MPU group.
-

4.11.3 **Reset Management Registers**

4.11.3.1 **Reset Control**

4.11.3.1.1 **PRM_RSTTIME (Reset Time Register)**

The reset time register provides control over reset duration. Two durations are configurable:

- RSTIME1: Minimum duration (by default, two cycles of the 32-kHz clock) of the global warm reset (sys_nreswarm) assertion for external devices, such as flash memories. At power-up reset, DPLLs are reset.
- RSTIME2: Minimum duration (by default, 16 cycles of the RM_ICLK clock) to control domain resets when the domain clocks are on.

For global cold and warm resets, the reset is applied for the RSTIME1 + RSTIME2 duration.

RSTIME1 and RSTIME2 can be reprogrammed for different behavior after the initial power up.

4.11.3.1.2 **RM_RSTCTRL_<domain_name> (Reset Control Register)**

The reset control register provides control over the local domain software reset.

Most device modules include an individual software reset that can be controlled using the related module SYS_CONFIG register.

The RM_RSTCTRL_<domain_name> register is used for specific subsystems or modules that do not support this local reset or that require a specific system control.

The PRM_RSTCTRL register also handles the global software warm reset control.

The device includes the following reset control registers:

- PRM_RSTCTRL: This register allows control of the assertion of the global software reset and the DPLL3 software reset. These bits are automatically cleared. Assertion of the DPLL3 software reset triggers a device global cold reset. The reset condition of this register depends on the bit field:
 - The RST_GS bit is set on any global source of reset (warm or cold).
 - The RST_DPLL3 bit is set only on a global cold source of reset.

4.11.3.1.3 **RM_RSTST_<domain_name> (Reset Status Register)**

The reset status register logs any source that has generated a reset in the related domain. Depending on the domain, several causes of reset can be logged:

- Global device cold reset
- Global device warm reset

- domain transition (INACTIVE to ACTIVE)
- Software reset
- Processor emulation reset

The PRM_RSTST register logs the source of the global reset:

- External warm reset
- Secure watchdog reset
- MPU watchdog reset
- Security violation reset
- Global software reset and DPLL3 software reset
- Global cold reset

The device includes the following reset status registers:

- RM_RSTST_MPU
- RM_RSTST_CORE
- RM_RSTST_DSS
- RM_RSTST_PER
- RM_RSTST_NEON
- RM_RSTST_SGX
- RM_RSTST_EMU
- PRM_RSTST
- RM_RSTST_USBHOST

Only the RM_RSTST_CORE and PRM_RSTST registers log software sources of reset.

Each bit of these registers is set on the effective release of the respective reset signal.

4.11.4 Power Management Registers

4.11.4.1 PM_PWSTST_<domain_name> (Power State Status Register)

The power state status register provides the status of the power state transition of the domain.

This register may hold the following bit fields:

- **POWERSTATESTATUS:** Indicates the current power state of the domain (ON or INACTIVE)
- **INTRANSITION:** Indicates an ongoing power state transition from ON power state to INACTIVE and from INACTIVE to ON power state

The device has the following power state status registers:

- **PM_PWSTST_MPU:** MPU domain power state status
- **PM_PWSTST_CORE:** CORE domain power state status
- **PM_PWSTST_SGX:** SGX domain power state status
- **PM_PWSTST_DSS:** DSS domain power state status
- **PM_PWSTST_PER:** PER domain power state status
- **PM_PWSTST_NEON:** NEON domain power state status
- **PM_PWSTST_EMU:** EMU domain power state status
- **PM_PWSTST_USBHOST:** USBHOST domain power state status

The MPU domain power state status register indicates the current domain state.

The CORE domain power state status register indicates the current domain state.

The SGX, DSS, PER, NEON, USBHOST, and EMU domain power state status registers indicate the current domain (ON or INACTIVE) power state or that the domain transition is in progress.

4.11.5 Generic Programming Examples

4.11.5.1 Clock Control

The module clock management is controlled through three programmable steps:

- Enabling or disabling the functional clocks
- Enabling or disabling the interface clocks
- Enabling or disabling the automatic idle mode for the interface clocks

4.11.5.1.1 Enabling and Disabling the Functional Clocks

The flow chart in [Figure 4-61](#) shows how to enable or disable a functional clock.

The first step before enabling a functional clock is to select the proper source clock using the corresponding clock selection register (**CM_CLKSEL_<domain_name>**). It can be either an external source clock or an internal clock; that is, **sys_altdclk** or **DPLL4_M3X2_CLK** for the **DSS_TV_FCLK** functional clock of the DSS.

If the source clock is a DPLL3 or DPLL4 output clock, the DPLL multiplier, divider, and output clock ratios are set in the **CM_CLKSELn_PLL** register, where n is from 1 to 3. The DPLL operating mode is set in the **CM_CLKEN_PLL** register.

The functional clock is enabled or disabled by writing the dedicated bit in the **CM_FCLKEN_<domain_name>** register. This bit has a direct effect on the clock activity:

- The functional clock is turned on if the bit is enabled and the clock is not yet active.
- The functional clock is turned off if the bit is disabled and the clock is not required by any other module.

Figure 4-61. Functional Clock Basic Programming Model

* Clock domain Idle conditions are:
a. No other module sharing the same clock domain needs the clock.
(All modules of the clock domain are idled)
b. No wake-up event.

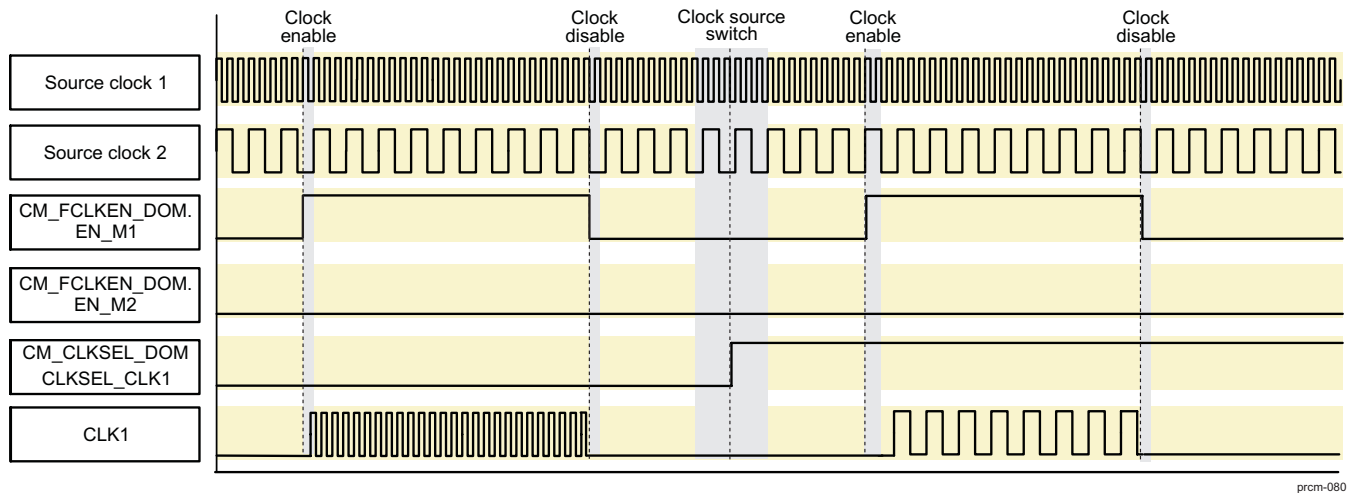

prcm-085

The functional clock must be disabled before switching or scaling its source clock. This means that all the modules using the particular functional clock must not be active during clock switching. To switch a source clock, perform the following sequence:

1. Disable the functional clock by setting the CM_FCLKEN_<domain>EN_<module> bits to 0.
2. Modify the CM_CLKSEL_<domain>CLKSEL_<clock> bits to select the new clock source or clock divider.
3. Enable the functional clock by setting the CM_FCLKEN_<domain>EN_<module> bits to 1.

The timing diagram in Figure 4-62 is a generic example of this sequencing for a functional clock (CLK1). The source clock can be switched between source clock 1 and source clock 2 using the CM_CLKSEL_DOM.CLKSEL_CLK1 bit (source clock 1 is selected when the bit is set to 0; otherwise, source clock 2 is selected). CLK1 can be requested by two modules, M1 and M2. The CM_FCLKEN_DOM.EN_M1 and CM_FCLKEN_DOM.EN_M2 bits control the functional clock enable for the two modules.

NOTE: The activation or deactivation of the clock is implementation-dependent, not one cycle of the source clock, as shown in Figure 4-62.

Figure 4-62. Functional Clock Switching

prcm-080

The following functional clocks require this switching sequence:

- sys_clkout2
- 48M_FCLK (and all gated versions of it)
- 12M_FCLK (and all gated versions of it)
- DSS_TV_CLK
- GPTx_FCLK (with x = 1, 10, and 11)
- GPTx_ALWON_FCLK (with x = 2 up to 9)

4.11.5.1.2 Enabling and Disabling the Interface Clocks

The flow chart in [Figure 4-63](#) shows the enable/disable sequence of the interface clock.

The first step before enabling an interface clock is to select the proper source clock using the corresponding clock selection register (CM_CLKSEL_<domain>). This register allows selection of the interconnect frequency (L3_ICLK, L4_ICLK) from among several divider ratios.

The interface clock is enabled or disabled by writing the dedicated bit in the CM_ICLKEN_<domain> register. This bit has a direct effect on the clock activity:

- The interface clock is turned on if the bit is enabled and the clock is not yet active.
- The interface clock is turned off if the bit is disabled and the clock is not required by any other module.

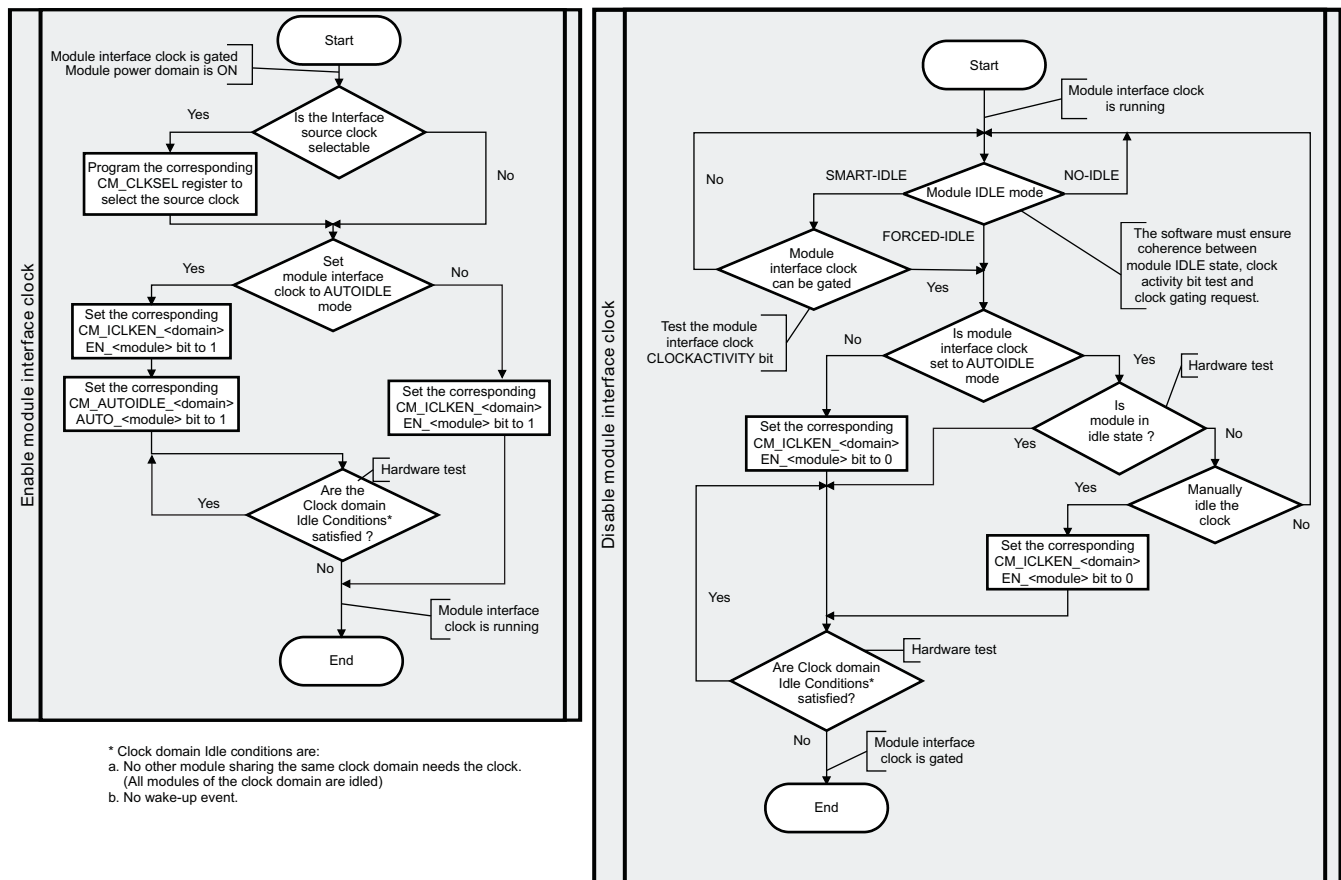

The interface clock can be automatically enabled or disabled by the PRCM, based on hardware conditions. This automatic clock activity control mode is enabled by writing the corresponding bit in the CM_AUTOIDLE_<domain > register. It takes effect only if the interface clock is enabled (the corresponding bit in the CM_ICLKEN_<domain > is set to 1).

The hardware conditions for automatic gating (deactivation) of the clock are as follows:

- The module activity; that is, the module is inactive.
- The domain activity; that is, all modules in the domain are inactive.

The software can read the idle status register CM_IDLESTAT_<domain> at any time to know whether the module is accessible. A module is inaccessible if its idle status bit is set. Accessing an idle module generates an error (if the interface clock is still running) or a time-out (if the interface clock is cut).

Figure 4-63. Interface Clock Basic Programming Model

prcm-086

The frequency ratio between the CORE_CLK, the L3_ICLK, and the L4_ICLK is configured by setting the corresponding CM_CLKSEL_CORE register bit fields. This configuration must be done before switching DPLL3 to lock mode. In this way, the clock ratio is switched while DPLL3 is operating at system clock frequency, and then only DPLL3 is switched to high-frequency locked mode.

If the configuration of the interface clock needs to be changed, first put DPLL3 in bypass mode, select the new configuration, and then relock DPLL3.

NOTE: When performing frequency scaling, the clock division can be done directly by programming the DPLL output divider. In this case, there is no need to change the configuration of the interface clock.

4.11.5.1.3 Enabling and Disabling the INACTIVE State

The flow chart in Figure 4-64 shows how to put a domain into INACTIVE state.

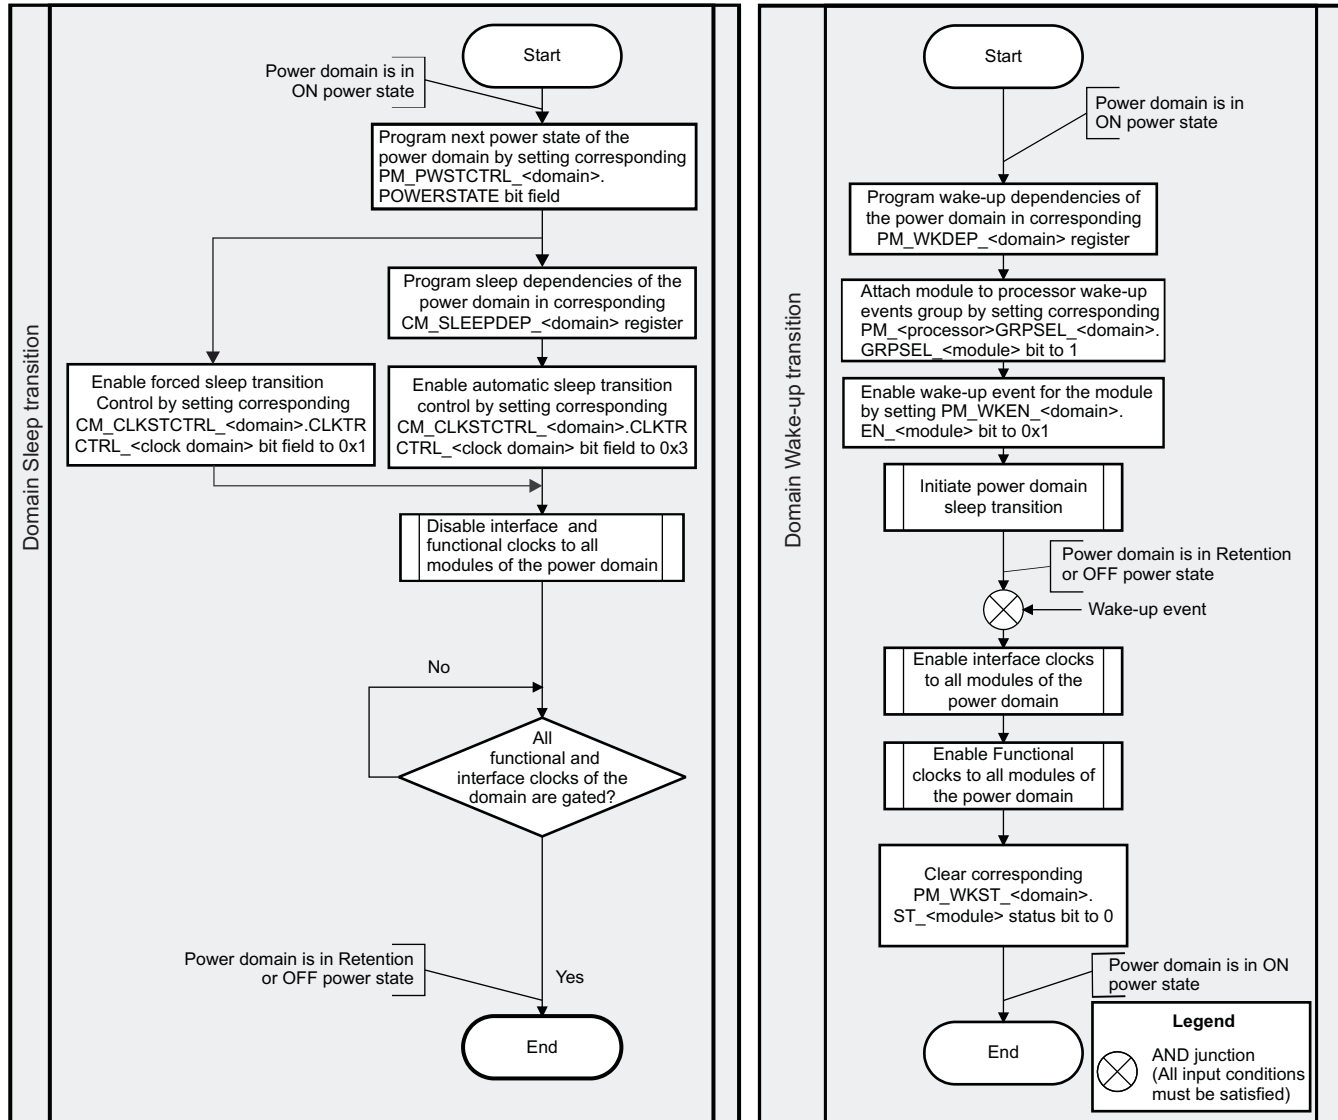

A domain is said to be in INACTIVE state if:

- All the functional and interface clocks of the domain are gated (deactivated).
- All the initiator modules are in standby mode.
- All the dependent domains have reached their mute state. The sleep dependency between the domains is configured by programming the CM_SLEEPDEP_<domain> register.

The domain transition from ACTIVE state to INACTIVE state is effective only if the CM_CLKSTCTRL_<domain> register is programmed for hardware-supervised state transition.

The CM_CLKSTST_<domain> register identifies whether a domain or a clock domain within the domain is accessible. A domain is inaccessible if its corresponding bit in the CM_CLKSTST_<domain> register is set to 1.

Figure 4-64. Domain INACTIVE STATE Basic Programming Model

prcm-087

4.11.5.1.4 Processor Clock Control

The flow chart in Figure 4-65 shows the control sequence of the processor clock.

The processor source clock is generated by the dedicated processor DPLL (DPLL1). After power up, the processor DPLL is in bypass or stop mode. This means the processor clock is either the system clock or is shut off.

The first step is to program the multiplier and divider ratios of the processor DPLL. Those two values are written in the CM_CLKSEL1_PLL_<processor> register.

For frequency scaling, the processor DPLL integrates an additional divider to scale down the synthesized clock. The value of this second divider is written in the CM_CLKSEL2_PLL_<processor> register. This divider can be configured dynamically (while the processor executes instructions), and the DPLL output clock is scaled without any glitches.

The processor DPLL must be locked at a desired frequency, provided the clock frequency is higher than the system clock. It can then be set to low-power bypass mode when the high-frequency clock is not required. The DPLL operating mode (locked or bypassed) is controlled by programming the `CM_CLKEN_PLL_processor` register.

The processor clock can be switched automatically, based on hardware conditions, between the processor DPLL synthesized clock and a bypass clock. This mode is enabled by programming the corresponding mode in the `CM_AUTOIDLE_PLL_processor` register. It takes effect only if the processor DPLL is locked (the `CM_CLKEN_PLL_processor` register is set in lock mode).

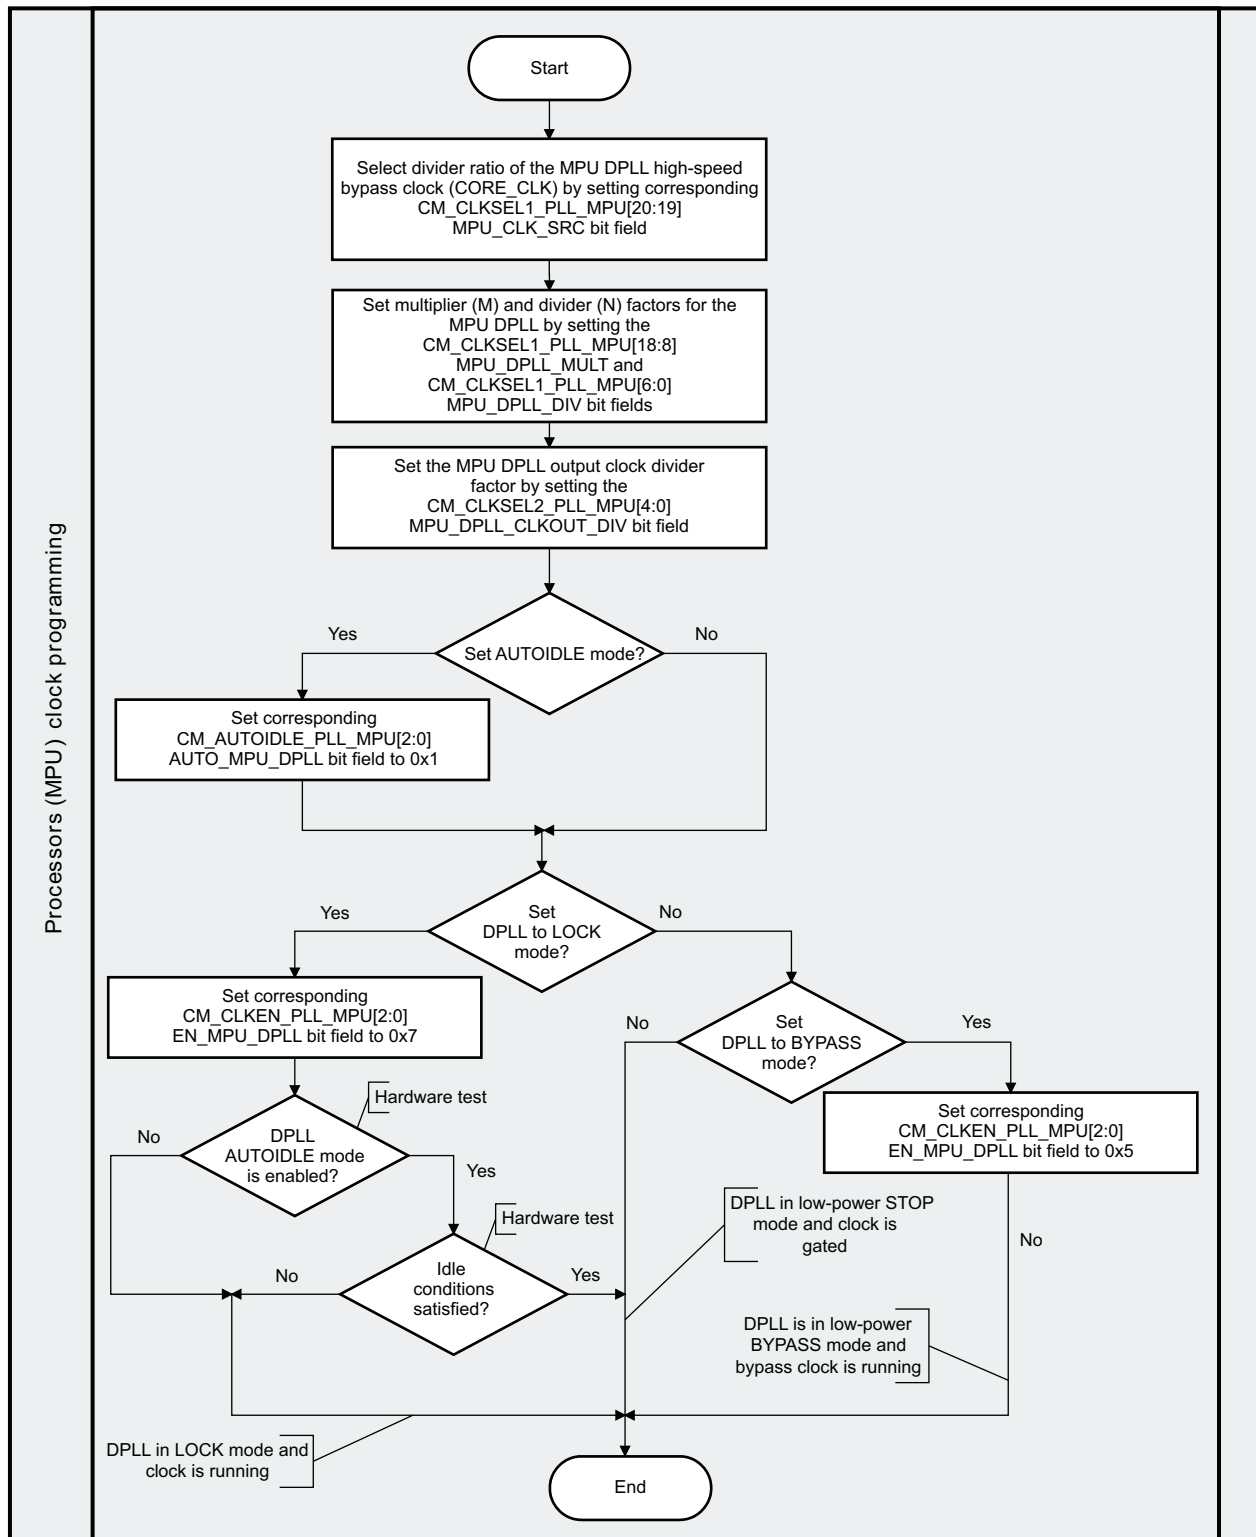

The HS bypass clock for the processor DPLL can be:

- The DPLL3 output clock (`CORE_CLK`)
- The DPLL3 output clock (`CORE_CLK`) divided by 2

The HS bypass clock is selected by programming the `CM_CLKSEL1_PLL_processor` > register.

The software can read the `CM_IDLEST_PLL_<processor >` register at any time to determine whether the DPLL is in lock mode (DPLL output is a high-frequency synthesized clock) or bypass mode (DPLL output is not the synthesized clock; the DPLL output is the bypass clock, or the DPLL is in transitioning state).

Figure 4-65. Processor Clock Basic Programming Model

prcm-088

4.11.5.2 Reset Management

The reset sequence is hardware-driven. On power on, once all the reset sources have been released, the PRM holds the entire device under reset long enough to ensure the stabilization of the power IC voltages and the oscillator system clock frequency. This reset delay is programmed in the PRM_RSTTIME register.

A domain reset status register (PRM_RSTST_domain) identifies the source of the current reset applied to the domain. The software must clear this status bit after reset.

A global reset status register (PRM_RSTST) provides information on the global source of resets. All sources of warm reset are logged separately in this register, and all sources of cold reset are logged in a common status bit.

4.11.5.3 Wake-Up Control

The flow chart in [Figure 4-66](#) shows the control sequence of the module wake-up event.

This procedure consists of the following steps:

1. Program the PRCM to consider the wake-up event.
2. Switch to idle mode and wait for the wake-up event.
3. Wake up on the wake-up event and activate the module functional clock.
4. Acknowledge the wake-up event.

The peripheral that can generate a wake-up event must be attached to a group of wake-up event generating modules for one or both processors by programming the PM_<processor>GRPSEL register. Writing 1 to this register allows the corresponding processor to be wakened on a peripheral wake-up event, assuming that the peripheral wake-up capability has been enabled by programming the register PM_WKEN_<domain>.

After this is configured, the PRCM initiates a wake-up procedure on receiving the peripheral wake-up event. The peripheral functional clock must be reenabled by programming the CM_FCLKEN_<domain > register, and then the wake-up event can be acknowledged by clearing the PM_WKST_<domain > register.

Figure 4-66. Wake-Up Basic Programming Model

prcm-084

A domain A can have a functional dependency on a domain B. Thus, when domain A wakes up, it may be necessary to wake up domain B. This wake-up dependency is hardcoded for the CORE domain, but is programmable for the other domains through the PM_WKDEP_<domain> register.

4.11.5.4 Event Generator Programming Examples

The event generator feature allows the MPU domain to be switched between on and idled modes. This is intended to implement an efficient activity modulation of the MPU power state with minimum software support.

When the event generator is activated, the PRCM ensures that the CORE domain always follows the MPU domain activity.

The PRCM.PM_EVGENONTIM_MPU and PRCM.PM_EVGENOFFTIM_MPU registers of the event generator counter allow the configuration of the on and off durations (the number of system clock cycles) for the MPU domain. The PRCM.PM_EVGENCTRL_MPU register allows the enabling/disabling of the event generator feature and control of the way on and off values are loaded in the counter.

There are three ways to load the counter with the next counting value:

- Load on update of the corresponding PRCM.PM_EVGENONTIM_MPU or PRCM.PM_EVGENOFFTIM_MPU register.
- Load the on-time value when the MPU domain wakes up, and the off-time value when the MPU domain starts the sleep transition (the MPU executes the WFI instruction).
- Automatically load the on-time value when the off-time value expires, and automatically load the off-time value when the on-time value expires.

When the counter times out at the end of the on/off time, it triggers the interrupt/wake-up transition, respectively. The software can use the on-time interrupt to trigger the WFI processor instruction to idle the processor clock. Similarly, the wake-up event at the end of the off time restarts the processor clock and interrupts the processor. To enable the corresponding interrupts, the MPU interrupts mask must be set in the PRCM.PRM_IRQENABLE_MPU register.

4.12 PRCM Registers

This section gives information about all modules and features in the high-tier device. See Chapter 1, *Device Family* section, to check availability of modules and features. For power savings considerations, ensure that unavailable features and unused modules have clocks properly gated.

[Table 4-73](#) lists the physical addresses of the CM modules. [Table 4-74](#) through [Table 4-85](#) provide register mapping summaries of the CM registers and describe the bits in the individual registers.

[Table 4-165](#) lists the physical addresses of the PRM modules. [Table 4-166](#) through [Table 4-170](#) provide register mapping summaries of the PRM registers and describe the bits in the individual registers.

4.12.1 CM Module Registers

| Bits | Field Name | Description | Type | Reset |
|------|------------|---|------|------------|
| 31:1 | RESERVED | Write 0's for future compatibility. Reads returns 0. | R | 0x00000000 |
| 0 | AUTOIDLE | Internal clock gating strategy (for the CM part of the PRCM) 0x0: Interface clock is free-running 0x1: Automatic clock gating strategy is enabled, based on the interface activity. | RW | 0x1 |

4.12.1.3 MPU_CM Register Descriptions

4.12.1.3.1 CM_CLKEN_PLL_MPU

Table 4-88. CM_CLKEN_PLL_MPU

| | | | |
|-------------------------|---|-----------------|--------|
| Address Offset | 0x0000 0004 | Instance | MPU_CM |
| Physical Address | 0x4800 4904 | | |
| Description | This register allows controlling the DPLL1 modes. | | |
| Type | RW | | |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---------------------|-------------------|------------------|----|----|------------------------|-------------|---|---|---|---|---|---|---|---|---|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| RESERVED | | | | | | | | | | | | | | | | EN_MPU_DPLL_LP_MODE | MPU_DPLL_RAMPTIME | MPU_DPLL_FREQSEL | | | EN_MPU_DPLL_DRIFTGUARD | EN_MPU_DPLL | | | | | | | | | |

| Bits | Field Name | Description | Type | Reset |
|-------|---------------------|--|------|----------|
| 31:11 | RESERVED | Write 0's for future compatibility. Read returns 0. | R | 0x000000 |
| 10 | EN_MPU_DPLL_LP_MODE | <p>This bit allows to enable or disable the LP mode of the MPU DPLL. Writing this bit to switch the mode between LP or normal mode will take effect only when the DPLL will have transition into the bypass or stop state, followed by a lock or re-lock of the DPLL.</p> <p>0x0: Disables the DPLL LP mode to re-enter the normal mode at the following lock or re-lock sequence.</p> <p>0x1: Enables the DPLL LP mode to enter the LP mode at the following lock or re-lock sequence.</p> | RW | 0x0 |
| 9:8 | MPU_DPLL_RAMPTIME | <p>The DPLL provides an output clock frequency ramping feature when switching from bypass clock to normal clock during lock and relock. The frequency ramping occurs in a maximum of four steps in frequency before the DPLL frequency lock indicator is asserted. The ramp step size is specified in the number of DPLL internal reference clock cycles. The internal DPLL reference clock cycle is given by: $F_{int} = \text{DPLL input reference clock frequency} / (N + 1)$, where N is the value in the CM_CLKSEL1_PLL_MPU[6:0] MPU_DPLL_DIV bit field. This register is used to enable and disable the DPLL ramping feature. If enabled, it is also used to select a range of ramp step sizes. The step size used per range depends on the DPLL internal reference clock frequency: the lower the frequency, the smaller the ramp step size.</p> <p>0x0: Disables the frequency ramping feature.</p> <p>0x1: Ramp step size range is 2–40 Fint cycles.</p> <p>0x2: Ramp step size range is 4–80 Fint cycles.</p> <p>0x3: Ramp step size range is 12–240 Fint cycles.</p> | RW | 0x0 |

| Bits | Field Name | Description | Type | Reset |
|-------------|------------------------|--|-------------|--------------|
| 7:4 | MPU_DPLL_FREQSEL | <p>This bit field allows selecting the proper range of the DPLL1 internal frequency depending on the DPLL reference clock and the N divider.</p> <p>0x3: 0.75 MHz—1.0 MHz 0x4: 1.0 MHz—1.25 MHz 0x5: 1.25 MHz—1.5 MHz 0x6: 1.5 MHz—1.75 MHz 0x7: 1.75 MHz—2.1 MHz 0xB: 7.5 MHz—10 MHz 0xC: 10 MHz—12.5 MHz 0xD: 12.5 MHz—15 MHz 0xE: 15 MHz—17.5 MHz 0xF: 17.5 MHz—21 MHz</p> | RW | 0x1 |
| 3 | EN_MPU_DPLL_DRIFTGUARD | <p>This bit allows to enable or disable the automatic recalibration feature of the MPU DPLL. The DPLL1 will automatically start a recalibration process upon assertion of the recal flag if this bit is set.</p> <p>0x0: Disables the DPLL1 automatic recalibration mode 0x1: Enables the DPLL1 automatic recalibration mode</p> | RW | 0x0 |
| 2:0 | EN_MPU_DPLL | <p>DPLL1 control; Other enums: Reserved</p> <p>0x5: Put the DPLL1 in low power bypass mode 0x7: Enables the DPLL1 in lock mode</p> | RW | 0x5 |

4.12.1.3.2 CM_IDLEST_MPU

Table 4-89. CM_IDLEST_MPU

| | | | |
|-------------------------|---|-----------------|--------|
| Address Offset | 0x0000 0020 | Instance | MPU_CM |
| Physical Address | 0x4800 4920 | | |
| Description | Modules access availability monitoring. This register is read only and automatically updated. | | |
| Type | R | | |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|--------|---|---|---|

|------|---------------------|---|------|------------|
| 31:1 | RESERVED | Write 0's for future compatibility. Read returns 0. | R | 0x00000000 |
| 0 | CLKACTIVITY_USBHOST | Interface clock activity status 0x0: No domain interface clock activity 0x1: Domain interface clock is active | R | 0x0 |

4.12.2 PRM Module Registers

This section describes the PRM module registers. [Table 4-165](#) lists the physical address of the PRM modules. [Table 4-166](#) through [Table 4-170](#) provide register mapping summaries and describe the bits in the individual registers.

Table 4-165. PRM Instance Summary

| Module Name | Base address (hex) | Size | Section |
|-----------------------|--------------------|-------------|-----------------------------------|
| Reserved | 0x4830 6000 | 8192 bytes | |
| OCP_System_Reg_PRM | 0x4830 6800 | 8192 bytes | Section 4.12.2.2 |
| MPU_PRM | 0x4830 6900 | 8192 bytes | Section 4.12.2.3 |
| CORE_PRM | 0x4830 6A00 | 8192 bytes | Section 4.12.2.4 |
| SGX_PRM | 0x4830 6B00 | 8192 bytes | Section 4.12.2.5 |

4.12.2.2 OCP_System_Reg_PRM Register Descriptions

4.12.2.2.1 PRM_REVISION

Table 4-178. PRM_REVISION

| | | | |
|-------------------------|--|-----------------|--------------------|
| Address Offset | 0x0000 0004 | Instance | OCP_System_Reg_PRM |
| Physical Address | 0x4830 6804 | | |
| Description | This register contains the IP revision code for the PRM part of the PRCM | | |
| Type | R | | |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|-----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| RESERVED | | | | | | | | | | | | | | | | REV | | | | | | | | | | | | | | | |

| Bits | Field Name | Description | Type | Reset |
|------|------------|---|------|----------|
| 31:8 | RESERVED | Reads returns 0. | R | 0x000000 |
| 7:0 | REV | IP revision [7:4] Major revision [3:0] Minor revision Examples: 0x10 for 1.0, 0x21 for 2.1 | R | 0x10 |

4.12.2.2.2 PRM_SYSCONFIG

Table 4-179. PRM_SYSCONFIG

| | | | |
|-------------------------|--|-----------------|--------------------|
| Address Offset | 0x0000 0014 | Instance | OCP_System_Reg_PRM |
| Physical Address | 0x4830 6814 | | |
| Description | This register controls the various parameters of the interface | | |
| Type | RW | | |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----------|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| RESERVED | | | | | | | | | | | | | | | | | AUTOIDLE | | | | | | | | | | | | | | |

| Bits | Field Name | Description | Type | Reset |
|------|------------|---|------|------------|
| 31:1 | RESERVED | Write 0's for future compatibility. Reads returns 0. | R | 0x00000000 |
| 0 | AUTOIDLE | Internal clock gating strategy (for the CM part of the PRCM) 0x0: Interface clock is free-running 0x1: Automatic clock gating strategy is enabled, based on the interface activity. | RW | 0x1 |

4.12.2.2.3 PRM_IRQSTATUS_MPU
Table 4-180. PRM_IRQSTATUS_MPU

| | | | |
|-------------------------|---|-----------------|--------------------|
| Address Offset | 0x0000 0018 | Instance | OCP_System_Reg_PRM |
| Physical Address | 0x4830 6818 | | |
| Description | This interrupt status register regroups all the status of the module internal events that can generate an interrupt. Write 1 to a given bit resets this bit. This registers applies on the interrupt line 0 mapped to the MPU interrupt controller. | | |
| Type | RW | | |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|--------------------|----|----|----|----|----|----|----|----------|----|----|----|----|----|----|----|-------------|----------------|--------------|---------------|-------------|------------|----------|---------|---|---|---|---|---|---|---|---|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| RESERVED | | | | | | | | RESERVED | | | | | | | | MPU_DPLL_ST | PERIPH_DPLL_ST | CORE_DPLL_ST | TRANSITION_ST | EVGENOFF_ST | EVGENON_ST | RESERVED | WKUP_ST | | | | | | | | |
| SND_PERIPH_DPLL_ST | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |

| Bits | Field Name | Description | Type | Reset |
|-------|--------------------|--|------|-------|
| 31:26 | RESERVED | Write 0's for future compatibility. Reads returns 0. | R | 0x00 |
| 25 | SND_PERIPH_DPLL_ST | DPLL5 recalibration event status 0x0: Status bit unchanged 0x0: DPLL5 recalibration event is false 0x1: DPLL5 recalibration event is true (pending) 0x1: Status bit is cleared to 0 | RW | 0x0 |
| 24:8 | RESERVED | Write 0's for future compatibility. Reads returns 0. | R | 0x0 |
| 7 | MPU_DPLL_ST | DPLL1 recalibration event status 0x0: Status bit unchanged 0x0: DPLL1 recalibration event is false 0x1: DPLL1 recalibration event is true (pending) 0x1: Status bit is cleared to 0 | RW | 0x0 |
| 6 | PERIPH_DPLL_ST | DPLL4 recalibration event status 0x0: Status bit unchanged 0x0: DPLL4 recalibration event is false 0x1: DPLL4 recalibration event is true (pending) 0x1: Status bit is cleared to 0 | RW | 0x0 |
| 5 | CORE_DPLL_ST | DPLL3 recalibration event status 0x0: Status bit unchanged 0x0: DPLL3 recalibration event is false 0x1: DPLL3 recalibration event is true (pending) 0x1: Status bit is cleared to 0 | RW | 0x0 |
| 4 | TRANSITION_ST | Software supervised transition completed event status 0x0: Status bit unchanged 0x0: Software supervised transition completed event is false 0x1: Software supervised transition completed event is true (pending) 0x1: Status bit is cleared to 0 | RW | 0x0 |

| Bits | Field Name | Description | Type | Reset |
|------|-------------|--|------|-------|
| 3 | EVGENOFF_ST | Event Generator endOFFtime status 0x0: End of OFF time event is false 0x0: Status bit unchanged 0x1: Status bit is cleared to 0 0x1: End of OFF time event is true (pending) | RW | 0x0 |
| 2 | EVGENON_ST | Event Generator endONtime status 0x0: End of ON time event is false 0x0: Status bit unchanged 0x1: End of ON time event is true (pending) 0x1: Status bit is cleared to 0 | RW | 0x0 |
| 1 | RESERVED | Write 0's for future compatibility. Reads returns 0. | R | 0x0 |
| 0 | WKUP_ST | MPU peripherals group wake-up event status 0x0: Status bit unchanged 0x0: Wake-up event is false 0x1: Wake-up event is true (pending) 0x1: Status bit is cleared to 0 | RW | 0x0 |

4.12.2.2.4 PRM_IRQENABLE_MPU
Table 4-181. PRM_IRQENABLE_MPU

| | | | |
|-------------------------|--|-----------------|--------------------|
| Address Offset | 0x0000 001C | Instance | OCP_System_Reg_PRM |
| Physical Address | 0x4830 681C | | |
| Description | The interrupt enable register allows masking/unmasking the module internal sources of interrupt, on a event-by-event basis. This registers applies on the interrupt line 0 mapped to the MPU interrupt controller. | | |
| Type | RW | | |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|----|--------------------------|----------|----|----|----|----|----|----|----|----|----|-------------------|----------------------|--------------------|---------------|-------------|------------|----------|---------|---|---|---|---|---|---|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| RESERVED | | | | | | | SND_PERIPH_DPLL_RECAL_EN | RESERVED | | | | | | | | | | MPU_DPLL_RECAL_EN | PERIPH_DPLL_RECAL_EN | CORE_DPLL_RECAL_EN | TRANSITION_EN | EVGENOFF_EN | EVGENON_EN | RESERVED | WKUP_EN | | | | | | |

| Bits | Field Name | Description | Type | Reset |
|-------|--------------------------|--|------|-------|
| 31:26 | RESERVED | Write 0's for future compatibility. Reads returns 0. | R | 0x00 |
| 25 | SND_PERIPH_DPLL_RECAL_EN | DPLL5 recalibration mask 0x0: DPLL5 recalibration event is masked 0x1: DPLL5 recalibration event generates an interrupt | RW | 0x0 |
| 24:8 | RESERVED | Write 0's for future compatibility. Reads returns 0. | R | 0x0 |
| 7 | MPU_DPLL_RECAL_EN | DPLL1 recalibration mask 0x0: DPLL1 recalibration event is masked 0x1: DPLL1 recalibration event generates an interrupt | RW | 0x0 |
| 6 | PERIPH_DPLL_RECAL_EN | DPLL4 recalibration mask 0x0: DPLL4 recalibration event is masked 0x1: DPLL4 recalibration event generates an interrupt | RW | 0x0 |
| 5 | CORE_DPLL_RECAL_EN | DPLL3 recalibration mask 0x0: DPLL3 recalibration event is masked 0x1: DPLL3 recalibration event generates an interrupt | RW | 0x0 |
| 4 | TRANSITION_EN | Software supervised transition completed event mask 0x0: Software supervised transition completed event is masked. 0x1: Software supervised transition completed event generates an interrupt. | RW | 0x0 |
| 3 | EVGENOFF_EN | Event Generator endOFFtime mask 0x0: End of OFF time event is masked 0x1: End of OFF time event generates an interrupt | RW | 0x0 |
| 2 | EVGENON_EN | Event Generator endONtime mask 0x0: End of ON time event is masked 0x1: End of ON time event generates an interrupt | RW | 0x0 |
| 1 | RESERVED | Write 0's for future compatibility. Reads returns 0. | R | 0x0 |

| Bits | Field Name | Description | Type | Reset |
|-------------|-------------------|---|-------------|--------------|
| 0 | WKUP_EN | MPU peripherals group wake-up event mask 0x0: MPU peripherals group wake-up event is masked 0x1: MPU peripherals group wake-up event generates an interrupt | RW | 0x0 |

4.12.2.3 MPU_PRM Register Descriptions

4.12.2.3.1 RM_RSTST_MPU

Table 4-182. RM_RSTST_MPU

| | | | |
|-------------------------|---|-----------------|---------|
| Address Offset | 0x0000 0058 | Instance | MPU_PRM |
| Physical Address | 0x4830 6958 | | |
| Description | This register logs the different reset sources of the MPU domain. Each bit is set upon release of the domain reset signal. Must be cleared by software. | | |
| Type | RW | | |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|----|----|----|----|----|-------------------|----------|----|----|----|----|----|----|----|----|----|---|----------------|----------------|---|---|---|---|---|---|---|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| RESERVED | | | | | | | | | | | EMULATION_MPU_RST | RESERVED | | | | | | | | | | | GLOBALWARM_RST | GLOBALCOLD_RST | | | | | | | |

| Bits | Field Name | Description | Type | Reset |
|-------|-------------------|--|------|---------|
| 31:12 | RESERVED | Write 0's for future compatibility. Read returns 0. | R | 0x00000 |
| 11 | EMULATION_MPU_RST | Emulation reset 0x0: Status bit unchanged 0x0: No emulation reset. 0x1: Status bit is cleared to 0 0x1: MPU domain has been reset upon an emulation reset | RW | 0x0 |
| 10:2 | RESERVED | Write 0's for future compatibility. Read returns 0. | R | 0x00 |
| 1 | GLOBALWARM_RST | Global warm reset 0x0: Status bit unchanged 0x0: No global warm reset. 0x1: MPU domain has been reset upon a global warm reset 0x1: Status bit is cleared to 0 | RW | 0x0 |
| 0 | GLOBALCOLD_RST | Global cold reset 0x0: Status bit unchanged 0x0: No global cold reset. 0x1: Status bit is cleared to 0 0x1: MPU domain has been reset upon a global cold reset | RW | 0x1 |

4.12.2.3.2 PM_WKDEP_MPU

Table 4-183. PM_WKDEP_MPU

| | | | |
|-------------------------|---|-----------------|---------|
| Address Offset | 0x0000 00C8 | Instance | MPU_PRM |
| Physical Address | 0x4830 69C8 | | |
| Description | This register allows enabling or disabling the wake-up of the MPU domain upon another domain wakeup events. | | |
| Type | RW | | |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|--------|----------|--------|---------|----|----|---|---------|---|---|---|---|---|---|---|---|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| RESERVED | | | | | | | | | | | | | | | | EN_PER | RESERVED | EN_DSS | RESERVE | | | | EN_CORE | | | | | | | | |

| Bits | Field Name | Description | Type | Reset |
|------|------------|---|------|----------|
| 31:8 | RESERVED | Write 0's for future compatibility. Read returns 0. | R | 0x000000 |
| 7 | EN_PER | PER domain dependency 0x0: MPU domain is independent of PER domain wake-up event. 0x1: MPU domain is woken-up upon PER domain wake-up event. | RW | 0x1 |
| 6 | RESERVED | Write 0's for future compatibility. Read returns 0. | R | 0x0 |
| 5 | EN_DSS | DSS domain dependency 0x0: MPU domain is independent of DSS domain wake-up event. 0x1: MPU domain is woken-up upon DSS domain wake-up event. | RW | 0x1 |
| 4:1 | RESERVED | Write 0's for future compatibility. Read returns 0. | R | 0x0 |
| 0 | EN_CORE | CORE domain dependency 0x0: MPU domain is independent of CORE domain wake-up event. 0x1: MPU domain is woken-up upon CORE domain wake-up event. | RW | 0x1 |

4.12.2.3.3 PM_EVGENCTRL_MPU
Table 4-184. PM_EVGENCTRL_MPU

| | | | |
|-------------------------|--|-----------------|---------|
| Address Offset | 0x0000 00D4 | | |
| Physical Address | 0x4830 69D4 | Instance | MPU_PRM |
| Description | This register allows controlling the feature of the event generator. | | |
| Type | RW | | |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|-------------|------------|--------|---|---|---|---|---|---|

| OFFTIMEVAL | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |

| Bits | Field Name | Description | Type | Reset |
|------|------------|---|------|------------|
| 31:0 | OFFTIMEVAL | Number of system clock cycles for the OFF period. | RW | 0x00000000 |

4.12.2.3.6 PM_PWSTCTRL_MPU
Table 4-187. PM_PWSTCTRL_MPU

| | | | |
|-------------------------|---|-----------------|---------|
| Address Offset | 0x0000 00E0 | Instance | MPU_PRM |
| Physical Address | 0x4830 69E0 | | |
| Description | This register controls the MPU domain power state transition. | | |
| Type | R/W | | |
| Write Latency | Immediate | | |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|----|----|----------------|----------|----|----|----|----|----|----|----|-----------------|----------|----|----|----|--------------|----------------------|------------|---|---|---|---|---|---|---|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| RESERVED | | | | | | | | L2CACHEONSTATE | RESERVED | | | | | | | | L2CACHERETSTATE | RESERVED | | | | MEMORYCHANGE | LOGICL1CACHERETSTATE | POWERSTATE | | | | | | | |

| Bits | Field Name | Description | Type | Reset |
|-------|----------------------|---|------|--------|
| 31:18 | RESERVED | Write 0's for future compatibility. Read returns 0. | R | 0x0000 |
| 17:16 | L2CACHEONSTATE | L2 Cache memory state when domain is ON; Other enums: Reserved 0x0: Reserved 0x1: Reserved 0x2: Reserved 0x3: L2 Cache memory is ON when domain is ON. | R/W | 0x3 |
| 15:9 | RESERVED | Write 0's for future compatibility. Read returns 0. | R | 0x00 |
| 8 | L2CACHERETSTATE | L2 Cache memory state when domain is RETENTION 0x0:Reserved 0x1: L2 Cache memory is retained when domain is in RETENTION state. | R/W | 1 |
| 7:4 | RESERVED | Write 0's for future compatibility. Read returns 0. | R | 0x0 |
| 3 | MEMORYCHANGE | Memory change control in ON state 0x0: Disable memory change 0x1: Enable memory change state in ON state. This bit is automatically cleared when memory state is effectively changed. | R/W | 0 |
| 2 | LOGICL1CACHERETSTATE | Logic and L1 Cache state when domain is RETENTION 0x0: Reserved 0x1: Logic and L1 Cache are retained when domain is in RETENTION state. | R/W | 1 |
| 1:0 | POWERSTATE | Power state control 0x0: Reserved 0x1: RETENTION state 0x2: Reserved 0x3: ON State | R/W | 0x3 |

NOTE: This register should not be programmed with reserved values of bit fields for proper functioning of power state control.

4.12.2.3.7 PM_PWSTST_MPU
Table 4-188. PM_PWSTST_MPU

| | | | |
|-------------------------|--|-----------------|---------|
| Address Offset | 0x0000 00E4 | Instance | MPU_PRM |
| Physical Address | 0x4830 69E4 | | |
| Description | This register provides a status on the MPU domain power state. | | |
| Type | R | | |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|----|----|--------------|----------|----|----|----|----|----|----|----|--------------|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

| Bits | Field Name | Description | Type | Reset |
|-------------|-------------------|--|-------------|--------------|
| 1:0 | POWERSTATE | Power state control 0x0: Reserved 0x1: RETENTION state 0x2: Reserved 0x3: ON State | R/W | 0x3 |

NOTE: This register should not be programmed with reserved values of bit fields for proper functioning of power state control.

4.12.2.4.7 PM_PWSTST_CORE
Table 4-196. PM_PWSTST_CORE

| | | | |
|-------------------------|---|-----------------|----------|
| Address Offset | 0x0000 00E4 | Instance | CORE_PRM |
| Physical Address | 0x4830 6AE4 | | |
| Description | This register provides a status on the power state transition of the CORE domain. | | |
| Type | R | | |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|----|----|--------------|----------|----|----|----|----|----|----|----|--------------|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| RESERVED | | | | | | | | INTRANSITION | RESERVED | | | | | | | | POWERSTATEST | | | | | | | | | | | | | | |

| Bits | Field Name | Description | Type | Reset |
|-------|--------------|--|------|-------|
| 31:21 | RESERVED | Read returns 0. | R | 0x000 |
| 20 | INTRANSITION | Domain transition status 0x0: No transition 0x1: CORE domain transition is in progress. | R | 0x0 |
| 19:2 | RESERVED | Read returns 0. | R | 0x000 |
| 1:0 | POWERSTATEST | Current power state status 0x0: Reserved 0x1: Reserved 0x2: Power domain is INACTIVE 0x3: Power domain is ON | R | 0x3 |

4.12.2.4.8 PM_PREPWSTST_CORE
Table 4-197. PM_PREPWSTST_CORE

| | | | |
|-------------------------|---|-----------------|----------|
| Address Offset | 0x0000 00E4 | Instance | CORE_PRM |
| Physical Address | 0x4830 6AE4 | | |
| Description | This register provides a status on the power state transition of the CORE domain. | | |
| Type | R/W | | |
| Write Latency | Not relevant | | |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----------------------|----|----------------------|----|----------|----|-----------------------|---|-----------------------|---|---|---|---|---|---|---|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|--|------|------------|
| 31:3 | RESERVED | Write 0's for future compatibility. Read returns 0. | R | 0x00000000 |
| 2 | EN_USBTTLL | USB TLL wake-up control 0x0: USB TLL wake-up is disabled 0x1: USB TLL wake-up event is enabled | RW | 0x1 |
| 1:0 | RESERVED | Write 0's for future compatibility. Read returns 0. | R | 0x0 |

4.12.2.4.10 PM_MPUGRPSEL3_CORE
Table 4-199. PM_MPUGRPSEL3_CORE

| | | | |
|-------------------------|---|-----------------|----------|
| Address Offset | 0x0000 00F8 | | |
| Physical Address | 0x4830 6AF8 | Instance | CORE_PRM |
| Description | This register allows selecting the group of modules that wake-up the MPU. | | |
| Type | RW | | |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---------------|----------|---|---|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| RESERVED | | | | | | | | | | | | | | | | | | | | | | | | | | | | GRPSEL_USBTLL | RESERVED | | |

| Bits | Field Name | Description | Type | Reset |
|------|---------------|--|------|------------|
| 31:3 | RESERVED | Write 0's for future compatibility. Read returns 0. | R | 0x00000000 |
| 2 | GRPSEL_USBTLL | Select the USB TLL in the MPU wake-up events group 0x0: USB TLL is not attached to the MPU wake-up events group. 0x1: USB TLL is attached to the MPU wake-up events group. | RW | 0x1 |
| 1:0 | RESERVED | Write 0's for future compatibility. Read returns 0. | R | 0x0 |

4.12.2.5 SGX_PRM Register Descriptions

4.12.2.5.1 RM_RSTST_SGX

Table 4-200. RM_RSTST_SGX

| | | | |
|-------------------------|---|-----------------|---------|
| Address Offset | 0x0000 0058 | Instance | SGX_PRM |
| Physical Address | 0x4830 6B58 | | |
| Description | This register logs the different reset sources of the SGX domain. Each bit is set upon release of the domain reset signal. Must be cleared by software. | | |
| Type | RW | | |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----------------|----|----------------|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| RESERVED | | | | | | | | | | | | | | | | GLOBALWARM_RST | | GLOBALCOLD_RST | | | | | | | | | | | | | |

| Bits | Field Name | Description | Type | Reset |
|------|----------------|--|------|------------|
| 31:2 | RESERVED | Write 0's for future compatibility. Read returns 0. | R | 0x00000000 |
| 1 | GLOBALWARM_RST | Global warm reset 0x0: Status bit unchanged 0x0: No global warm reset. 0x1: Status bit is cleared to 0 0x1: SGX domain has been reset upon a global warm reset | RW | 0x0 |
| 0 | GLOBALCOLD_RST | Global cold reset 0x0: No global cold reset. 0x0: Status bit unchanged 0x1: SGX domain has been reset upon a global cold reset 0x1: Status bit is cleared to 0 | RW | 0x1 |

4.12.2.5.2 PM_WKDEP_SGX
Table 4-201. PM_WKDEP_SGX

| | | | |
|-------------------------|--|-----------------|---------|
| Address Offset | 0x0000 00C8 | Instance | SGX_PRM |
| Physical Address | 0x4830 6BC8 | | |
| Description | This register allows enabling or disabling the wake-up of the SGX domain upon another domain wakeup. | | |
| Type | RW | | |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---------|----------|--------|----------|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| RESERVED | | | | | | | | | | | | | | | | | | | | | | | | | | | | EN_WKUP | RESERVED | EN_MPU | RESERVED |

| Bits | Field Name | Description | Type | Reset |
|------|------------|---|------|------------|
| 31:5 | RESERVED | Write 0's for future compatibility. Read returns 0. | R | 0x00000000 |
| 4 | EN_WKUP | WAKEUP domain dependency 0x0: SGX domain is independent of WKUP domain wake-up event. 0x1: SGX domain is woken-up upon WKUP domain wake-up event. | RW | 0x1 |
| 3:2 | RESERVED | Write 0's for future compatibility. Read returns 0. | R | 0x0 |
| 1 | EN_MPU | MPU domain dependency 0x0: SGX domain is independent of MPU domain wake-up. 0x1: SGX domain is woken-up upon MPU domain wake-up. | RW | 0x1 |
| 0 | RESERVED | Write 0's for future compatibility. Read returns 0. | R | 0x0 |

4.12.2.5.3 PM_PWSTCTRL_SGX
Table 4-202. PM_PWSTCTRL_SGX

| | | | |
|-------------------------|--|-----------------|----------|
| Address Offset | 0x0000 00E0 | Instance | CORE_PRM |
| Physical Address | 0x4830 6AE0 | | |
| Description | This register controls the CORE domain power state transition. | | |
| Type | R/W | | |
| Write Latency | Immediate | | |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|------------|----|----------|----|----|----|---|---|-------------|---|----------|---|---|---|---------------|---|------------|--|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 | | |
| RESERVED | | | | | | | | | | | | | | | | MEMONSTATE | | RESERVED | | | | | | MEMRETSTATE | | RESERVED | | | | LOGICRETSTATE | | POWERSTATE | |

| Bits | Field Name | Description | Type | Reset |
|-------|---------------|--|------|--------|
| 31:18 | RESERVED | Write 0's for future compatibility. Read returns 0. | R | 0x0000 |
| 17:16 | MEMONSTATE | Memory state when ON 0x3: Memory is always ON when domain is ON. | R | 0x3 |
| 15:9 | RESERVED | Write 0's for future compatibility. Read returns 0. | R | 0x00 |
| 8 | MEMRETSTATE | Memory state when RETENTION 0x1: Memory is always retained when domain is in RETENTION state. | R | 1 |
| 7:3 | RESERVED | Write 0's for future compatibility. Read returns 0. | R | 0x00 |
| 2 | LOGICRETSTATE | Logic state when RETENTION 0x1: Logic is always retained when domain is in RETENTION state. | R | 1 |
| 1:0 | POWERSTATE | Power state control 0x0: Reserved 0x1: RETENTION state 0x2: Reserved 0x3: ON State | R/W | 0x3 |

NOTE: This register should not be programmed with reserved values of bit fields for proper functioning of power state control.

4.12.2.5.4 PM_PWSTST_SGX
Table 4-203. PM_PWSTST_SGX

| | | | |
|-------------------------|--|-----------------|---------|
| Address Offset | 0x0000 00E4 | Instance | SGX_PRM |
| Physical Address | 0x4830 6BE4 | | |
| Description | This register provides a status on the power state transition of the SGX domain. | | |
| Type | R | | |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |

| Bits | Field Name | Description | Type | Reset |
|------|------------|---|------|----------|
| 31:8 | RESERVED | Write 0's for future compatibility. Read returns 0. | R | 0x000000 |
| 7 | CLKOUT_EN | This bit controls the external output clock (sys_clkout1) activity 0x0: sys_clkout1 is disabled 0x1: sys_clkout1 is enabled | RW | 0x1 |
| 6:0 | RESERVED | Write 0's for future compatibility. Read returns 0. | R | 0x00 |

4.12.2.8 DSS_PRM Register Descriptions

4.12.2.8.1 RM_RSTST_DSS

Table 4-210. RM_RSTST_DSS

| | | | |
|-------------------------|---|-----------------|---------|
| Address Offset | 0x0000 0058 | Instance | DSS_PRM |
| Physical Address | 0x4830 6E58 | | |
| Description | This register logs the different reset sources of the DSS domain. Each bit is set upon release of the domain reset signal. Must be cleared by software. | | |
| Type | RW | | |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----------------|----|----------------|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| RESERVED | | | | | | | | | | | | | | | | GLOBALWARM_RST | | GLOBALCOLD_RST | | | | | | | | | | | | | |

| Bits | Field Name | Description | Type | Reset |
|------|----------------|--|------|-----------|
| 31:2 | RESERVED | Write 0's for future compatibility. Read returns 0. | R | 0x0000000 |
| 1 | GLOBALWARM_RST | Global warm reset 0x0: Status bit unchanged 0x1: No global warm reset. 0x2: DISPLAY domain has been reset upon a global warm reset 0x3: Status bit is cleared to 0 | RW | 0x0 |
| 0 | GLOBALCOLD_RST | Global cold reset 0x0: No global cold reset. 0x1: Status bit unchanged 0x2: DISPLAY domain has been reset upon a global cold reset 0x3: Status bit is cleared to 0 | RW | 0x1 |

4.12.2.8.2 PM_WKEN_DSS
Table 4-211. PM_WKEN_DSS

| | | | |
|-------------------------|---|-----------------|---------|
| Address Offset | 0x0000 00A0 | | |
| Physical Address | 0x4830 6EA0 | Instance | DSS_PRM |
| Description | This register allows enabling/disabling modules wake-up events. | | |
| Type | RW | | |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|--------|---|---|---|

| RESERVED | | | | | | | | | | | | | | | | | | | | | | | | | | | | EN_WKUP | RESERVED | EN_MPU | RESERVED |

| Bits | Field Name | Description | Type | Reset |
|------|------------|---|------|------------|
| 31:5 | RESERVED | Write 0's for future compatibility. Read returns 0. | R | 0x00000000 |
| 4 | EN_WKUP | WAKEUP domain dependency 0x0: DSS domain is independent of WKUP domain wake-up event. 0x1: DSS domain is woken-up upon WKUP domain wake-up event. | RW | 0x1 |
| 3:2 | RESERVED | Write 0's for future compatibility. Read returns 0. | R | 0x0 |
| 1 | EN_MPU | MPU domain dependency 0x0: DSS domain is independent of MPU domain wake-up. 0x1: DSS domain is woken-up upon MPU domain wake-up. | RW | 0x1 |
| 0 | RESERVED | Write 0's for future compatibility. Read returns 0. | R | 0x0 |

4.12.2.8.4 PM_PWSTCTRL_DSS
Table 4-213. PM_PWSTCTRL_DSS

| | | | |
|-------------------------|---|-----------------|---------|
| Address Offset | 0x0000 00E0 | Instance | DSS_PRM |
| Physical Address | 0x4830 6EE0 | | |
| Description | This register controls the DISPLAY domain power state transition. | | |
| Type | R/W | | |
| Write Latency | Immediate | | |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|------------|----|----------|----|----|----|---|---|-------------|---|----------|---|---|---|---------------|---|------------|--|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 | | |
| RESERVED | | | | | | | | | | | | | | | | MEMONSTATE | | RESERVED | | | | | | MEMRETSTATE | | RESERVED | | | | LOGICRETSTATE | | POWERSTATE | |

| Bits | Field Name | Description | Type | Reset |
|-------|---------------|--|------|--------|
| 31:18 | RESERVED | Write 0's for future compatibility. Read returns 0. | R | 0x0000 |
| 17:16 | MEMONSTATE | Memory state when ON 0x3: Memory is always ON when domain is ON. | R | 0x3 |
| 15:9 | RESERVED | Write 0's for future compatibility. Read returns 0. | R | 0x00 |
| 8 | MEMRETSTATE | Memory state when RETENTION 0x1: Memory is always retained when domain is in RETENTION state. | R | 1 |
| 7:3 | RESERVED | Write 0's for future compatibility. Read returns 0. | R | 0x00 |
| 2 | LOGICRETSTATE | Logic state when RETENTION 0x1: Logic is always retained when domain is in RETENTION state. | R | 1 |
| 1:0 | POWERSTATE | Power state control 0x0: Reserved 0x1: RETENTION state 0x2: Reserved 0x3: ON State | R/W | 0x3 |

NOTE: This register should not be programmed with reserved values of bit fields for proper functioning of power state control.

4.12.2.8.5 PM_PWSTST_DSS
Table 4-214. PM_PWSTST_DSS

| | | | |
|-------------------------|--|-----------------|---------|
| Address Offset | 0x0000 00E4 | | |
| Physical Address | 0x4830 6EE4 | Instance | DSS_PRM |
| Description | This register provides a status on the power state transition of the DSS domain. | | |
| Type | R | | |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|----|----|--------------|----------|----|----|----|----|----|----|----|--------------|----|----|----|----|---|---|---|---|---|---|---|---|---|---|

|------|----------------|--|------|------------|
| 31:2 | RESERVED | Write 0's for future compatibility. Read returns 0. | R | 0x00000000 |
| 1 | GLOBALWARM_RST | Global warm reset 0x0: Status bit unchanged 0x0: No global warm reset. 0x1: Status bit is cleared to 0 0x1: MPU domain has been reset upon a global warm reset | RW | 0x0 |
| 0 | GLOBALCOLD_RST | Global cold reset 0x0: No global cold reset. 0x0: Status bit unchanged 0x1: MPU domain has been reset upon a global cold reset 0x1: Status bit is cleared to 0 | RW | 0x1 |

4.12.2.11 Global_Reg_PRM Register Descriptions
4.12.2.11.1 PRM_RSTCTRL
Table 4-225. PRM_RSTCTRL

| | | | |
|-------------------------|--|-----------------|----------------|
| Address Offset | 0x0000 0050 | Instance | Global_Reg_PRM |
| Physical Address | 0x4830 7250 | | |
| Description | Global software and DPLL3 reset control. This register is auto-cleared. Only write 1 is possible. A read returns 0 only. | | |
| Type | RW | | |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|-----------|--------|----------|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| RESERVED | | | | | | | | | | | | | | | | RST_DPLL3 | RST_GS | RESERVED | | | | | | | | | | | | | |

| Bits | Field Name | Description | Type | Reset |
|------|------------|---|------|------------|
| 31:3 | RESERVED | Write 0's for future compatibility. Read returns 0. | R | 0x00000000 |
| 2 | RST_DPLL3 | DPLL3 software reset control. This bit is reset only upon a global cold source of reset. 0x0: DPLL3 software reset is cleared. 0x1: Asserts the DPLL3 software reset and induces a global cold reset on the whole chip. The software must ensure the SDRAM is properly put in self-refresh mode before applying this reset. | RW | 0x0 |
| 1 | RST_GS | Global software reset control. This bit is reset upon any global source of reset (warm and cold). 0x0: Global software reset is cleared. 0x1: Asserts a global software reset. | RW | 0x0 |
| 0 | RESERVED | Write 0's for future compatibility. Read returns 0. | R | 0x0 |

| Bits | Field Name | Description | Type | Reset |
|-------|-------------------|--|------|----------|
| 31:11 | RESERVED | Write 0's for future compatibility. Read returns 0. | R | 0x000000 |
| 10 | ICECRUSHER_RST | IceCrusher reset event. This is a source of warm reset initiated by the emulation. 0x0: No IceCrusher reset. 0x0: Status bit unchanged 0x1: Status bit is cleared to 0 0x1: IceCrusher reset has occurred. | RW | 0x0 |
| 9 | ICEPICK_RST | IcePick reset event. This is a source of warm reset initiated by the emulation. 0x0: No IcePick reset. 0x0: Status bit unchanged 0x1: Status bit is cleared to 0 0x1: IcePick reset has occurred. | RW | 0x0 |
| 8:7 | RESERVED | Write 0's for future compatibility. Read returns 0. | RW | 0x0 |
| 6 | EXTERNAL_WARM_RST | External warm reset event 0x0: Status bit unchanged 0x0: No global warm reset. 0x1: Status bit is cleared to 0 0x1: Global external warm reset has occurred. | RW | 0x0 |
| 5 | SECURE_WD_RST | Secure watchdog reset event 0x0: Status bit unchanged 0x0: No security watchdog reset. 0x1: Status bit is cleared to 0 0x1: Security watchdog reset has occurred. | RW | 0x0 |
| 4 | MPU_WD_RST | MPU watchdog reset event 0x0: Status bit unchanged 0x0: No MPU watchdog reset. 0x1: MPU watchdog reset has occurred. 0x1: Status bit is cleared to 0 | RW | 0x0 |

| Bits | Field Name | Description | Type | Reset |
|------|-------------------|--|------|-------|
| 3 | SECURITY_VIOL_RST | Security violation reset event 0x0: Status bit unchanged 0x0: No security violation reset. 0x1: Status bit is cleared to 0 0x1: Security violation reset has occurred. | RW | 0x0 |
| 2 | RESERVED | Write 0's for future compatibility. Read returns 0. | R | 0x0 |
| 1 | GLOBAL_SW_RST | Global software reset event 0x0: No global software reset. 0x0: Status bit unchanged 0x1: Global software reset has occurred. 0x1: Status bit is cleared to 0 | RW | 0x0 |
| 0 | GLOBAL_COLD_RST | Power-up (cold) reset event 0x0: No power-on reset. 0x0: Status bit unchanged 0x1: Power-on reset has occurred. 0x1: Status bit is cleared to 0 | RW | 0x1 |

4.12.2.11.4 PRM_CLKSRC_CTRL
Table 4-228. PRM_CLKSRC_CTRL

| | | | |
|-------------------------|--|-----------------|----------------|
| Address Offset | 0x0000 0070 | Instance | Global_Reg_PRM |
| Physical Address | 0x4830 7270 | | |
| Description | This register provides control over the device source clock. | | |
| Type | RW | | |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|-----------|----|----------|----------------|----|----|----------|-----------|---|---|---|---|---|---|---|---|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| RESERVED | | | | | | | | | | | | | | | | SYSCLKDIV | | RESERVED | AUTOEXTCLKMODE | | | RESERVED | SYSCLKSEL | | | | | | | | |

| Bits | Field Name | Description | Type | Reset |
|------|----------------|--|------|----------|
| 31:8 | RESERVED | Write 0's for future compatibility. Read returns 0. | R | 0x000000 |
| 7:6 | SYSCLKDIV | This field controls the system clock input divider 0x0: reserved 0x1: Syst_clk is external clock / 1 0x2: Syst_clk is external clock / 2 0x3: reserved | RW | 0x1 |
| 5 | RESERVED | Write 0's for future compatibility. Read returns 0. | R | 0x0 |
| 4:3 | AUTOEXTCLKMODE | This field allows to control the external clock request (CLKREQ) and the oscillator 0x0: CLKREQ is kept asserted or the oscillator is always active (in master mode) 0x1: CLKREQ is de-asserted or the oscillator is put in power-down mode (in master mode) when all the voltages domains are SLEEP, RETENTION or OFF states. 0x2: CLKREQ is de-asserted or the oscillator is put in power-down mode (in master mode) when all the voltages domains are RETENTION or OFF states. 0x3: CLKREQ is de-asserted or the oscillator is put in power-down mode (in master mode) only when all the voltage domains are in OFF states. | RW | 0x0 |
| 2 | RESERVED | Write 0's for future compatibility. Read returns 0. | R | 0x0 |
| 1:0 | SYSCLKSEL | This field reflects the mode of the oscillator. It is automatically set accordingly to the external tied-off configuration and its value is insignificant before the release of the power-on reset. 0x0: Bypass mode: the system clock is issued from an external square clock source 0x1: Oscillator mode: the system clock is issued from an external quartz 0x2: Reserved 0x3: Unknown state (not know before release of the power-on reset) | R | 0x3 |

| | | | |
|-------------------------|--|-----------------|----------------|
| Address Offset | 0x0000 0080 | Instance | Global_Reg_PRM |
| Physical Address | 0x4830 7280 | | |
| Description | This register logs the observable signals (18 bits). This register is intended to be read through the debugger interface when the device is in standby mode. | | |
| Type | R | | |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|---------|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| RESERVED | | | | | | | | | | | | | | OBS_BUS | | | | | | | | | | | | | | | | | |

| Bits | Field Name | Description | Type | Reset |
|-------|------------|--|------|---------|
| 31:18 | RESERVED | Read is undefined. | R | 0x0000 |
| 17:0 | OBS_BUS | Indicates the current value on the observable bus. | R | 0x00000 |

4.12.2.11.6 PRM_CLKSETUP

Table 4-230. PRM_CLKSETUP

| | | | |
|-------------------------|---|-----------------|----------------------|
| Address Offset | 0x0000 0098 | Instance | Global_Registers_PRM |
| Physical Address | 0x4830 7298 | | |
| Description | This register allows setting the setup time of the oscillator system clock (sys_clk), based on number of 32 kHz clock cycles. | | |
| Type | R/W | | |
| Write Latency | Immediate | | |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|------------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| RESERVED | | | | | | | | | | | | | | | | SETUP_TIME | | | | | | | | | | | | | | | |

| Bits | Field Name | Description | Type | Reset |
|-------|------------|---|------|--------|
| 31:16 | RESERVED | Write 0's for future compatibility. Read returns 0. | R | 0x0000 |
| 15:0 | SETUP_TIME | Number of 32kHz clock cycles for the SETUP duration | R/W | 0x0000 |

4.12.2.12 NEON_PRM Register Descriptions

4.12.2.12.1 RM_RSTST_NEON

Table 4-232. RM_RSTST_NEON

| | | | |
|-------------------------|--|-----------------|----------|
| Address Offset | 0x0000 0058 | Instance | NEON_PRM |
| Physical Address | 0x4830 7358 | | |
| Description | This register logs the different reset sources of the NEON domain. Each bit is set upon release of the domain reset signal. Must be cleared by software. | | |
| Type | RW | | |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----------------|----|----------------|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

Interconnect

This chapter describes the Interconnect.

NOTE:

- The L3 interconnect is an instantiation of the **SonicsMX**[®] interconnect from **Sonics, Inc.**
- The L4 interconnects are instantiations of the **Sonics3220**[™] interconnect from **Sonics, Inc.**

This document contains materials that are ©2003-2007 Sonics, Inc., and that constitute proprietary information of **Sonics, Inc.**

5.1 Interconnect Overview

This chapter gives information about all modules and features in the high-tier device. To flag interconnect response being blocked, the time-out of target agents attached to unavailable modules can be enabled with the lowest setting.

NOTE: Some features may not be available or supported in your particular device. For more information, see Chapter 1, the *Device Family* section, and your device-specific data manual.

5.1.1 Terminology

The following terminology is critical to understanding the interconnect:

- **Initiator:** Module able to initiate read and write requests to the chip interconnect (typically: processors, DMA, etc.).
- **Target:** Unlike an initiator, a target module cannot generate read/write requests to the chip interconnect, but it can respond to these requests. However, it may generate interrupts or a DMA request to the system (typically: peripherals, memory controllers).

NOTE: A module can have several separate ports; therefore, a module can be both an initiator and a target.

- **Agent:** Each connection of one module to one interconnect is done using an agent, which is an adaptation (sometimes configurable) between the module and the interconnect. A target module is connected by a target agent (TA), and an initiator module is connected by an initiator agent (IA).
- **OCP:** Open-core protocol (www.ocpip.org) is point-to-point standard protocol between one master port and one slave port.
- **OCP master port:** Port that can generate OCP commands. An initiator includes at least one master port.
- **OCP slave port:** Port that responds to OCP commands. A target includes one slave port.
- **Interconnect:** The decoding, routing, and arbitration logic that enables the connection between multiple initiator modules and multiple target modules connected on it.
- **Register target (RT):** Special TA used to access the interconnect internal configuration registers.
- **Dataflow signal:** Any OCP signal that is part of a clearly identified OCP transfer or dataflow (typically: command, address, byte enables, etc.). The signal behavior is defined by the OCP protocol semantics.
- **Sideband signal:** Any OCP signal whose behavior is not associated to a precise OCP transaction or dataflow. The OCP standard does not define specific semantics for these signals.
- **Out-of-band error:** Any OCP signal whose behavior is associated to an error-reporting scheme of the device, as opposed to in-band errors.

NOTE: Interrupt requests and DMA requests are not routed by the interconnect in the device.

- **Firewall:** A programmable security feature integrated in a target agent for each module requiring a secure data path. A firewall can be configured using three criteria:
 - Initiator requesting access
 - Address space access
 - Type of access
- **Thread:** Logical entities that allow to have separate independent data flows on a single port.
- **Multithreaded ports:** A physical port able to simultaneously handle several outstanding transactions. On a multithreaded port, one physical channel (port) is used concurrently for several logical channels (threads). The transfer in each thread must remain in order with respect to each other, but the order between threads can change between requests and responses. Thread management is used for performance optimization purposes and is automatically handled by the system.
- **ConnID:** Any transaction in the system interconnect is tagged by an in-band qualifier ConnID, which uniquely identifies the initiator at a given interconnect point. A ConnID is transmitted inband with the request and is used for security and error-logging mechanism.

- Firewall comparison mechanism: A comparison made in the firewall between access in-band qualifiers and access permissions that are programmed in the firewall configuration registers. If the comparison is successful, access is allowed; otherwise, access is denied.
- MCmd qualifier: Command bus that indicates the type of transfer requested. [Table 5-1](#) lists the commands encoded.

Table 5-1. MCmd Qualifier Description

| MCmd[2:0] | Transaction Type |
|-----------|------------------|
| 0 0 0 | Idle |
| 0 0 1 | Write |
| 0 1 0 | Read |
| 0 1 1 | ReadEx |
| 1 0 0 | Not used |
| 1 0 1 | Write nonposted |
| 1 1 0 | Not used |
| 1 1 1 | Not used |

- MReqInfo qualifier: Four MReqInfo qualifiers describe the access during the use of the firewall comparison mechanism, as described in [Table 5-2](#).

Table 5-2. MReqInfo Qualifier Description

| Qualifiers | Description |
|----------------|---|
| MReqType | 0: Data access 1: Opcode fetch |
| MReqSupervisor | 0: User mode 1: Supervisor mode |
| MReqDebug | 0: Functional access 1: Debug access |
| MReqSecure | 0: Public transaction 1: Secure transaction ⁽¹⁾ |

⁽¹⁾ In GP device MReqSecure = 1 (Secure value), is not supported.

- L3_PM_REQ_INFO_PERMISSION_i: Register that configures the combination of the MReqInfo, allowing access permission to the TM based on the MReqInfo in-band qualifier values.
- SError: Target that indicates an error condition to the initiator.
- SResp qualifier: Response from the target to the initiator concerning the transaction.

Table 5-3. SResp Qualifier Description

| SResp[1:0] | Description |
|------------|-------------------|
| 0 0 | No response |
| 0 1 | Data valid/accept |
| 1 0 | Not used |
| 1 1 | Error |

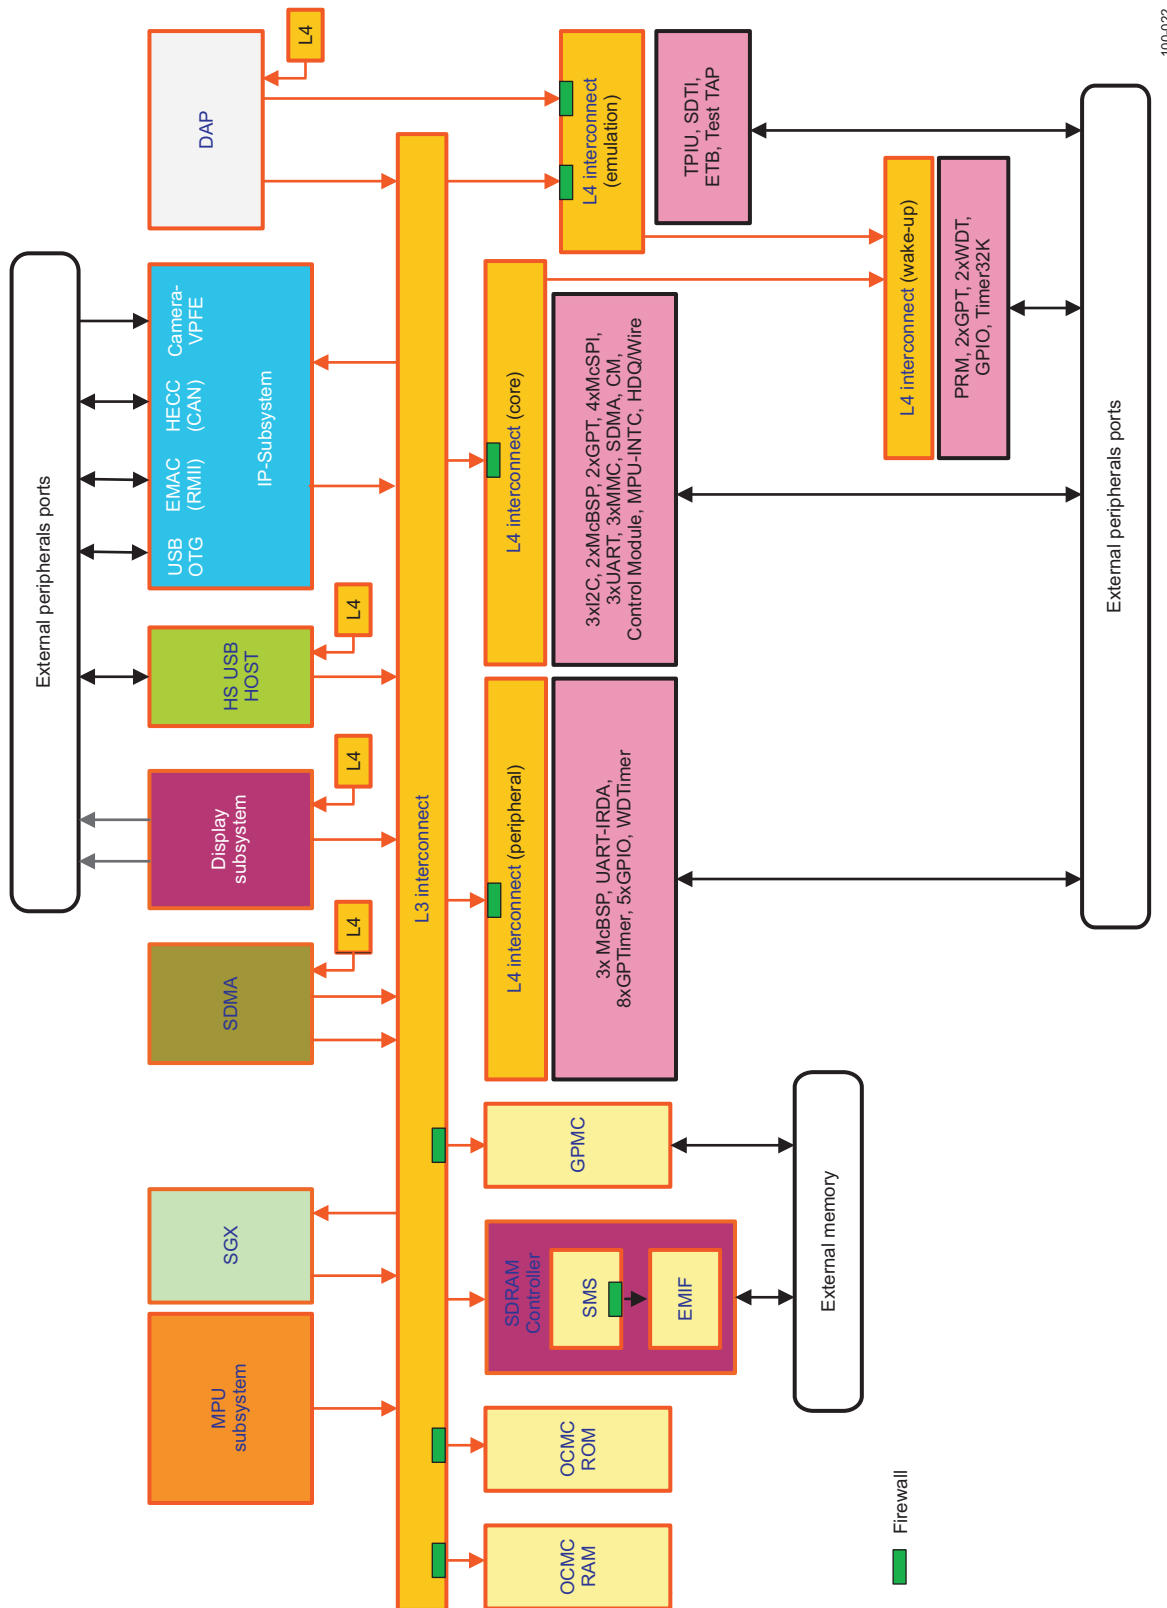

5.1.2 Architecture Overview

The device memory hierarchy includes four levels:

- L1 is internal to the CPUs. It concerns data exchange with the internal Level1 cache memory subsystem, and it is the closest memory to the microprocessor unit (MPU) core.
- L2 is included in the MPU subsystem.
- The chip-level interconnect consists of one L3 interconnect and four L4 interconnects. It enables communication among the modules and subsystems in the device. [Figure 5-1](#) shows an overview of the L3 and L4 interconnect architecture.
 - L3 handles many types of data transfers, especially exchanges with system-on-chip/external

- memories. L3 transfers data with a maximum width of 64 bits from the initiator to the target. The L3 interconnect is a little-endian platform
- L4 is composed of the L4-Core, L4-Per, L4-Wakeup, and L4-Emu interconnects and handles data transfers to peripherals. It supports 32-bit data width transfer and is optimized to support the interconnection of many peripheral targets. These backplanes assume little-endian transactions for narrower targets (8-bit, 16-bit) when doing data packing and unpacking.

Figure 5-1. Interconnect Architecture Overview

100-022

Modules are connected to the interconnect through an IA for the initiator module and a TA for target modules. Each module/subsystem connection is statically configured to tune the access depending on the characteristics of the module.

To secure a data path, some TAs include configurable firewalls (FWs) for security purposes. A firewall restricts or filters the accesses allowed to an initiator according to different access criteria. The firewalls can usually be configured by software.

The L3 and L4 interconnect default setting is fully functional; it enables all possible functional data paths and a minimal default security setting. However, it is possible to modify the interconnect parameters to fit user expectations.

5.1.3 Module Distribution

IAs and TAs provide the interface to connect the different modules and the interconnect.

[Table 5-4](#) through [Table 5-13](#) list the device modules, subsystems, and associated agents. The agents are listed for each interconnect domain:

- L3 initiator and target agents
- L4-Core initiator and target agents
- L4-Per initiator and target agents
- L4-Emu initiator and target agents
- L4-Wakeup initiator and target agents

5.1.3.1 L3 Interconnect Agents

[Table 5-4](#) and [Table 5-5](#) list the IAs and TAs, respectively, of the L3 interconnect.

Table 5-4. L3 Initiator Agents

| Module Name | Description |
|--------------------------|---|
| MPU SS | MPU subsystem port |
| Display SS | Display subsystem port |
| IPSS | IP-Subsystem initiator port (Camera-VPFE, USBOTG, and EMAC) |
| SGX SS | Graphics subsystem port |
| sDMA read | System DMA read port |
| sDMA write | System DMA write port |
| High-Speed (HS) USB Host | Universal serial bus High-Speed port Host Controller |
| DAP | Debug access port (JTAG/Emulation access to system resources) |

Table 5-5. L3 Target Agents

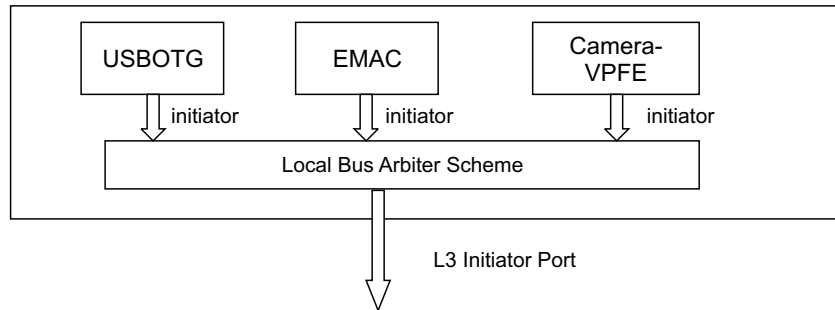

| Module Name | Description |
|----------------|---|
| SMS | SDRAM memory scheduler port |
| GPMC | General-purpose memory controller (for flash memory, SRAM, SRAM, etc.) port |
| OCM-ROM | On-chip memory ROM port |
| OCM-RAM | On-chip memory RAM port |
| SGX | Graphics subsystem port |
| IPSS | Register target port for IPSS |
| RT | Register target port to configure L3 |
| L4-Core | Port for L4-Core interconnect |
| L4-Peripherals | Port for L4-Per interconnect |
| L4-Emu | Port for L4-Emu interconnect |

NOTE: The IP-Subsystem (abbreviated as IPSS) integrates the following modules:

- Camera-VPFE
- EMAC
- USBOTG
- CAN-HECC

The camera-VPFE, EMAC and USBOTG are initiators on L3 and share one L3 initiator port as shown in Figure 5-2.

Figure 5-2. L3 Port Initiators

All IPSS modules (Camera-VPFE, EMAC, USBOTG, and CAN-HECC) have a register target port on L3. For more details on the register target module, see Section 5.4.2, Register Target.

5.1.3.2 L4-Core Agents

Table 5-6. L4-Core Initiator Agent

| Module Name | Description |
|-----------------|----------------------|
| L3 interconnect | L3 interconnect port |

NOTE: A unique L3 port is used for communication with the L4-Core. For the list of initiators allowed to access the L4 Core peripherals, see Table 5-14.

Table 5-7. L4-Core Target Agents

| Module Name | Description |
|--------------------------|--|
| Display subsystem | Display subsystem configuration port |
| High-Speed (FS) USB Host | Universal serial bus High-Speed port Host controller |
| UART1 | Universal asynchronous receiver transmitter port 1 |
| UART2 | Universal asynchronous receiver transmitter port 2 |
| UART4 | Universal asynchronous receiver transmitter port 4 |
| I2C1 | Multimaster interintegrated circuit 1 |
| I2C2 | Multimaster interintegrated circuit 2 |
| I2C3 | Multimaster interintegrated circuit 3 |
| McBSP1 | Multichannel buffered serial port 1 |
| McBSP5 | Multichannel buffered serial port 5 |
| GPTIMER10 | General-purpose timer 10 |
| GPTIMER11 | General-purpose timer 11 |
| SPI1 | Serial peripheral interface 1 |
| SPI2 | Serial peripheral interface 2 |

Table 5-7. L4-Core Target Agents (continued)

| Module Name | Description |
|-------------|-------------------------------------|
| MMCHS1 | Multimedia memory controller SDIO 1 |
| MMCHS2 | Multimedia memory controller SDIO 2 |
| MMCHS3 | Multimedia memory controller SDIO 3 |
| HDQ/1-Wire | Single wire serial link low rate |
| MG | MagicGate® |
| SPI1 | Serial peripheral interface 1 |
| SPI2 | Serial peripheral interface 2 |
| SPI3 | Serial peripheral interface 3 |
| SPI4 | Serial peripheral interface 4 |
| sDMA | System DMA controller |
| L4-Wakeup | L4-Wakeup interconnect |
| CM | Clock manager |
| SCM | System control module |

5.1.3.3 L4-Per Agents

Table 5-8. L4-Per Initiator Agent

| Module Name | Description |
|-----------------|----------------------|
| L3 interconnect | L3 interconnect port |

NOTE: A unique L3 port is used for communication with L4-Per. For the list of initiators allowed to access the L4-Per peripherals, see [Table 5-14](#).

Table 5-9. L4-Per Target Agents

| Module Name | Description |
|-------------|--|
| UARTIrDA | Universal asynchronous receiver/transmitter and infrared data association port |
| McBSP2 | Multichannel buffered serial port 2 |
| McBSP3 | Multichannel buffered serial port 3 |
| GPTIMER2 | General-purpose timer 2 |
| GPTIMER3 | General-purpose timer 3 |
| GPTIMER4 | General-purpose timer 4 |
| GPTIMER5 | General-purpose timer 5 |
| GPTIMER6 | General-purpose timer 6 |
| GPTIMER7 | General-purpose timer 7 |
| GPTIMER8 | General-purpose timer 8 |
| GPTIMER9 | General-purpose timer 9 |
| GPIO2 | General-purpose I/O 2 |
| GPIO3 | General-purpose I/O 3 |
| GPIO4 | General-purpose I/O 4 |
| GPIO5 | General-purpose I/O 5 |
| GPIO6 | General-purpose I/O 6 |

5.1.3.4 L4-Emu Agents

Table 5-10. L4-Emu Initiator Agents

| Module Name | Description |
|-----------------|----------------------|
| L3 interconnect | L3 interconnect port |
| DAP | DAP port |

NOTE: The L3 and DAP ports are used for communication with L4-Emu. For the list of initiators allowed to access the L4-Emu peripherals, see [Table 5-14](#).

Table 5-11. L4-Emu Target Agents

| Module Name | Description |
|-------------|------------------------------|
| L4-Wakeup | L4 wake-up interconnect |
| SDTI | System debug trace interface |
| ETB | Embedded trace buffer |
| TPIU | Trace port interface unit |
| DAPCTL | Debug access port |

5.1.3.5 L4-Wakeup Agents

Table 5-12. L4-Wakeup Initiator Agent

| Module Name | Description |
|----------------------|--------------------------------|
| L4-Core interconnect | L4-Core interconnect port |
| L4-Emu interconnect | L4-Emulation interconnect port |

NOTE: The L4-Emu and L4-Core ports are used to communicate with the L4-Wakeup. For the list of initiators allowed to access the L4-Wakeup peripherals, see [Table 5-14](#).

Table 5-13. L4-Wakeup Target Agents

| Module Name | Description |
|--------------------------|------------------------------|
| PRM | Power reset management |
| GPIO1 | General-purpose I/O 1 |
| GPTIMER1 | General-purpose timer 1 |
| GPTIMER12 ⁽¹⁾ | General-purpose timer 12 |
| WDTIMER1 ⁽¹⁾ | Secure watchdog timer |
| WDTIMER2 | MPU subsystem watchdog timer |
| 32KTIMER | 32-kHz timer |

⁽¹⁾ Not available in GP device.

5.1.4 Connectivity Matrix

[Table 5-14](#) lists the functional paths between the L3 interconnect initiator modules and the L3 and L4 TAs. The functional paths are indicated by the use of the following:

- Cell contains a + sign when a functional path exists.
- Cell is blank when no functional path exists.

Table 5-14. Connectivity Matrix

| Initiator Ports | L4-Core Target ⁽¹⁾ | L4-Per Target ⁽¹⁾ | L4-Emu Target ⁽¹⁾ | L4-Wakeup Target ⁽¹⁾ | SMS Target | GPMC Target | OCM RAM Target | OCM ROM Target | RT Target | IPSS Target | SGX Target |
|-----------------|-------------------------------|------------------------------|------------------------------|---------------------------------|------------|-------------|----------------|----------------|-----------|-------------|------------|
| MPU IA | + | + | + | + | + | + | + | + | + | + | + |
| SGX IA | | | | | + | + | + | | | | |
| IPSS IA | | | | | + | + | + | | | | |
| DSS IA | | | | | + | | + | | | | |
| USB Host IA | | | | | + | + | + | | | | |
| sDMA RD IA | + | + | + | + | + | + | + | | | | + |
| sDMA WR IA | + | + | + | + | + | + | + | | | | + |
| DAP IA | + | + | + | + | + | + | + | + | + | + | + |

⁽¹⁾ A functional data path always exists from L4 IAs (Core, Per, Emu, and Wakeup) to any L4 target module (Core, Per, Emu, and Wakeup). As a consequence, all L3 initiator modules for which a data path exists to an L4 TA can access L4 peripherals. Restrictions on peripheral access depend on the security settings and L4 protection mechanism programming. For more details, see [Section 5.9.3, L4 Security and Firewalls](#).

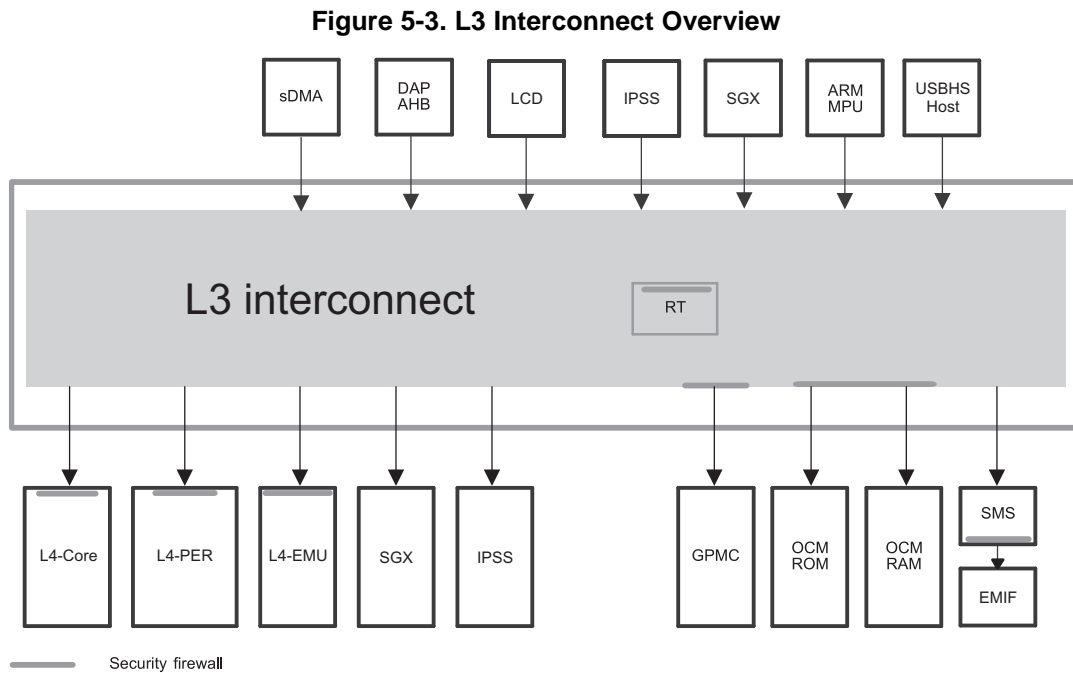

5.2 L3 Interconnect

This section describes the L3 interconnect and its components. With the exception of register points, each component includes functionality for both the request and response network.

5.2.1 Overview

The L3 interconnect links cores in a flexible topology that couples low power with high performance. Innovative physical structures and advanced protocols ensure bandwidth and latency to individual IP cores, providing dedicated connections between IP cores and logical connections over a shared interconnect.

Figure 5-3 shows the L3 interconnect.

100-007

The following are the main features of the L3 interconnect:

- 64-bit multipath interconnect to eliminate on-chip bottlenecks
- Special internal target for access to L3 registers (RT)
- Guaranteed quality of service for real-time hardware operators, while maintaining optimal memory latency for MPU accesses to memory resources
- True little-endian platform
- Transaction error tracking and logging
- Built-in security features:
 - Allow access only to authorized initiator
 - Distributed region-based firewalls for system resource sharing and protection management
- Signaling support for chip-level power management infrastructure
- Two interrupt line signaling transaction error

5.3 L3 Interconnect Integration

5.3.1 Clocking, Reset, and Power-Management Scheme

5.3.1.1 Clocks

The power, reset, and clock management (PRCM) module provides the L3_ICLK as the main clock to the L3 interconnect.

In addition to L3_ICLK, four additional sample signals are provided to module agents to allow internal synchronization. The modules are as follows:

- L4-Core
- L4-Per

For more details on the L3 clock and its setting, see the *Power, Reset, and Clock Management* chapter.

Table 5-15. L3 Interconnect Clocks

| Type | Name | Source | Description |
|----------------------|---------|--------|--------------------------------|
| Interface/functional | L3_ICLK | PRCM | Main clock for L3 interconnect |

5.3.1.2 Resets

The L3 interconnect receives a single reset signal, CORE_RST, from the PRCM module. CORE_RST is the reset signal to the core power domain. (For more details, see the *Power, Reset, and Clock Management* chapter.) When asserted, CORE_RST resets the L3 internal registers. There is no software reset for the L3 interconnect.

Table 5-16. L3 Interconnect Reset

| Type | Reset Domain | Source | Description |
|----------|--------------|--------|--|
| Hardware | CORE_RST | PRCM | Asynchronous reset for the entire interconnect |

5.3.1.3 Power Management

As part of the system-wide power-management scheme, the L3 interconnect enters an idle state at the request of the PRCM module. (For more details, see the *Power, Reset, and Clock Management* chapter.) The L3 interconnect is always in smart-idle mode; that is, it goes into idle state after receiving the request from the PRCM module once all transfer requests are serviced. This functionality is handled by hardware. The L3 interconnect sends an acknowledge signal back to the PRCM module when it enters the idle state.

5.3.2 Hardware Requests

5.3.2.1 Interrupt Requests

Three interrupt lines are present at the boundary of the L3 interconnect (see [Table 5-17](#)). They are used for hardware error management.

Table 5-17. L3 Interconnect Hardware Requests

| Type | Name | Destination | Description |
|-----------|----------|---|---|
| Interrupt | M_IRQ_9 | MPU interrupt controller for debug errors | L3 interconnect provides a mechanism to group core-detected and internal interconnect errors. See Section 5.9.4, Error Handling . |
| Interrupt | M_IRQ_10 | MPU interrupt controller for application errors | |

5.4 L3 Interconnect Functional Description

5.4.1 Initiator Identification

An InitiatorID is assigned to every thread on every initiator socket. The ID uniquely identifies the initiator and thread for an interconnect transfer see [Table 5-18](#). The interconnect uses InitiatorIDs for a number of purposes, including the following:

- Initiator source identification for the protection mechanism (see [Section 5.4.3, L3 Security and Firewalls](#))
- Response route generation (performed internally to the TAs)
- Firewall error logging
- L3 interconnect error logging

Table 5-18. InitiatorID Definition

| Initiator | InitiatorID |
|---|--------------------|
| HS USB Host | 0 |
| IP-Subsystem (Camera-VPFE, USBOTG, and EMAC) | 2 |
| sDMA rd | 3 , 4 , 5, 6 |
| sDMA wr | 7, 8 |
| DAP | 9 |
| SGX | 13 |
| MPU SS | 23, 24, 25, 26, 27 |
| LCD | 29 |

5.4.2 Register Target

An RT is a specialized TA used to access L3 interconnect internal configuration registers.

RT configuration options are a subset of those available for TAs. For more details, see [Section 5.6.5](#).

5.4.3 L3 Security and Firewalls

Security in the device relies heavily on L3 firewalls and their configuration. Nine targets are protected through the use of firewalls. The number of protected regions varies on the target, with a maximum of eight regions. [Table 5-19](#) lists the security configuration and the number of protected regions for each target.

Table 5-19. Target Firewall and Region Configuration

| Target | Firewall | Number of Regions |
|---|----------------------------|--|
| SMS | Included in the SMS module | See the <i>Memory Subsystem</i> chapter. |
| GPMC | Yes | 8 |
| OCM-RAM | Yes | 8 |
| OCM-ROM | Yes | 2 |
| IP-Subsystem (Camera-VPFE, USBOTG, EMAC and CAN-HECC) | Yes | |
| L4-Core | Included in the L4 module | See Section 5.7 , L4 Interconnect. |
| L4-Wakeup | Included in the L4 module | See Section 5.7 , L4 Interconnect. |
| L4-Emu | Included in the L4 module | See Section 5.7 , L4 Interconnect. |
| RT | Yes | 2 |

The protection mechanism designates protection regions within the address space of certain targets. Access to these regions is granted only for certain initiators, based on transaction attributes (transmitted through MReqInfo). Each protection region is characterized with several configurable attributes (base address, size, specific access rights, and priority setting).

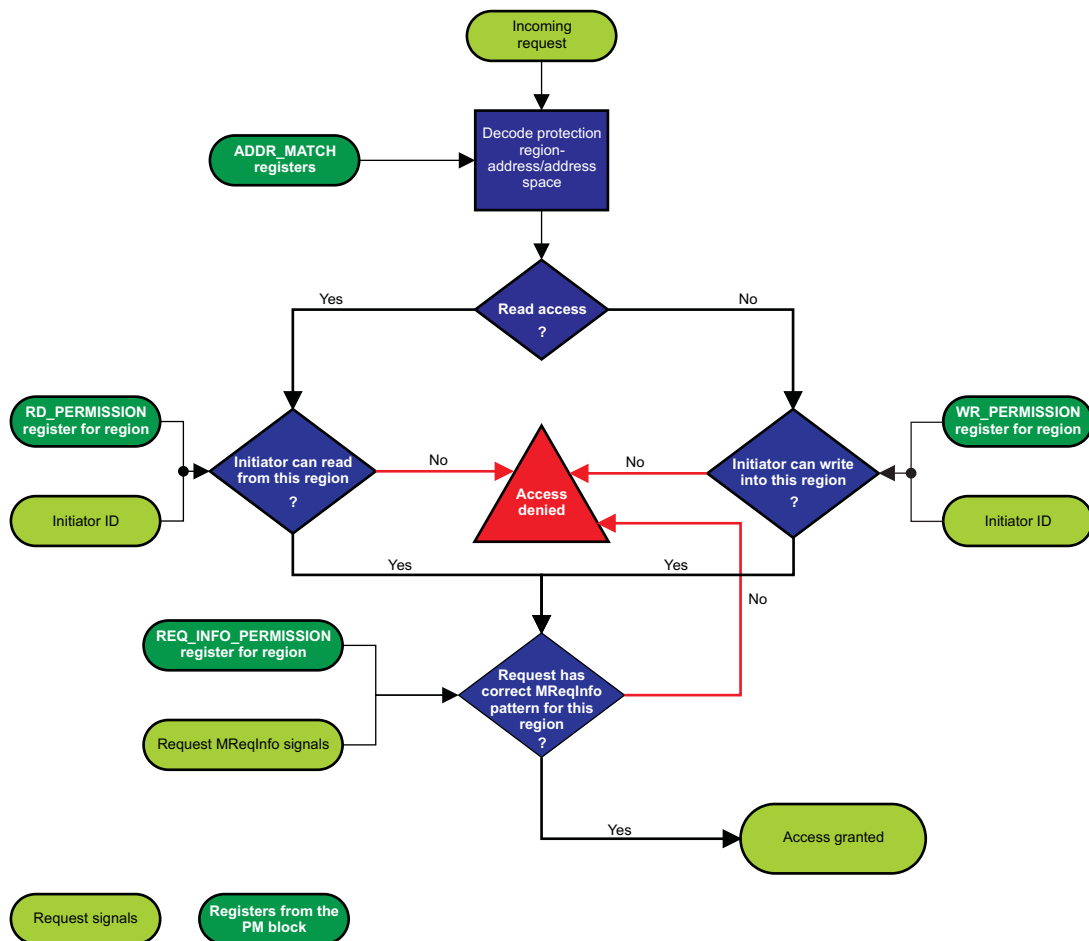

The protection mechanism uses the following attributes of a request:

- The address field and the address space field are used to determine which region has been hit. The region ID selects one table entry of the firewall look-up table.
- The region ID points to a unique set of permission registers: Read_Permission, Write_Permission, ReqInfo_Permission.
- The Initiator ID is used to determine the permission of the initiator (read/write permission) with respect to the concerned region.
- The access types (read or write) and the transaction attributes (MReqInfo in-band qualifiers) are used to grant or reject the access.

The first check determines whether the type of incoming request (read or write) is allowed, according to the Initiator MConnID and its read and write permissions. The second check determines whether the MReqInfo bits of the incoming request are within the allowed pattern established by the MReqInfo permission bits. If both check results are positive, the request is allowed to access the target. Otherwise, the access is denied, the request is not forwarded to the target, an out-of-band error indication is reported, and an in-band error response is returned to the initiator (except for writes that were posted at the IA).

Figure 5-4 shows the flow used to identify and accept a new request.

Figure 5-4. Flowchart of the Protection Mechanism

100-014

To summarize, firewalls accept or reject a request depending on the following:

- Initiator originating the request

- Command (read or write) requested
- MReqInfo bus state
- Region access in the target memory space

Software must configure the L3 firewalls properly to allow the right initiators, with the right MReqInfo access, on the well-defined size region. All the registers relative to the L3 firewalls are grouped in the protection mechanism (PM) register block.

NOTE: The PM qualifies the protection mechanism register associated with a firewall target. The targets protected by a firewall are listed in [Table 5-19](#). These PM registers do not exist if no firewall is associated with the target.

5.4.3.1 Protection Region

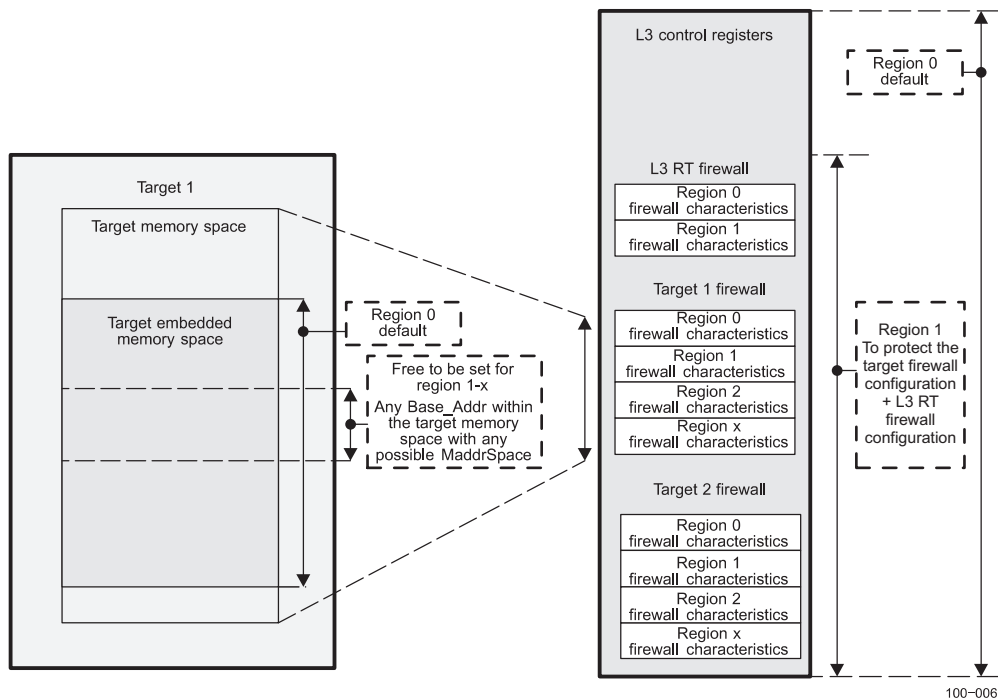

Two types of regions are distinguished in a target firewall (see [Figure 5-5](#)):

- Default region: Available in all targets; spans the entire target address range
- Normal region: Number varies in a target; they have identical capabilities

Each region has the following characteristics:

- A base address, relative to the target address itself, and an address space
- A size
- Specific access rights, as defined through the MReqInfo qualifiers
- A priority level, from 0 (lowest) to 3 (highest)

Figure 5-5. L3 Firewall Implementation

5.4.3.1.1 Default Region/Region0

Region 0 is the default region of a whole target; it spans the entire target address space.

The default region is always the lowest priority. This region is systematically overlapped when other regions are set.

The L3_PM_ADDR_MATCH_k register is not accessible. Its configuration corresponds to all the possible addresses for the target, including all of ADDR_SPACE. It is not possible to program multiple ADDR_SPACE addresses in a normal region.

5.4.3.1.2 Normal Regions

Normal regions have identical features.

A given request either maps into a specific protection region or is considered to have hit the default protection region if no normal region is hit.

The protection regions can only be configured for a memory space that is power-of-two in size and size-aligned using the SIZE bit field L3_PM_ADDR_MATCH_k [7:3] (as listed in Table 5-20). When the SIZE bit field L3_PM_ADDR_MATCH_k [7:3] is set to 0, the region is disabled.

NOTE: k denotes the region number. Depending on the target, n varies from 0 to 7.

Table 5-20 lists the size encoding for each value set in the SIZE bit field.

Table 5-20. L3 Firewall Size Parameter Definition

| Possible Configuration | | |
|------------------------|-----------------------------------|--------------------------|
| Size ⁽¹⁾ | Region Size | Base_Addr ⁽²⁾ |
| 0x0 | Region disabled | Any (nonsignificant) |
| 0x1 | 1K-byte secure | 0x0000000 |
| | | 0x0000400 |
| | | 0x0000800 |
| 0x2 | 2K-byte secure | 0x0000000 |
| | | 0x0000800 |
| | | 0x0001000 |
| ... | ... | ... |
| 0x17 | 2 ⁽¹⁷⁻¹⁾ K-byte secure | |
| Others | Not allowed | - |

⁽¹⁾ When the size parameter is set to 0, the region is disabled.

⁽²⁾ The base address depends on user settings.

5.4.3.2 Priority Level Overview

Each L3 firewall region is prioritized. Depending on its priority level, a region can override the settings of another region.

- Region 0 is the only allowed priority 0 region (lowest priority).
- Region 1 is the only allowed priority 3 region (highest priority).
- Others regions are defined as priority 1 or 2.

CAUTION

LEVEL bitfield value of ADDR_MATCH_1 register (Region 1 firewall configuration) must be kept to his default reset value and must not be changed; otherwise, the result will be unpredictable and can create unexpected security holes or denial of service.

Protection level is defined by the LEVEL bit L3_PM_ADDR_MATCH_k , where n is greater than 2. [Figure 5-6](#) represents the priority level with associated regions.

When an address hits two or more regions with different priority levels, the highest priority region protections are applied. The overlay region can overlap all or a part of a nonoverlay region.

CAUTION

Configuring two overlapping protection regions with the same priority level leads to undefined behavior.

Hardware behavior in the case of overlapping protection regions is undefined. A region with higher priority must be used to mask a region that is being reprogrammed, and any security holes must be avoided during this reconfiguration.

To change the protection settings of a region, follow this procedure:

1. Ensure that a free region is available to be used as a high-priority region.
2. Program this region as a high-priority region so its parameters match the region to be changed. The final programming must be the L3_PM_ADDR_MATCH_k register, which includes the priority attribute and the size parameter to enable the region.
3. Disable the region to be configured or reconfigure it by setting the SIZE bit field to 0.
4. Set up all region control registers with the new configuration. The final programming must be the L3_PM_ADDR_MATCH_k register, which includes the size parameter to enable the region.
5. Disable the high-priority region by setting its size to 0.

This procedure must be used each time there is an overlap between the originally defined region and the newly defined region. The use of a high-priority region is required to keep security active during programming.

Figure 5-6. L3 Region Overlay and Priority Level Overview

100-008

5.4.3.3 Read and Write Permission

Read permission and write permission are configured using two registers:

- L3_PM_READ_PERMISSION_i
- L3_PM_WRITE_PERMISSION_i

The L3_PM_READ_PERMISSION_i and L3_PM_WRITE_PERMISSION_i registers allow the setting of read and write permission to one or more initiators. To grant read or write access, set the bit associated with the initiator to 1.

5.4.3.4 REQ_INFO_PERMISSION Configuration

The firewall comparison mechanism enables access to a protected target only when a correct combination of four MReqInfo in-band parameters is transmitted.

MReqInfo is a combination of a fixed 4-bit pattern that corresponds to a combination of the parameters MReqSecure, MRreqDebug, MrReqType, and MReqSupervisor.

NOTE: In GP device MReqSecure = 1 (Secure value), is not supported.

Different valid MReqInfo combinations can be defined for each L3 firewall region based on the L3_PM_REQ_INFO_PERMISSION_i value, which is programmed by software.

For each region, L3_PM_REQ_INFO_PERMISSION_i lists the possible MReqInfo combinations. Setting a Reqbit in this register determines the type of access allowed to the initiator.

Table 5-21 lists the MReqInfo combinations available and the Reqbit associated with it.

Table 5-21. MReqInfo Parameter Combinations

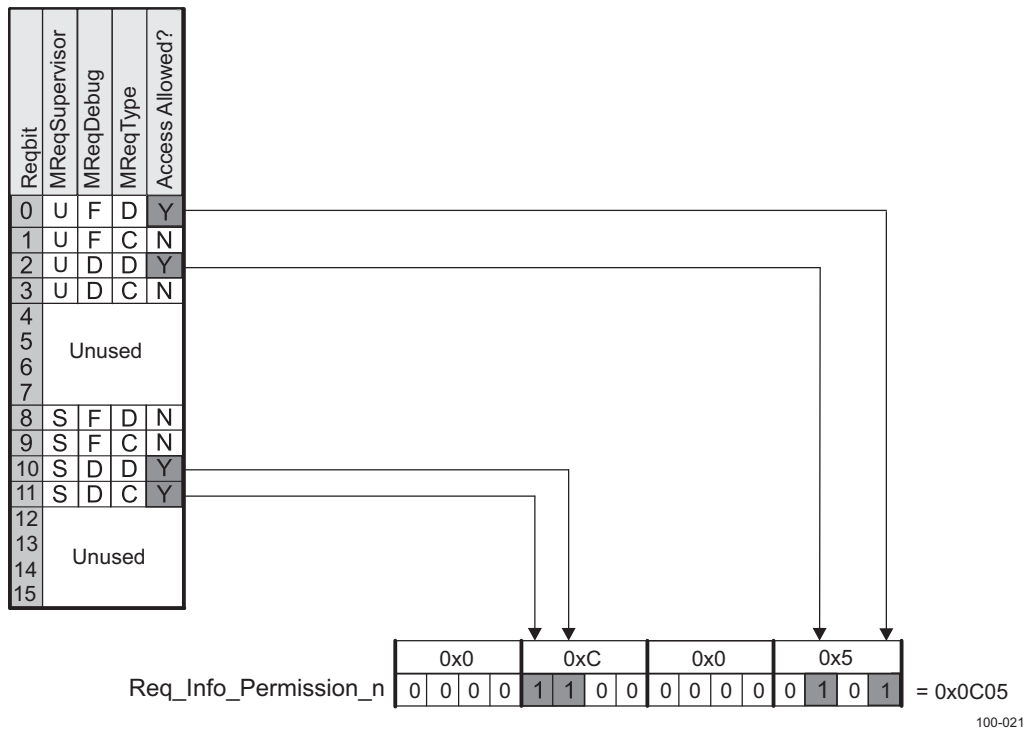

| Reqbit | MReqInfo | | | |
|--------|----------------|---------------------------|------------|----------|
| | MReqSupervisor | MReqSecure ⁽¹⁾ | MReqDebug | MReqType |
| 0 | User | Public | Functional | Data |
| 1 | User | Public | Functional | Code |
| 2 | User | Public | Debug | Data |
| 3 | User | Public | Debug | Code |
| 4 | User | Secure ⁽¹⁾ | Functional | Data |
| 5 | User | Secure ⁽¹⁾ | Functional | Code |
| 6 | User | Secure ⁽¹⁾ | Debug | Data |
| 7 | User | Secure ⁽¹⁾ | Debug | Code |
| 8 | Supervisor | Public | Functional | Data |
| 9 | Supervisor | Public | Functional | Code |
| 10 | Supervisor | Public | Debug | Data |
| 11 | Supervisor | Public | Debug | Code |
| 12 | Supervisor | Secure ⁽¹⁾ | Functional | Data |
| 13 | Supervisor | Secure ⁽¹⁾ | Functional | Code |
| 14 | Supervisor | Secure ⁽¹⁾ | Debug | Data |
| 15 | Supervisor | Secure ⁽¹⁾ | Debug | Code |

⁽¹⁾ In GP device MReqSecure = 1 (Secure value), is not supported.

Figure 5-7 shows an example of the L3_PM_REQ_INFO_PERMISSION_i setting. In this example, L3_PM_REQ_INFO_PERMISSION_i is set to 0x0C14 (16'b0000_1100_0001_0100) for a specific region, which will grant access only if the request:

- User + Public + Debug + Data
- User + Secure + Functional + Data
- Supervisor + Public + Debug + Data
- Supervisor + Public + Debug + Code

Figure 5-7. Example of REQ_INFO_PERMISSION Register

As another example, to configure a target accessible only for data and in a public mode, Reqbit 0, 2, 8, and 10 must be set. Therefore, the L3_PM_REQ_INFO_PERMISSION_i register must be set to 0x5050.

5.4.3.5 L3 Firewall Registers Overview

Table 5-22 lists the L3 firewall permission-setting registers. L3_PM_ADDR_MATCH_k, which is shown in this table, is not an accessible register.

Table 5-22. L3 Firewall Permission-Setting Registers

| Register Name | Register Field Name | Field Modifiability | Parameter Comments | Region Comments |
|-----------------------------------|------------------------|---------------------|---|---|
| Region 0 | | | | This region is the default region. The default setting can be changed only with correct access according to L3 RT register. |
| L3_PM_ADDR_MATCH_k (k=0) | ADDR_SPACE[2:0] | Hard coded | Corresponds to all the target memory space | |
| | SIZE[7:3] | Hard coded | Corresponds to all the target memory space | |
| | Reserved | | Default region: Level 0 | |
| | BASE_ADDR[63:10] | Hard coded | Target-dependent | |
| L3_PM_REQ_INFO_PERMISSION_i (i=0) | REQ_INFO[15:0] | Yes | Type of access permitted. See Table 5-21. | |
| L3_PM_READ_PERMISSION_i (i=0) | READ_PERMISSION[15:0] | Yes | Initiator read permission, depending on connections. See Table 5-14. | |
| L3_PM_WRITE_PERMISSION_i (i=0) | WRITE_PERMISSION[15:0] | Yes | Initiator write permission, depending on connections. See Table 5-14. | |

Table 5-22. L3 Firewall Permission-Setting Registers (continued)

| Register Name | Register Field Name | Field Modifiability | Parameter Comments | Region Comments |
|-----------------------------|------------------------|---------------------|---|---|
| Region 1-7 | | | | The default settings can be changed only with correct access based on the L3 RT register. |
| L3_PM_ADDR_MATCH_k | ADDR_SPACE[2:0] | Yes | | |
| | SIZE [7:3] | Yes | The regions are power-of-two in size and size-aligned with Base_Addr reference. When Size = 0x0, the firewall is deactivated. | |
| | LEVEL[9] | Yes | Protection region level 0x0: Level 1 0x1: Level 2 Region 1 is always Level 3. | |
| | BASE_ADDR[63:10] | Yes | Target-dependent | |
| L3_PM_REQ_INFO_PERMISSION_i | REQ_INFO[15:0] | Yes | Type of access permitted. See Table 5-21 . | |
| L3_PM_READ_PERMISSION_i | READ_PERMISSION[15:0] | Yes | Initiators read permission, depending on connections. See Table 5-14 . | |
| L3_PM_WRITE_PERMISSION_i | WRITE_PERMISSION[15:0] | Yes | Initiators write permission, depending on connections. See Table 5-14 . | |

5.4.3.6 L3 Firewall Error-Logging Registers

Table 5-23 lists the L3 firewall error-logging registers.

Table 5-23. L3 Firewall Error Logging Registers

| Register Name | Register Field Name | Field Modifiability | Parameter Comments |
|-----------------|---------------------|---------------------|--|
| L3_PM_ERROR_LOG | CMD[2:0] | Read only | Log the OCP command of the request that caused a protection violation. See Table 5-1 . |
| | REGION[6:4] | Read only | Log the region number targeted by the request that caused the protection violation. |
| | INITIATOR_ID[15:8] | Read only | Log the InitiatorID request that caused the protection violation. See Table 5-18 |
| | REQ_INFO[20:16] | Read only | Log the MReqInfo bits of the request that caused the protection violation. See Table 5-21 . |
| | CODE[27:24] | Read/write | Log the error that occurred. See Table 5-25 . |
| | MULT[31] | Read/write | If a second error is detected before the first is cleared, the MULT bit is set. Once set by hardware, the CODE and MULT bits can be cleared only by software or a full hardware reset. Software clears the CODE and MULT bits by writing a non-zero value to the CODE field and writing 1 to the MULT bit. |

NOTE: This error log can be cleared in public mode by a read access. For more details, see [Section 5.5.3.2, Acknowledging Errors](#).

5.4.3.7 L3 Firewall and System Control Module

When a security violation occurs, an interrupt is sent to the MPU interrupt controller (if enabled). An in-band error is sent back, and an out-band error is logged in the CONTROL.CONTROL_SEC_ERR_STATUS register. Two logging registers are used, depending on the functional mode:

- In application mode:
 - CONTROL.CONTROL_SEC_ERR_STATUS [00]: OCM-ROM security violation
 - CONTROL.CONTROL_SEC_ERR_STATUS [01]: OCM-RAM security violation
 - CONTROL.CONTROL_SEC_ERR_STATUS [02]: GPMC security violation
 - CONTROL.CONTROL_SEC_ERR_STATUS [04]: SMS security violation
 - CONTROL.CONTROL_SEC_ERR_STATUS [07]: L4-Core security violation
 - CONTROL.CONTROL_SEC_ERR_STATUS [12]: L3 RT security violation
 - CONTROL.CONTROL_SEC_ERR_STATUS [16]: L4-Per security violation
 - CONTROL.CONTROL_SEC_ERR_STATUS [17]: L4-Emu security violation
- In debug mode:
 - CONTROL.CONTROL_SEC_ERR_STATUS_DEBUG [00]: OCM-ROM security violation
 - CONTROL.CONTROL_SEC_ERR_STATUS_DEBUG [01]: OCM-RAM security violation
 - CONTROL.CONTROL_SEC_ERR_STATUS_DEBUG [02]: GPMC security violation
 - CONTROL.CONTROL_SEC_ERR_STATUS_DEBUG [03]: SMS security violation
 - CONTROL.CONTROL_SEC_ERR_STATUS_DEBUG [12]: L3 RT security violation
 - CONTROL.CONTROL_SEC_ERR_STATUS_DEBUG [16]: L4-Per security violation
 - CONTROL.CONTROL_SEC_ERR_STATUS_DEBUG [17]: L4-Emu security violation

When a violation occurs, these bits are cleared when the L3 or L4 firewall embedded error log registers are cleared.

The L3 interconnect allows the inputting of the reset value of some of its internal registers from the system control module. This feature is used to configure the L3 firewalls in a secure state at start-up when required for the different targets. For more information on these registers, see the *System Control Module* chapter.

CAUTION

The exported reset value registers in the system control module can be accessed only when the MPU is in secure mode. They cannot be accessed on general-purpose devices. Outside secure mode, a read to this register returns 0.

5.4.4 Error Handling

5.4.4.1 Error Detection and Logging

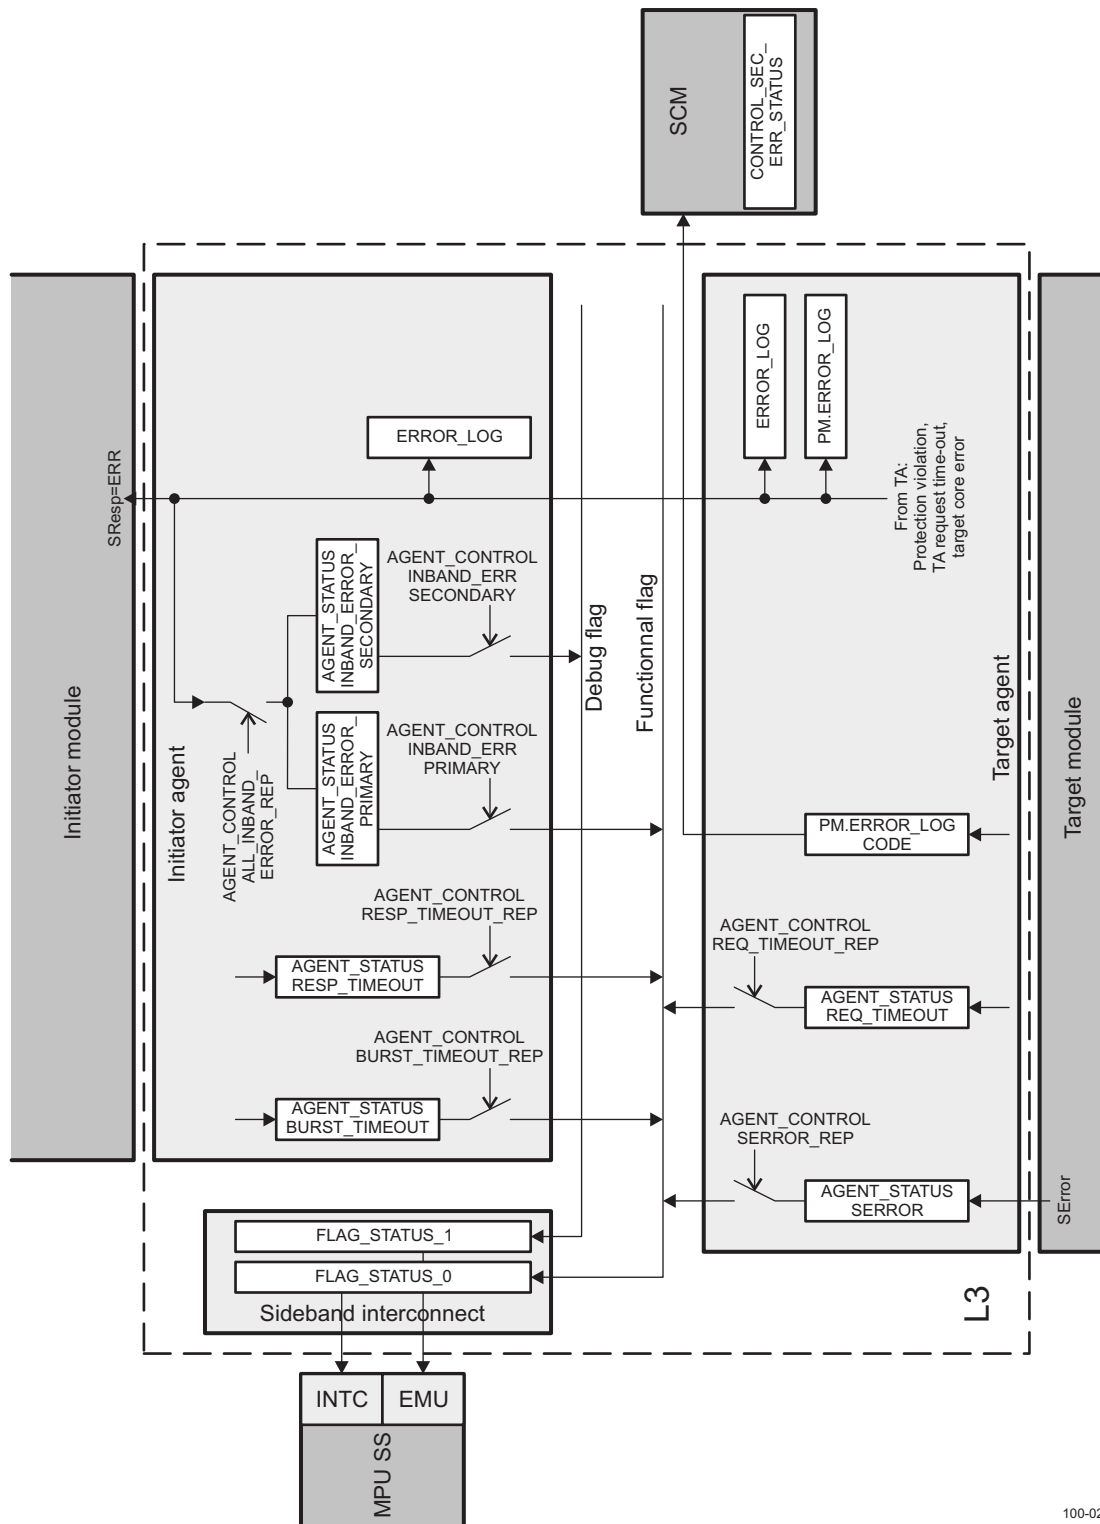

The L3 interconnect provides mechanisms for the detection, logging, and distribution of module-detected and internal interconnect errors. Hardware support is provided to assist in logging errors and cleaning up the state to allow error recovery software to run.

Two types of errors are identified by the L3 interconnect:

- Errors detected by modules and passed along by the interconnect:
 - SResp error: Using the SResp in-band qualifier from the target, the initiator is informed that its request was unsuccessful (see [Table 5-3](#)). This error is nonspecific and further analysis is required to find its cause.
 - SError: This out-of-band qualifier reports that the target is denied service due to an internal cause. No further analysis can be done in the L3 itself.
- Errors detected by the L3 interconnect:
 - Unsupported command: This error reports that the initiator sent a command that cannot be processed, because the target cannot accept it and no conversion to another command is possible. This error is detected only once per burst.
 - Address hole: This error reports an unknown address for a request. The address map is local to each IA; therefore, an address hole error is reported each time an initiator requests an access to a target it is not logically connected to, even if this address exists in the global L3 address map. This error is detected only once per burst.
 - Protection violation: This error indicates a request was rejected by a firewall.
 - Requests time-out: This error reports that the module did not end or respond to the request presented by the TA in the correct time interval. If the time interval for any request exceeds the time-out period, a time-out occurs. The target stops servicing requests.
 - Response time-out: This error reports that the module did not end the response presented by the IA in the correct time interval. If the time interval for any response exceeds the time-out period, a time-out occurs. The initiator stops servicing responses.
 - Burst open time-out: This error reports that a burst or ReadEx/Write pair is open and no command is presented to the module to end it. If the time interval for any command exceeds the time-out period, a time-out occurs. The initiator does not complete a burst or ReadEx/Write pair.

[Figure 5-8](#) shows a global view of the register link to the error reporting structure in an initiator and the target agents.

Figure 5-8. L3 Error Reporting Structure

100-023

Most errors are reported to the IA that originated the request, except for the following:

- Initiator time-outs are reported only out-of-band. Any time-out in the IA results in flagging it as unavailable. A software reset of the agent is required to accept any new requests from the attached core.

- Posted write request, because the IA immediately generates a valid response to the initiator core. This error is only in out-of-band.

Table 5-24 lists where the errors are detected and logged.

Table 5-24. Error Types

| Error | Detection | Logging | In-band Report | Out-of-band Report |
|------------------------------|-------------|-------------------------------|--------------------|--------------------|
| SResp error | None needed | At IA | Yes ⁽¹⁾ | Yes |
| SError assertion from target | None needed | At TA | No | Yes |
| Unsupported command | At IA | At IA | Yes | Yes |
| Address hole | At IA | At IA | Yes | Yes |
| Protection violation | At TA | At protection mechanism agent | Yes ⁽¹⁾ | Yes |
| Request time-out | At TA | At TA | Yes ⁽¹⁾ | Yes |
| Response time out | At IA | At IA | No | Yes |
| Burst time-out | At IA | At IA | No | Yes |

⁽¹⁾ In case of a posted write, errors cannot be reported in-band.

The time-out errors (request/response and burst) are persistent and require the software to reset both the module and the agent. No request can be processed in the agent until the reset is performed.

Other errors affect only the current request. Subsequent requests are treated normally. Errors are logged, however, and the information about the error used for debugging is kept until the software acknowledges the error.

Table 5-25 lists the information logged for each error code. Information logged in the two error-logging registers (L3_IA_ERROR_LOG, L3_IA_ERROR_LOG_ADDR, L3_TA_ERROR_LOG and L3_TA_ERROR_LOG_ADDR for each IA and TA) depends on the error itself. The CODE field ERROR_LOG[27:24] identifies the type of error occurring for the IA and TA.

Table 5-25. CODE Field Definition

| CODE[3:0] | Error Type | Type of Agent | | | Information Logged | | | | |
|-----------|-------------------------------|---------------|----|----|--------------------|-----------|-------------|-----|---------|
| | | IA | TA | PM | REQ_INFO | Secondary | InitiatorID | CMD | Address |
| 0 | No error | x | x | | | | | | |
| 1 | Unsupported command | x | | | x | x | x | x | x |
| 2 | Address hole | x | | | x | x | x | x | x |
| 3 | Protection violation | | | x | x | | x | x | |
| 4 | In-band error | x | | | | x | x | | |
| 5 | Not used | | | | | | | | |
| 6 | Not used | | | | | | | | |
| 7 | Request time-out not accepted | | x | | x | | x | x | x |
| 8 | Request time-out, no response | | x | | | | x | | |
| 9-15 | Not used | | | | | | | | |

5.4.4.2 Time-Out

This section gives information about all modules and features in the high-tier device. See the *Device Family* chapter to check availability of modules and features. To flag interconnect response being blocked, the time-out of target agents attached to unavailable modules can be enabled with the lowest setting.

A time-out mechanism can be enabled in the target agent and initiator agent register. When the mechanism is enabled for a target agent or initiator agent and commands are not accepted or responses are not returned within the expected delay, the L3 interconnect generates an error event.

The error is logged in the target agent REQ_TIMEOUT bit L3_TA_AGENT_STATUS[8] for a target agent time-out, the BURST_TIMEOUT bit L3_IA_AGENT_STATUS[16] bit for an initiator burst time-out, and the RESP_TIMEOUT bit L3_IA_AGENT_STATUS[8] for an initiator response time-out. The affected agent enters an error state that causes it to send error responses to any new request. To recover from this state, the target agent must be reset by system software.

The time-out is counted starting from the moment a command is presented to the target, whatever the target response to this command is. The L3 interconnect implements a centralized time-base circuit that broadcasts a set of four periodic pulse signals to all connected target agents. These four signals are referred to as 1x time-base, 4x time-base, 16x time-base, and 64x time-base.

The time-base circuit offers four possible sets of four time-base signals selected by programming the TIMEOUT_BASE field L3_RT_NETWORK_CONTROL[10:8]. [Table 5-26](#) lists all of the values in the number of L3 clock cycles.

Each target agent can be programmed to refer to one of the four time-base signals. A time-out condition is detected when either the command acceptance or the response is not received after a delay of between one and three time-base periods. After the time-out is detected and logged, the behavior of the attached module is ignored. A new request to the module arriving at the timed-out target agent receives an error response. If the request is addressed to the agent internal registers, it is processed normally.

To recover from a time-out error, the software is assumed to reset first the faulty module using its internal soft-reset bit, and then the agent using software reset.

Table 5-26. L3 Timeout Register Target and Agent Programming

| REQ_TIMEOUT[2:0], BURST_TIMEOUT[2:0], and RESP_TIMEOUT[2:0] | | | | | |
|---|--|------|-------|-------|--------|
| TIMEOUT_BASE[2:0] | 0 | 1 | 2 | 3 | 4 |
| 0 | All L3 time-out features are disabled. | | | | |
| 1 | Locally disabled | 64 | 256 | 1024 | 4096 |
| 2 | | 256 | 1024 | 4096 | 16384 |
| 3 | | 1024 | 4096 | 16384 | 65536 |
| 4 | | 4096 | 16384 | 65536 | 262144 |

5.4.4.3 Error Steering

The error reporting structure consist of errors logged individually in the initiator or TAs. Some errors can be enabled and reported out-of-band by setting the following bits to 1:

- L3_IA_AGENT_CONTROL.BURST_TIMEOUT_REP bit for burst time-out
- L3_IA_AGENT_CONTROL.RESP_TIMEOUT_REP bit for response time-out
- L3_TA_AGENT_CONTROL.REQ_TIMEOUT_REP bit for request time-out
- L3_TA_AGENT_CONTROL.SERROR_REP bit for request time-out

Setting the L3_IA_AGENT_CONTROL.ALL_INBAND_ERROR_REP bit causes all in-band errors returned to the IA to be reported out-of-band.

IAs connected to processors capable of generating the debug-flagged requests (the MPU subsystems) use error steering. Any error linked to an application (nondebug) request is qualified as primary; any error linked to a debug request is qualified as secondary. Setting the IA.INBAND_ERROR_PRIMARY_REP or INBAND_ERROR_SECONDARY_REP bit to 1 allows the reporting of in-band to out-of-band primary and secondary errors.

The level of the current error is indicated in SECONDARY bit L3_IA_ERROR_LOG[30]. If an error occurs while another error is pending, the following occurs:

- If the pending error is primary, the new error is discarded at the IA level. MULTI bit L3_IA_ERROR_LOG[31] is set in the initiator error log register to indicate that another error has been detected; no further information can be stored.

- If both the pending error and the new error are secondary, the latest error is discarded and MULTI bit L3_IA_ERROR_LOG[31] is set.
- If the pending error is secondary and the incoming error is primary, MULTI bit L3_IA_ERROR_LOG[31] is set and all useful information about the new error (MCmd, MAddr, MReqInfo, etc.) is stored. All information relative to the secondary error is discarded.

For protection violation, errors are detected at the TA and steered to the control module (see [Section 5.4.3.7, L3 Firewall and System Control Module](#)).

5.4.4.4 Global Error Reporting

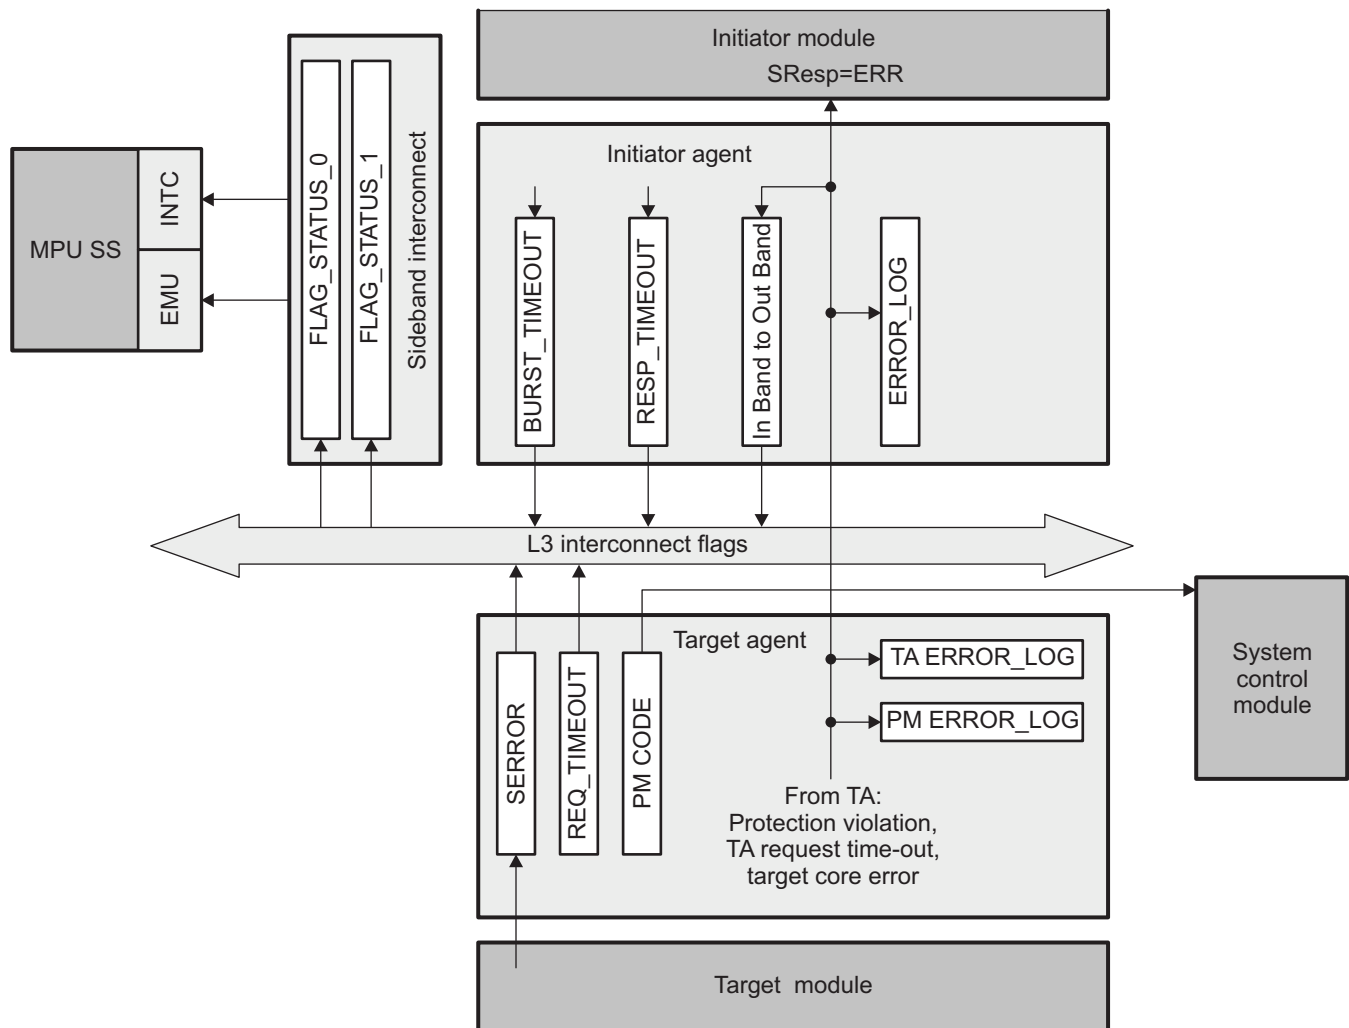

An out-of-band error refers to any flag output from the L3. It is not a formal error in the sense that it is not processed directly by the interconnect module; however, it is interpreted as such by one or several processors, typically by mapping it to an interrupt controller. All L3 out-of-band errors are ORed together and the result is transmitted to one or several interrupt controllers. All out-of-band errors are active high and must be acknowledged through a register access to be de-asserted.

Out-of-band errors are reported through error or flag signals, asynchronously to any other data flow, but synchronously to the clock.

All errors are reported out-of-band to the MPU subsystem simultaneously. The processors must check whether an error is relevant to the subsystems. These errors are routed not only to the MPU subsystem interrupt controllers, but also to their emulation logic (see [Figure 5-9](#)). Two composite flags help in asserting the error origin and criticality:

- The L3 application error flag reports application or nonattributable (not related to a request such as a time-out, SError) errors.
- The L3 debug error flag reports debug errors.

Figure 5-9. Global Error Routing

100-011

In addition to the SResp qualifier error reporting, some external targets use an SError signal to indicate that an internal error has occurred. Some resetting action may be required before any new request can be accepted, depending on the module and on the error itself. These signals are routed as flags internally to the L3. Table 5-27 lists the possible errors reported through an SError, propagated externally to the L3 interconnect, and aggregated to the L3 application error flag.

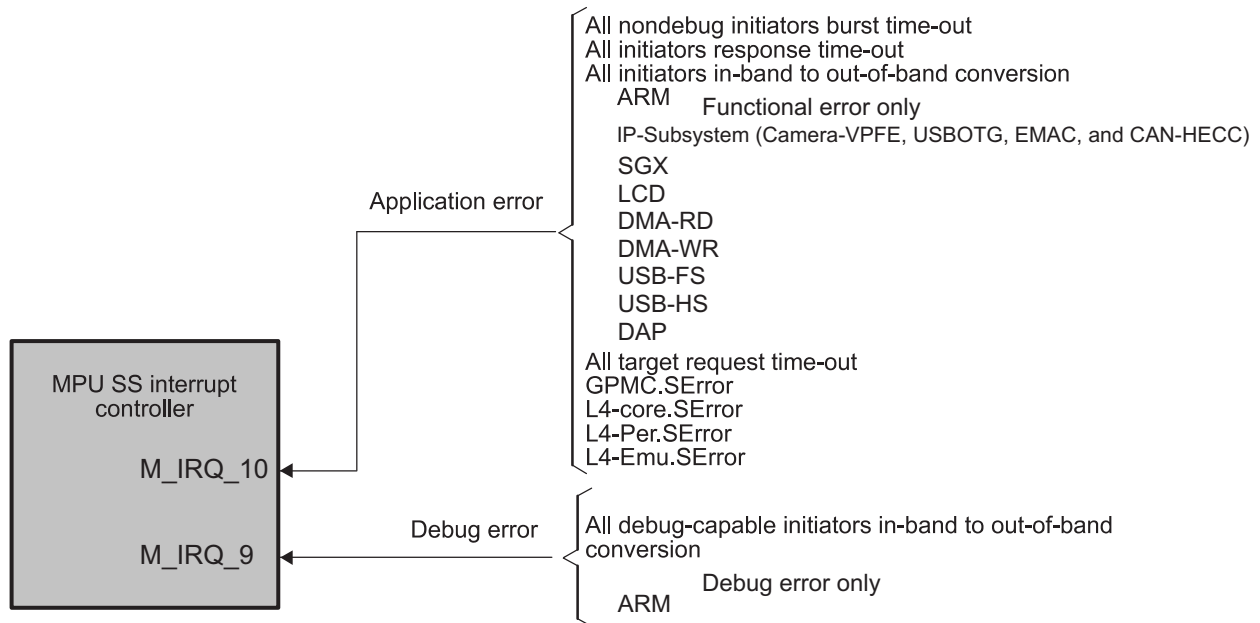

Table 5-27. L3 External Input Flags

| Target | Flag | Description | Software Visible? |
|---------|--------|---|---|
| GPMC | SError | General-purpose error occurs in GPMC module | Yes, in FLAG_STATUS register and in L3 TA SERROR bit AGENT_STATUS[24] |
| L4-Core | SError | General-purpose error occurs on L4-Core | Yes, in FLAG_STATUS register and in L3 TA SERROR bit AGENT_STATUS[24] |
| L4-Emu | SError | General-purpose error occurs on L4-Emu | Yes, in FLAG_STATUS register and in L3 TA SERROR bit AGENT_STATUS[24] |
| L4-Per | SError | General-purpose error occurs on L4-Per | Yes, in FLAG_STATUS register and in L3 TA SERROR bit AGENT_STATUS[24] |

NOTE: The user must ensure that the corresponding IRQ lines are set correctly in the interrupt controllers of the MPU subsystem.

Figure 5-10 shows the routing of errors to the application and debug error composite flags.

Figure 5-10. L3 Error Routing

100-005

Table 5-28 lists the bit and source for the STATUS bit field L3_SI_FLAG_STATUS_0[63:0] for an application error, and Table 5-29 lists the bit and source for the STATUS bit field L3_SI_FLAG_STATUS_1[63:0] for an application error for a debug error.

Protection errors are reported in-band to the IA when possible. This may not be possible for posted writes, however. These errors are also reported asynchronously to the module.

Additionally, all protection errors (even posted writes) are seen by the in-band-to-out-of-band conversion logic in the IAs. Therefore, all protection errors feed into the L3 application error and L3 debug error composite flags, and hence back to the MPU subsystem.

The SMS, L4-Core, L-4 Per, and L4-Emu interconnects have internal firewalls that use the same reporting scheme. These errors are not routed directly to the L3 interconnect but are reported in-band to the initiator, which routes them to the composite flags. The SMS, L4-Core, L4-Per, and L4-Emu interconnects always provide an error on the in-band SResp qualifier for protection violations.

Table 5-28. L3_SI_FLAG_STATUS_0 for Application Error

| Flag Bit Number | Source | | Flag Bit Number | Source | |
|-----------------|----------|-------------------------|-----------------|----------|-------------------------|

5.5 L3 Interconnect Basic Programming Model

5.5.1 General Recommendation

The L3 interconnect registers must be read or written with little-endian attributes; otherwise, the result is undefined.

CAUTION

Overlapping between protection regions with the same priority level leads to unpredictable behavior and must be avoided.

5.5.2 Initialization

At the release of power on reset, the L3 firewall default configuration enables all accesses to target modules, except for a section of the OCM ROM for which default Region 0 is configured to enable access for the MPU with the secure attribute only (this section corresponds to the secure boot ROM in the device memory mapping).

Therefore, the settings of Region 1 in the OCM ROM firewall allow access to 32K bytes of the OCM (this accessible 32K bytes corresponds to the public boot ROM in memory space mapping). For more details, see the *Memory Mapping* chapter.

Generally, software must configure the firewall properly to avoid poor use of the hardware resources.

L3 time-out capabilities are also disabled at reset.

5.5.3 Error Analysis

The information required to analyze an error source is logged in several registers (see [Table 5-25](#)). The number of registers to access depends on the error source. When investigating the origin of an error, software reads a set of error log registers. At each stage, the register either states the current error or points to the next agent in which the error is logged. [Figure 5-11](#) shows the software sequence required in most cases.

Figure 5-11. Typical Error Analysis Sequence

100-012

Errors that do not result from an in-band to out-of-band conversion can be extracted immediately from the application or debug error flag by reading the STATUS field L3_SI_FLAG_STATUS_0[63:0] and L3_SI_FLAG_STATUS_1[63:0] register; therefore, they do not require the whole analysis sequence shown in [Table 5-25](#).

When analysis leads to a TA error, software must read the initiator agent ADDR field L3_IA_ERROR_LOG_ADDR[39:0] to extract the TA address causing the error.

5.5.3.1 Time-out Handling

This section gives information about all modules and features in the high-tier device. See the *Device Family* chapter to check availability of modules and features. To flag interconnect response being blocked, the time-out of target agents attached to unavailable modules can be enabled with the lowest setting.

Example 1

In this example, the MPU interrupt handler detects an error from the L3 interconnect. A read access from the L3_SI_FLAG_STATUS_0 register reports a value of 0x40000. As described in [Table 5-28](#), the error detected is a burst time-out from the sDMA read port.

As with any time-out error, the affected module is now considered to be out-of-service. If necessary, the error can be cleared by sending a soft reset command to the agent (set CORE_RESET bit L3_IA_AGENT_CONTROL[0] to 1, and then to 0). During this time the initiator is off-line. Although the rest of the system still behaves normally, a time-out error is usually severe enough to require a complete reset of the chip.

Before resetting the agent or the system, the error log registers can learn the status of the interconnect and determine the type of failure. Reading the IA_SDMA_RD.L3_IA_AGENT_STATUS register shows whether the time-out was detected during a burst or during a read/write sequence.

5.5.3.2 Acknowledging Errors

Time-out errors can never be acknowledged. To return to a normal operation after an error, the faulty agent must be reset. An agent can be reset by asserting CORE_RESET bit L3_IA_AGENT_CONTROL[0] or L3_TA_AGENT_CONTROL[0], or by resetting the L3 interconnect through the PRCM.

Functional errors, including an in-band signal reporting a protection error, must be inactivated through software. Setting the INBAND_ERROR_PRIMARY and INBAND_ERROR_SECONDARY bits L3_IA_AGENT_STATUS[28-29] in an IA, or setting the SERROR bit L3_IA_AGENT_STATUS[24] in a TA clears the reported error. [Table 5-30](#) lists the bit to clear and the associated type of error.

The L3_IA_ERROR_LOG or L3_TA_ERROR_LOG register must also be cleared by writing a nonzero value simultaneously to the CODE bit field and the values currently stored in the MULTI and SECONDARY fields.

Table 5-30. Error Clearing

| Agent Type | Error | Register Field |
|------------|-------------------------------------|------------------------|
| Initiator | In-band primary (application) error | INBAND_ERROR_PRIMARY |
| | In-band secondary (debug) error | INBAND_ERROR_SECONDARY |
| Target | Target asserts SError | SERROR |

The procedure to clear protection errors depends on the system security configuration:

- Write a nonzero value simultaneously into CODE bit field L3_PM_ERROR_LOG[27:24] and the value currently stored in the MULTI bit L3_PM_ERROR_LOG[31] of the corresponding PM register block.
- Alternately, read either L3_PM_ERROR_CLEAR_SINGLE or L3_PM_ERROR_CLEAR_MULTI, depending on the current value of the MULTI field in the L3_PM_ERROR_LOG register. This solution, which allows the clearing of protection errors without having a write access on other protection registers, preserves security.

L3_SI_FLAG_STATUS_0 or L3_SI_FLAG_STATUS_1 must be checked at the end of any error acknowledging sequence to confirm that the acknowledgement was successful and that no other error is pending.

5.6 L3 Interconnect Registers

Table 5-31 lists the base address and address space for all L3 register blocks.

Table 5-31. Instance Summary

| Module Name | Base Address | Size |
|---|--------------|---------|
| RT | 0x6800 0000 | 1K byte |

5.6.1 L3 Initiator Agent (L3 IA) Register Mapping Summary

This section describes the IA register block. Each IA in L3 interconnect has its own IA register block.

The following are the IA registers:

- MPU subsystem port
- SGX subsystem port
- High-Speed USB Host
- IP-Subsystem (Camera-VPFE, USBOTG, and EMAC)
- System DMA read port
- System DMA write port
- Display subsystem port
- DAP port

Table 5-32 through Table 5-35 list the IA registers and their physical addresses, depending on the module instance.

Table 5-32. Initiator Agent Common Register Mapping Summary

5.6.3 L3 Target Agent (L3 TA) Register Mapping Summary

This section describes the TA register block. Each TA in L3 interconnect has its own register block.

The following are the TA registers:

- SDRAM memory scheduler (TA_SMS module)
- General-purpose memory controller (TA_GPMC module)
- On-chip memory RAM (TA_OCM_RAM module)
- On-chip memory ROM (TA_OCM_ROM module)
- IP-Subsystem (Camera-VPFE, USBOTG, EMAC and CAN-HECC)
- SGX subsystem (TA_SGX module)
- L4-Core interconnect (TA_L4_CORE module)
- L4-Per interconnect (TA_L4_PER module)
- L4-Emu interconnect (TA_L4_EMU module)

Table 5-40 through Table 5-43 lists all initiator target registers and their physical addresses depending on the module instance.

Table 5-44 through Table 5-47 describe the individual common registers in the module instance.

Table 5-40. Target Agent Common Register Mapping Summary

| Bits | Field Name | Description | Type | Reset |
|-------|--------------------|---|------|----------------|
| 63:57 | Reserved | Reserved | R | 0x00 |
| 56 | CLOCK_GATE_DISABLE | Overrides fine grained hardware clock gating | RW | 0 |
| 55:11 | Reserved | Reserved | R | 0x000000000000 |
| 10:8 | TIMEOUT_BASE | Timeout base period in register target clock cycles Program the timeout base period. Each of the agent timeout features is programmed as a multiple of the timeout base period. These timeout bases are: 0x0: Timeout disabled 0x1: L3 interconnect clock cycles divided by 64 0x2: L3 interconnect clock cycles divided by 256 0x3: L3 interconnect clock cycles divided by 1024 0x4: L3 interconnect clock cycles divided by 4096 | RW | 0x0 |
| 7:0 | Reserved | Reserved | R | 0x00 |

5.6.7 Protection Mechanism (PM) Register Mapping Summary

This section describes the protection mechanism register block.

The following are the protection mechanism registers:

- Register target (PM_RT module)
- General-purpose memory controller (PM_GPMC module)
- On-chip RAM (PM_OCM_RAM module)
- On-chip ROM (PM_OCM_ROM module)
- IP-Subsystem (PM_IPSS module)

Table 5-52 and Table 5-54 list the protection registers and their physical addresses, depending on the module instance.

Table 5-55 through Table 5-60 describe the individual common registers in the module instance.

Table 5-52. Protection Mechanism Common Register Mapping Summary

| Register Name | Type | Register Width (Bits) | PM_RT Physical Address | PM_GPMC Physical Address | Section |
|--|------|-----------------------|------------------------|--------------------------|---------------------------------|
| L3_PM_ERROR_LOG | RW | 64 | 0x6801 0020 | 0x6801 2420 | Section 5.6.8.1 |

5.6.8.8 Bit Availability and Initialization Values for L3_PM_READ_PERMISSION_i and L3_PM_WRITE_PERMISSION_i

[Table 5-63](#) shows bit available in L3_PM_READ_PERMISSION_i and L3_PM_WRITE_PERMISSION_i registers. All N/A are considered as reserved bits with a Read access.

Table 5-63. Bit Availability and Initialization Values for L3_PM_READ_PERMISSION_i and L3_PM_WRITE_PERMISSION_i⁽¹⁾

| PM | BITS | | | | | | | |
|--|-----------|------------|--------------------|------------------|-----------------------|------------|------------|--------------------|
| | 1: MPU | 3: SDMA | 4: IPSS_ OTG | 8: DISP SS | 9: USB_HS_ Host | 12: DAP | 14: SGX | 63-15: Reserved |
| PM_RT region 0 to 1 | 1 | N/A | N/A | N/A | N/A | 1 | N/A | 0x00000000000000 |
| PM_GPMC region 0 to 7 | 1 | 1 | 1 | N/A | 1 | 1 | 1 | 0x00000000000001 |
| PM_OCM_RAM region 0 to 7 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 0x00000000000001 |
| PM_OCM_ROM region 0 to 1 (ro) ⁽²⁾ | 1 | N/A | N/A | N/A | N/A | 1 | N/A | 0x00000000000000 |
| PM_IP Subsystem region 0 to 3 | 1 | 1 | N/A | N/A | N/A | 1 | N/A | 0x00000000000000 |

⁽¹⁾ Some firewall reset value are exported from the system control module. Values in this table are valid for GP device only. HS value may differ.

⁽²⁾ ROM is a read only memory; therefore, the write permission is set to 0. The value for Region 0 is exported from control module (PLATFORM_MPU_OCMROM_DT_FW_RD).

5.6.9 Sideband Interconnect (SI) Register Mapping Summary

This section describes the sideband interconnect register block.

[Table 5-66](#) lists the SI registers and their physical addresses.

[Table 5-67](#) through [Table 5-69](#) describe the individual registers in the module instance.

Table 5-66. SI Register Mapping Summary

| Register Name | Type | Register Width (Bits) | Address Offset | Physical Address | Section |
|---------------------|------|-----------------------|----------------|------------------|-----------------------------------|
| L3_SI_CONTROL | RW | 64 | 0x020 | 0x6800 0420 | Section 5.6.10.1 |

5.7 L4 Interconnects

5.7.1 Overview

To connect peripheral modules, the device uses four separate L4 interconnect structures. Although all L4 interconnects handle transfers with peripherals, the interconnects are in different power domains. The L4 interconnect is composed of the following:

- L4-Core: Includes the majority of the peripherals and the configuration interface for L3 interconnect system modules
- L4-Per: Includes peripherals that do not need to be mapped in the CORE power domain
- L4-Wakeup: Includes the peripherals attached to the WKUP power domain
- L4-Emu: Includes emulation peripherals attached to the EMU power domain

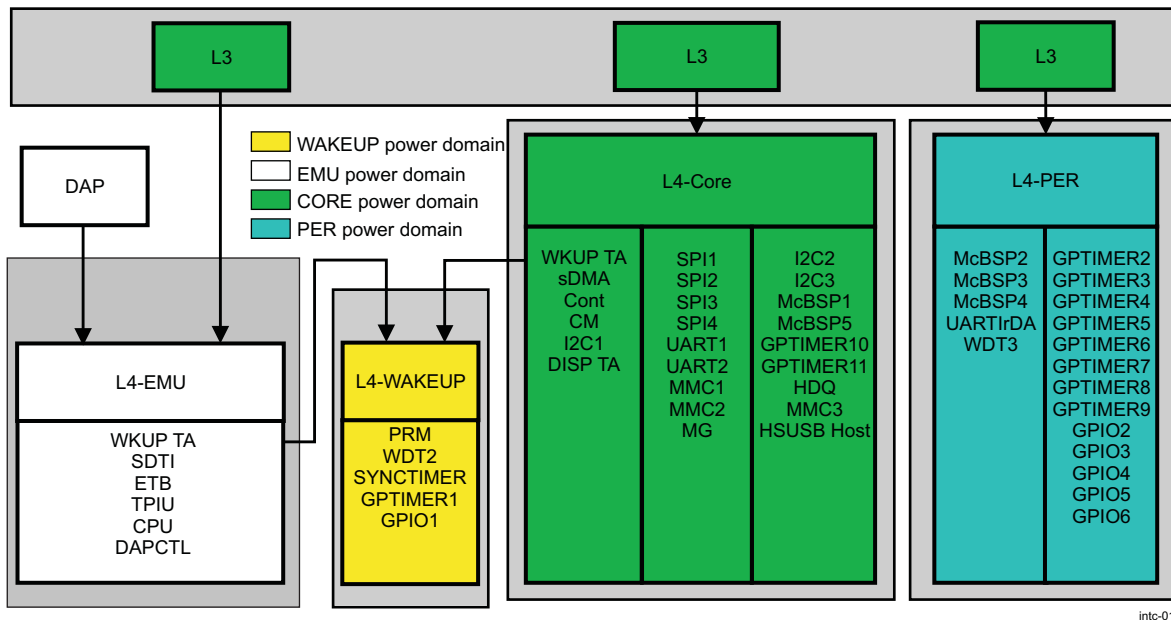

The following are the main features of the L4 interconnects:

- Single port to connect to L3 interconnect
 - L4-Core
 - L4-Per
- Dual ports for the following:
 - L4-Emu to connect to the L3 interconnect and DAP
 - L4-Wakeup to connect to the L4-Core and L4-Emu
- Single 32-bit initiator for the L3 port
- Multi target ports (one per target interface on the L4 interconnect)
- 8-, 16-, or 32-bit data, single, or burst transactions
- Little-endian
- Non-blocking with fair arbitration between threads
- Target interfaces: Fully synchronous or divided synchronous
- Peak bandwidth of 2x M bytes/sec of L4 frequency (in MHz)
- Latency: Three cycles on request, one cycle on response
- Security logic provides user-configurable access control to targets by each initiator:
 - Firewall in L4-Core protects the core and wake-up peripherals.
 - Firewall in L4-Per protects per peripherals.
 - Firewall in L4-Emu protects emulation and wake-up peripherals

NOTE: L4-Wakeup has two input ports from L4-Core and L4-Emu. Therefore, wake-up peripherals appear in two locations in the memory mapping. Normally, L4-Emu limits its access except when debugging.

Figure 5-12 shows an overview of the L4 interconnects and the peripherals attached to them.

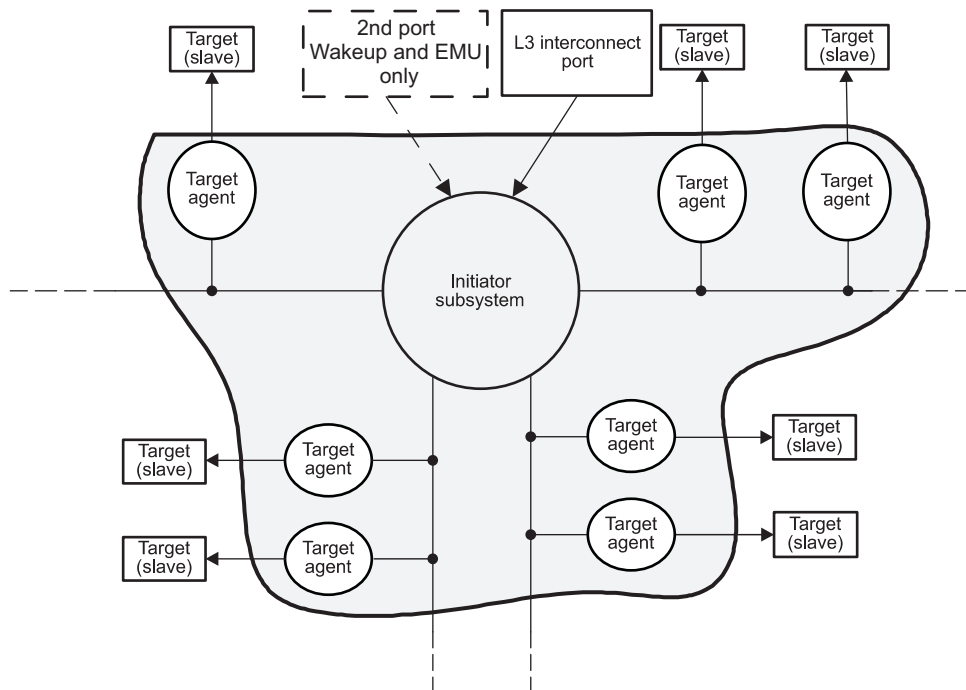

Figure 5-12. L4 Interconnect Overview

intc-019

Figure 5-13 shows an internal view of the L4 interconnects in the overall interconnect. This architecture, with only one initiator module (the initiator subsystem) distributing transactions to all target modules (peripherals), enables the firewall functions of the L4 interconnects to be centralized at the L4 initiator level. The L4 firewall filters the accesses according to the configurable protection groups defined in the L4 address protection (AP) registers. Each module or agent is assigned to a protection group. Configuration is also defined in the L4 AP and is programmable on a module-per-module basis.

Figure 5-13. L4 Initiator-Target Connectivity for L4-Core and L4-Per

100-010

NOTE: As [Figure 5-13](#) shows, targets are attached to branches. These branches have no functional effect and are present for timing closure reasons only.

5.7.1.1 L4-Core Interconnect

The L4-core interconnect handles only transfers to peripherals in the CORE power domain. [Table 5-70](#) lists the TAs.

Table 5-70. L4-Core Target Agents

| Module Name | Description |
|-------------------|--|
| Display subsystem | Display subsystem configuration port |
| USBHS Host | Universal serial bus High-Speed port Host |
| USBTLL | USB Transceiver Less Link |
| UART1 | Universal asynchronous receiver transmitter port 1 |
| UART2 | Universal asynchronous receiver transmitter port 2 |
| I2C1 | Multimaster inter-integrated circuit 1 |
| I2C2 | Multimaster inter-integrated circuit 2 |
| I2C3 | Multimaster inter-integrated circuit 3 |
| McBSP1 | Multichannel buffered serial port 1 |
| McBSP5 | Multichannel buffered serial port 5 |
| GPTIMER10 | General-purpose timer 10 |
| GPTIMER11 | General-purpose timer 11 |
| SPI1 | Serial peripheral interface 1 |
| SPI2 | Serial peripheral interface 2 |
| MMCHS1 | Multimedia memory controller SDIO 1 |
| MMCHS2 | Multimedia memory controller SDIO 2 |
| MMCHS3 | Multimedia memory controller SDIO 3 |
| HDQ/1-Wire | Single wire serial link low rate |
| MG | MagicGate |
| SPI1 | Serial peripheral interface 1 |
| SPI2 | Serial peripheral interface 2 |
| SPI3 | Serial peripheral interface 3 |
| SPI4 | Serial peripheral interface 4 |
| sDMA | System DMA controller |
| L4-Wakeup | L4-Wakeup interconnect |
| CM | Clock manager |
| SCM | System control module |

NOTE: A unique port is used for communication between the L3 interconnect and the L4-Core interconnect to allow the L3 initiators to access the L4-Core targets.

For the list of initiators authorized to access the L4-Core peripherals, see [Table 5-14](#). For details on restricted access, see [Section 5.9.3.1](#), *Protection Mechanism*.

5.7.1.2 L4-Per Interconnect

The L4-Per interconnect handles only transfers to peripherals in the PER power domain. [Table 5-71](#) lists the TAs.

Table 5-71. L4-Per Target Agents

| Module Name | Description |
|-------------|--|
| UARTIrDA | Universal asynchronous receiver/transmitter and infrared data association port |
| McBSP2 | Multichannel buffered serial port 2 |
| McBSP3 | Multichannel buffered serial port 3 |
| GPTIMER2 | General-purpose timer 2 |
| GPTIMER3 | General-purpose timer 3 |
| GPTIMER4 | General-purpose timer 4 |
| GPTIMER5 | General-purpose timer 5 |
| GPTIMER6 | General-purpose timer 6 |
| GPTIMER7 | General-purpose timer 7 |
| GPTIMER8 | General-purpose timer 8 |
| GPTIMER9 | General-purpose timer 9 |
| GPIO2 | General-purpose I/O 2 |
| GPIO3 | General-purpose I/O 3 |
| GPIO4 | General-purpose I/O 4 |
| GPIO5 | General-purpose I/O 5 |
| GPIO6 | General-purpose I/O 6 |

NOTE: A unique port is used for communication between the L3 interconnect and the L4-Core interconnect to allow the L3 initiators to access the L4-Per targets.

For the list of initiators authorized to access the L4-Per peripherals, see [Table 5-14](#). For details on restricted access, see [Section 5.9.3.1, Protection Mechanism](#).

5.7.1.3 L4-Emu Interconnect

The L4-Emu interconnect handles only transfers to peripherals in the EMU power domain. [Table 5-72](#) lists the TAs.

Table 5-72. L4-Emu Target Agents

| Module Name | Description |
|-------------|------------------------------|
| L4-Wakeup | L4-Wakeup interconnect |
| SDTI | System debug trace interface |
| ETB | Embedded trace buffer |
| TPIU | Trace port interface unit |
| DAPCTL | Debug access port |

Not all initiators can access all the targets in the L4-Emu interconnect. Additional restrictions affect the ability of these initiators to access the L4-Emu peripherals. [Table 5-73](#) lists which initiators can access the L4-Emu interconnect.

NOTE: For the list of initiators authorized to access the L4-Emu peripherals, see [Table 5-14](#). For details on restricted access, see [Section 5.9.3.1, Protection Mechanism](#).

Table 5-73. L4-Emu Initiator Agents

| Module Name | Description |
|-----------------|----------------------|
| L3 interconnect | L3 interconnect port |
| DAP | DAP port |

5.7.1.4 L4-Wakeup Interconnect

The L4-Wakeup interconnect handles only transfers to peripherals in the WKUP power domain. [Table 5-74](#) lists the TAs.

Table 5-74. L4-Wakeup Target Agents

| Module Name | Description |
|--------------------------|------------------------------|
| PRM | Power reset manager |
| GPIO1 | General-purpose I/O 1 |
| GPTIMER1 | General-purpose timer 1 |
| GPTIMER12 ⁽¹⁾ | General-purpose timer 12 |
| WDTIMER1 ⁽¹⁾ | Secure watchdog timer |
| WDTIMER2 | MPU subsystem watchdog timer |
| 32KTIMER | 32-kHz timer |

⁽¹⁾ Not available in GP device.

Initiators that can access the L4-Core or L4-Emu can access all the targets in the L4-Wakeup interconnect. [Table 5-75](#) lists the initiators that can access the L4-Wakeup interconnect. For details on restricted access, see [Section 5.9.3.1, Protection Mechanism](#).

Table 5-75. L4-Wakeup Initiator Agents

| Module Name | Description |
|----------------------|---------------------------|
| L4-Core interconnect | L4-Core interconnect port |
| L4-Emu interconnect | L4-Emu interconnect port |

5.8 L4 Interconnects Integration

5.8.1 Clocking, Reset, and Power-Management Scheme

5.8.1.1 Clocks

Four functional clocks are used in each L4 interconnect (see [Table 5-76](#)).

Table 5-76. L4 Interconnect Clocks

| Clock | Frequency | Name | Comments |
|------------------------------|----------------------|---------------|--|
| L4-Core interconnect clock | Up to Core_L3_ICLK/2 | CORE_L4_GICLK | Source, control, and gating handled by PRCM module |
| L4-Per interconnect clock | Up to Core_L3_ICLK/2 | PER_L4_GICLK | Source, control, and gating handled by PRCM module |
| L4-Emu clock | | L4_EMU | Clock for emulation |
| L4-Wakeup interconnect clock | | WKUP_L4_GICLK | Source, control, and gating handled by PRCM module |

5.8.1.2 Resets

5.8.1.2.1 Hardware Reset

L4 interconnects receive a reset signal from the PRCM module, which is the reset signal to the CORE power domain. For more details, see the *Power, Reset, and Clock Management* chapter.

[Table 5-77](#) lists the hardware reset for the L4-Core interconnect.

Table 5-77. L4 Interconnect Hardware Reset

| Interconnect | Reset Domain |
|------------------------|--------------|
| L4-Core interconnect | CORE_RST |
| L4-Per interconnect | PER_RST |
| L4-Wakeup interconnect | WKUP_RST |
| L4-Emu interconnect | EMU_RST |

5.8.1.2.2 Software Reset

The L4 interconnects have hardware reset capabilities, but do not have software reset capabilities. The hardware reset capabilities are controlled by the PRCM module and are applied to the L4 interconnects and the connected L4 TAs and L4 target modules.

5.8.1.3 Power Domain

For more details on power voltage scaling, see the *Power, Reset, and Clock Management* chapter.

[Table 5-78](#) lists the power domains for the L4-Core and L4-Wakeup interconnects.

Table 5-78. L4 Interconnect Power Domains

| Interconnect | Power Domain |
|------------------------|--------------|
| L4-Core interconnect | CORE |
| L4-Per interconnect | PER |
| L4-Emu interconnect | EMU |
| L4-Wakeup interconnect | WKUP |

5.8.1.4 Power Management

5.8.1.4.1 Module Power-Saving

The L4 interconnect automatically performs internal clock autogating to reduce power consumption. Though not recommended, it is possible to deactivate clock autogating by writing 1 to the `CLOCK_GATE_DISABLE` bit `L4_LA_NETWORK_CONTROL_H[24]` of each L4 interconnect. Clock autogating is enabled by default.

5.8.1.4.2 System Power Management and Wakeup

As part of the system-wide power-management scheme, the L4 interconnect enters an idle state at the request of the PRCM module (for more information, see the *Power, Reset, and Clock Management* chapter). The L4 interconnect is always in smart-idle mode; that is, it goes into idle state after receiving the request from the PRCM module once all the transfer requests are complete. This functionality is handled by hardware. The L4 interconnect sends an acknowledge signal back to the PRCM module when it enters idle state.

5.9 L4 Interconnects Functional Description

5.9.1 L4-Interconnects Initiator Identification

In the device interconnect, a ConnID is an initiator module identifier. The L4 interconnect uses the same ConnID as L3.

5.9.2 Endianness Management

Both L4 interconnects are little-endian only. Any initiator accessing the L4 interconnect module must consider byte ordering and perform a conversion, if necessary.

5.9.3 L4 Security and Firewalls

5.9.3.1 Protection Mechanism

The following two parameters are used to set up access permission because of the large address spaces and the number of peripherals connected to the L4 interconnects:

- Programmable groups for initiators:
 - 8 protection groups for the L4-Core interconnect
 - 8 protection groups for the L4-Per interconnect
 - 6 protection groups for the L4-Emu interconnect
- Each segment is divided into regions of 2K bytes:
 - 100 regions for the L4-Core interconnect
 - 43 regions for the L4-Per interconnect
 - 26 regions for the L4-Emu interconnect

NOTE: Regions and segments are present for the L4-Wakeup interconnect but cannot be programmed. The L4-Wakeup protection is done through the L4-Core and L4-Emu interconnects.

A protection group is a group of targets that have the same security settings. Initiator access is defined by CONNID_BIT_VECTOR field L4_AP_PROT_GROUP_k_L[15:0]. The initiators have the same access permission to all regions in this group.

A region is programmed to allow access to a unique selectable protection group by using PROT_GROUP_ID field L4_AP_REGION_l_H[22:20].

NOTE: k denotes the protection group number.

l denotes the region number.

5.9.3.2 Protection Group

A protection group defines which initiators with a given MReqInfo can access the targets agent protected by this group.

The CONNID_BIT_VECTOR field L4_AP_PROT_GROUP_MEMBERS_k[15:0] (see [Figure 5-14](#)) is a 1-bit vector that sets up initiator permission access regions. A protection group is accessible by an initiator if the bit position corresponding to its ConnID is set to one in the CONNID_BIT_VECTOR field.

The ENABLE field L4_AP_PROT_GROUP_ROLES_k[31:0] lists all possible MReqInfo combinations. Setting a Req bit in this register determines the type of access allowed to the initiator. See [Section 5.4.3.4, REQ_INFO_PERMISSION Configuration](#), for more information. MReqInfo is used in L4 the same way it is used in the L3 firewall configuration.

NOTE: Permissions are identical for read and write accesses in L4 interconnect targets.

Figure 5-14 shows an example of CONNID_BIT_VECTOR.

Figure 5-14. Example of CONNID_BIT_VECTOR

Setting bits 1 and 4 in the PROT_GROUP_ID_1 defines a group initiator able to access targets in protection group 1, and includes:

- MPU SS

Protection group 1 (PG1) can be applied to multiple protection regions without limitation. Each protection region I that is configured with PG1 enables permission access to these two initiators only.

The firewall default configuration for the L4-Core interconnect contains eight protection groups to ensure security:

- Most regions are, by default, set with protection group 7 (PG7), which is configured for all access (see [Table 5-79](#)).
- Protection group 0 (PG0) is restricted to the MPU subsystem in public.
- By default, the hardware crypto-processors (DES, SHA1-MD5, AES, FPKA, RNG, and WDTIMER1 not available in GP device) are attached to PG1 and are publicly accessible by all the initiators that can access the L4-Core.
- The LCD is attached to protection group 2 (PG2).
- The GPTIMER12 of the L4-Wakeup interconnect is attached to protection group 4 (PG4) (not available in GP device).
- By default, PG5 to PG7 are configured for all access.

NOTE: System control module and secure watchdog timer have an embedded firewall.

The L4-Per interconnect contains eight protection groups:

- By default, PG0 to PG7 are configured for all access.
- By default, most regions are set with PG7, which is configured for all access (see [Table 5-80](#)).

The L4-Emu interconnect contains six protection groups:

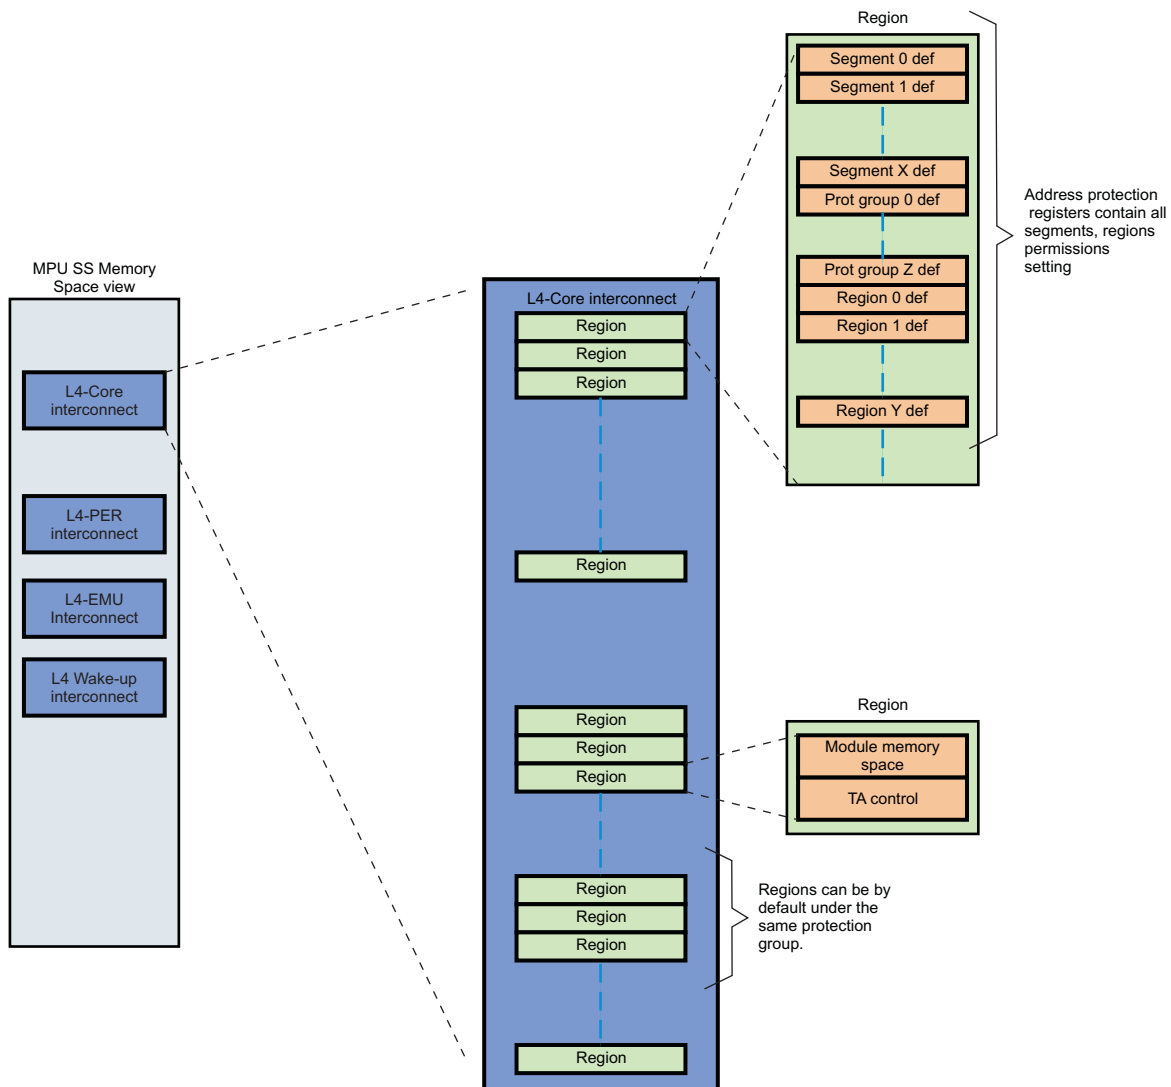

- By default, most regions are set with PG5, which is configured for all access (see [Table 5-81](#)).

- The AP is attached to PG0.
- The WDTIMER1 is attached to PG1 (not available in GP device).
- The GPTIMER12 is attached to PG2 (not available in GP device).
- The emulation organs are attached to PG3.

5.9.3.3 Segments and Regions

The protection mechanism for L4 interconnects is based on a hierarchical segmentation (see Figure 5-15). By default, some regions are attached to a specific protection group. This specificity allows the user to set up the permission access for certain types of modules that require the same access protection without managing the region allocation.

Figure 5-15. L4 Firewall Overview

100-018

All interconnect address spaces are covered by regions. Table 5-79 to Table 5-81 list the module mapping, including the address, region number, and default protection group allocated to it.

By setting ENABLE bit L4_AP_REGION_y_H[0] to 0, the region becomes inactive and therefore inaccessible. Setting the bit to 1 activates the region.

Table 5-79. Region Allocation for L4-Core Interconnect

| Device Name | Start Address (hex) | Description | Region Number | Default Protection Group |
|-----------------------|---------------------|-------------------------|---------------|--------------------------|

5.9.3.4 L4 Firewall Address and Protection Registers Setting

Table 5-82 lists the settings of the AP registers for an L4 interconnect firewall. These values are computed based on the physical implementation of each L4 interconnect.

Table 5-82. L4 Firewall Register Description Overview

| Register Type | Register Name | Bits | Field | Description |
|-------------------|------------------------------|------------------------------|---------------------|---|
| Segment | L4_AP_SEGMENT_I_L | 23:0 | Base | Segment base address |
| | L4_AP_SEGMENT_I_H | 4:0 | SIZE | Segment size equals to 2 power of SIZE |
| Protection groups | L4_AP_PROT_GROUP_MEMBERS_K_L | 15:0 | CONNID_BIT_VECTOR | See Section 5.9.1 for L4ConnID). |
| | L4_AP_PROT_GROUP_ROLES_K_L | 15:0 | ENABLE | Refer to Table 5-21 for MReq description |
| Region setting | L4_AP_REGION_I_L | 23:0 | BASE | Define the base address of region in respect to its respective segment base address |
| | L4_AP_REGION_I_H | 27:24 | SEGMENT_ID | Segment ID number of the region |
| | | 22:20 | PROT_GROUP_ID | The protection group attached to the region |
| | | 19:17 | BYTE_DATA_WIDTH_EXP | Determine the number of bytes in an access |
| | | 5:1 | SIZE | Size of the region equals to 2 power of SIZE |
| 0 | ENABLE | Enable the region protection | | |

5.9.4 Error Handling

5.9.4.1 Overview

The L4 interconnect provides mechanisms for handling either internally detected errors or errors reported by modules attached to the L4 target ports. Hardware support facilitates logging errors and cleaning up the state to allow error recovery software to treat the error.

As an L3 target, the L4 interconnect reports errors to the L3 interconnect in-band whenever possible. In-band error reporting is the default and recommended configuration. It is assumed that INBAND_ERROR_REP bit L4_IA_AGENT_CONTROL_L[27] is set to 1.

NOTE: *L4_IA* denotes which interconnect is considered: L4-Core, L4-Per, L4-Emu, or L4-Wakeup.

L4_TA denotes the module name, such as UART1, McBSP1, etc.

The L4 interconnects handle three types of errors:

- No target core found or address hole
- Request protection violation
- Failure of the target to service a request before a time-out expires

5.9.4.2 Error Logging

5.9.4.2.1 No Target Core Found/Address Hole

This error indicates that a request was addressed to a hole in the L4 address map.

When this occurs, an in-band error response is returned to the L3 level.

The error is also logged into the INBAND_ERROR bit L4_IA_AGENT_STATUS_L[27].

Additionally, an address hole error code is logged into the CODE field L4_IA_ERROR_LOG_L[25:24].

The L4_IA_ERROR_LOG register also includes MULTI bit L4_IA_ERROR_LOG_L[31], which is asserted when multiple errors are detected. In this case, the error code corresponds to the first error that occurs.

5.9.4.2.2 Protection Violation

This error indicates that an initiator has accessed a restricted region. This error is reported using an in-band error. It is written to the INBAND_ERROR field. A protection violation error code is also saved in the CODE field L4_IA_ERROR_LOG_L[25:24].

The security violation is also logged in the CONTROL_SEC_ERR_STATUS [7] register of the system control module.

NOTE: There is no specific error signal for the security violation that goes out from the L4 interconnects. The out-band error that goes to the system control module indicates a SECURITY_VIOLATION, but it also indicates normal interconnect errors.

5.9.4.2.3 Time-Out

This section gives information about all modules and features in the high-tier device. See the *Device Family* chapter to check availability of modules and features. To flag interconnect response being blocked, the time-out of target agents attached to unavailable modules can be enabled with the lowest setting.

A time-out mechanism can be enabled on a per-target basis in the L4_TA_AGENT_CONTROL_L register. If the mechanism is enabled for a TA, and commands are not accepted or responses are not returned within the expected delay, the L4 interconnect generates an error event.

The error is logged in the target agent REQ_TIMEOUT bit L4_TA_AGENT_STATUS_L[8]. The affected TA enters an error state that causes it to send error responses to any new request targeted at it. To recover from this state, the TA must be reset by system software. The time-out is counted starting from the moment a command is presented to the target, regardless of how the target responds to the command.

The L4 interconnect implements a centralized time-base circuit that broadcasts a set of four periodic pulse signals to all connected TAs. These four signals are referred to as 1X-time base, 4X-time base, 16X-time base, and 64X-time base.

The time-base circuit offers four possible sets of time-base signals. Selection is done by programming TIMEOUT_BASE field L4_LA_NETWORK_CONTROL_L[10:8]. [Table 5-83](#) lists the values in the number of L4 clock cycles.

Table 5-83. L4 Time-Out Link and TA Programming

| TIMEOUT_BASE[2:0] | REQ_TIMEOUT[2:0] | | | | |
|-------------------|--|------|-------|-------|--------|
| | 0 | 1 | 2 | 3 | 4 |
| 0 | All L4 time-out features are disabled. | | | | |
| 1 | Locally disabled | 64 | 256 | 1024 | 4096 |
| 2 | | 256 | 1024 | 4096 | 16384 |
| 3 | | 1024 | 4096 | 16384 | 65536 |
| 4 | | 4096 | 16384 | 65536 | 262144 |

The reset value is 0x4, resulting in the longest possible time-out.

The selected time-base signals are available at any TA. Each TA can be programmed to refer to one of these four time-base signals, by using REQ_TIMEOUT field L4_TA_AGENT_CONTROL_L[10:8] (see [Table 5-84](#)).

Table 5-84. L4 Time-Out TA Programming

| REQ_TIMEOUT | Target Agent Time-out Reference |
|-------------|---------------------------------|
| 0 | Time-out locally disabled |
| 1 | 1X-base cycle |

Table 5-84. L4 Time-Out TA Programming (continued)

| REQ_TIMEOUT | Target Agent Time-out Reference |
|-------------|---------------------------------|
| 2 | 4X-base cycle |
| 3 | 16X-base cycle |
| 4 | 64X-base cycle |

A time-out condition is detected when the command acceptance or the response is not received after a delay of between one and three time-base periods.

Example:

- L4 frequency = 100 MHz
- TIMEOUT_BASE = 4 in the L4_LA_NETWORK_CONTROL_L register
- REQ_TIMEOUT = 2 in the L4_TA_AGENT_CONTROL_L for target agent A
- REQ_TIMEOUT = 4 in the L4_TA_AGENT_CONTROL_L for target agent B

At agent A, the time-base unit is 16384 cycles. A time-out is issued when a request to the attached module is not accepted or no response is sent after a delay of 164 μ s to 492 μ s.

At agent B, the time-base unit is 262,144 cycles. A time-out is issued when a request to the attached module is not accepted or no response is sent after a delay of 2.6 ms to 7.8 ms.

On detection of a time-out condition, the agent automatically generates an error response to the inter_IA, which is forwarded to the L3. The agent also logs the time-out to REQ_TIMEOUT bit L4_TA_AGENT_STATUS_L[8].

After the time-out has been detected and logged, the behavior of the attached module is ignored. A new request targeting the module arriving at the timed out TA receives an error response. If the request is addressed to the agent internal registers, it is processed normally.

To recover from a time-out error, the software is assumed to reset first the faulty module by using its internal soft reset bit, and then the TA by using OCP_RESET bit L4_TA_AGENT_CONTROL_L[0].

5.9.4.3 TA Software Reset

Writing 1 to OCP_RESET bit L4_TA_AGENT_CONTROL_L[0] initiates the software reset period. The software reset must be asserted for at least 16 cycles of the target module OCP clock, which can be a divided clock with respect to the L4 clock.

During the software reset period the following occur:

- Requests sent to the target module receive error responses. Therefore, if the faulty request is part of a DMA transfer, it is necessary to stop the DMA to avoid getting unwanted errors.
- Requests sent to the TA register block are processed as usual.
- The L4_TA_AGENT_STATUS_L[8] REQ_TIMEOUT status bit is cleared.

Writing 0 to the L4_TA_AGENT_CONTROL_L[0] OCP_RESET bit terminates the software reset period.

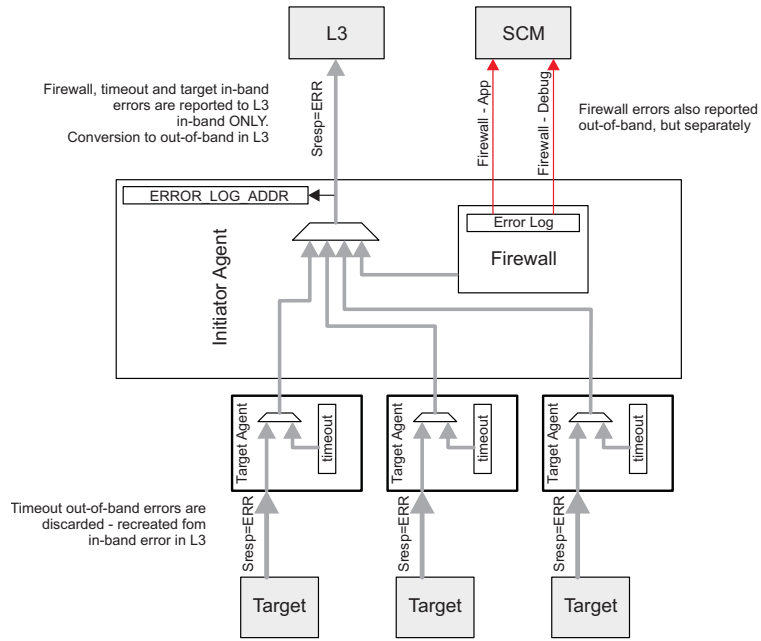

The attached module must then be reset to complete the recovery.

5.9.4.4 Error Reporting

Figure 5-16 illustrates the error-reporting scheme used in the L4_Core, L4_Per, and L4_EMU interconnects.

- Timeout error generation is enabled at each TA.
- Timeout error and target in-band errors are only reported in-band to the L3 initiator.
- Protection violations are reported out-of-band. Error steering is used to distinguish between application or debug errors.

Figure 5-16. L4 Error Reporting

5.10 L4 Interconnects Registers

A summary of the hardware interface for the L4-Core, L4-Per, L4-Emu and L4-Wkup interconnects is given in [Table 5-85](#) to [Table 5-88](#). Each module instance in the design is shown with the module register map and bit definitions for each bit field.

Table 5-85. L4- Core Instance Summary

| Module Name | Base Address | Size |

5.10.1 L4 Initiator Agent (L4 IA) Register Mapping Summary

This section provides information on the L4 IA module. Each of the registers within the module instance is described separately in [Table 5-89](#) to [Table 5-90](#).

The initiator OCP interface register block (IA) consists of the status, control, and error log registers that can be used to configure the interface of an initiator OCP. There can be only one register block for each initiator OCP interface.

Table 5-89. L4 IA Register Mapping Summary (1)

| Register Name | Type | Register Width (Bits) | CORE_IA Physical Address | PER_IA Physical Address | EMU_IA_L3 Physical Address | Section |

| Bits | Field Name | Description | Type | Reset |
|-------|------------------|---|----------|-----------|
| 31:28 | Reserved | Read returns 0. | R | 0x0 |
| 27 | INBAND_ERROR_REP | 0x0 No In-Band error present. 0x1 In-Band error present. | R 1toClr | 0x0 |
| 26:25 | Reserved | Read returns 0. | R | 0x0 |
| 24 | MERROR_REP | 0x0 No MError error present. 0x1 MError error present. | R | 0x0 |
| 23:0 | Reserved | Read returns 0. | R | 0x0000000 |

5.10.2.3 L4_IA_ERROR_LOG_L

Table 5-93. L4_IA_ERROR_LOG_L

| | |
|-------------------------|---|
| Address Offset | 0x058 |
| Physical address | Please refer from Table 5-89 to Table 5-90 |
| Description | Log information about error conditions. The CODE field logs any protection violation or address hole errors detected by the initiator subsystem while decoding a request. |
| Type | RW |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|-------|----------|----|----|----|------|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| MULTI | Reserved | | | | CODE | Reserved | | | | | | | | | | | | | | | | | | | | | | | | | |

| Bits | Field Name | Description | Type | Reset |
|-------|------------|--|------|-------|
| 31 | MULTI | While the CODE field is not zero, the MULTI bit is asserted whenever an additional error is detected. Once set by hardware, the MULTI bit can only be cleared by writing a 1 to it while writing a value other than zero to the CODE field. | RW | 0 |
| 30:26 | Reserved | Read returns 0. | R | 0x00 |
| 25:24 | CODE | The error code of an initiator request. 0x00: No errors 0x01: Reserved 0x10: Address hole 0x11: Protection violation The CODE field, once set by hardware, can only be cleared by writing a non-zero value to it, in conjunction with writing a 1 to the MULTI bit field. | RW | 0x0 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|-----------------|------|----------|
| 23:0 | Reserved | Read returns 0. | R | 0x000000 |

5.10.3 L4 Target Agent (L4 TA) Register Mapping Summary

This section provides information on the L4 Target agent (TA) register module. Each of the registers within the module instance is described separately in [Table 5-94](#) to [Table 5-122](#).

[Table 5-94](#) to [Table 5-123](#) provide information on the L4 Target Agent having two supplementary registers OCP_CONTROL and OCP_STATUS

The TA register block consists of the status and control registers that can be used to configure the interfaces of the targets.

5.10.4 L4 Target Agent (L4 TA) Register Descriptions

5.10.4.1 L4_TA_AGENT_CONTROL_L

Table 5-124. L4_TA_AGENT_CONTROL_L

| | |
|-------------------------|---|
| Address Offset | 0x020 |
| Physical address | Please refer from Table 5-94 to Table 5-123 |
| Description | Enable error reporting |
| Type | RW |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|----|----|------------|----------|----|----|----|----|----|----|----|-------------|----------|----|----|----|---|---|---|---|-----------|---|---|---|---|---|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Reserved | | | | | | | | SERROR_REP | Reserved | | | | | | | | REQ_TIMEOUT | Reserved | | | | | | | | OCP_RESET | | | | | |

| Bits | Field Name | Description | Type | Reset |
|-------|-------------|--|------|-------|
| 31:25 | Reserved | Read returns 0. | R | 0x00 |
| 24 | SERROR_REP | Enable logging of error | R | 0x0 |
| 23:11 | Reserved | Read returns 0. | | |
| 10:8 | REQ_TIMEOUT | Timeout Bound. Values are:0 - No timeout 1 - 1x base cycles 2 - 4x base cycles 3 - 16x base cycles 4 - 64x base cycles | RW | 0x2 |
| 7:1 | Reserved | Read returns 0. | R | 0x00 |
| 0 | OCP_RESET | The OCP_RESET field controls the OCP reset signal to the attached core. Setting this bit clears any pending transfers and resets the OCP interface. The bit must be cleared to de-assert the OCP reset signal. When the software reset feature is available on a target agent, the target agent OCP must also have a reset signal directed to the target core. | RW | 0 |

5.10.4.2 L4_TA_AGENT_CONTROL_H

Table 5-125. L4_TA_AGENT_CONTROL_H

| | |
|-------------------------|---|
| Address Offset | 0x024 |
| Physical address | Please refer from Table 5-94 to Table 5-123 |
| Description | Enable clock power management |
| Type | RW |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|-----------|----------|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Reserved | | | | | | | | | | | | | | | | EXT_CLOCK | Reserved | | | | | | | | | | | | | | |

| Bits | Field Name | Description | Type | Reset |
|------|------------|--|------|----------|
| 31:9 | Reserved | Read returns 0. | R | 0x000000 |
| 8 | EXT_CLOCK | When set to 1, the ext_clk_off_i signal on a target agent indicates when the target agent should shut off. | R | 0 |
| 7:0 | Reserved | Read returns 0. | R | 0x00 |

5.10.4.3 L4_TA_AGENT_STATUS_L

Table 5-126. L4_TA_AGENT_STATUS_L

| | |
|-------------------------|---|
| Address Offset | 0x028 |
| Physical address | See Table 5-94 to Table 5-123 |

| Reserved | | | | | | | | Reserved | | | | | | | | | | | | | | | | REQ_TIMEOUT | Reserved | | | | | | | |

| Bits | Field Name | Description | Type | Reset |
|-------|-------------|--|----------|--------|
| 31:24 | Reserved | Read returns 0. | R | 0x00 |
| 23:9 | Reserved | Read returns 0. | R | 0x0001 |
| 8 | REQ_TIMEOUT | 0x0: No request timeout 0x1: A request timeout has occurred | R 1toCLR | 0 |
| 7:0 | Reserved | Read returns 0. | R | 0x00 |

5.10.5 L4 Link Register Agent (LA) Register Mapping Summary

This section provides information on the L4-Core link agent (LA) register module. Each of the registers within the module instance is described separately in [Table 5-127](#).

The LA register block contains the initiator subsystem information register and the composite sideband signal mask and status registers.

Table 5-127. L4 LA Register Mapping Summary

| Register Name | Type | Register Width (Bits) | CORE_LA Physical Address | PER_LA Physical Address | EMU_LA Physical Address | WKUP_LA Physical Address | |

| Reserved | | | | PROT_GROUPS | | | | NUMBER_REGIONS | | | | | | | | Reserved | | | | | | | | SEGMENTS | | | | | | | |

| Bits | Field Name | Description | Type | Reset |
|-------|----------------|---|------|---------------------------------|
| 31:28 | Reserved | Read returns 0. | R | 0x0 |
| 27:24 | PROT_GROUPS | The number of protection groups. The PROT_GROUPS field contains read-only configuration information for the address mapping and security structure of the initiator subsystem. If the PROT_GROUPS field is set to 0, there are no protection group registers. | R | see Table 5-130 |
| 23:16 | NUMBER_REGIONS | The number of regions. The NUMBER_REGIONS field contains read-only configuration information for the region register of the initiator subsystem. | R | see Table 5-130 |
| 15:4 | Reserved | Read returns 0. | R | 0x000 |
| 3:0 | SEGMENTS | The number of segments. The SEGMENT fields contains read-only configuration information for the segment register of the initiator subsystem. | R | see Table 5-130 |

Table 5-130. Reset value for L4_LA_INITIATOR_INFO_L

| Field Name | CORE_LA | PER_LA | EMU_LA | WKUP_LA |
|----------------|---------|--------|--------|---------|
| PROT_GROUPS | 0x8 | 0x8 | 0x8 | 0x8 |
| NUMBER_REGIONS | 0x64 | 0x2B | 0x1A | 0x13 |
| SEGMENTS | 0x6 | 0x5 | 0x3 | 0x2 |

| Bits | Field Name | Description | Type | Reset |
|-------|---------------------|---|------|---------------------------------|
| 31:19 | Reserved | Read returns 0. | R | 0x0000 |
| 18:16 | THREADS | The THREADS field specifies the number of initiator threads connected to the interconnect. The field contains read-only configuration information for the initiator subsystem. | R | see Table 5-132 |
| 15 | Reserved | Read returns 0. | R | 0 |
| 14:12 | CONNID_WIDTH | The initiator subsystem connID width. The CONNID_WIDTH field contains read-only configuration information for the initiator subsystem. | R | see Table 5-132 |
| 11 | Reserved | Read returns 0. | R | 0 |
| 10:8 | BYTE_DATA_WIDTH_EXP | This field specifies the initiator subsystem data width. 1:2^1 bytes specifies a 16-bit data width and 2:2^2 bytes specifies a 32-bit data width. The BYTE_DATA_WIDTH_EXP field contains read-only configuration information for the initiator subsystem. | R | see Table 5-132 |
| 7:5 | Reserved | Read returns 0. | R | 0x0 |
| 4:0 | ADDR_WIDTH | This field specifies the initiator subsystem address width. The ADDR_WIDTH field contains read-only configuration information for the initiator subsystem. | R | see Table 5-132 |

Table 5-132. Reset value for L4_LA_INITIATOR_INFO_H

| Bits | Field Name | Description | Type | Reset |
|-------|--------------|--|------|----------|
| 31:11 | Reserved | Read returns 0. | R | 0x000000 |
| 10:8 | TIMEOUT_BASE | The TIMEOUT_BASE field indicates the timeout period (that is, base cycles) for the highest frequency time-base signal sent from the L4 initiator subsystem to all target agents that have timeout enabled. Values for the field are: 0 - Timeout disabled 1 - L4 interconnect clock cycles divided by 64 2 - L4 interconnect clock cycles divided by 256 3 - L4 interconnect clock cycles divided by 1024 4 - L4 interconnect clock cycles divided by 4096 | RW | 0x4 |
| 7:0 | Reserved | Read returns 0. | R | 0x00 |

5.10.6.5 L4_LA_NETWORK_CONTROL_H

Table 5-134. L4_LA_NETWORK_CONTROL_H

| | |
|-------------------------|---|
| Address Offset | 0x024 |
| Physical address | Please refer to Table 5-127 |
| Description | Control interconnect global power control |
| Type | RW |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|----|--------------------|----------|----|-------------|----------|----|----|----|----|----|----|-----------|----------|----|----|---|---|---|---|---|---|---|---|---|---|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Reserved | | | | | | | CLOCK_GATE_DISABLE | Reserved | | THREAD0_PRI | Reserved | | | | | | | EXT_CLOCK | Reserved | | | | | | | | | | | | |

| Bits | Field Name | Description | Type | Reset |
|-------|--------------------|--|------|-------|
| 31:25 | Reserved | Read returns 0. | R | 0x00 |
| 24 | CLOCK_GATE_DISABLE | When set to 1 this field disables all clock gating. | RW | 0 |
| 23:21 | Reserved | Read returns 0. | R | 0x0 |
| 20 | THREAD0_PRI | Sets thread priority. If the field is set to 0, the default, all initiator threads are treated the same. Setting the THREAD0_PRI field to 1 assigns a higher arbitration priority to thread 0 of the first initiator OCP interface. To avoid starvation, arbitration is imposed by the initiator subsystem. When multiple requests from different initiator threads are dispatched to targets simultaneously, the oldest request is dispatched first. If thread 0 is assigned a higher priority, a request on thread 0 always wins arbitration. Assigning thread 0 of the first initiator OCP the highest priority on a request or response can result in the starvation of other threads. | R | 1 |
| 19:9 | Reserved | Read returns 0. | R | 0x000 |
| 8 | EXT_CLOCK | When set to 1, the ext_clk_off_i signal on the initiator subsystem instructs the entire L4 to shut off. | R | 1 |
| 7:0 | Reserved | Read returns 0. | R | 0x00 |

5.10.7 L4 Address Protection (AP) Register Mapping Summary

This section provides information on the L4-Core link agent (LA) register module. Each of the registers within the module instance is described separately in [Table 5-135](#).

The AP register block contains the segment, address region, and protection group registers that can be used to specify the addressing scheme or restrict the access of target address regions.

Table 5-135. L4 AP Register Mapping Summary

| Register Name | Type | Register Width (Bits) | CORE_AP Physical Address | PER_AP Physical Address | Section |
|---|------|-----------------------|--------------------------|-------------------------|----------------------------------|
| L4_AP_SEGMENT_i_L ⁽¹⁾ | RW | 32 | 0x4804 0100 + (0x08*i) | 0x4900 0100 + (0x08*i) | Section 5.10.8.1 |
| L4_AP_SEGMENT_i_H ⁽¹⁾ | RW | 32 | 0x4804 0104 + (0x08*i) | 0x4900 0104 + (0x08*i) | Section 5.10.8.2 |

| Bits | Field Name | Description | Type | Reset |
|-------|---------------------|--|------|--|
| 31:28 | Reserved | Read returns 0 | R | 0x0 |
| 27:24 | SEGMENT_ID | Identifies the segment to which the region is part of. | R | See Table 5-137 to Table 5-140 |
| 23 | Reserved | Read returns 0. | R | 0 |
| 22:20 | PROT_GROUP_ID | The protection group containing this region. | RW | See Table 5-137 to Table 5-140 |
| 19:17 | BYTE_DATA_WIDTH_EXP | The target OCP data byte width is 2 ^(BYTE_DATA_WIDTH_EXP) bytes. The value of this field is derived from the target OCP data_width parameter. | R | See Table 5-137 to Table 5-140 |
| 16:6 | Reserved | Read returns 0. | R | 0x0 |
| 5:1 | SIZE | Define the size of the region in bytes. 2 ^{SIZE} equals the region. | R | See Table 5-137 to Table 5-140 |
| 0 | ENABLE | 0x0: Disable the region, no access allows 0x1: Enable the region, with access as define in registers | R | See Table 5-137 to Table 5-140 |

System Control Module

This document describes the system control module.

NOTE: This chapter gives information about all modules and features. See Chapter 1, to check availability of modules and features on your specific device.

| Topic | Page |
|--|------|
| 6.1 System Control Module Overview | 614 |
| 6.2 System Control Module Environment | 615 |
| 6.3 System Control Module Integration | 617 |
| 6.4 System Control Module Functional Description | 620 |
| 6.5 System Control Module Programming Model | 684 |
| 6.6 System Control Module Registers | 689 |
| 6.7 Revision History | 794 |

6.1 System Control Module Overview

The system control module (SCM) allows software control of the various static modes supported by the device. The SCM is on the L4-Core interconnect, but it is sensitive only to the device internal power-on reset. It is not affected by the L4-Core reset.

For emulator devices, the power-on reset can also be controlled by the debugger through the JTAG interface.

The device uses the SCM as the primary point of control for these areas:

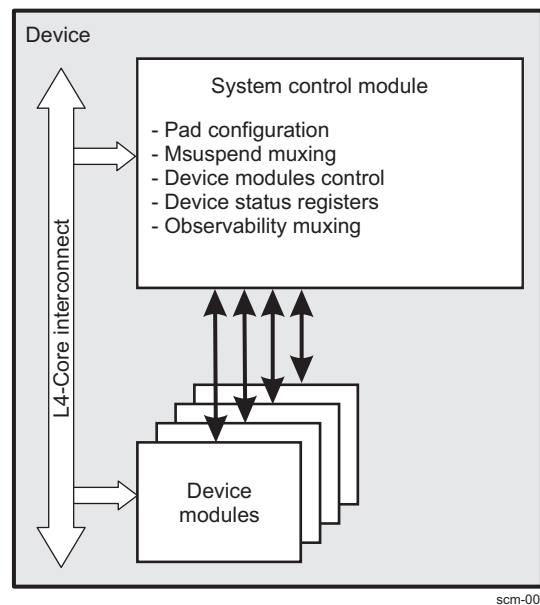

- Functional I/O multiplexing
- Pad configuration (pull-up or pull-down enable)
- Emulation controls
- Device status
- Peripheral sensitivity to the MPU MSuspend signals
- Static device configuration
- Debug and observability I/O multiplexing

NOTE: Some features may not be available or supported in your particular device. For more information, see Chapter 1, the *Device Family* section, and your device-specific data manual.

NOTE: Power domains are not supported but the IP/Modules are still part of the logical design partition in the processor's domain partition architecture.

Figure 6-1 provides an overview of the SCM.

Figure 6-1. System Control Module Overview

The SCM primarily implements a bank of registers accessible by the software. Some are read-only registers that carry status information, and others are fully accessible (read/write).

The read/write registers are divided into the following classes:

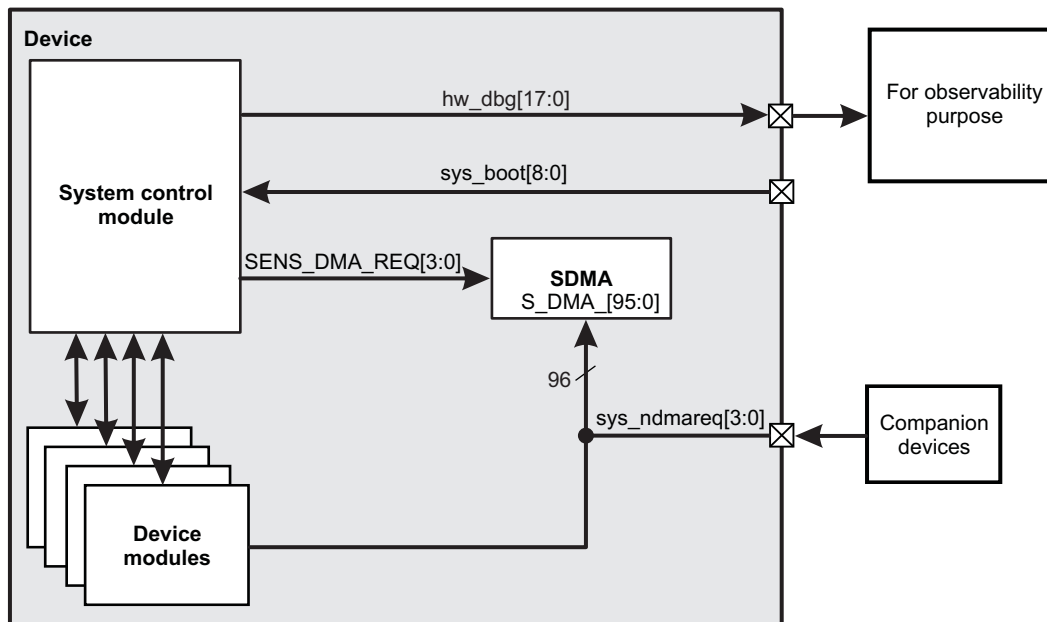

- Pad functional multiplexing and configuration registers (32-bit registers, one register per two pins)
- Debug and observability I/O multiplexing register (32-bit read/write register)
- Static device configuration registers (32-bit read/write registers for module specific configuration)
- Scratchpad memory bank (256* 32-bit)

6.2 System Control Module Environment

The SCM allows the setting of external system DMA (sDMA) request pin sensitivity and controls the multiplexing of device internal modules signals routed to external pins for hardware debug purposes. The SCM also integrates the decoding logic of sys_boot[8:0].

Figure 6-2 shows an overview of the SCM environment.

Figure 6-2. System Control Module Environment Overview

108-002

The seven sys_ndamreq[3:0] pins are optional external direct memory access (DMA) requests that can be managed directly by the sDMA controller. The SCM can configure these requests to either level sensitive (active low) or edge sensitive (falling edge) through the correct setting of the SENSNDMAREQN bit (where N is between 0 and 3) in the CONTROL.CONTROL_DEVCONF0 and CONTROL.CONTROL_DEVCONF1 registers.

The sys_boot[5:0] pins are read-accessible in a status register (SYSBOOT field CONTROL.CONTROL_STATUS[5:0]) following a power-on reset. The SCM does not use sys_boot[6]. Sys_boot[8:7] are read accessible in CONTROL_DEVCONF2[18:19].

With the correct pad configuration, the SCM maps the hw_dbg[17:0] pins at the device boundary to observe hardware debug signals from device modules. The internal observable signals are PRCM signals, DMA requests, and interrupts.

6.2.1 Functional Interfaces

6.2.1.1 Basic System Control Module Pins

Figure 6-3 shows the SCM functional interface configured to observe device module debug signals.

Figure 6-3. System Control Module Interface Signals

6.2.1.2 System Control Module Interface Description

Table 6-1 lists the SCM input and output configured to observe device module debug signals.

Table 6-1. SCM I/O Description

| Signal Name | I/O ⁽¹⁾ | Description | Reset Value |
|---------------|--------------------|-------------------------------------|-------------|
| hw_dbg[17:0] | O | Debug signals 0 to 17 | N/A |
| sys_boot[8:0] | I | Boot configuration mode bits 0 to 8 | Unknown |

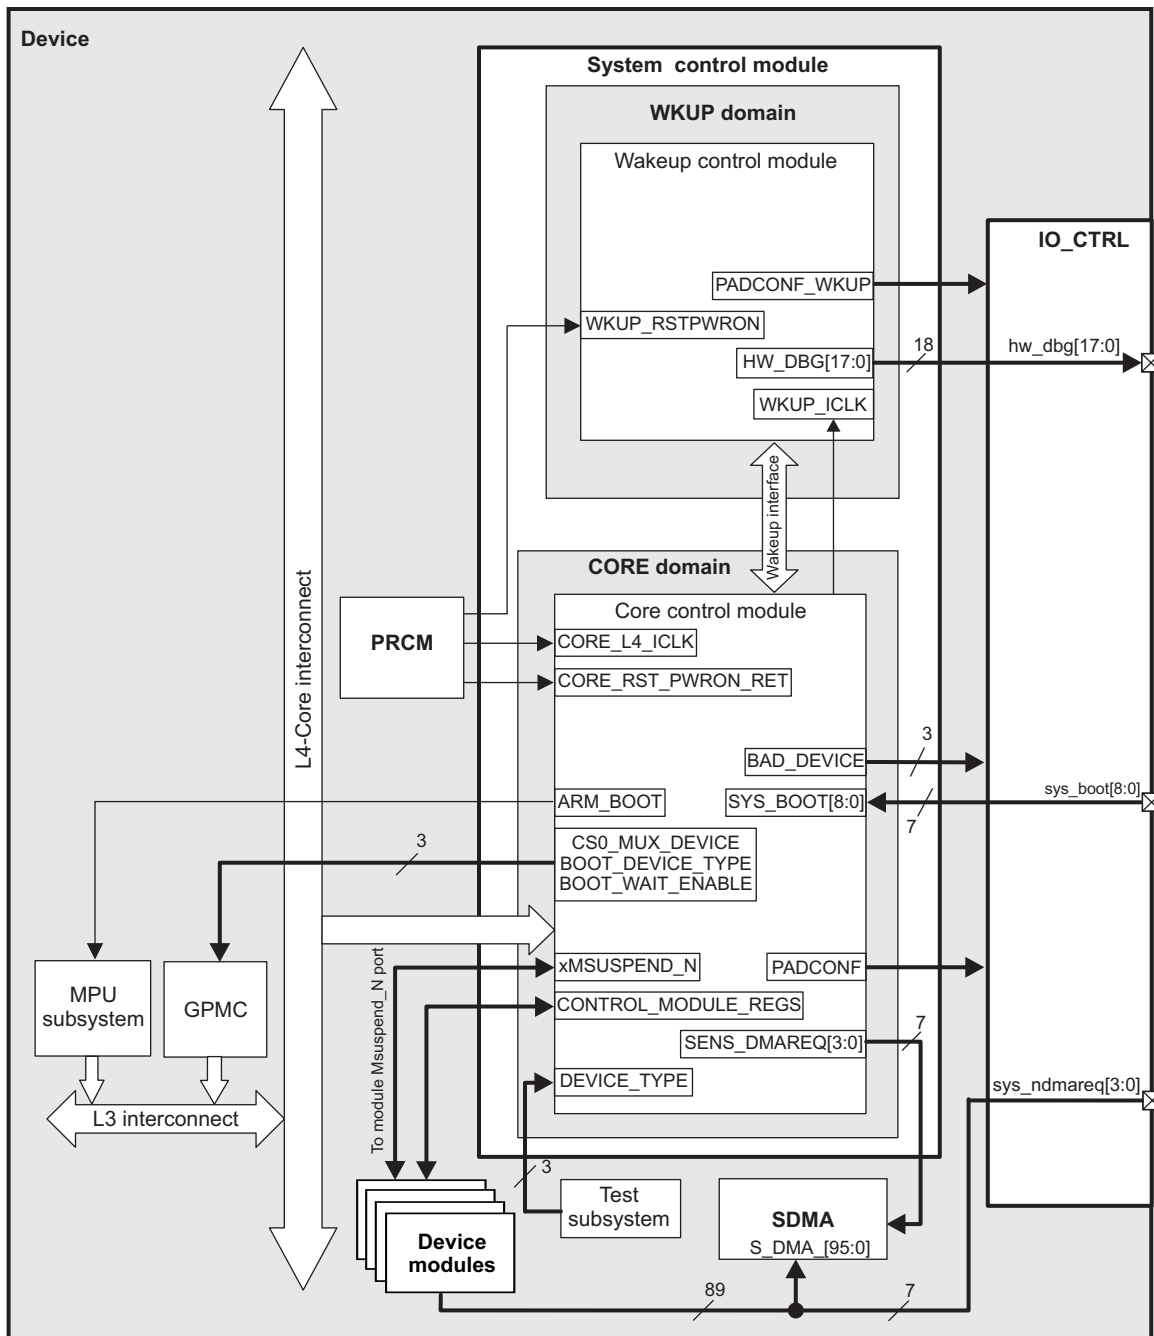

⁽¹⁾ I = Input, O = Output

6.3 System Control Module Integration

This section describes the integration of the SCM within the device.

Figure 6-4 shows the SCM integration in the device.

Figure 6-4. System Control Module Integration

108-004

The SCM is split into two blocks: the core control module in the CORE domain, and the wake-up control module in the WKUP domain. The wake-up control module contains some observability multiplexing, pad configurations, and security registers. For further information on the wake-up control module, see [Section 6.4.3, Wake-up Control Module](#).

The software sets the configuration registers to the desired values depending on the configuration of the requested device. Static device configuration registers can be set by the software at any time and are effective immediately.

The SCM is connected on the L4-Core interconnect. The power, reset, and clock management (PRCM) module provides the module interface clock (CORE_L4_ICLK) and the power-on reset signal. The PRCM generates one global reset per domain (CORE_RST_PWRON_RET for the CORE domain and WKUP_RSTPWRON for the WKUP domain). The SCM does not respond to a warm reset or to an L4 reset.

6.3.1 Clocking, Reset, and Power-Management Scheme

6.3.1.1 Clock

The main sequential logic within the SCM is accessible in a register file through the L4-Core. The only clock provided to the SCM is the interface clock, CORE_L4_ICLK. This clock comes from the PRCM module and is controlled by the EN_SCMCTRL bit PRCM.CM_ICLKEN1_CORE[6] (0 = disables the clock, 1 = enables the clock) and the AUTO_SCMCTRL bit PRCM.CM_AUTOIDLE1_CORE[6] (enables/disables automatic control of the interface clock).

The wake-up control module is configured through the L4-Core interface of the core control module and is accessed from the core control module through a dedicated interface. This interface uses the L4-Core interface clock (CORE_L4_ICLK) divided by 4 or 2 according to the WKUPCTRLCLOCKDIV bit CONTROL.CONTROL_PADCONF_OFF[2]. Only this wake-up interface clock (WKUP_ICLK) is propagated to the wake-up control module.

For further information, see the *Power, Reset, and Clock Management* chapter.

6.3.1.2 Resets

The SCM responds only to the internal power-on reset and to the device type (secure, emulator, general-purpose, test, or bad). The SOFTRESET bit CONTROL.CONTROL_SYSCONFIG[1] has no effect; the SCM is not affected by a warm reset.

The internal power-on reset is not a direct image of the power-on reset input pin (SYS_NRESPWRON). The PRCM module generates an internal power-on reset signal per domain and activates the internal power-on reset when the eFuse-related settings (such as the device type) are initialized. The core control module of the CORE domain responds to the CORE power-on reset (CORE_RST_PWRON_RET). The wake-up control module of the WKUP domain responds to the power-on reset (WKUP_RSTPWRON).

NOTE: References in the TRM to the power-on reset refer to the internal power-on reset as seen by the SCM.

On emulator devices, the debugger can also control the internal power-on reset signal through the JTAG interface.

For further information, see the *Power, Reset, and Clock Management* chapter.

6.3.1.3 Power Management

6.3.1.3.1 System Power Management

The PRCM module can require the SCM to be idled to save power. The SCM enters idle mode through the IDLEMODE field CONTROL.CONTROL_SYSCONFIG[4:3].

The PRCM module requests idle mode, and the SCM always accepts an idle command. Idle mode can be configured to either force-idle or smart-idle mode.

When the SCM is in force-idle mode (IDLEMODE bits CONTROL.CONTROL_SYSCONFIG[4:3] = 0b00) and it receives an idle request from the PRCM module (PRCM.CM_ICLKEN1_CORE[6] set to 0 or PRCM.CM_AUTOIDLE1_CORE[6] set to 1 and the L4-Core interface clock idle transitions), the SCM waits unconditionally for active system clock gating by the PRCM module. Active system clock gating occurs only when all peripherals supplied by the same L4-Core interface clock domain are also ready for idle.

In smart-idle mode (IDLEMODE bits CONTROL.CONTROL_SYSCONFIG[4:3] = 0b10), an idle command is accepted only when the save mechanism completes.

In idle mode (when the PRCM module has gated the interface clock), the SCM is not active and the interface clock paths are gated.

NOTE: The ST_SCMCTRL bit PRCM.CM_IDLEST1_CORE[6] (0b0 = active, 0b1 = idle) can check the SCM idle state.

The SCM idle mode is a function of the EN_SCMCTRL bit PRCM.CM_ICLKEN1_CORE[6] configuration and can be controlled automatically with hardware, depending on the AUTO_SCMCTRL bit PRCM.CM_AUTOIDLE1_CORE[6] configuration.

6.3.1.3.2 Module Power Saving

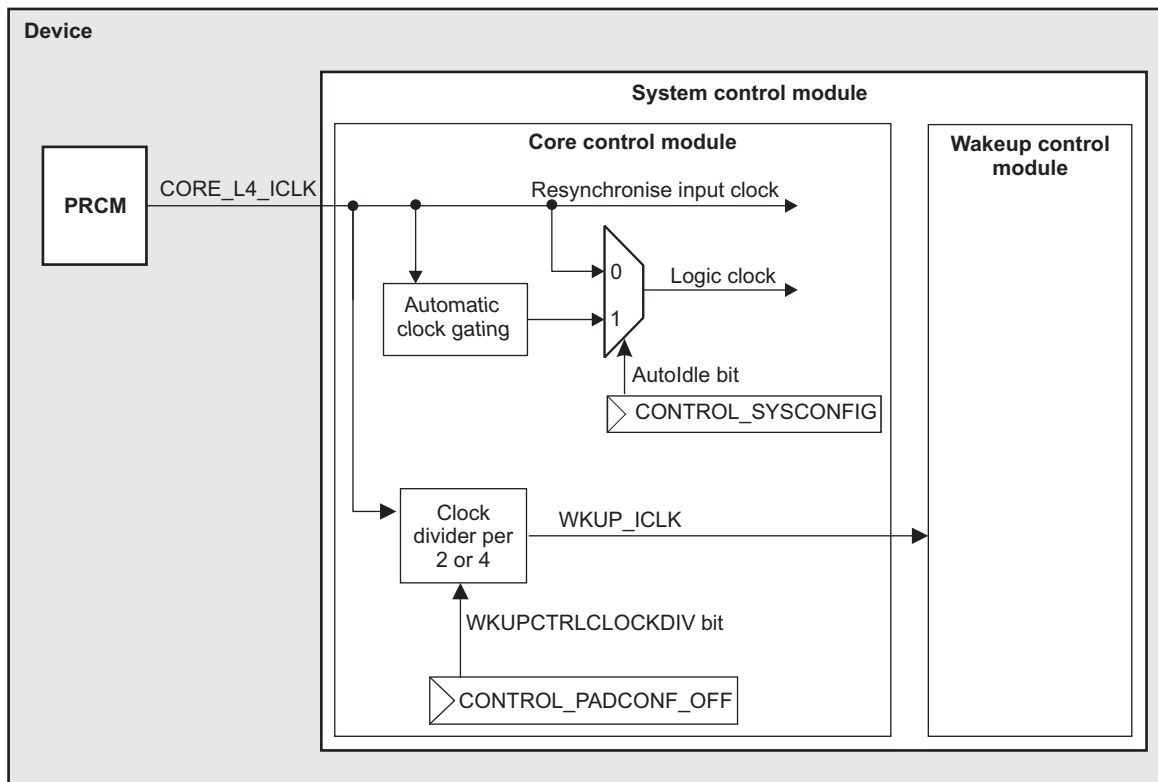

An internal interface clock-gating feature provides SCM local power management. The clock for the logic within the module can be gated when there is no access to the module according to the AUTOIDLE bit CONTROL.CONTROL_SYSCONFIG[0]. Otherwise, this logic is free-running on the interface clock CORE_L4_ICLK.

The L4-Core interface clock (CORE_L4_ICLK) is also used to synchronize and resample module inputs. The clock for those functions must always be free-running. Therefore, it is not gated.

The wake-up control module is clocked only by a local wake-up interface clock from the core control module. The wake-up interface clock (WKUP_ICLK) uses the L4-Core interface clock (CORE_L4_ICLK) divided by 4 or 2 to reduce power consumption according to the WKUPCTRLCLOCKDIV bit CONTROL.CONTROL_PADCONF_OFF[2] (0 = divided by 4, 1 = divided by 2).

Figure 6-5 shows the SCM internal clock implementation.

Figure 6-5. Internal Clock Implementation

108-005

6.3.2 Hardware Requests

The SCM does not generate interrupt or wake-up requests.

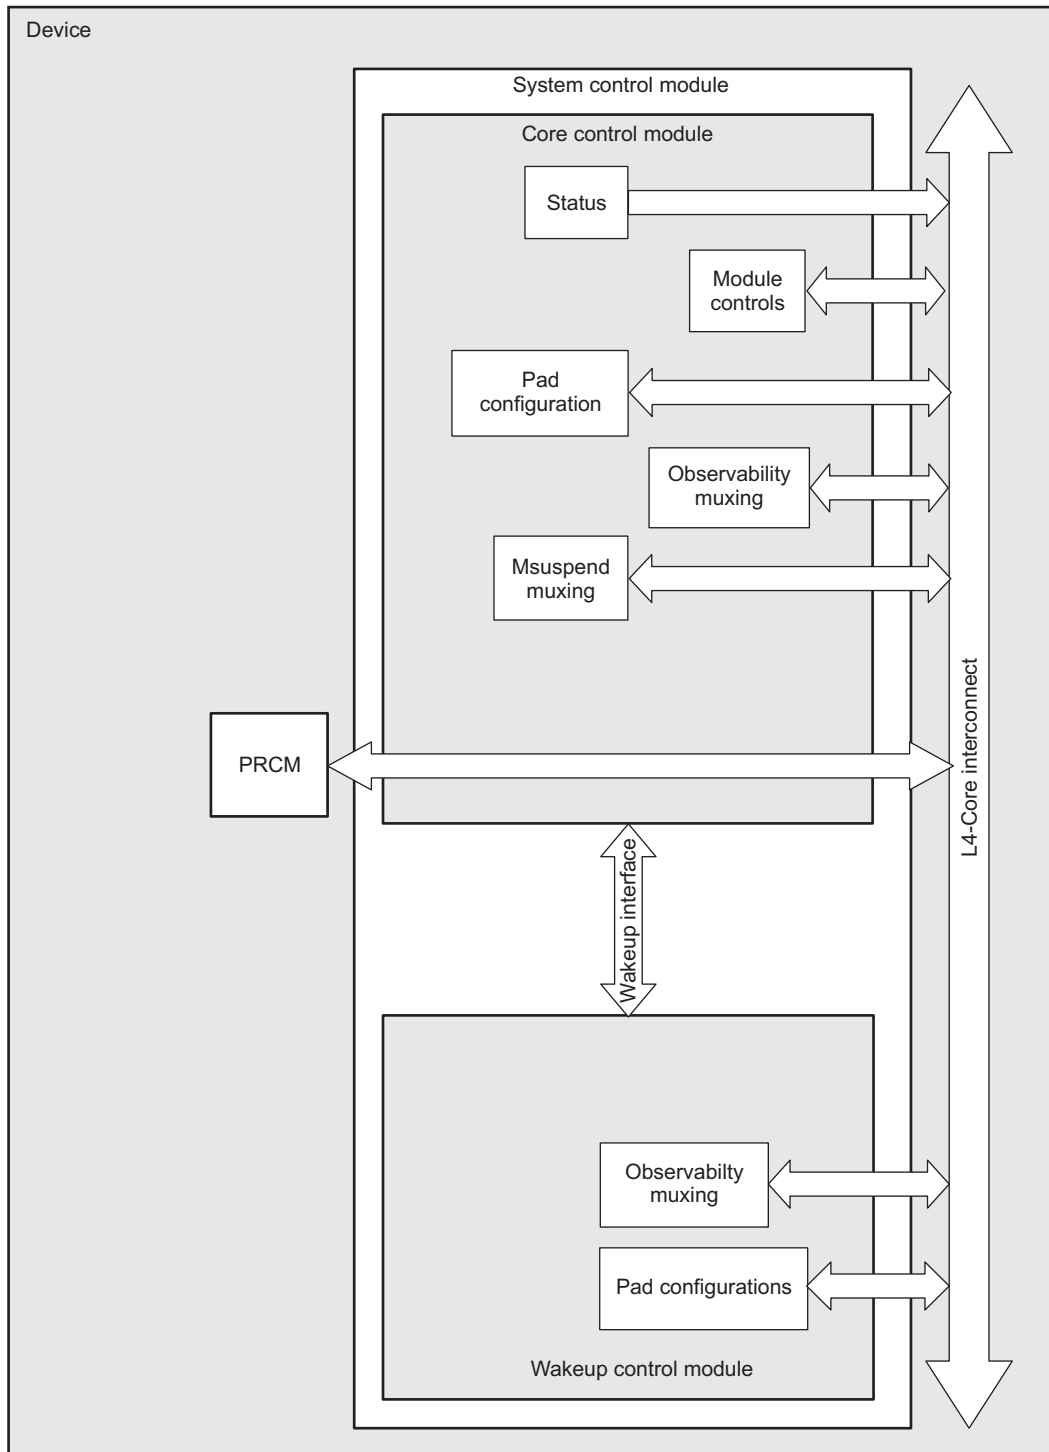

6.4 System Control Module Functional Description

6.4.1 Block Diagram

The SCM controls various device modules settings through register configuration and internal signals. It also controls the pad configuration and multiplexing and the routing of internal signals (such as PRCM signals or DMA requests) to observable pins for debug.

Figure 6-6 shows the SCM block diagram.

Figure 6-6. System Control Module Block Diagram

scm-006

The following sections describe the functionality of the SCM registers.

6.4.2 System Control Module Initialization

The SCM responds only to the internal power-on reset and to the device type. At power-on, reset values for the registers define the safe state for the device. In the initialization mode, only modules used at boot time are associated with the pads. Other module inputs are internally tied, and outputs pads are turned off each time the feature is available.

For the pad configuration, pull-up/pull-down fields are set according to the device pin list. For further information, see the pin list tables in your device-specific data manual.

The device type (for example, emulator, secure, general-purpose) affects the reset values and access rights for some emulation and security-related configuration bits (see Section 6.6, *SCM Registers*).

General-purpose devices (that is, those with no secure mode available) include features that are inaccessible or unavailable. These inaccessible registers define the default or fixed device configuration or behavior.

This technical reference manual focuses only on GP devices. To determine if a HS version of your device is available and for more information on HS devices, please refer to your device-specific data manual.

6.4.3 Wake-Up Control Module

The wake-up control module in the SCM belongs to the WKUP domain. It contains a 1 K-byte memory which is used to save the pad configuration registers in the core control module before switching to off mode. Pad configuration registers driving the I/O pad control in the WKUP domain are also instantiated in the wake-up control module. In this module, there is also a subset of observability multiplexing registers dedicated to PRCM observable signals and security registers (CONTROL.CONTROL_SEC_TAP and CONTROL.CONTROL_SEC_EMU).

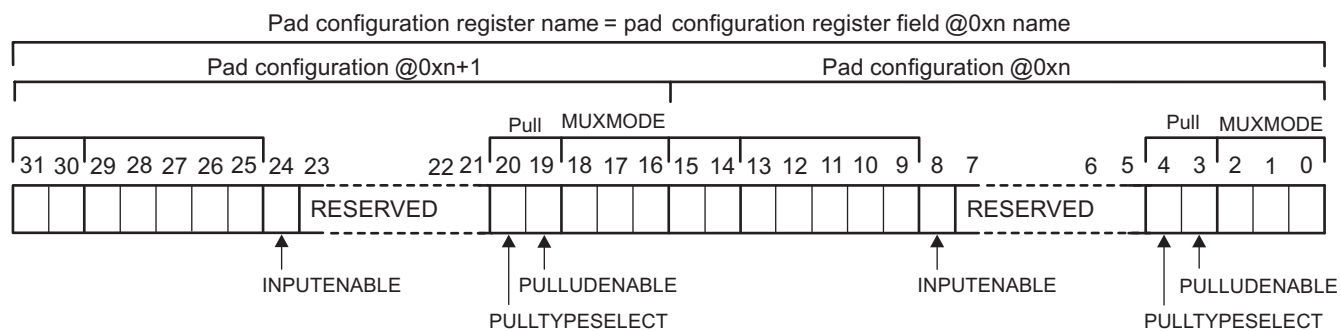

The wake-up control module is configured through the L4-Core interface in the core control module and is accessed from the core control module through a dedicated interface. This interface between the core control module and the wake-up control module uses the CORE_L4_ICLK clock divided by 4 or 2 to reduce power consumption in the WKUP domain.

6.4.4 Pad Functional Multiplexing and Configuration

After power-on reset, the software sets the pad functional multiplexing and configuration registers to the requested device pad configurations. Data written in these registers command directly the multiplexing of the pad configuration logic.

Each pin is configurable by software using its associated pad configuration register field, which is 16 bits wide (see Figure 6-7).

Figure 6-7. Pad Configuration Register Functionality

scm-008

One pad configuration register field is available for each pin. Each 32-bit pad configuration register is grouped into two 16-bit pad configuration register fields. One pad configuration register provides control for two different pins.

Some pad configuration registers control the configuration of pads in the CORE domain. These registers are instantiated in the CORE domain of the SCM (core control module, physical addresses 0x4800 2030 to 0x4800 2260). Pad configuration registers also control the configuration of pads in the WKUP domain. These registers are instantiated in the WKUP domain of the SCM (wake-up control module, physical addresses 0x4800 2A00 to 0x4800 2A4C).

NOTE: These registers can be accessed using 8-, 16-, and 32-bit operations.

The functional bits of a pad configuration register field are divided into the following five fields:

- MUXMODE (3 bits) defines the multiplexing mode applied to the pin. A mode corresponds to the selection of the functionality mapped on the pin with six (0 to 5) possible functional modes for each pin.
- PULL (2 bits) for combinational pull-up/pull-down configuration:
 - PULLTYPESELECT: Pull-up/pull-down selection for the pin.
 - PULLUDENABLE: Pull-up/pull-down enable for the pin.
- INPUTENABLE (1 bit) drives an input enable signal to the I/O CTRL.
 - INPUTENABLE = 0: Input Disable. Pin is configured in output only mode.
 - INPUTENABLE = 1: Input Enable. Pin is configured in bi-directional mode.

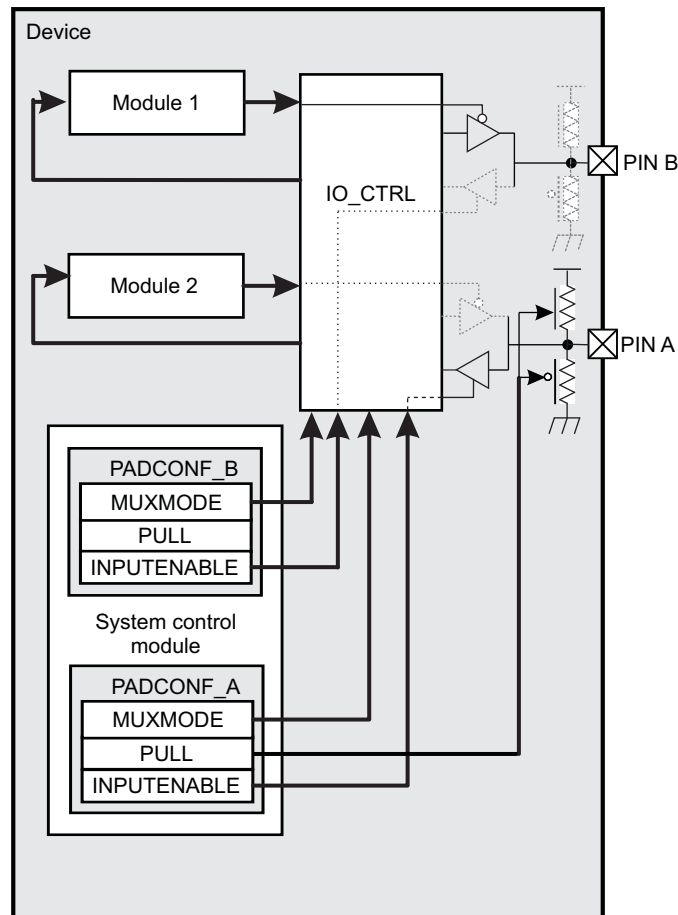

Table 6-2 lists the bit directions of the CONTROL_PADCONF_x registers.

Table 6-2. Bit Directions for CONTROL_PADCONF_x Registers

| CONTROL_PADCONF_x Bit | Bit Direction | |
|-----------------------|------------------------------|----------------------------|
| | 0 | 1 |
| PULLUDENABLE | Not activated | Activated |
| PULLTYPESELECT | Pulldown | Pullup |
| INPUTENABLE | Input enable signal inactive | Input enable signal active |

Figure 6-8 shows the pad configuration functionality when off mode is inactive.

Figure 6-8. Pad Configuration Diagram

scm-009

6.4.4.1 Mode Selection

Table 6-3 lists the multiplexing modes and settings.

Table 6-3. Mode Selection

| MUXMODE | Selected Mode |
|---------|-----------------------|
| 0b000 | Primary mode = Mode 0 |
| 0b001 | Mode 1 |
| 0b010 | Mode 2 |
| 0b011 | Mode 3 |
| 0b100 | Mode 4 |
| 0b101 | Mode 5 |
| 0b110 | Mode 6 |
| 0b111 | Safe mode = Mode 7 |

The MUXMODE field in the CONTROL_PADCONF_X register defines the multiplexing mode applied to the pad. Modes are referred to by their decimal (from 0 to 7) or binary (from 0b000 to 0b111) representation. Functional modes are defined from 0b000 to 0b101; mode 0b111 is referred to as the safe mode.

For most pads, the reset value for the MUXMODE field in the CONTROL_PADCONF_X register is 0b111. The exceptions are pads to be used at boot time to transfer data from selected peripherals to the external flash memory.

Mode 0 is the primary mode. When mode 0 is set, the function mapped to the pin to the name of the pin.

Mode 1 to mode 6 are possible modes for alternate functions. On each pin, some modes are used effectively for alternate functions, while other modes are unused and correspond to no functional configuration.

The safe mode avoids any risk of electrical contention by configuring the pin as an input with no functional interface mapped to it. The safe mode is used mainly as the default mode for all pins containing no mandatory interface at the release of power-on reset.

For more information about the configurable mode on each pin, see [Table 6-5](#).

6.4.4.2 Pull Selection

Whichever pull value is configured, pulls are automatically disabled when a pin is configured as an output (see [Table 6-4](#)).

Table 6-4. Pull Selection

| PULL | | Pin Behavior |
|----------------|--------------|---|
| PULLTYPESELECT | PULLUDENABLE | |
| 0b0 | 0b0 | Pull-down selected but not activated |
| 0b0 | 0b1 | Pull-down selected and activated if pin is NOT configured as OUTPUT |
| 0b1 | 0b0 | Pull-up selected but not activated |
| 0b1 | 0b1 | Pull-up selected and activated if pin is NOT configured as OUTPUT |

For more information on the pull available on each pin, see [Table 6-5](#).

6.4.4.3 Pad Multiplexing Register Fields

[Table 6-5](#) provide for each pad configuration register field the address offset and the associated signal name for each multiplexing mode (as set by bit field MUXMODE). Mode 0 is always defined. Modes with no signal name are undefined for the given pad.

NOTE: [Table 6-5](#) lists the pad configuration registers instantiated in the CORE domain and WKUP domain that drive the pads in the CORE domain and WKUP domain respectively. An empty cell indicates that the mode or pull is not available for this pin.

Table 6-5. Core and Wakeup Control Module Pad Configuration Registers

| Register Name | Physical Address | Mode 0 | Mode 1 | Mode 2 | Mode 3 | Mode 4 | Mode 5 | Mode 6 | Mode 7 |

NOTE: Pad names are signal names available in mode 0.

For more information on the pad default states, please refer to your device-specific data manual.

6.4.5 Functional Register Description

6.4.5.1 Static Device Configuration Registers

[Table 6-6](#) describes the static device configuration registers.

Table 6-6. Static Device Configuration Registers

| Physical Address | Register Name | Description | Access |
|------------------|------------------|---------------------------------|--------|
| 0x4800 2274 | CONTROL_DEVCONF0 | Module dedicated configurations | R/W |
| 0x4800 22D8 | CONTROL_DEVCONF1 | Module dedicated configurations | R/W |
| 0x4800 2580 | CONTROL_DEVCONF2 | Module dedicated configurations | R/W |
| 0x4800 2584 | CONTROL_DEVCONF3 | Module dedicated configurations | R/W |

These registers allow the static configuration of device modules such as USB, McBSP, and I²C. For example, they allow selecting external or internal clocks for McBSP modules.

6.4.5.2 MPU MSuspend Configuration Registers

Table 6-7 describes the MPU MSuspend configuration registers.

Table 6-7. MSuspendMux Control Registers

| Physical Address | Register Name | Description | Access |
|------------------|-----------------------|--|--------|
| 0x4800 2290 | CONTROL_MSUSPENDMUX_0 | Control the use of MSuspend signals at module level. | R/W |
| 0x4800 2294 | CONTROL_MSUSPENDMUX_1 | Control the use of MSuspend signals at module level. | R/W |
| 0x4800 2298 | CONTROL_MSUSPENDMUX_2 | Control the use of MSuspend signals at module level. | R/W |
| 0x4800 22A0 | CONTROL_MSUSPENDMUX_4 | Control the use of MSuspend signals at module level. | R/W |
| 0x4800 22A4 | CONTROL_MSUSPENDMUX_5 | Control the use of MSuspend signals at module level. | R/W |
| 0x4800 22A8 | CONTROL_MSUSPENDMUX_6 | Control the use of MSuspend signals at module level. | R/W |

These registers provide an entry for each module that must consider the MSuspend signals from the MPU processor. For each module, the sensitivity to the MSuspend signals is defined within possibilities (coded using 3 bits):

- 0b000: No sensitivity; no MSuspend signal reaches the module.
- 0b001: Sensitivity to the MPU MSuspend signal
- Other values: Reserved; other values are not supported.

The logic used to combine the MSuspend signals from the processor is implemented within the SCM. MSuspend signals are active low.

CAUTION

Not all modules use the MSUSPEND signal. See the TRM chapter for each module to determine whether the module supports the MSUSPEND signal.

All MSUSPEND signals coming out of the MPU and DSP are resynchronized within the SCM by using the control module interface clock.

6.4.5.3 Device Status Registers

Table 6-8 lists the status registers.

Table 6-8. Device Status Registers

| Physical Address | Register Name | Description | Access |
|------------------|----------------|------------------------|----------------------|
| 0x4800 22F0 | CONTROL_STATUS | Device status register | Public privilege (R) |

The CONTROL.CONTROL_STATUS register is read-only and has no access restriction.

The CONTROL_STATUS register bits[5:0] logs the status of sys_boot [5:0] pins at Power on Reset.

The lower three sys_boot[4:0] pins allow the selection of the booting sequence of interfaces or devices for ROM code when booting. Sys_boot[5] switches between memory (0) and peripheral (1) booting.

For further information on the configuration of the sys_boot pins, see the *Initialization* chapter.

After booting, these pins can be used optionally for other functions. When the pins are reused, the associated sysboot registers are not modified by the new functionality. It is recommended that the output function on the sys_boot pins be reused.

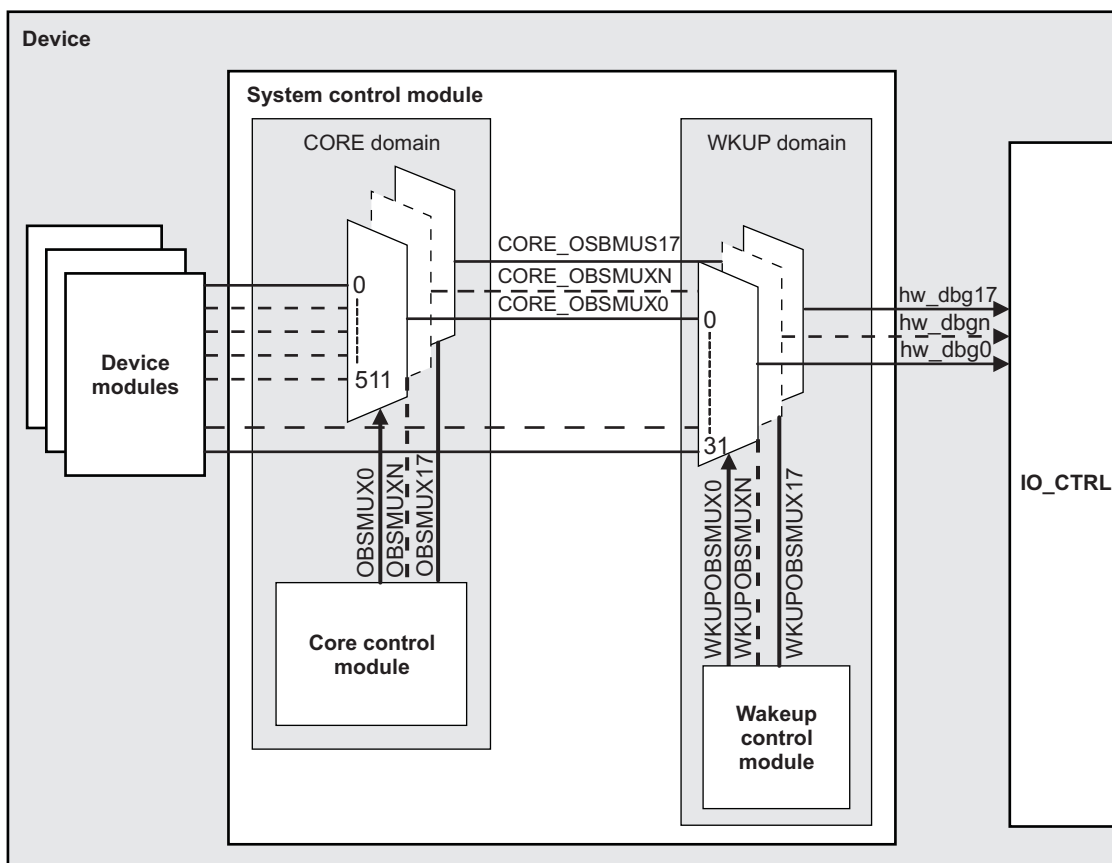

6.4.6 Debug and Observability

6.4.6.1 Description

NOTE: This feature is restricted to emulator and GP devices.

Figure 6-9 shows an overview of observability multiplexing, which minimizes the number of signals exchanged at the domain boundary.

Figure 6-9. Overview of the Debug and Observability Register Functionality

Two layers of multiplexer are used to select the set of internal observable signals (PRCM signals, DMA requests, and interrupts) to be routed to the pins dedicated to the hardware debug.

The first layer is in the CORE domain. It is controlled by the core control module registers and selects the set of internal signals from the CORE domain to be routed. The second layer is in the WKUP domain. It is controlled by the wake-up control module registers and selects the set of internal signals from the WKUP domain.

The pads used for the hardware debug must be properly configured by selecting the hardware debug function (hw_dbg) of the pad. To configure the pads, select mode 5 (0b101) in the MUXMODE bit field of the CONTROL.CONTROL_PADCONF_CCDC_x register (only for hw_dbg0 to hw_dbg11), or select mode 7 (0b111) in the MUXMODE bit field of the CONTROL.CONTROL_PADCONF_ETK_x register (for all hw_dbg).

Before selecting the CORE signals, the WKUPOBSMUX field of the CONTROL.CONTROL_WKUP_DEBOBS_n registers must be set to 0.

NOTE: The pads used for the hardware debug must be properly configured by selecting the hardware debug function (hw_dbg) of the pad. To configure the pads, select mode 5 (0b101) in the MUXMODE bit field of the CONTROL.CONTROL_PADCONF_CCDC_x register (only for hw_dbg0 to hw_dbg11), or select mode 7 (0b111) in the MUXMODE bit field of the CONTROL.CONTROL_PADCONF_ETK_x register (for all hw_dbg).

Table 6-9. Observability Registers

| Physical Address | Register Name | Description | Access | |
|------------------|-----------------------|---|-------------|-----|
| | | | Device Type | |
| | | | E/T/G | S/B |
| 0x4800 2420 | CONTROL_DEBOBS_0 | Set and configure CORE observable signals 1 and 0 | R/W | R |
| 0x4800 2424 | CONTROL_DEBOBS_1 | Set and configure CORE observable signals 3 and 2 | R/W | R |
| 0x4800 2428 | CONTROL_DEBOBS_2 | Set and configure CORE observable signals 5 and 4 | R/W | R |
| 0x4800 242C | CONTROL_DEBOBS_3 | Set and configure CORE observable signals 7 and 6 | R/W | R |
| 0x4800 2430 | CONTROL_DEBOBS_4 | Set and configure CORE observable signals 9 and 8 | R/W | R |
| 0x4800 2434 | CONTROL_DEBOBS_5 | Set and configure CORE observable signals 11 and 10 | R/W | R |
| 0x4800 2438 | CONTROL_DEBOBS_6 | Set and configure CORE observable signals 13 and 12 | R/W | R |
| 0x4800 243C | CONTROL_DEBOBS_7 | Set and configure CORE observable signals 15 and 14 | R/W | R |
| 0x4800 2440 | CONTROL_DEBOBS_8 | Set and configure CORE observable signals 17 and 16 | R/W | R |
| 0x4800 2A68 | CONTROL_WKUP_DEBOBS_0 | Set and configure WKUP observable pins 3, 2, 1, 0 | R/W | R |
| 0x4800 2A6C | CONTROL_WKUP_DEBOBS_1 | Set and configure WKUP observable pins 7, 6, 5, 4 | R/W | R |
| 0x4800 2A70 | CONTROL_WKUP_DEBOBS_2 | Set and configure WKUP observable pins 11, 10, 9, 8 | R/W | R |
| 0x4800 2A74 | CONTROL_WKUP_DEBOBS_3 | Set and configure WKUP observable pins 15, 14, 13, 12 | R/W | R |
| 0x4800 2A78 | CONTROL_WKUP_DEBOBS_4 | Set and configure WKUP observable pins 17, 16 | R/W | R |

The write capabilities of these registers differ according to the device type.

Perform the following steps to configure observability:

1. To configure the pads properly for hardware debug and observability, select the hardware debug (hw_dbg) function mode 5 in the MUXMODE field of the CONTROL.CONTROL_PADCONF_CCDC_x or mode 7 in the MUXMODE field of the CONTROL.CONTROL_PADCONF_ETK_X registers.

2. For the observability pads, set the proper values of the WKUPOBSMUX field CONTROL.CONTROL_WKUP_DEBOBS_n. Up to 5 bits are used to select the signal set to be observed (0x00 selection sets the output to CORE_OSMUXn signal). For more information, see the description of each register in [Section 6.4.6.2, Observability Tables](#).
3. To observe the CORE_OSMUXn signals from the first layer of the multiplexer, set the WKUPOBSMUX field CONTROL.CONTROL_WKUP_DEBOBS_n to 0x00, and then set the proper values of the OBSMUX field CONTROL.CONTROL_DEBOBS_n. A maximum of 7 bits is used to select the signal set to be observed (0b0000000 selection sets the output to 0).

For more information, see the description of each register in [Section 6.4.6.2, Observability Tables](#).

6.4.6.2 Observability Tables

This section gives information about all modules and features in the high-tier device. See Chapter 1, the *Device Family* section, to check availability of modules and features. Unavailable module and feature pins are not functional.

[Table 6-10](#) through [Table 6-45](#) define the mapped internal signals for each OBSMUX and WKUPOBSMUX value.

Table 6-10. Internal Signals Multiplexed on OBSMUX0

| Out Signal Name | Muxed Signal Name | OBSMUX0 Field CONTROL.CONTROL_DEBOBS_0 [22:16] (dec) | Description | High State | Low State |
|-----------------------------|--------------------------|--|---|---------------------|----------------------|
| CORE_OBSMUX0 ⁽¹⁾ | tie_low | 0 | Signal tied low | - | Active state low |

6.4.7 Electromagnetic Interference Reduction for Clocking Generation (Spreading)

6.4.7.1 Overview

There are two major forms of digital signals: digital-data and digital-clock (CLK). Digital signals are the principal signal form in today's digital electronic products.

- A digital-data signal can be viewed as a sequence of pulses with different pulse widths
- A clock (CLK) signal is usually a string of rectangular pulses with the same pulse width

In the case of a clock, the generated signal has a predetermined frequency. Electromagnetic radiations such as radio frequency emissions are also generated from the constant frequency clock signals and their harmonics. Unfortunately, a problem exists with some devices such as communication devices for example in that the system clock generates unwanted spurious signals that interfere with the decoding of information from received signals by a receiver of the communication device. Note that data periodicity also causes interference.

This periodicity generates a significant power peak at the selected frequency, which in turn causes an EMI disturbance to the environment.

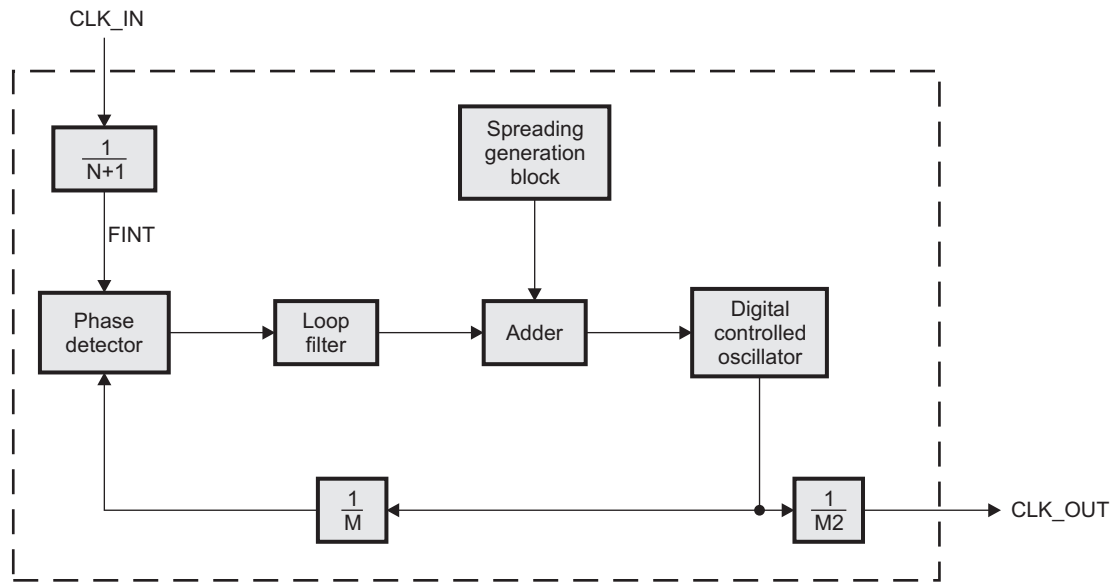

The harmonics of the generated signal system clock radiates in the other modules of the device, and the spurious energy can be enough to cause enough interference, which results in performance degradation (in the form of high bit error rates in case of a wireless communication interface for example).

In order to reduce the power peaks (and thus the energy of the electromagnetic noise generated for a specific frequency), an internal frequency modulation of the DPLL is used to distribute the energy to many different frequencies, thus reducing the power peaks.

This frequency modulation feature is directly integrated in some DPLLs of the device. The DPLLs that support this additional feature are called DPLL-D in the following.

Figure 6-10 shows a diagram of a DPLL that supports the EMI reduction feature.

Figure 6-10. DPLL with EMI Reduction Feature

108-033

The additional features of the DPLL compliant with EMI reduction are:

- EMI Reduction using Triangular frequency modulation, also called Spread Spectrum Clocking (SSC).

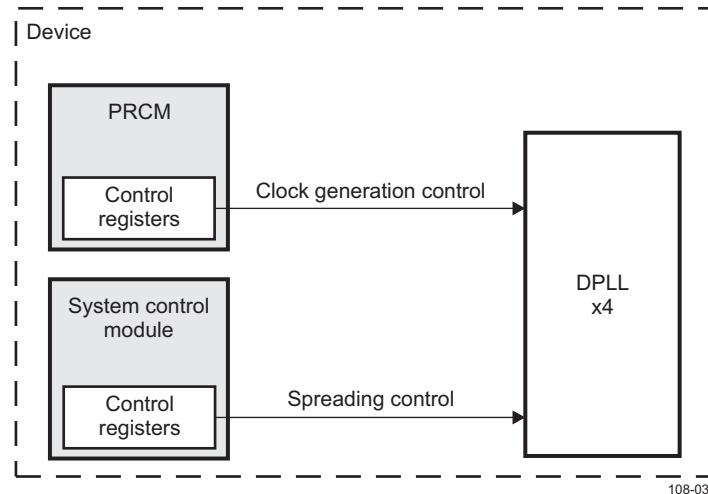

6.4.7.2 Integration

The four following DPLLs/Domains of the devices that support the EMI reduction feature are:

- DSS/DSI DPLL
- CORE domain DPLL
- PER domain DPLL
- USBHOST DPLL

Figure 6-11 highlights the four DPLL-D integration in the device.

Figure 6-11. DPLL-D Integration

The control of the DPLL is done both by the PRCM and the System Control Module:

- The PRCM controls the clocking generation of the DPLL. For more information, see the *Power Reset and Clock Management* chapter.
- The System Control Module contains all necessary bits that controls the EMI Reduction feature (Spread Spectrum Clocking).

6.4.7.2.1 Clocking, Reset, and Power Management Scheme

Please see the *Power Reset and Clock Management* chapter.

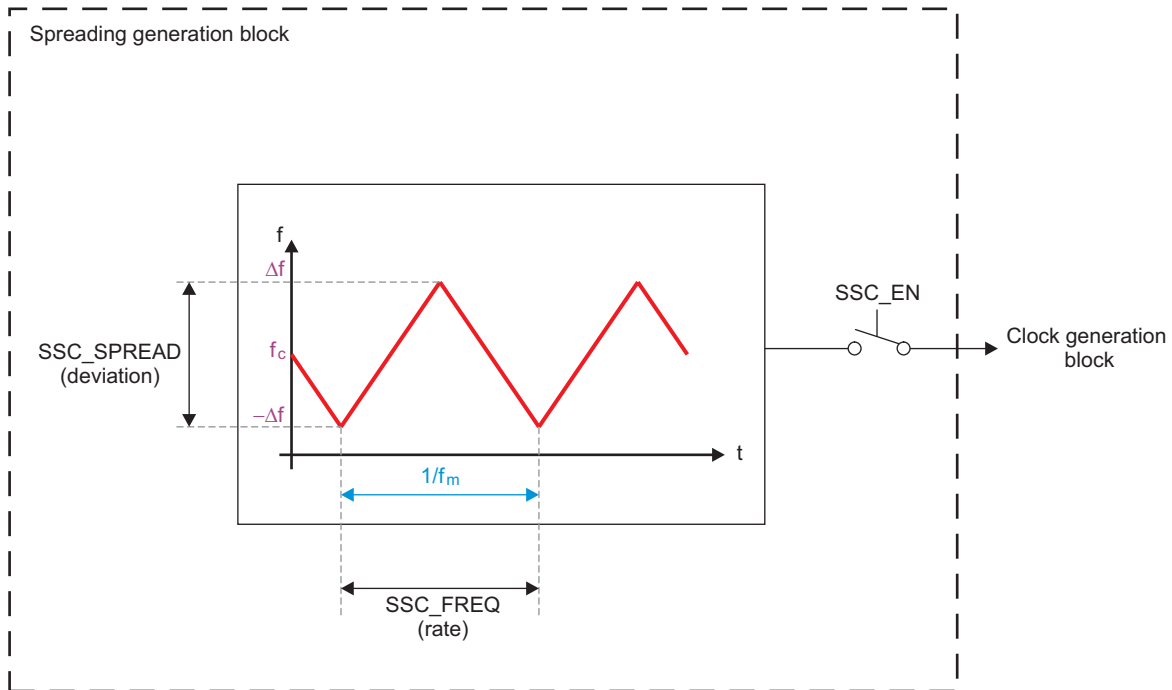

NOTE: DSI is not available on all devices. See Chapter 1, the *Device Family* section, to check availability of this module.

6.4.7.3 Functional Description

6.4.7.3.1 Spreading Generation Block

Figure 6-12 shows a diagram of the Spreading Generation block.

Figure 6-12. Spreading Generation Block Diagram

108-035

NOTE: Δf is the deviation from the center frequency. The total spreading deviation is equal to twice Δf .

f_c is the original clock frequency.

f_m is the spreading frequency.

This additional block generates the required waveform used to reduce EMI. This waveform is then modulated with the initial signal in order to add some controlled deviation in the clock signal frequency, which spreads the energy of the clock and its harmonics into a band of frequencies, and then reduces the Electromagnetic Interferences.

The **SSC_SPREAD** value handles the deviation (amplitude) of the generated signal from the original signal. It is controlled by the CONTROL.CONTROL_XXX_DPLL_SPREADING[3:2] XXX_SPREADING_AMPLITUDE bit field of the corresponding registers (where XXX is the name of the concerned DPLLs). Note that this register contains only a spreading ratio K, which is equal to $\Delta f / f_m$.

The **SSC_FREQ** value controls the rate of the generated signal. It is controlled by the CONTROL.CONTROL_XXX_DPLL_SPREADING[1:0] XXX_SPREADING_RATE bit field of the corresponding registers (where XXX is the name of the concerned DPLLs).

The **SSC_EN** signal enables/disables the frequency modulation feature of the DPLL. It is controlled by the CONTROL.CONTROL_XXX_DPLL_SPREADING[4] XXX_SPREADING_ENABLE bit field of the corresponding registers (where XXX is the name of the concerned DPLLs).

In any case the frequency modulation will be programmed in the System Control Module and it is not generally something that needs to be changed in real time.

6.4.7.3.2 Spread Spectrum Clocking (SSC)

6.4.7.3.2.1 Definition

The aim of the Spread Spectrum Clocking is to add a variation in the frequency of an original clock, which spreads the generated interferences over a larger band of frequency.

In theory, Spread Spectrum Clocking means that the clock signal is varied around the desired frequency. For example, for a 1 GHz clock, the frequency might be 999.5 Mhz at one moment in time and 1.0005 GHz at another. Doing this constantly causes the power of the tone to be "spread" out more over a broader band of tight frequencies (centered at the desired tone). To realize this constant variation on the original signal, a modulation with an additional signal (called spreading waveform) is realized.

Creating a spread-spectrum clock by spreading the initial clock frequency is done by defining the following parameters:

- The spreading frequency (deviation), which is the ratio of the range of spreading frequency over the original clock frequency.
- The modulation rate (f_m), which is used to determine the clock-frequency spreading-cycling rate, and is the time during which the generated clock frequency varies through Δf and returns to the original frequency.
- The modulation waveform, which describes the variation curve in term of time.

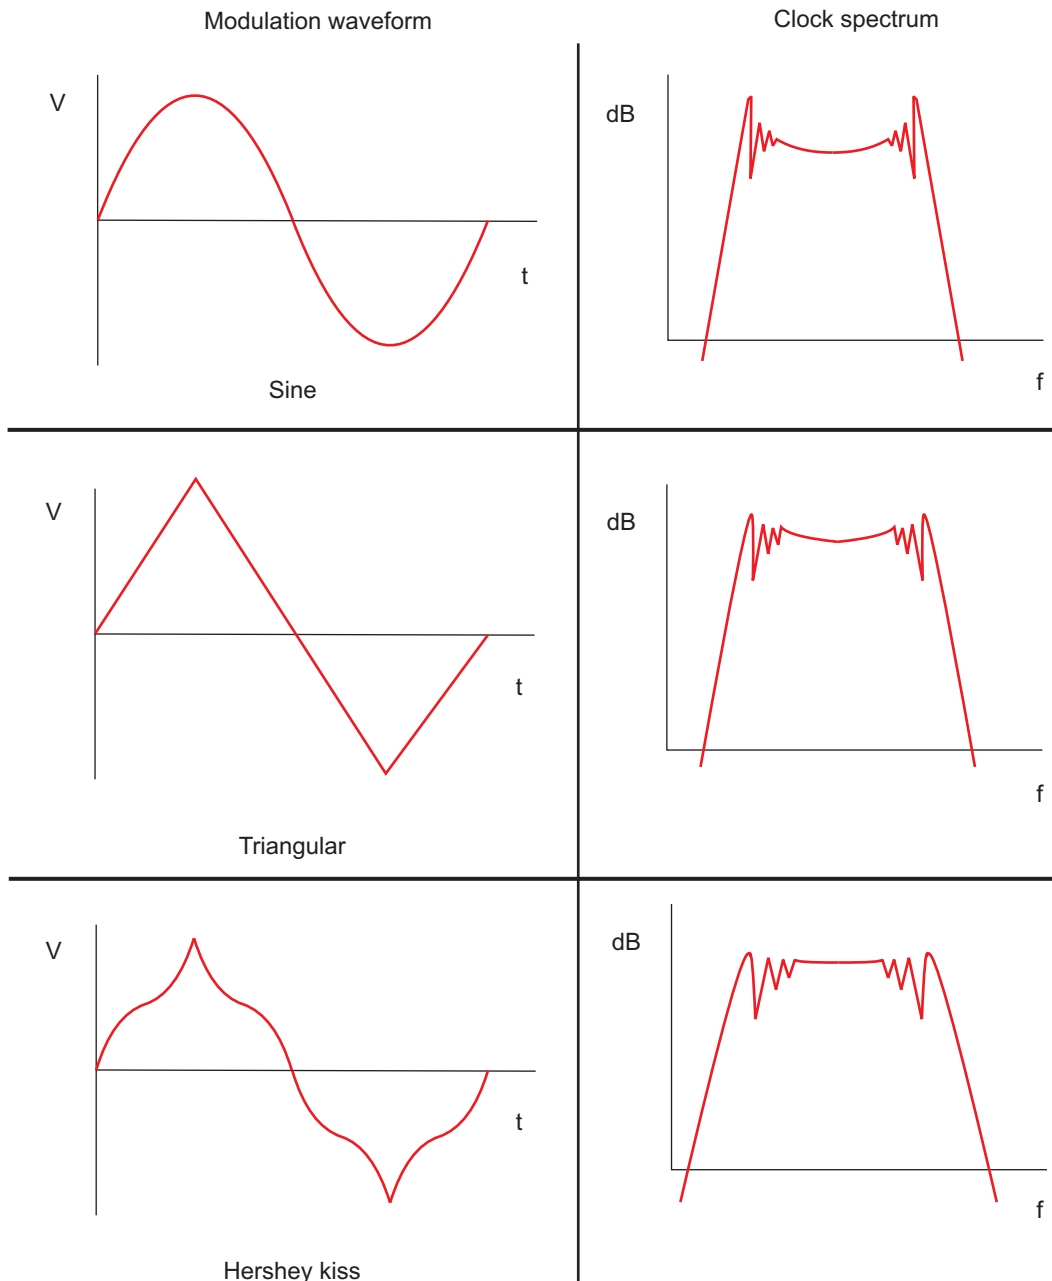

The spectral power reduction in the DPLL clocks is dependent on the Modulation Index (K) which is a ratio of spreading frequency, calculated from the frequency deviation (Δf) and the modulation rate (f_m).

6.4.7.3.2.2 The Modulation Waveforms

The shape (profile) of the generated clock signal depends on the modulation waveform that is used during the frequency modulation. Several profiles can be used, according to the desired shaping for the energy spreading.

Figure 6-13 shows three examples of modulation waveforms and the spectrum of the corresponding modulated clock signal.

Figure 6-13. Modulation Profiles

108-036

The triangular wave gives a relatively flat spectrum and is also easy to generate. The triangular waveform is used by the DPLL-D.

6.4.7.3.2.3 Effects on the Clock Signal

Figure 6-14 gives an example of the effect of a triangular spreading on a clock signal.

Figure 6-14. Effect of the SSC in Frequency

Figure 6-14 highlights the power reduction of the main peak, but also the flatter aspect of the modulated signal. One could notify that the minimum level of the second signal is higher than the first one. This effect is normal and is due to the "noise" added for the modulation.

NOTE: The spreading technique "scatters" the energy of the peaks on the other frequencies, which reduces the power of the peaks but increases the global "noise" of the signal.

Figure 6-15 shows the effect of a triangular spreading on a clock signal in the Time Domain.

Figure 6-15. Effect of the SSC in the Time Domain

6.4.7.3.2.4 Estimation of the EMI Reduction Level

Figure 6-16 shows the effect of the spreading on a clock and its harmonics.

Figure 6-16. Peaks Reduction Due to Spreading

108-037

The electromagnetic interference reduction can be estimated with the following equation:

$$(1) \text{ Peak_power_reduction} = 10 * \log ((\text{Deviation} * f_c) / f_m)$$

With:

- Peak_power_reduction in dB
- Deviation in % of the initial clock frequency (f_c), equals to $\Delta f / f_c$
- f_c is the original clock frequency, in MHz
- f_m is the spreading frequency, in MHz

According to equation (1), it is also possible to compute the deviation, and then Δf , for a required peak power reduction:

$$(2) \text{ Deviation} = (f_m / f_c) * 10^{(\text{Peak_power_reduction} / 10)}$$

Example:

For $f_c=400\text{MHz}$, Deviation =1% peak from $f_c(\Delta f = 4\text{MHz})$ and $f_m=400\text{kHz}$, the estimated peak power reduction is 10dB.

6.4.7.3.2.5 Bandwidth Calculation (Carson Bandwidth Rule)

Carson's bandwidth rule defines the approximate bandwidth requirements of communications system components for a carrier signal that is frequency modulated by a continuous or broad spectrum of frequencies rather than a single frequency.

Carson's bandwidth rule is expressed by the relation $\text{CBR} = 2 * (\Delta f + f_m)$ where CBR is the bandwidth requirement, Δf is the peak frequency deviation, and f_m is the highest frequency in the modulating signal.

For example, an FM signal with 5kHz peak deviation, and a maximum audio frequency of 3 kHz, would require an approximate bandwidth $2*(5+3) = 16$ kHz.

Theoretically any FM signal will have an infinite number of sidebands and hence an infinite bandwidth but in practice all significant sideband energy (98% or more) is concentrated within the bandwidth defined by Carson's rule.

6.4.7.3.3 Frequency Limitations

There are some limitations on the use of the Spreading feature. Figure 6-17 shows the supported Spreading frequency and deviation.

Figure 6-17. Supported Spreading Frequency and Deviation

| | | SPREADING_AMPLITUDE (bits [3:2]) | | | |
|-----------------------------|-----------------------|----------------------------------|--------------|--------------|---------------|
| | | 00 | 01 | 10 | 11 |
| | | K | | | |
| | | 4 | 6 | 8 | 10 |
| SPREADING_RATE (bits [1:0]) | Min to Max rate (kHz) | Frequency deviation +/- kHz | | | |
| 00 | 62.5 to 125 | 250 to 500 | 375 to 750 | 500 to 1000 | 625 to 1250 |
| 01 | 125 to 250 | 500 to 1000 | 750 to 1500 | 1000 to 2000 | 1250 to 2500 |
| 10 | 250 to 500 | 1000 to 2000 | 1500 to 3000 | 2000 to 4000 | 2500 to 5000 |
| 11 | 500 to 1000 | 2000 to 4000 | 3000 to 6000 | 4000 to 8000 | 5000 to 10000 |

 Not recommended. PLL jitter degradation and modulation amplitude not a linear function of FM.

108-040

Even if all the previous frequencies and deviations are supported by the DPLL-D, a range of "Safe operating regions" has been defined according to its impact on jitter.

Figure 6-17 shows the supported safe operating regions supported by the DPLL-D.

Figure 6-18. Supported Safe Operating Regions and Jitter Impact

| CLKOUT FREQUENCY (25–900 MHz) | Recommended safe operating region | | | | Max jitter impact in % due to spreading |
|-------------------------------|---|---|---|---|---|
| 400–900 |  |  |  |  | +/- 1.25% |
| 200–399 | |  |  |  | +/- 1.25% |
| 100–199 | | |  |  | +/- 1.25% |
| 50–99 | | | |  | +/- 1.00% |
| 25–49 | | | |  | +/- 2.00% |

108-041

(1) Please see Figure 6-17 for color coding)

6.4.7.4 Basic Programming Model

6.4.7.4.1 Spread Spectrum Clocking Configuration

The configuration of the spreading feature is not mandatory when programming the DPLL. This feature is usually enabled when the DPLL clocks generate harmonics which can potentially interfere with the GSM carrier frequencies.

Once the "clock generation control" registers are configured, it is possible to configure the spreading on the clock signal.

The first thing to do is to calculate the *Deviation* and/or the *Spreading Rate* according to the desired peak power reduction. In addition to this, it is necessary to have K (modulation index), which value is equal to $\Delta f / f_m$.

Then, both `XXX_SPREADING_AMPLITUDE` and `XXX_SPREADING_RATE` bitfields can be configured with the calculated values.

Finally, the spreading has to be enabled using the `XXX_SPREADING_ENABLE` bit.

NOTE: It is necessary to carefully configure the spreading on a clock in order to avoid adding some "noise" on frequencies that are used by another module. For example, adding spreading on a clock to reduce noise on GSM frequencies can "move" the generated noise to the memory controller's frequency, and then degrade its performances.

Example:

For $f_c=400\text{MHz}$, $\text{Deviation}=1\%$ peak from f_c ($\Delta f = 4\text{MHz}$) and $f_m=400\text{kHz}$, the estimated peak power reduction is 10dB. K is then equal to 10. The DPLL can be configured as follow:

- `XXX_SPREADING_RATE = 10` (250 to 500 KHz)
- `XXX_SPREADING_AMPLITUDE = 11` ($K = 10$)
- `XXX_SPREADING_ENABLE = 1`

The state of the modulation feature can be monitored with the `XXX_SPREADING_ENABLE_STATUS` bit of the corresponding register.

NOTE:

- To support the spreading feature the DPLL Bandwidth is restricted to a max of 70KHz. This implies the Reference Clock frequency to be in range 0.75MHz to 2.1MHz, and then the `XXX_DPLL_FREQSEL[3:0]` bitfield to be in range "0011" to "0111".
 - The required Δf (Frequency deviation) is targeted on the CLKOUT Frequency is achieved when $M2$ is programmed to 1. Otherwise the frequency deviation will be scaled down by the factor of $M2$ value. However, this does not affect the deviation, so frequency change of harmonics at GSM frequencies is the same.
 - The spread of modulation frequency within each range is due to an internal auto-ranging function and specific frequencies cannot be selected.
 - The lowest range (62.5 to 125 KHz) should only be selected when Reference Clock (PLL internal reference frequency) < 1.1 MHz is being used, to prevent the PLL feedback loop from canceling the modulation.
-

When deactivating the spreading (`XXX_SPREADING_ENABLE = 0`), the End-of-Spreading is synchronous to the internal spreading cycle. So there is no residual average frequency error. `PER_DPLL_SPREADING_RATE` option is not supported.

6.5 System Control Module Programming Model

6.5.1 Feature Settings

6.5.1.1 Video Driver

This section gives information about all modules and features in the high-tier device. See Chapter 1, the *Device Family* section, to check availability of modules and features. Unavailable module and feature pins are not functional.

- TVOUTBYPASS bit CONTROL.CONTROL_DEVCONF1[18]:
 - 0b0: Dual 10-bit video DAC TV out bypass disable
 - 0b1: Dual 10-bit video DAC TV out bypass enable
- TVACEN bit CONTROL.CONTROL_DEVCONF1[11]:
 - 0b0: Enables dc coupling for TV output
 - 0b1: Enables ac coupling for TV output

For more details on video DACs, see the *Display Subsystem* chapter.

6.5.1.2 McBSP1 Internal Clock

The McBSP1 internal clock gates the internal interconnect clock and selects the FSR, CLKR, and CLKS input for the McBSP1.

- MCBSP1_FSR bit CONTROL.CONTROL_DEVCONF0[4]:
 - 0: FSR is from the pin mcbasp1_fsr.
 - 1: FSR is from the pin mcbasp1_fsx.
- MCBSP1_CLKR bit CONTROL.CONTROL_DEVCONF0[3]:
 - 0: CLKR is from the pin mcbasp1_clkr.
 - 1: CLKR is from the pin mcbasp1_clkx.
- MCBSP1_CLKS bit CONTROL.CONTROL_DEVCONF0[2]:
 - 0: CLKS is from the PRCM functional clock.
 - 1: CLKS is from the pin mcbasp_clks.

For more details on McBSP, see the *Multichannel Serial Port Interface* chapter.

6.5.1.3 McBSP2 Internal Clock

The McBSP2 internal clock gates the internal interconnect clock and selects the FSR, CLKR, and CLKS input for the McBSP2. The McBSP2 does not have mcbasp2_clkr and mcbasp2_fsr external pins. Clock input is from the mcbasp2_clkx pin; FSR input is from the mcbasp2_fsx pin.

- MCBSP2_CLKS register bit CONTROL.CONTROL_DEVCONF0[6]:
 - 0: Clock is from the PRCM functional clock.
 - 1: Clock is from the external pin mcbasp_clks.

For more details on McBSP, see the *Multichannel Serial Port Interface* chapter.

6.5.1.4 McBSP3 Internal Clock

The McBSP3 internal clock gates the internal interconnect clock and selects the FSR, CLKR, and CLKS input for the McBSP3. The McBSP3 does not have mcbasp3_clkr and mcbasp3_fsr external pins. Clock input is from the mcbasp3_clkx pin; FSR input is from the mcbasp3_fsx pin.

- MCBSP3_CLKS register bit CONTROL.CONTROL_DEVCONF1[0]:
 - 0: Clock is from the PRCM functional clock.
 - 1: Clock is from the external pin mcbasp_clks.

For more details on McBSP, see the *Multichannel Serial Port Interface* chapter.

6.5.1.5 McBSP4 Internal Clock

The McBSP4 internal clock gates the internal interconnect clock and selects the FSR, CLKR, and CLKS input for the McBSP4. The McBSP4 does not have `mcbbsp4_clkr` and `mcbbsp4_fsr` external pins. Clock input is from the `mcbbsp4_clkx` pin; FSR input is from the `mcbbsp4_fsx` pin.

- `MCBSP4_CLKS` register bit `CONTROL.CONTROL_DEVCONF1[2]`:
 - 0: Clock is from the PRCM functional clock.
 - 1: Clock is from the external pin `mcbbsp_clks`.

For more details on McBSP, see the *McBSP* chapter.

6.5.1.6 McBSP5 Internal Clock

The McBSP5 internal clock gates the internal interconnect clock and selects the FSR, CLKR, and CLKS input for the McBSP5. The McBSP5 does not have `mcbbsp5_clkr` and `mcbbsp5_fsr` external pins. Clock input is from the `mcbbsp5_clkx` pin; FSR input is from the `mcbbsp5_fsx` pin.

- `MCBSP5_CLKS` register bit `CONTROL.CONTROL_DEVCONF1[4]`:
 - 0: Clock is from the PRCM functional clock.
 - 1: Clock is from the external pin `mcbbsp_clks`.

For more details on McBSP, see the *McBSP* chapter.

6.5.1.7 MMC/SD/SDIO2 Module Input Clock Selection

- `MMCSPIO2ADPCLKISEL` bit `CONTROL.CONTROL_DEVCONF1[6]`:
 - 0: Input clock is from the external pin.
 - 1: Internal loopback, module input clock is copied from the module output clock.

6.5.1.8 Setting Sensitivity on `SYS_NDMAREQ[3:0]` Input Pins

The seven `SYS_NDMAREQ0` to `SYS_NDMAREQ6` input pins can be either level or edge sensitive.

- `SENSDMAREQ0` bit `CONTROL.CONTROL_DEVCONF0[0]`:
 - 0: Level sensitivity
 - 1: Edge sensitivity
- `SENSDMAREQ1` bit `CONTROL.CONTROL_DEVCONF0[1]`:
 - 0: Level sensitivity
 - 1: Edge sensitivity
- `SENSDMAREQ2` bit `CONTROL.CONTROL_DEVCONF1[7]`:
 - 0: Level sensitivity
 - 1: Edge sensitivity
- `SENSDMAREQ3` bit `CONTROL.CONTROL_DEVCONF1[8]`:
 - 0: Level sensitivity
 - 1: Edge sensitivity

For more details on DMA, see the *DMA* chapter.

6.5.1.9 Force MPU Writes to Be Nonposted

`MPUFORCEWRNP` bit `CONTROL.CONTROL_DEVCONF1[9]` bit is for debugging only. When this bit is set to 1 (for debugging), all writes are forced to nonposted and the cache attributes are ignored. By default, this bit should be set to 0 (posted writes). For the best performance, keep this bit at 0.

6.5.2 Pad Configuration Programming Points

To configure the pad, ensure that the following are done:

- Identify signals required on the interface based on the target application.
Example: You want to configure UART1 interface on balls. The required signals are: `uart1_tx`, `uart1_rts`, `uart1_cts`, and `uart1_rx`.

- Choose the pads used for those signals. Some signals could be available on several pads and/or may be multiplexed with other signals that can be need for an other application. Refer to [Section 6.4.4.3, Pad Multiplexing Register Fields](#).

Example: Each UART1 interface signals are available on two pads. These signals are multiplexed with a McBSP signal.

Assume that the McBSP interface is required in the system. Therefore, for the UART1 interface signals, pads must be used where those signals are not multiplexed with the McBSP signal.

- Identify the pad configuration registers associated to the pads you will use in your application. Refer to [Section 6.4.4.3, Pad Multiplexing Register Fields](#).

Example: With the previous hypothesis the pad configuration registers to program are:

- uart1_cts: CONTROL.CONTROL_PADCONF_DSS_DATA0[15:0]
- uart1_rts: CONTROL.CONTROL_PADCONF_DSS_DATA0[31:16]
- uart1_tx: CONTROL.CONTROL_PADCONF_DSS_DATA6[15:0]
- uart1_rx: CONTROL.CONTROL_PADCONF_DSS_DATA6[31:16]

NOTE: In that configuration, dss_datan (where n = 0) signals will not be available on these balls.

- Configure the MUXMODE field of each pad configuration registers (CONTROL.[CONTROL_PADCONF_X](#)) associated to the pads used. [Section 6.4.4.3, Pad Multiplexing Register Fields](#) lists the entire mode available for each pin. Write the binary value of the mode used in the MUXMODE field of the pad configuration registers.

Example: UART1 signals are available in mode 2. So you should write 0b010 in the corresponding MUXMODE field of pad configurations registers to program.

- Configure the pull of the pad when you use it as input. When the pad is used as output the pull is automatically disabled. [Section 6.4.4.3, Pad Multiplexing Register Fields](#) lists the pull available on each pad and it reset value. Set the appropriate value for PULLTYPESELECT bit of the pad configuration register to set the pull value (0b0 = Pull Down selected, 0b1 = Pull Up selected) and set the PULLUDENABLE bit of the pad configuration register to enable the pull on the pad (0b0 = pull disabled, 0b1 = pull enabled)

Example: uart1_rts and uart1_tx are output signals, so the pull will be automatically disabled on the pad. uart1_cts and uart1_rx are input signals, so you should configure the pull for these pads:

- uart1_cts: enable pull-up (write 0b1 in the PULLTYPESELECT bit and 0b1 in the PULLUDENABLE bit of the corresponding pad configuration register)
- uart1_rx: enable pull-up (write 0b1 in the PULLTYPESELECT bit and 0b1 in the PULLUDENABLE bit of the corresponding pad configuration register)

- Set the INPUTENABLE bit of the pad configuration register if your pin is use as input.

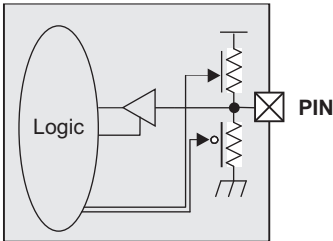

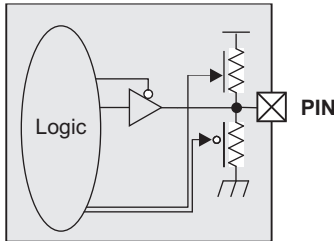

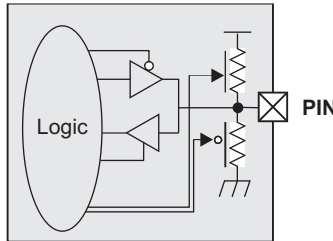

Example: uart1_rts and uart1_tx are output signals, so clear the INPUTENABLE bit of the corresponding pad configuration register. uart1_cts and uart1_rx are input signals, so set the INPUTENABLE bit of the corresponding pad configuration register.

NOTE: The order is unimportant for the previous setting of the pad configuration bits.

6.5.3 I/O Power Optimization Guidelines

In order to optimize I/O power, it is important to avoid unconnected or incorrectly-pulled pins. According to the type of the pins, the way to reduce power consumption can differ. Table 6-46 shows the 3 available pin (or ball) types.

Table 6-46. Existing Pin Types

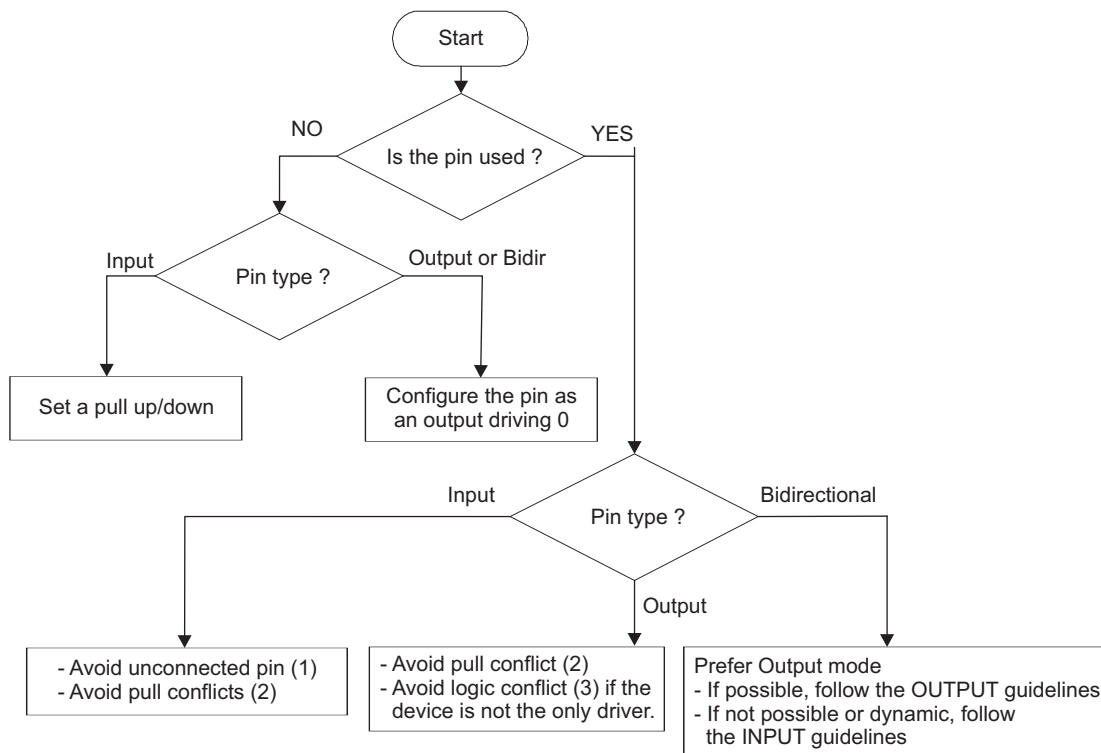

| Input | Output | Bidirectional |
|---|--|---|
|  |  |  |

The configuration differs according to the I/O cell types. The following describes some pieces of advice which can be useful to avoid extra current leakage:

- For input pins, use a pull up/down when possible.
 - For output pins, check existing pulls to avoid conflicts.
 - For bidirectional pins, reconfigure the pin as an output driving 0 when possible.
- Some I/O configurations involve modifications during the software setup of I/Os and sometimes require several hardware updates.

Figure 6-19 shows how to optimize the power consumption of pads.

Figure 6-19. I/O Power Optimization Flowchart

The following notes give additional explanations about the pin configuration.

1. In order to avoid unconnected pins, the configuration depends on its use:
 - If the pin is not driven externally, a pull up/down is required.
 - Otherwise, a pull up/down is not necessary.
2. Pull conflicts occur when there are different pulls on the same line. In order to correctly configure the pin, avoid external and internal pull together.
3. Logic conflicts consist in different electrical levels at the same time on one line. This can occur when several devices are connected to the same line. The two possible cases are:
 - If no external device drives the line, configure the pin to drive a '0'.
 - If another device drives the line, either the same value has to be driven or the pin has to be disconnected (HZ).

NOTE: It is advised to use high impedance logical state either on the device or the external component when the line is driven by both components.

The I/O pads are software-controlled by:

- Writing to the CONTROL_PADCONF_X registers in the Control Module for input/output and pull up/down configuration.
 - Writing to the GPIOi.GPIO_OE registers in the GPIO module for input/output configuration.
- For more information about how to configure the I/O pads, see [Chapter 6](#), *System Control Module*.

For more information about the GPIO module, see the *General-Purpose Interface* chapter.

NOTE: For a correct configuration of each pin direction (input, output, bidirectional), both the CONTROL_PADCONF_X and the GPIOi.GPIO_OE registers must be written.

For more information about the I/O cell types and the corresponding optimized configuration, please contact your TI representative.

6.6 System Control Module Registers

This section gives information about all modules and features in the high-tier device. See Chapter 1, the *Device Family* section, to check availability of modules and features. Unavailable module and feature pins are not functional.

Table 6-47 lists the base address and address space for the SCM instances.

Table 6-47. Instance Summary

| Module Name | Base Address | Size |
|---------------|--------------|-----------|
| INTERFACE | 0x4800 2000 | 36 bytes |
| PADCONFS | 0x4800 2030 | 564 bytes |
| GENERAL | 0x4800 2270 | 767 bytes |
| MEM_WKUP | 0x4800 2600 | 1K byte |
| PADCONFS_WKUP | 0x4800 2A00 | 80 bytes |
| GENERAL_WKUP | 0x4800 2A60 | 31 bytes |

Some register description tables in this section are divided into different device types and ModeSP according to their access rights and reset value. For example, CONTROL.CONTROL_EXT_SEC_CONTROL is divided into seven tables named "TypeAModeB Bitfield Details" where:

- A can take different expressions depending on the device type:
 - E: EMULATOR device
 - G: General-purpose device
 - T: TEST device
 - S: SECURE device
 - B: BAD device
 - X: DON'T CARE device

These access rights are enumerated in register descriptions as needed.
- B can take different expressions depending on the mpu mode:
 - SP: SECURE PRIVILEGE mode
 - NSP: NON SECURE PRIVILEGE mode
 - X: DON'T CARE mode

6.6.1 System Control Module Register Mapping Summary

NOTE: All module registers are 8-, 16-, or 32-bit accessible through the L4 interconnect (little endian encoding).

Table 6-48 lists the INTERFACE registers.

Table 6-48. INTERFACE Registers Mapping Summary

| Register Name | Type | Register Width (Bits) | Address Offset | Physical Address | Section |
|-------------------|------|-----------------------|----------------|------------------|---------------------------------|
| CONTROL_REVISION | R | 32 | 0x0000 0000 | 0x4800 2000 | Section 6.6.2.1 |
| CONTROL_SYSCONFIG | RW | 32 | 0x0000 0010 | 0x4800 2010 | Section 6.6.2.2 |

Table 6-49 lists the PADCONFS registers.

Table 6-49. PADCONFS Registers Mapping Summary

| Register Name | Type | Register Width (Bits) | Address Offset | Physical Address | Section |
|-------------------------|------|-----------------------|----------------|------------------|-------------------------------|
| CONTROL_PADCONF_SDRC_D0 | RW | 32 | 0x0000 0000 | 0x4800 2030 | Section 6.6.3 |

6.6.2 INTERFACE Register Descriptions

Table 6-150 through Table 6-55 describe the interface register bits.

6.6.2.1 CONTROL_REVISION

Table 6-54. CONTROL_REVISION

| | | | | |
|-------------------------|--------------------------------|--|-----------------|-----------|
| Address Offset | 0x00 | | Instance | INTERFACE |
| Physical address | 0x4800 2000 | | | |
| Description | Control module Revision number | | | |
| Type | R | | | |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| RESERVED | | | | | | | | | | | | | | | | REVISION | | | | | | | | | | | | | | | |

| Bits | Field Name | Description | Type | Reset |
|------|------------|---------------------------|------|----------|
| 31:8 | RESERVED | Read returns reset value. | R | 0x000000 |
| 7:0 | REVISION | Revision number | R | - |

6.6.2.2 Control System Configuration Register (CONTROL_SYSCONFIG)
Table 6-55. Control System Configuration Register (CONTROL_SYSCONFIG)

| | | | |
|-------------------------|--|-----------------|-----------|
| Address Offset | 0x10 | Instance | INTERFACE |
| Physical address | 0x4800 2010 | | |
| Description | Set various parameters relative to the Idle mode of the Control module | | |
| Type | RW | | |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|----------|-----------|-----------|----------|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| RESERVED | | | | | | | | | | | | | | | | | | | | | | | | | | | | IDLEMODE | ENAWAKEUP | SOFTRESET | AUTOIDLE |

| Bits | Field Name | Description | Type | Reset |
|------|------------|--|------|------------|
| 31:5 | RESERVED | Read returns reset value. | R | 0x00000000 |
| 4:3 | IDLEMODE | Power Management, req/ack control 0x0: Force-idle. An idle request is acknowledged unconditionally 0x1: Reserved 0x2: Smart-idle. Acknowledgement to an idle request is given based on the internal activity of the module 0x3: Reserved | R/W | 0x0 |
| 2 | ENAWAKEUP | Wake-up enable. Not used in the module | R | 0x0 |
| 1 | SOFTRESET | Software reset. Not used in the module | R | 0x0 |
| 0 | AUTOIDLE | Internal interface clock gating strategy 0x0: Interface clock is free-running 0x1: Automatic interface clock gating strategy is applied, based on the interconnect interface activity | R/W | 0x0 |

6.6.3 PADCONFS Register Description

Each 32-bit PADCONF register gathers the configuration of two pads. For example, CONTROL.CONTROL_PADCONF_GPMC_7 is used to configure gpmc_7 pad (bits [15:0]) and gpmc_8 pad (bits [31:16]). See [Figure 6-8](#) for more information about PADCONF registers.

According to the pad type, some features are configurable or not. [Table 6-56](#) gives the description of a fully configurable pad.

Table 6-56. CONTROL_PADCONF_X

| | | | |
|-------------------------|--------------------------------|-----------------|---------------|
| Address Offset | 0x0000 0000 - 0x0000 05C8 | | |
| Physical address | See Table 6-49 | Instance | SYSC_PADCONFS |
| Description | Pad configuration register | | |
| Type | RW | | |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|----|----|--------------|----------|----|-----------------|---------------|----------|----|----------|----|----|----|----|----|----|---|--------------|----------|---|-----------------|---------------|----------|---|---|---|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

| Bits | Field Name | Description | Type | Reset |
|-------|-----------------|---|------|---------------|
| 31:25 | RESERVED | Reserved | R | 0 |
| 24 | INPUTENABLE1 | Input enable value for pad_x | R/W | 1 |
| 23:21 | RESERVED | Reserved | R | 0 |
| 20 | PULLTYPESELECT1 | Pull-Up/Down selection for pad_x: 0: Pull-Down selected 1: Pull-Up selected | R/W | Pad dependent |
| 19 | PULLUDENABLE1 | Pull-Up/Down enable for pad_x: 0: Pull-Up/Down disabled 1: Pull-Up/Down enabled | R/W | Pad dependent |
| 18:16 | MUXMODE1 | Functional multiplexing selection for pad_x | R/W | Pad dependent |
| 15:9 | RESERVED | Reserved | R | 0 |
| 8 | INPUTENABLE0 | Input enable value for pad_y | R/W | 1 |
| 7:5 | RESERVED | Reserved | R | 0 |
| 4 | PULLTYPESELECT0 | Pull-Up/Down selection for pad_y: 0: Pull-Down selected 1: Pull-Up selected | R/W | Pad dependent |
| 3 | PULLUDENABLE0 | Pull-Up/Down enable for pad_y: 0: Pull-Up/Down disabled 1: Pull-Up/Down enabled | R/W | Pad dependent |
| 2:0 | MUXMODE0 | Functional multiplexing selection for pad_y | R/W | Pad dependent |

NOTE: The Bits field gives the field number for the pairs of pads gathered in each register.

[Table 6-57](#) describes the reset values and the corresponding register for each pad.

NOTE:

- All '-' assume that the corresponding bit is not available. These bits are considered as Reserved.
 - The reset value for Reserved bits is 0.
 - In the MUX Reset States column and the PU/PD Reset States column of [Table 6-57](#), a dash (-) indicates that the field is hardwired to logic 0. No corresponding control block ports are implemented for these bits.
-

6.6.4 GENERAL Register Descriptions

[Table 6-58](#) through [Table 6-151](#) describe the GENERAL registers bits.

6.6.4.1 CONTROL_PADCONF_OFF

Table 6-58. CONTROL_PADCONF_OFF

| | | | |
|-------------------------|-------------------------------------|-----------------|---------|
| Address Offset | 0x0000 0000 | Instance | GENERAL |
| Physical address | 0x4800 2270 | | |
| Description | Off mode pad configuration register | | |
| Type | RW | | |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|------------------|----|----------|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| RESERVED | | | | | | | | | | | | | | | | WKUPCTRLCLOCKDIV | | RESERVED | | | | | | | | | | | | | |

| Bits | Field Name | Description | Type | Reset |
|------|------------------|--|------|-----------|
| 31:3 | RESERVED | Read returns reset value. | R | 0x0000000 |
| 2 | WKUPCTRLCLOCKDIV | Wkup_ctrl module clock divider 0x0: Clock is divided by 4 0x1: Clock is divided by 2 | R/W | 0x0 |
| 1:0 | RESERVED | Reserved | R | 0x0 |

6.6.4.2 CONTROL_DEVCONF0
Table 6-59. CONTROL_DEVCONF0

| | | | |
|-------------------------|--|-----------------|---------|
| Address Offset | 0x0000 0004 | Instance | GENERAL |
| Physical address | 0x4800 2274 | | |
| Description | Static device configuration register-0. Module dedicated functions | | |
| Type | R/W | | |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|----|----|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|-------------|----------|------------|-------------|-------------|-------------|-------------|---|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| RESERVED | | | | | | | | RESERVED | | | | | | | | | | | | | | | | MCBSP2_CLKS | RESERVED | MCBSP1_FSR | MCBSP1_CLKR | MCBSP1_CLKS | SENSDMAREQ1 | SENSDMAREQ0 | |

| Bits | Field Name | Description | Type | Reset |
|-------|-------------|---|------|-------|
| 31:27 | RESERVED | Reserved bits | R/W | 0x00 |
| 26 | RESERVED | Reserved bit | R/W | 0x1 |
| 25 | RESERVED | Reserved bit | R/W | 0x0 |
| 24:7 | RESERVED | Read returns reset value | R | 0x000 |
| 6 | MCBSP2_CLKS | Select the CLKS input for the module McBSP2 Note : There are no external pins McBSP2_CLKR and McBSP2_FSR for the module McBSP2. For this module, CLKR input is from the pin McBSP2_CLKX and FSR input is from the pin McBSP2_FSX 0x0: CLKS is from the PRCM functional clock 0x1: CLKS is from the external pin McBSP_CLKS | R/W | 0x0 |
| 5 | RESERVED | Read returns reset value. | R | 0 |
| 4 | MCBSP1_FSR | Select the FSR input for the module McBSP1 0x0: FSR is from the pin McBSP1_FSR 0x1: FSR is from the pin McBSP1_FSX | R/W | 0x0 |
| 3 | MCBSP1_CLKR | Select the CLKR input for the module McBSP1 0x0: CLKR is from the pin McBSP1_CLKR 0x1: CLKR is from the pin McBSP1_CLKX | R/W | 0x0 |
| 2 | MCBSP1_CLKS | Select the CLKS input for the module McBSP1 0x0: CLKS is from the PRCM functional clock 0x1: CLKS is from the external pin McBSP_CLKS | R/W | 0x0 |
| 1 | SENSDMAREQ1 | Set sensitivity on SYS_NDMAREQ1 input pin 0x0: Level sensitivity 0x1: Edge sensitivity | R/W | 0x0 |
| 0 | SENSDMAREQ0 | Set sensitivity on SYS_NDMAREQ0 input pin 0x0: Level sensitivity 0x1: Edge sensitivity | R/W | 0x0 |

6.6.4.3 CONTROL_MEM_DFTRW0
Table 6-60. CONTROL_MEM_DFTRW0

| | | | |
|-------------------------|---|-----------------|---------|
| Address Offset | 0x0000 0008 | Instance | GENERAL |
| Physical address | 0x4800 2278 | | |
| Description | DFT Read and Write Controls for memory blocks | | |
| Type | R/W | | |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|-------------------|-------------------|---------------------|--------------------|----------|---------------------|--------------------|-------------------|---------------------|--------------------|---|---|---|---|---|---|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

|-------|--------------------|--|------|-------|
| 31:27 | Reserved | Reserved | R | 0 |
| 26 | VDD_HVMODEOUT | IO Voltage detect cell (CQdetect) output: 0 : 1.8V IO operation 1 : 3.3V IO operation | R | |
| 25:24 | Reserved | Reserved. | R | 0 |
| 23 | USBPHY_GPIO_MODE | Selects the GPIO mode of USB PHY 0 : USB PHY normal mode operation 1 : UART3 Tx/Rx are coming on DP and DM pins of USBPHY | R/W | 0 |
| 22:20 | Reserved | Reserved | R | 0 |
| 19 | FUNC_SYS32K_SEL | Sys_boot7 value 0 : External 32K Oscillator is selected 1 : Internal 32K clock is selected which is derived from sys clock divided by 800 | R | |
| 18 | FUNC_MODE_SEL | Sys_boot8 value 0 : Normal mode DDR 32 Bit 1 : Reduced package mode DDR 16 Bit | R | |
| 17 | Reserved | Reserved | R | 0 |
| 16 | FUSE_AVDAC_DISABLE | Goes high when AVDAC is disabled using efuse. 0 : AVDAC Disabled 1 : AVDAC Enabled | R | |
| 15:14 | USBOTG_OTGMODE | These two bits will control whether the USB2.0 PHY comparators for VBUS and ID pins are used to drive the VBUSVALID, SESSVALID, SESEND [3 different levels on VBUS in] and the IDDIG [ID pin value] to the USB controller. In cases where OTG is not needed, it may be more convenient to configure VBUS and ID from MMRs than actually having to drive the VBUS and ID pins to specific levels. Encoding is: | R/W | 3 |

| Bits | Field Name | Description | Type | Reset |
|------|------------------------|---|------|-------|
| | | OTGMODE = 00 : Do not override phy values. Let PHY drive signals to controller based on its comparators for the VBUS and ID pins. OTGMODE = 01 : Override phy values to force USB Host Operation OTGMODE = 10 : Override phy values to force USB Device Operation OTGMODE = 11 : Override phy values to force USB Host Operation with VBUS low | | |
| 13 | USBOTG_SESENDEEN | 1 : Will turn on the Session end comparator | R/W | 0 |
| 12 | USBOTG_VBUSDETECTEN | 1 : Will turn on all comparators (except session end comparator) on the vbus line | R/W | 0 |
| 11:8 | USBOTG_SELINPUTCLKFREQ | USB PHY PLL reference clock frequency 0001 : Reserved 0010 : Reserved 0011 : Reserved 0100 : Reserved 0101 : Reserved 0110 : Reserved 0111 : sys_clk 1000 : Reserved 1001 : Reserved | R/W | 7 |
| 7 | USBOTG_PWRCLKGOOD | Goes high when Clock is present from oscillator, all power sources are good and PLL is locked. | R | - |
| 6 | USBOTG_VBUSSENSE | Detects the presence of VBUS irrespective of the VDDA supplies. Goes high when VBUS goes above a threshold. | R | - |
| 5 | USBOTG_PHY_PLLON | 0 : Turn off USB PHY PLL 1 : Turn on the USB PHY PLL | R/W | 0 |
| 4 | USBOTG_PHY_RESET | 0 : USB PHY is out of Reset 1 : USB PHY is in Reset | R/W | 1 |
| 3 | USBOTG_PHY_PD | 0 : USB PHY is Power Up 1 : USB PHY Power down | R/W | 1 |
| 2 | USBOTG_POWERDOWNOTG | 0 : Power up the OTG module of USB PHY 1 : Power down the OTG module of USB PHY | R/W | 1 |
| 1 | USBOTG_DATAPOLARITY | 0 : Inverted polarity 1 : Normal polarity | R/W | 1 |
| 0 | VPFE_PCLK_INVERT_EN | 0 : Do not Invert the pclk clock coming from IO buffer and going to VPFE module 1 : Invert the pclk clock coming from IO buffer and going to VPFE module | R/W | 0 |

NOTE: DSI is not available on all devices. See Chapter 1, the *Device Family* section, to check availability of this module.

6.6.5 MEM_WKUP Register Descriptions

0x4800 2600 to 0x4800 29FC physical addresses are memories mapped for save and restore location (1Kbytes).

- 0x4800 2600 - 0x4800 2830: non accessible (pad configuration)
- 0x4800 2834 - 0x4800 29FC: user accessible

6.6.6 PADCONFS_WKUP Register Description

Each 32-bit PADCONF register gathers the configuration of two pads. For example, CONTROL.CONTROL_PADCONF_GPMC_7 is used to configure gpmc_7 pad (bits [15:0]) and gpmc_8 pad (bits [31:16]). See [Figure 6-8](#) for more information about PADCONF registers.

According to the pad type, some features are configurable or not. [Table 6-56](#) gives the description of a fully configurable pad.

[Table 6-152](#) describes the reset values, the capabilities, and the corresponding register for each pad.

NOTE:

- All '-' assume that the corresponding bit is not available. These bits are considered as Reserved.
 - The reset value for Reserved bits is 0.
 - In the MUX Reset States and PU/PD Reset States columns of [Table 6-152](#), a dash (-) indicates that the field is hardwired to logic 0. No corresponding control block ports are implemented for these bits.
-

Table 6-152. CONTROL_PADCONF_WKUP_CAPABILITIES

6.7 Revision History

Table 6-171 lists the changes made since the previous version of this document.

Table 6-171. Document Revision History

| Reference | Additions/Modifications/Deletions |
|------------------|--|
| Global | Removed CONTROL_SEC_CTRL register. |
| Global | Removed the CONTROL_GENERAL_PURPOSE_STATUS register. |
| Global | Removed CONTROL_MSUSPENDMUX_3 register. |
| Global | Changed CONTROL_CBA_PRIORITY address offset from 0x0000 031C to 0x0000 0320. |
| Global | Changed CONTROL_CBA_PRIORITY physical address from 0x4800 258C to 0x4800 2590. |
| Global | Changed CONTROL_LVL_INTR_CLEAR address offset from 0x0000 031C & 0x0000 0320 to 0x0000 0324. |
| Global | Changed CONTROL_LVL_INTR_CLEAR physical address from 0x4800 258C & 0x4800 2590 to 0x4800 2594. |
| Global | Changed CONTROL_IP_SW_RESET address offset from 0x0000 0320 & 0x0000 0324 to 0x0000 0328. |
| Global | Changed CONTROL_IP_SW_RESET physical address from 0x4800 2590 & 0x4800 2594 to 0x4800 2598. |
| Global | Changed CONTROL_IPSS_CLK_CTRL address offset from 0x0000 0324 & 0x0000 0328 to 0x0000 032C. |
| Global | Changed CONTROL_IPSS_CLK_CTRL physical address from 0x4800 2594 & 0x4800 2598 to 0x4800 259C. |
| Global | Deleted reserved register CONTROL_DEVCONF4. |
| Global | Changed CONTROL_PADCONF_SDR_CKE physical address from 0x4800 2260 to 0x4800 2264. |
| Global | Changed CONTROL_PADCONF_SDR_CKE address offset from 0x0000 0230 to 0x0000 0234. |
| Global | Changed CONTROL_PADCONF_SDR_CKE0 physical address from 0x4800 2260 to 0x4800 2264. |
| Global | Changed CONTROL_PADCONF_SDR_CKE0 address offset from 0x0000 0230 to 0x0000 0234. |
| Global | Changed CONTROL_PADCONF_SDR_CKE1 physical address from 0x4800 2260 to 0x4800 2264. |

7.1 SDMA Module Overview

The System Direct Memory Access (SDMA), also called DMA4, performs high-performance data transfers between memories and peripheral devices without microprocessor unit (MPU) support during transfer. A DMA transfer is programmed through a logical DMA channel, which allows the transfer to be optimally tailored to the requirements of the application.

The device also embeds dedicated DMA controllers: the camera image signal processor (ISP) DMA; the enhanced DMA (EDMA), which is embedded in the IVA2.2 subsystem; the display DMA; and the universal serial bus (USB) high-speed (HS) DMA. For more information, see , *Camera ISP Subsystem*; , *IVA Subsystem*; [Chapter 12, Display Subsystem](#); and [Chapter 20, High-Speed USB Controllers](#).

The DMA controller includes the following main features:

- Data transfer support in either direction between:
 - Memory and memory
 - Memory and peripheral device
- 32 logical DMA channels supporting:
 - Multiple concurrent transfers
 - Independent transfer profile for each channel
 - 8-bit, 16-bit, or 32-bit data element transfer size
 - Software-triggered or hardware-synchronized transfers
 - Flexible source and destination address generation
 - Burst read and write
 - Chained multiple-channel transfers
 - Endianism conversion
- First-come, first-serve DMA scheduling with fixed priority
- Up to 96 DMA requests
- Constant fill
- Transparent copy
- Four programmable interrupt request output lines
- Software or hardware enabling
- FIFO depth: 256 x 32-bits
- Data buffering
- FIFO budget allocation
- Power-management support
- Auto-idle power-saving support
- Implementation of retention flip-flops (RFFs) to support dynamic power saving (DPS) between system power modes without MPU involvement

[Figure 7-1](#) shows an overview of the SDMA module.

Figure 7-1. SDMA Overview

DMA-001

The SDMA module has two ports—one read and one write—and provides multiple logical channel support. A dynamically allocated FIFO queue memory pool provides buffering between the read and write ports.

The MPU configures the SDMA through the L4 interconnect.

7.2 SDMA Controller Environment

7.2.1 Environment Overview

The read and write ports of the SDMA controller are connected to the device through the L3 interconnect. The control port is connected to the L4 interconnect. The SDMA interrupt lines are connected to the interrupt lines of the MPU interrupt controller. The SDMA can handle up to 96 DMA requests, including four external hardware DMA requests.

7.2.2 SDMA Request Scheme

The hardware DMA request line schemes can be either edge-sensitive or transition-sensitive.

The sensitivity selection of the DMA request line can be configured in the system control module with the following register bits:

- CONTROL.CONTROL_DEVCONF0[0] SENSDMAREQ0 register bit for sys_ndmareq0
- CONTROL.CONTROL_DEVCONF0[1] SENSDMAREQ1 register bit for sys_ndmareq1
- CONTROL.CONTROL_DEVCONF1[7] SENSDMAREQ2 register bit for sys_ndmareq2
- CONTROL.CONTROL_DEVCONF1[8] SENSDMAREQ3 register bit for sys_ndmareq3

The default scheme is transition sensitive. All internal peripherals of the device use the transition-sensitive scheme.

Figure 7-2 shows the DMA request captured on a falling edge in the edge-sensitive scheme.

Figure 7-2. Edge-Sensitive DMA Request Scheme

108-013

For a transition-sensitive DMA request (see Figure 7-3), the line must be maintained low (asserted) until the first DMA access is complete, after which the line must be maintained high (deasserted) for a minimum of one clock cycle (CORE_L3_ICLK):

When the deassertion time is less than one clock cycle, the SDMA might not detect the deassertion.

When the channel is enabled one cycle after a DMA request is disabled, the channel detects the DMA request and starts the corresponding transfer.

When the channel is enabled two cycles after the DMA request is disabled, the channel does not detect the DMA request.

Figure 7-3. Transition-Sensitive DMA Request Scheme

108-012

7.3 SDMA Module Integration

Figure 7-4 highlights the SDMA controller integration.

Figure 7-4. SDMA Controller Integration

7.3.1 External SDMA Request Interface Description

The sys_ndmareq pins are optional external DMA requests used by external devices to establish direct hardware synchronization with the SDMA controller. A logical channel can be configured to respond to an external synchronization request. These requests can be configured to either active low on level or falling edge active by the control module.

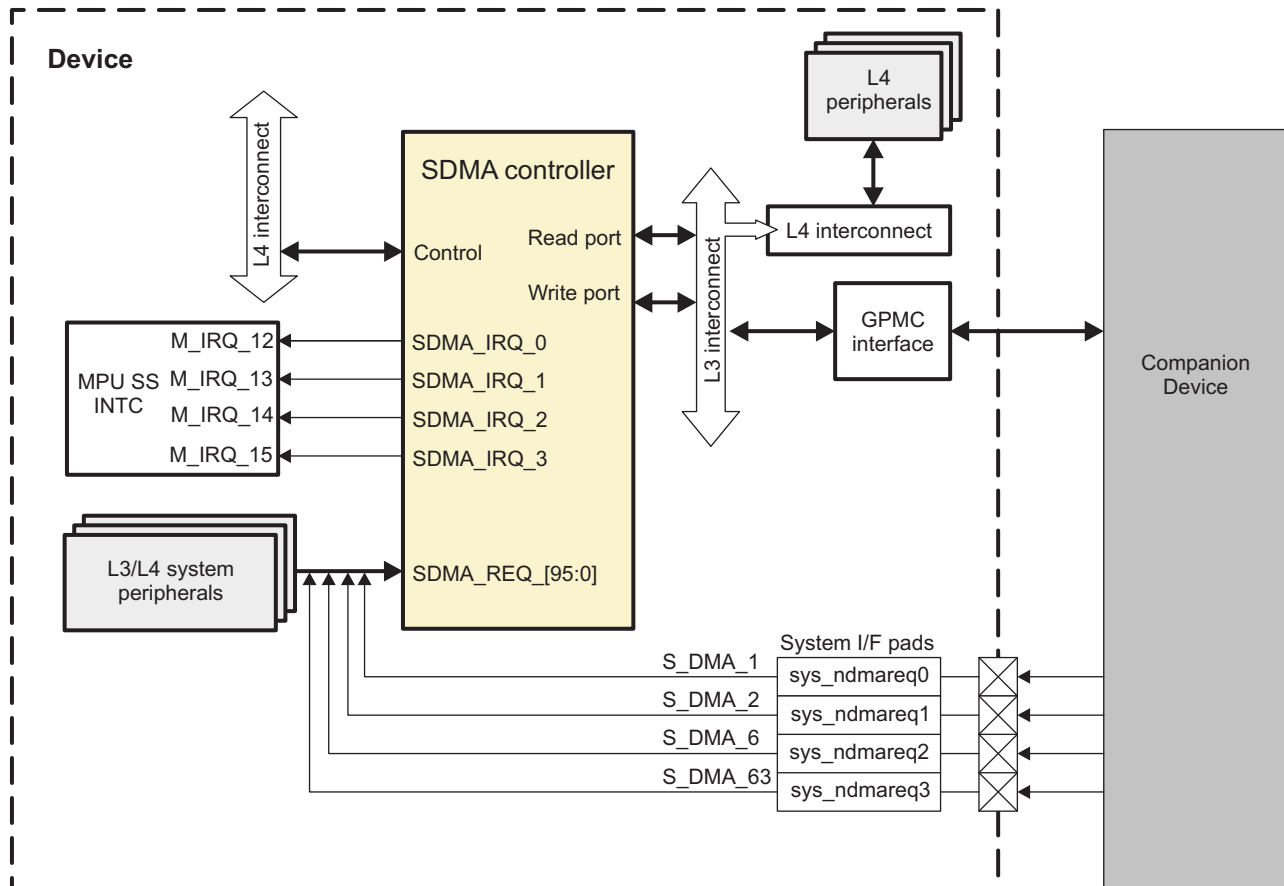

Table 7-1 shows the I/O description of the external DMA request pin.

Table 7-1. Description External DMA Request Pin

| Signal Name | IO | Description | Reset |
|--------------|----|---|---------|
| sys_ndmareq0 | I | External DMA request to the SDMA controller | Unknown |
| sys_ndmareq1 | I | External DMA request to the SDMA controller | Unknown |
| sys_ndmareq2 | I | External DMA request to the SDMA controller | Unknown |
| sys_ndmareq3 | I | External DMA request to the SDMA controller | Unknown |

Figure 7-5 shows the SDMA environment with an example of how to use the external hardware DMA request pins.

Figure 7-5. Example of External DMA Requests Use to the SDMA Controller

dma-003

For example, an external device can use the external DMA request pins to start a logical channel transfer over the general-purpose memory controller (GPMC) interface. The transfer can be a memory-to-memory transfer in which the source memory is in the external device.

The external DMA request signals are not available on external pins by default after cold reset. See [Chapter 6, System Control Module](#), for instructions on multiplexing out the seven signal lines to pins.

7.3.2 Clocking, Reset, and Power-Management Scheme

7.3.2.1 Clocking

The SDMA controller uses two clock domains:

- CORE_L4_ICLK supports the configuration port.
- CORE_L3_ICLK is both a functional clock for all internal logic and for the two master read and write ports.

The SDMA controller supports a software-controlled standby mode with an input clock shutoff. Setting the PRCM.CM_IDLEST1_CORE[2] ST_DMA status bit to 1 allows detection of the SDMA power mode.

For more information about power management and clock idle, see [Section 7.4.20, Power Management](#).

7.3.2.2 Resets

7.3.2.2.1 Asynchronous Hardware Reset

The SDMA controller is part of the CORE_RST reset domain.

7.3.2.2.2 Software Reset Through the Configuration Port

The SDMA controller can be reset independently by software through the SDMA.DMA4_OCP_SYSCONFIG[1] SOFTRESET bit. Setting the bit to 1 enables an active software reset that is functionally equivalent to a hardware reset.

Hardware and software resets initialize all of the logic in the SDMA module and the global registers and some of the per-channel registers (such as the enable bit hardware request line number and link bit field) implemented in flip-flops. However, all remaining per-channel registers are memory-based and, therefore, are not reset.

7.3.2.3 Power Domain

The SDMA controller is part of the CORE power domain.

7.3.3 Hardware Requests

7.3.3.1 Interrupts to the MPU Subsystem

DMA4 has four interrupt lines, numbered L_j with $j=0..3$. Each logical channel can request an interrupt over any line. The attachment of a channel interrupt event to one of these four external lines is programmable. The software determines whether it attaches a channel interrupt to a single IRQ line or to multiple IRQ lines.

There are two different registers per interrupt line:

- SDMA.DMA4_IRQSTATUS_Lj CH_31_0_Lj field shows the status of the different sources of interrupt. If the SDMA.DMA4_IRQENABLE_Lj bit i is 1, the channel i is the source of interrupt in line j . In contrast to the SDMA.DMA4_CSRi registers, the SDMA.DMA4_IRQSTATUS_Lj registers are updated regardless of the corresponding bits in the SDMA.DMA4_IRQENABLE_Lj registers.
- SDMA.DMA4_IRQENABLE_Lj CH_31_0_Lj_EN field masks/unmasks the channel interrupt. If the SDMA.DMA4_IRQENABLE_Lj bit i is set to 0, the channel interrupt i of the line j is masked.

Each logical channel can generate 10 different interrupt events when enabled (that is, set to 1) in the SDMA.DMA4_CICRi register. Each status bit is updated in the SDMA.DMA4_CSRi register only when the corresponding enable bit is enabled in the SDMA.DMA4_CICRi register.

To determine an interrupt source when an interrupt rises on an interrupt line L_j , you must:

- Identify the channel (LCH_i) generating the interrupt.
Read the SDMA.DMA4_IRQSTATUS_Lj.LCHi (LCH0 to LCH31). If $LCH_i = 1$, channel i is the originator of the interrupt.
- Identify the interrupt event.
Read the LCH_i SDMA.DMA4_CSRi. For example, if the drop event (the SDMA.DMA4_CSRi[1] DROP bit) is 1, there will be a request collision.
The interrupt event status bit in the SDMA.DMA4_CSRi register is immediately reset after it is written to 1.
The interrupt status bit in the SDMA.DMA4_IRQSTATUS_Lj register is cleared after it is written to 1.

Table 7-2 shows how the SDMA module interrupt lines are connected to the interrupt lines of the MPU interrupt controller.

Table 7-2. SDMA Interrupt Mapping to the MPU Subsystem

| IRQ | Source | Description |
|----------|------------|--------------------------|
| M_IRQ_12 | SDMA_IRQ_0 | SDMA interrupt request 0 |
| M_IRQ_13 | SDMA_IRQ_1 | SDMA interrupt request 1 |
| M_IRQ_14 | SDMA_IRQ_2 | SDMA interrupt request 2 |
| M_IRQ_15 | SDMA_IRQ_3 | SDMA interrupt request 3 |

7.3.3.2 DMA Requests to the SDMA Controller

This section gives information about all modules and features in the high-tier device. See [Section 1.4, Device Family](#), to check availability of modules and features. Ensure that DMA requests of unavailable modules and features are masked in DMA subsystems.

All peripherals internal to the device use the transition-sensitive scheme for DMA requests. For more information on the transition-sensitive scheme, see [Section 7.2.2, SDMA Request Scheme](#). [Table 7-3](#) lists the SDMA request mapping.

7.4 SDMA Functional Description

The SDMA module provides high-performance data transfers between memories and peripheral devices with low processor use. A DMA transfer is programmed through a logical DMA channel, which allows the transfer to be optimally tailored to the requirements of the application.

Figure 7-6 shows the SDMA controller top-level block diagram.

Figure 7-6. SDMA Controller Top-Level Block Diagram

108-005

7.4.1 Logical Channel Transfer Overview

As Figure 7-6 shows, the SDMA module has one read port and one write port operating independently of each other. Buffering is provided between the read and write ports through a FIFO queue memory pool that is shared dynamically between the active logical channels.

- Logical channel synchronization
A logical channel is described as hardware-synchronized when the DMA transfers are triggered by DMA requests from a hardware device. Alternatively, a logical channel is described as nonsynchronized when the DMA transfer is triggered by software.
- Logical channel activation
A logical channel becomes active as follows:

- For hardware-synchronized transfers, when the logical channel is enabled and the hardware DMA request line is asserted
- For software-triggered (nonsynchronized) transfers, as soon as software enables the logical channel
- Logical channel transfer composition

A DMA transfer is divided automatically into a number of transactions. Depending on the logical channel context configured, transfer size, the start address alignment, the addressing mode, and the configured maximum burst size, each transaction can be either a single access or a burst of accesses.
- Logical channel scheduling

When several logical channels are active at the same time, schedulers manage the read and write ports. The scheduling of logical channel transfers is similar for both read and write ports. When a logical channel becomes active, it is added to the tail of a scheduling queue. If more than one logical channel becomes active at the same time, the one with the lower number is queued first. This mechanism provides a first-come, first-serve scheduling scheme between the concurrently active logical channels.

In addition, each read and write port has a high-priority queue and a low-priority queue. The priority bit in the logical channel `SDMA.DMA4_CCRi` register determines if a logical channel is queued as high or low priority. The relative weighting of the scheduling of the high-priority queue to the low priority queue is programmable from 1:1 to 1:256 through the DMA global channel register (`SDMA.DMA4_GCR`).

NOTE: The `SDMA.DMA4_GCR[23:16]` `ARBITRATION_RATE` field is not dependent on the `SDMA.DMA4_GCR[13:12]` `HI_THREAD_RESERVED` field. The `ARBITRATION_RATE` field is dependent on the `SDMA.DMA4_CCRi[26]` `WRITE_PRIORITY` bit and the `SDMA.DMA4_CCRi[6]` `READ_PRIORITY` bit.

- Read/write port access scheduling policy

When either the read or write port becomes available, the port access scheduler selects the next logical channel for which to perform a DMA transaction from either the high- or low-priority queue. When the current DMA transaction (single or burst access) is complete and the full DMA transfer is not finished, the logical channel returns to the tail of the queue. Because the port access scheduling is on a per-transaction basis, a logical channel can be queued repeatedly this way several times during a single transfer.

The SDMA module can have up to four outstanding read transactions and two outstanding write transactions in the system interconnect; four read and two write thread IDs exist. For an arbitration cycle to occur, these two conditions must be met:

- At least one channel is requesting.
- At least one free thread ID is available.

On an arbitration cycle, the scheduler grants the highest priority channel that has an active request, allocates the thread ID, and tags this thread as busy. At a given time, a channel cannot be allocated for more than one thread ID.

NOTE: If more than one channel is active, each channel is given a thread ID for the current service only, not for the whole channel transfer.

When only one channel is active, one thread ID is allocated during the channel transfer. The access can be up to a 16 x 32-bit access (that is, 16 32-bit single access, four bursts of 16bytes, two bursts of 32bytes, or one burst of 64bytes) without rescheduling the channel at the end of each burst transfer.

When nonburst alignment is at the beginning of the transfer, the channel is rescheduled for each smaller access until burst-aligned. When the end of the transfer is not burst-aligned, the channel is rescheduled for each of the remaining smaller accesses.

For a logical channel transfer completion, when the last access is written to the destination, the logical channel becomes inactive. If enabled, an interrupt request is generated (see [Section 7.4.12, Interrupt Generation](#)).

7.4.2 FIFO Queue Memory Pool

A FIFO queue memory pool provides buffering between the read and write ports. The hardware allocates the space dynamically to a number of FIFO queues, and each queue is associated with an active logical channel.

To avoid a memory pool overflow, if there are fewer entries in the FIFO queue memory pool than are required for the maximum configured source burst size of the next logical channel to be scheduled, the logical channel is returned to the tail of the queue, and the port access scheduler continues to search the queue until it finds a logical channel that can be scheduled.

The maximum FIFO depth that can be allocated to each individual logical channel can be limited globally through the `SDMA.DMA4_GCR` register. This value should be configured to allow a fair allocation of the memory pool between the active channels.

A logical channel is scheduled if it has not yet reached its allocation limit, even if the access to be performed will exceed this limit. This means that the effective number of entries used by a particular logical channel is limited to the configured maximum entries per channel + channel maximum configured burst size (in words) - 1.

7.4.3 Addressing Modes

A DMA transfer block consists of a number of frames (FN). Each frame consists of a number of elements, and each element can have a size of 8, 16, or 32 bits, as follows:

transfer block size = number of frames x number of elements per frame x element size

The FN, number of elements per frame (EN), and size of elements are common for both the source and destination. However, the way in which the data is represented (addressing profile/mode) is independently programmable for the source and destination devices, using one of these four addressing modes:

- Constant: The address remains the same for consecutive element accesses.
- Post-increment: The address increases by the element size (ES), even across consecutive frames.
- Single-index: The address increases by the ES, plus the element index (EI) value minus one (even across consecutive frames).
- Double-index: The address increases by the ES, plus the EI value minus one within a frame. When a full frame is transferred, the address increases by the ES plus the frame index (FI) value minus 1.

The ES, EI, and FI values are expressed in bytes. The EI and FI values can be positive or negative.

When calculating the EI and FI values, it is critical to note that, after an element is accessed, the logical channel address pointer equals the address of the last byte (highest address) of the accessed element. The correct value for the EI or FI should be such that, when added to the logical channel address pointer, results in the address of the first byte (lowest address) of the next element to be accessed.

The EI and FI values must be configured so that the address of each element in the transfer is aligned on an ES boundary.

Consequently, the single-index addressing mode with EI = 1 or double-index addressing mode with EI = 1 and FI = 1 is equivalent to post-increment addressing.

NOTE: The source and destination start addresses must also be aligned on an ES boundary.

When the address of an element to be accessed is not aligned on an ES boundary, the transfer is stopped and an address error interrupt occurs, if enabled (see [Section 7.4.12, Interrupt Generation](#)).

The `SDMA.DMA4_CFNi` register configures the FN in a block.

The `SDMA.DMA4_CENi` register configures the EN.

The `SDMA.DMA4_CSDPi` register configures the ES.

The `SDMA.DMA4_CSSAi` and `SDMA.DMA4_CDSAi` registers configure the source and destination start addresses.

The `SDMA.DMA4_CCRi` register configures the source and destination addressing modes.

The SDMA.DMA4_CSEi, SDMA.DMA4_CSF_i, SDMA.DMA4_CDEi, and SDMA.DMA4_CDF_i registers configure the source EI, source FI, destination EI, and destination FI, respectively.

The addressing profiles are expressed as equations as follows:

Equation 1. Constant addressing:

$$A(n+1) = A(n)$$

Equation 2. Post-increment addressing:

$$A(n+1) = A(n) + ES$$

Equation 3. Single-indexed addressing:

$$A(n+1) = A(n) + ES + (EI - 1)$$

Equation 4. Double-indexed addressing:

When not at the end of a frame or transfer (that is, when the element counter $\neq 0$):

$$A(n+1) = A(n) + ES + (EI - 1)$$

When at the end of a frame but not at the end of the transfer (that is, when the element counter = 0 and the frame counter $\neq 0$):

$$A(n+1) = A(n) + ES + (FI - 1)$$

Calculate the element and frame index as follows:

Equation 5. Element index

$$EI = [(Stride EI - 1) * ES] + 1$$

Equation 6. Frame index

$$FI = [(Stride FI - 1) * ES] + 1$$

where:

A(n): Byte address of the element n within the transfer.

ES is in bytes, ES \in {1, 2, 4}.

EI is in bytes, specified in a configuration register, $-32768 \leq EI \leq 32767$.

Stride EI: The difference in the number of elements between the start of the current element, n, to the start of next element, n+1.

Element counter: A counter that is (re)initiated with the number of elements per frame or per transfer. Decreased by 1 for each element transferred. The initial value is configured in the register DMA channel element number, SDMA.DMA4_CEN_i.

F is in bytes, specified in a configuration register, $-2147483648 \leq FI \leq 2147483647$.

Stride FI: The difference in the number of elements between the start of the last element of the current frame and the beginning of the first element of the next frame.

Frame counter: A counter that is (re)initiated with the FN per transfer. Decreased by 1 for each frame transferred. The initial value is configured in the register DMA channel frame number, SDMA.DMA4_CFN_i.

Figure 7-7 shows how a stride EI and FI are defined. When handling complex configurations, using strides can make it easier to calculate EI and FI because you can calculate in elements instead of bytes. (This approach is used in the 90Degrees clockwise image rotation example shown in Figure 7-11.) The double-index addressing example shown in Figure 7-7 has ES = 4, EN = 2, EI = 5, FI = 5, and FN = 2.

Figure 7-7 through Figure 7-10 show examples of addressing mode configurations. Table 7-4 lists parameter values for the examples.

Figure 7-7. Example Showing Double-Index Addressing, Elements, Frames, and Strides

Figure 7-9. Addressing Mode Example (b)

108-009

Figure 7-10. Addressing Mode Example (c)

108-008

Table 7-4. Parameter Values for Addressing Mode Examples (a), (b), and (c)

| Parameter | Example (a) | Example (b) | Example (c) |
|-----------------|----------------------------------|--------------|--------------|
| Addressing mode | Single index (or post-increment) | Double index | Double index |
| Start address | 0 | 0 | 8 |
| ES | 4 (32-bit) | 4 (32-bit) | 2 (16-bit) |
| EN | 3 | 2 | 2 |
| EI | 1 | 5 | 1 |
| FN | 1 | 2 | 2 |
| Frame index | N/A | 5 | -9 |

Double indexing can occur either on source (read) or destination (write). Equations for rotation of xx degrees on destination are obtained by taking equations for rotation of $(360-xx)$ degrees on source, and swapping x and y in them. The opposite is also true. Table 7-5 list the equations for rotation for 90, 180 and 270°.

Table 7-5. Equations for Rotation

| | | 90° Rotation | 180° Rotation | 270° Rotation |
|--|--------------------|----------------------|---------------|----------------------|
| Double indexing on destination (write) | Base address | $ES*(y-1)$ | $ES*(x*y-1)$ | $ES*y*(x-1)$ |
| | Element index (EI) | $ES*(y-1)+1$ | $1-2*ES$ | $1-ES*(y+1)$ |
| | Frame index (FI) | $1 - ES*[(x-1)*y+2]$ | $1-2*ES$ | $1+ES*(x-1)*y$ |
| Double indexing on source (read) | Base address | $ES*x*(y-1)$ | $ES*(x*y-1)$ | $ES*(x-1)$ |
| | Element index (EI) | $1-ES*(x+1)$ | $1-2*ES$ | $ES*(x-1)+1$ |
| | Frame index (FI) | $1+ES*(y-1)*x$ | $1-2*ES$ | $1 - ES*[(y-1)*x+2]$ |

Table 7-6 and Figure 7-11 show the configuration required to perform a 90° clockwise image rotation of a 240 x 160 pixel, 32-bit image. The EI, frame size, and FI values are configured so that the image is rotated line by line starting at the left-hand end of the top line.

NOTE: The FI value for the destination is negative so that the first pixel of each subsequent line of the source image is written to the correct location at the destination.

Equation 5 and Equation 6 calculate the destination FI and EI. The example assumes that the image lines are stored at consecutive addresses in memory, meaning that both EI and FI on the source side are 1.

Rotations:

Section 7.5.7, *90° Clockwise Image Rotation*, describes how to program this example.

Observe that:

- One pixel = one element
- One line = one DMA frame
- Pixel size = element size = ES

Table 7-6. Example Parameter Values for a 90° Clockwise Image Rotation

| Parameter | Source Value | Destination Value |
|-----------------------------|----------------------------------|--|
| Bits per pixel | 32 | 32 |
| ES | 4 | 4 |
| Image width | SW | SH |
| Image height | SH | SW |
| Stride elements (stride EI) | 1 element | SH |
| Stride frames (stride FI) | 1 element | $-[(SW-1)*SH+1] = -38241$ elements |
| Start address | 0x100000 | $0x200000 + (SH - 1) \times ES = 0x20027C$ |
| EN | SW | SW |
| EI | $[(Stride EI - 1) * ES] + 1 = 1$ | $[(Stride EI - 1) * ES] + 1 = 637$ |
| FN | SH | SH |
| FI | $[(Stride FI - 1) * ES] + 1 = 1$ | $[(Stride FI - 1) * ES] + 1 = -152967$ |

Figure 7-11. Example of a 90° Clockwise Image Rotation

7.4.4 Packed Accesses

When the logical channel ES is less than the DMA module read/write port size, and the addressing profile supports it (that is, post-increment mode or single- or double-index mode with EI = 1), the number of elements to transfer in each read/write port access may be maximized by specifying that the source or destination is packed through the channel SDMA.DMA4_CSDPi register. Thus:

- For a read/write port size of 32 bits, the source or destination can be configured as packed for transfer ESs of 8 bits (four elements per access) and 16 bits (two elements per access).
- For a read/write port size of 64 bits, the source or destination can be configured as packed for transfer ESs of 8 bits (eight elements per access), 16 bits (four elements per access), and 32 bits (two elements per access).

Depending on the start address and transfer length, the first or last packed access might be only partially filled. This is indicated to the source or destination using the byte-enable signals.

NOTE: When a constant addressing mode is specified, only nonpacked accesses are used, and specifying the accesses as packed has no effect.

7.4.5 Burst Transactions

Transfer performance can be improved, where the source or destination and addressing profile supports it, by configuring the logical channel to perform burst transactions consisting of multiple instead of single accesses. The channel can be programmed to use burst sizes equivalent to 16, 32, or 64 bytes through the `SDMA.DMA4_CSDPi` register, with the read burst size being programmable independently of the write burst size. Typically, the optimal burst size is 64 bytes (16 accesses for a 32-bit read/write port size or 8 accesses for a 64-bit read/write port size).

To obtain the maximum benefit from burst transactions, the source and destination start addresses should be aligned with the burst size. If this is not the case, the start of the transfer can consist of a number of smaller (single or burst) transactions until the first burst size boundary is reached.

Similarly, if the end of the transfer is not aligned on a burst size boundary, the final part of the transfer can consist of a number of smaller transactions.

NOTE: Except in the constant addressing mode, the source or destination must be specified as packed for burst transactions to occur.

7.4.6 Endianism Conversion

The source and destination are each specified as little-endian or big-endian through the `SDMA.DMA4_CSDPi` register for the particular logical channel. If the endianism of the source and destination differ, and the logical channel ES is less than the SDMA module read/write port size, an endianism conversion is applied to the data before it is written to the destination.

When transferring data between a source and a destination with different endianism, it is important to specify an ES that is equal to the type of data being transferred to preserve the correct data image at the destination.

In the system, endianism conversion can be performed in more than one place. It is possible to inform the source and/or destination to lock the endianism (that is, to not perform a conversion) through the logical DMA channel `SDMA.DMA4_CSDPi` register.

7.4.7 Transfer Synchronization

A logical channel can be programmed for either software-triggered or hardware synchronized transfers.

7.4.7.1 Software Synchronization

A transfer is software-triggered when the logical channel is set up and started by software. To specify a software-triggered transfer, set the channel DMA register bits `SDMA.DMA4_CCRi[4:0]` and `SDMA.DMA4_CCRi[20:19]` to 0. The transfer starts as soon as the DMA register bit `SDMA.DMA4_CCRi[7]` is set (that is, enters the scheduling process).

7.4.7.2 Hardware Synchronization

A transfer is hardware-synchronized if the logical channel activation is driven by hardware requests from either the source or destination target. A hardware synchronized transfer is specified by configuring the DMA request line number in the channel `SDMA.DMA4_CCRi` register to a value that corresponds to the DMA request line from the source or destination that generates the DMA requests. The DMA request numbers to be configured are specified in the DMA request mapping (see [Table 7-8](#)).

Specify the DMA request number in the channel DMA register bits `SDMA.DMA4_CCRi[4:0]` and `SDMA.DMA4_CCRi[20:19]`. After the DMA register bit `SDMA.DMA4_CCRi[7]` is set, the logical channel becomes enabled but not activated (that is, it does not enter the scheduling process), which means that channel registers are not updated until the first DMA request is received.

NOTE: DMA Request Line

A DMA request line must not be shared between concurrently enabled DMA channels. However, a DMA request line can be shared between several chained logical channels.

The channel synchronization control registers are 1-based. For example, to enable the `S_DMA_1` request, `SDMA.DMA4_CCRi[4:0]` `SYNCHRO_CONTROL` must be set to `0x2` (DMA request number + 1).

For hardware synchronization, the amount of data to be transferred for each assertion of the DMA request line is configured through the frame synchronization (FS) and block synchronization (BS) bits in the logical channel `SDMA.DMA4_CCRi` register and the DMA register bits `SDMA.DMA4_CCRi[5]` and `SDMA.DMA4_CCRi[18]`, respectively.

The amount of data can be any of the following:

- A single element transfer: A complete element defined by `Data_type`. For example, 8/16/32 bits are transferred in response to a DMA request.
- A full frame: A complete frame of several elements is transferred in response to a DMA request.
- A full block (a full channel transfer): A complete block of several frames is transferred in response to a DMA request.
- A full packet (a full channel transfer): A complete packet of several elements is transferred in response to a DMA request.

Packets allow the size of each part of the full DMA transfer to be configured independent of the organization of the data to be transferred (typically a number of elements). This can be useful when the source or destination has a buffer (such as a FIFO queue) with a size unrelated to the frame size of the transfer. The packet size then can be set to the size of the buffer.

Packet transfer must be used only where the source or destination is addressed in constant addressing mode, because FI registers are reused to specify size of the packet.

To support the burst mode, the logical channel must also be configured to use the source-port packed access mode. The packed address mode cannot be used with a constant address mode: it must be configured to use a post-increment address mode.

The packet size is configured based on the source/destination synchronization select bit in the `SDMA.DMA4_CCRi` register through either the channel `SDMA.DMA4_CDFi` register (source synchronized) or the `SDMA.DMA4_CSFi` register (destination synchronized).

When the logical channel transfer block is not an exact multiple of the packet size, the final packet consists of the remaining elements in the transfer, using burst or single accesses to complete the block transfer.

The maximum transfer size, regardless of the packet size, is always as follows:

$$\text{Block_size} = \text{Number_of_Frame_in_Block} * \text{Number_of_Element_in_Frame} * \text{Element_Size}$$

- Synchronized at the source

The DMA module optimizes the transfer with respect to the number and size of burst transactions for the given source and destination addressing profiles and configured maximum burst sizes. When writing to the destination is slower than reading from the source, data is buffered in the channel FIFO queue. If the transfer is packet-synchronized at the source, the end-of-packet interrupt is disabled (see [Section 7.4.11, Reprogramming an Active Channel](#)).

For a source synchronized transfer, buffering can be enabled or disabled by setting the `SDMA.DMA4_CCRi[25]` `BUFFERING_DISABLE` bit. For a packet source synchronization with buffering disabled and the packed/burst across the packet boundary, the last packed/burst write transaction is split in optimized smaller accesses to complete the packet transfer size. However, for a packet source synchronized transfer with buffering enabled and with the packed/burst across the packet boundary, the DMA module waits for the next DMA request(s) to read enough data to issue an atomic

packed/burst write transaction (assuming the address is packed/burst aligned).

NOTE: Regardless of whether buffering is enabled or not, buffering is not performed between frames. If the packed/burst is across the frame boundary, the last packed/burst write transaction is split into optimized smaller accesses to complete the frame transfer size.

- Synchronized at the destination

The performance of a hardware-synchronized transfer can be improved by using the prefetch mode, enabled through the channel DMA register bit SDMA.DMA4_CCRi[23]. Data is prefetched on the read port side in advance of the DMA request received and buffered in the FIFO queue. Up to a full transfer block can be prefetched, although this can be limited by the specified maximum channel FIFO queue depth (see Section 7.4.2, *FIFO Queue Memory Pool*).

Buffering disable is not allowed for a destination-synchronized transfer.

NOTE: Behavior is undefined when prefetch is enabled and a transfer is synchronized to the source.

Whether buffering is enabled or disabled, the last transaction in the frame or in the block is write nonposted (WNP) even if the write mode is specified as write last nonposted (WLNP; the WRITE_MODE bit field of the SDMA.DMA4_CSDPi register = 0x2). However, in a packet synchronization mode, the last transaction of each packet in the transfer is WNP only if buffering disable is on (even if the write mode is specified as WLNP).

Regardless of whether buffering disable is enabled or disabled, the packet interrupt is not generated in the packet source synchronized mode.

CAUTION

The BUFFERING_DISABLE bit field of the SDMA.DMA4_CCRi register must be filled with an allowed value, as specified in Table 7-7.

Table 7-7. Buffering Disable

| | BUFFERING_DISABLE (0: buffering enable, 1: buffering disable) | |
|--------------------------|--|-------------|
| Destination synchronized | 0 | Allowed |
| | 1 | Not allowed |
| Source synchronized | 0 | Allowed |
| | 1 | Allowed |

Synchronized transfer monitoring using CDAC (SDMA.DMA4_CDACi):

Context is restored only when the channel becomes active on a DMA request (not at software enable). The channel is software-enabled first, and then a DMA request is asserted followed by the first context restore.

The CDAC register is writable; thus, you can initialize the CDAC to monitor the transfer and determine if the transfer is started or not (see Section 7.5.4, *Synchronized Transfer Monitoring Using CDAC*, for more information).

NOTE: The CDAC register must be written or read so that the least-significant byte (LSByte) is read first; otherwise, the shadow registers do not update the CDAC registers.

This is not an issue for 32-bit read-write transactions. Nevertheless, for 16-bit transactions, start reading or writing the LSByte first to enable the register update.

7.4.8 Thread Budget Allocation

When several concurrent channels are latency critical and hardware synchronized, a specific latency cannot be ensured until the target is served. This situation occurs when the concurrent channel number is superior to the number of available threads.

NOTE: Four threads are available on the read port, and two threads are available on the write port.

For a hardware-synchronized transfer (memory to peripheral), a minimum bandwidth for a latency-critical transfer must be ensured to avoid collisions between two hardware requests.

Because it is latency critical, the software user is responsible for the following:

- Programming the synchronized channel as a high-priority channel
- Reserving one or several threads for high-priority channels

The proposed implementation is as follows (see [Section 7.5.5](#)):

Prevent the regular channel queue from exceeding more than a programmable (3, 2, or 1) number of threads on the read port and no more than one thread on the write port. This number can be set on the global register `SDMA.DMA4_GCR[13:12]`.

The thread reservation is programmable for maximum use of thread resources for concurrent, low-priority channel transfer. Programmability can also allow a partial throughput control by limiting in software the number of concurrent outstanding requests that break the pipelining.

Depending on the `SDMA.DMA4_GCR [13:12]` value, the following threadID on the read/write ports are allocated for a high-priority channel:

Read port priority thread reservation:

- `SDMA.DMA4_GCR[13:12] = 0x0` => No ThreadID is allocated for high-priority channels.
- `SDMA.DMA4_GCR[13:12] = 0x1` => Read ThreadID 0 is allocated for high-priority channels.
- `SDMA.DMA4_GCR[13:12] = 0x2` => Read ThreadID 0 and Read ThreadID 1 are allocated for high-priority channels.
- `SDMA.DMA4_GCR[13:12] = 0x3` => Read ThreadID 0, Read ThreadID 1, and Read ThreadID 2 are allocated for high-priority channels.

Write port priority thread reservation:

- `SDMA.DMA4_GCR[13:12] = 0x0` => No ThreadID is allocated for high-priority channels
- `SDMA.DMA4_GCR[13:12] = 0x1` => Write ThreadID 0 is allocated for high-priority channels.
- `SDMA.DMA4_GCR[13:12] = 0x2` => Write ThreadID 0 is allocated for high-priority channels.
- `SDMA.DMA4_GCR[13:12] = 0x3` => Write ThreadID 0 is allocated for high-priority channels.

Regardless whether or not the enabled channels are of high priority, only the setting of the `SDMA.DMA4_GCR[13:12]` value forces the thread reservation to these values. Set the appropriate value to avoid losing threads using only regular channels.

To have an independent read and write priority context, a per-channel bit `SDMA.DMA4_CCRi[26]` is added for write priority, and the previous priority bit becomes read priority bit `SDMA.DMA4_CCRi[6]`.

NOTE: The device has one priority bit per logical channel, not one per port.

7.4.9 FIFO Budget Allocation

To avoid fully occupying the FIFO with a high-priority transfer while low-priority channels wait in the arbitration queue, two separate FIFO budgets are specified: one for high-priority channels and one for low-priority channels. This is defined in the `SDMA.DMA4_GCR` register, allowing the user to share the FIFO budget between the low- and high-priority channels. The amount of the FIFO allocated by the low- and high-priority channels is fixed by the value set in the `SDMA.DMA4_GCR[15:14]`

`HI_LO_FIFO_BUDGET` field. The maximum channel FIFO depth is limited by the `HI_LO_FIFO_BUDGET` field as follows:

If the channel is low priority:

- When HI_LO_FIFO_BUDGET = 0x1, then low priority cannot exceed 75 percent of the total FIFO.
- When HI_LO_FIFO_BUDGET = 0x2, then low priority cannot exceed 25 percent of the total FIFO.
- When HI_LO_FIFO_BUDGET = 0x3, then low priority cannot exceed 50 percent of the total FIFO.

If channel is high priority

- When HI_LO_FIFO_BUDGET = 0x1, then high priority cannot exceed 25 percent of the total FIFO.
- When HI_LO_FIFO_BUDGET = 0x2, then high priority cannot exceed 75 percent of the total FIFO.
- When HI_LO_FIFO_BUDGET = 0x3, then high priority cannot exceed 50 percent of the total FIFO.

The user is responsible for performing the following equation:

- For a high-priority channel: $(\text{Per_Channel_Maximum FIFO Depth} + 1) \times \text{Number of High Channel} \leq \text{High Budget FIFO}$
- For a low-priority channel: $(\text{Per_Channel_Maximum FIFO Depth} + 1) \times \text{Number of Low Channel} \leq \text{Low Budget FIFO}$

NOTE: Ensure that *Number of High Channel* means *Number of Active High-Priority Channel* and that *Number of Low Channel* means *Number of Active Low-Priority Channel*.

7.4.10 Chained Logical Channel Transfers

Chaining multiple logical channels permits transfers consisting of multiple parts to be executed without repeated software intervention. This results in better performance than the alternative of software setting up and starting each transfer separately. Each part of a chained transfer can have the data addressed in a different manner that permits the programming of a variety of complex transfers. For example:

- Interlaced video data with one logical channel configured to transfer the even lines and another logical channel configured to transfer the odd lines
- Protocol headers with a separate DMA4 channel configured to transfer each field in the header

Channels can be chained through each channel SDMA.DMA4_CLNK_CTRLi register. When the transfer for the first channel completes, the next channel in the chain is enabled. The number of channels in the chain that are configured for hardware-synchronized transfers is flexible (although typically it might be all, none, or just the first one). The DMA request line number should be set to 0 to specify that any or all of the channels in a chain are software-triggered or nonsynchronized.

The last channel in a chain can be chained to the first channel to create a continuously looping chain. The continuously looping transfer can be stopped on the fly at a specific channel by disabling the SDMA.DMA4_CLNK_CTRLi[15] ENABLE_LNK bit. The looping transfer stops after the specified channel transfer is complete.

NOTE: DMA Request Line

A DMA request line must not be shared between concurrently enabled DMA channels. However, a DMA request line can be shared between several chained logical channels.

For more information on the programming model, see [Section 7.5, SDMA Basic Programming Model](#).

7.4.11 Reprogramming an Active Channel

A currently active logical DMA channel can be disabled through the SDMA.DMA4_CCRi[7] ENABLE bit. When any ongoing transaction is complete and the read-active and write-active bits in the SDMA.DMA4_CCRi register (SDMA.DMA4_CCRi[9] RD_ACTIVE and SDMA.DMA4_CCRi[10] WR_ACTIVE) are reset, the channel can be reprogrammed for a new transfer.

7.4.12 Interrupt Generation

The SDMA module has four interrupt request output lines, SDMA_IRQ_0 to SDMA_IRQ_3. One or more logical channels can be programmed to generate an interrupt request on any of these lines when any one of the maskable DMA events listed in [Table 7-8](#) occurs.

Table 7-8. Logical DMA Channel Events

| Event | Description |
|------------------------------|---|
| End of packet | A packet transfer completed. |
| End of block | A block transfer completed. |
| End of frame | A frame transfer completed. |
| Half of frame | Half of the current frame transferred. |
| Start of last frame | The first element of the last frame transferred. |
| Transaction error | A transaction error returned by the interconnect in either the read or write port. |
| Address error | An attempt was made to perform a DMA access to an address not aligned on an ES boundary. |
| Supervisor transaction error | An error occurred, for example, when an unauthorized initiator (that is not a supervisor) tries to use a supervisor transfer. |
| Synchronization error | A new DMA request arrived before completion of the transfer because of the previous DMA request. |
| Drain end | Drain is completed (SDMA.DMA4_CCRi[10] WR_ACTIVE becomes 0). |
| System transaction error | An error has occurred, for example, when an unauthorized initiator tries to set a normal channel to a System channel or tries to change a System channel to a normal channel or tries to access (write) any register of a System channel registers. |
| Drop error | A drop event interrupt is generated when a DMA request is being serviced while a second one is asserted and a third one arrives before the second DMA request is serviced. |

The logical DMA channels that generate an interrupt on a particular IRQ output are specified through the SDMA.DMA4_IRQENABLE_Lj register (where *l* is the IRQ number: 0, 1, 2, or 3). The events that generate an interrupt for a particular channel can be configured through the channel SDMA.DMA4_CICRi register.

When an interrupt is detected, the logical DMA channel generating the event can first be identified by reading the SDMA.DMA4_IRQSTATUS_Lj register. The event causing the interrupt then can be identified by reading the interrupt status via the relevant DMA channel SDMA.DMA4_CSRi register.

7.4.13 Packet Synchronization

A packet transfer notion is related to the behavior of some peripheral, which have certain buffering capability and requires to transfer the buffer content once an element number threshold is reached (a hardware DMA request is generated). To associate a frame synchronization to each DMA request is possible, but this limits the maximum transfer size. Indeed the maximum transfer size is proportional to the FIFO depth of the peripheral:

$$\text{maximum_transfer_size} = \text{peripheral_FIFO_depth} \times \text{number_of_frame_in_block}.$$

The packet synchronization allows to dissociate the transfer size from the FIFO depth of the peripheral. Only Constant addressing mode is allowed on RD port or WR port if source target or destination target is packet synchronized respectively.

Example:

Let's consider a camera interface, which have a FIFO_depth of 128 Words and a FIFO_element_number_threshold of 128 and a picture to transfer with a size 320 lines per 240 columns. If frame synchronization is associated to each DMA request then the maximum transfer size that can be performed is 128×2^{16} words. In this case, a frame is 128 words long, which does not fit the size of a line. Then it's not possible to generate an interrupt at the end of line. However with introducing the packet transfer notion, which is related to the peripheral FIFO behavior/structure, the maximum transfer size (maximum_transfer_size = $2^{24} \times 2^{16}$ words) is independent of both peripheral_FIFO_depth and FIFO_element_number_threshold. This allows, making an enough long transfer within one channel context and perform rotation operation on big image format.

The main features of DMA Packet transfer are as follows:

- DMA Packet Data Size for each DMA Request: typically this will be Peripheral_element_number_threshold Number of elements in a packet shares the SDMA.DMA4_CSFl_i and SDMA.DMA4_CDFl_i configuration registers. Indeed if the peripheral is the source target, respectively destination target, that means the used addressing mode is constant, consequently SDMA.DMA4_CSFl_i[15:0], respectively SDMA.DMA4_CDFl_i[15:0], is used to specify the packet data size (PKT_ELNT_NBR) and the bit fields [31:16] are unused. To specify the Packet data size in the SDMA.DMA4_CSFl_i or SDMA.DMA4_CDFl_i, the user must set the SDMA.DMA4_CCRi[24]

SEL_SRC_DST_SYNC respectively to 1 or 0.

NOTE: The packet size can be a sub-multiple or non sub-multiple of a frame size. If DMA Packet_Data_Size is aligned on DMA channel block data size boundary, DMA will transfer the last data in channel block boundary and stop at block boundary for the last packet DMA request. If the Packet_Data_size is not aligned on the block boundary, the remaining data smaller than a packet size are transferred using burst or single accesses to complete the block.

- DMA Packet_Data_Transfer does not affect DMA channel capabilities in term of packing and bursting. The Packet synchronization mode is active when SDMA.DMA4_CCRi[5] FS = SDMA.DMA4_CCRi[18] BS = 1. Then
 - if SDMA.DMA4_CCRi[24] SEL_SRC_DST_SYNC=0; SDMA.DMA4_CDFIi[15:0] gives the number of element in packet and SDMA.DMA4_CDFIi[31:16] is unused for the packet size.
 - if SDMA.DMA4_CCRi[24] SEL_SRC_DST_SYNC=1; SDMA.DMA4_CSFII[15:0] gives the number of element in packet and SDMA.DMA4_CSFII[31:16] is unused for the packet size.

NOTE: The maximum transfer size, regardless of the packet size, is always: Block_size = Number_of_Frame_in_Block x Number_of_Element_in_Frame x Element_Size. If the DMA channel packet/burst access is across packet boundary, DMA hardware automatically splits this packing/burst access into multiple smaller accesses, which will be aligned on packet boundary. Otherwise, the DMA transfers data as usual packing/burst access.

7.4.14 Graphics Acceleration Support

The SDMA supports two graphic acceleration features:

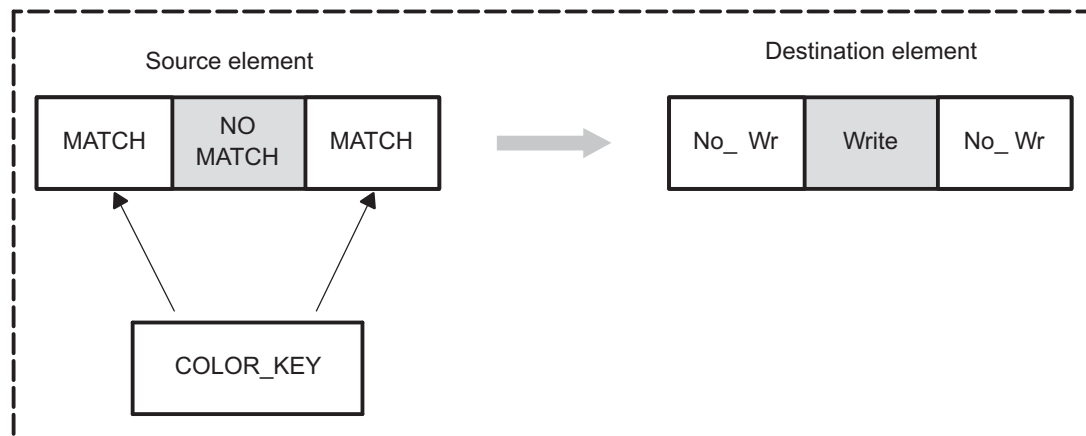

- Transparent copy
- Constant fill

Only one of these features can be enabled at any given time through the SDMA.DMA4_CCRi register for the particular logical DMA channel.

The transparent copy feature enables specification of a particular color through the SDMA.DMA4_COLORi register, so that when it is recognized in the data from the source, it is not copied to the corresponding location in the destination, but instead leaves the data in the corresponding location in the destination as it is.

Figure 7-12 shows the 2-D graphic transparent color block diagram.

Figure 7-12. 2-D Graphic Transparent Color Block Diagram

108-004

The constant fill feature provides the ability to specify a particular color through the SDMA.DMA4_COLORi register for every specified location in the destination. In this case, the transfer consists only of writing to the destination without reading from a source.

Both features support 8 bpp (bits per pixel), 16 bpp, and 24 bpp, depending on what is specified as the DMA transfer ES via the SDMA.DMA4_CSDPi register. An ES of 32 bits corresponds to 24 bpp. During a 32-bit (24 bpp) transfer, the most-significant 8 bits ([31:24]) are 0. Both features are compatible with packed and burst transactions.

7.4.15 Supervisor Modes

A logical DMA channel can be configured to operate in supervisor mode through the corresponding bits in the channel SDMA.DMA4_CCRi register. This must be done using supervisor access. Once a channel is configured in supervisor mode, the channel configuration is protected from nonsupervisor accesses. All DMA transactions on a supervisor channel are supervisor transactions.

7.4.16 Posted and Nonposted Writes

A logical channel can be configured in its DMA register bits SDMA.DMA4_CSDPi[17:16] to use one of three write access handshake modes for the destination:

- Nonposted write: Each write must complete before transfer can continue or complete.
- Posted write: Transfer continues without waiting for each write to complete (might improve performance with slow devices).
- Posted with final write nonposted: Transfer continues without waiting for each write to complete, but final write is completed before transfer can complete.

7.4.17 Disabling a Channel During Transfer

When a channel is disabled during a transfer, the channel will undergo an abort, except if the channel was hardware source synchronized with buffering Enabled (SDMA.DMA4_CCRi[25] BUFFERING_DISABLE='0'). In that case, the fifo will be drained in order to avoid losing data. See [Section 7.4.18](#) for details on this feature.

7.4.18 FIFO Draining Mechanism

When a source synchronized channel is disabled during a transfer, then the current hardware request (element/packet/frame/block) service is completed and the channel SDMA.DMA4_CCRi[9] RD_ACTIVE bit is set to 0, which means the channel is not active on the read port. The remaining data in the corresponding disabled channel FIFO is drained onto the write port and transferred to the programmed destination as in normal transfer.

At the end of the draining the SDMA.DMA4_CCRi[10] WR_ACTIVE bit is set to 0 (channel is no more active on the write port) and if the SDMA.DMA4_CICRI[12] DRAIN_END_IE is set to 1, the status bit DMA4_CSRi[12] DRAIN_END is updated and an interrupt is generated.

Once a channel is disabled during a transfer, it needs to wait for SDMA.DMA4_CCRi[9] RD_ACTIVE and SDMA.DMA4_CCRi[10] WR_ACTIVE to become '0' before being re-enabled for a new transfer. The FIFO drain for a channel will happen only in the following cases:

- If the channel is a source synchronized channel and SDMA.DMA4_CCRi[25] BUFFERING_DISABLE='0' and
- If the channel is not a solid fill channel and
- If the channel is not a transparent and copy channel

NOTE: In case of a self-linked or chain-linked channel, it is user responsibility to disable the SDMA.DMA4_CLNK_CTRLi[15] ENABLE_LINK bit before disabling the channel.

In all other cases, the channel will undergo an abort.

NOTE: If the channel intended to be used is a drain candidate, always enable DRAIN END INTERRUPT for that channel.

When the sDMA is in smart standby mode, before disabling a drain candidate channel (DMA4_CCRi[7] ENABLE = 0x0), the sDMA must be configured to be in force standby mode (DMA4_OCP_SYSCONFIG[13:12] = 0x0) or in no standby mode (DMA4_OCP_SYSCONFIG[13:12] = 0x1). After the occurrence of DRAIN END INTERRUPT EVENT from that channel, the sDMA can be switched back to smart standby mode (DMA4_OCP_SYSCONFIG[13:12] = 0x2).

7.4.19 Reset

Following a software or hardware reset, all fields in the logical channel registers have undefined values, except 5 bits in the SDMA.DMA4_CCRi and SDMA.DMA4_CICRi registers. Thus, when programming a channel for the first time, the remaining fields in all channel registers must be configured before enabling the channel.

NOTE: After a reset, the global registers take their specified reset values.

7.4.20 Power Management

The SDMA module provides two methods to reduce power consumption:

- Interconnect clock auto-idle
- Automatic standby mode

7.4.20.1 Interconnect Clock Auto-Idle

The interconnect clock auto-idle power-saving mode is enabled or disabled in DMA register bit SDMA.DMA4_OCP_SYSCONFIG[0]. When this mode is enabled and there is no activity on the interconnect interface, the interconnect clock is disabled internally to the module to reduce power consumption. When there is new activity on the interconnect interface, the interconnect clock is restarted without any latency penalty. After reset, this mode is disabled by default. Enabling this mode is recommended to reduce power consumption.

7.4.20.2 Automatic Standby Mode

As part of the system-wide power-management scheme, the module can go into a standby mode at the request of the power, reset, and clock management (PRCM) module (for more information, see *Power, Reset, and Clock Management*).

The module can be configured to one of the following standby modes using the DMA register bits SDMA.DMA4_OCP_SYSCONFIG[13:12]:

- No standby mode: The module never goes into standby mode.
- Force standby mode: The module goes into standby mode only when all the DMA channels are disabled.
- Smart standby mode: The module enters standby mode when:
 - All DMA channels are disabled.
 - No nonsynchronized channel is enabled, no DMA request line is asserted, and no DMA request is pending in the module.

7.5 SDMA Basic Programming Model

7.5.1 Setup Configuration

After a software or hardware reset, program all fields in the logical channel registers to default values for any channels used, because most fields are undefined following reset.

Before programming any DMA transfers, the priority arbitration rate and the maximum FIFO depth must be configured through the `SDMA.DMA4_GCR` register, and any required interrupts must be enabled through the `SDMA.DMA4_IRQENABLE_Lj` registers and the logical channel `SDMA.DMA4_CICRi` registers.

Software clears the `SDMA.DMA4_CSRi` register and the `IRQSTATUS` bit for the different interrupt lines before enabling the channel.

7.5.2 Software-Triggered (Nonsynchronized) Transfer

To program a software-triggered DMA transfer:

1. Configure the transfer parameters in the logical DMA channel registers:

- `SDMA.DMA4_CSDPi`:
 - Transfer ES (8 bits, 16 bits, or 32 bits) and DMA register bits `SDMA.DMA4_CSDPi[1:0]`
 - Read and write port access types (single/burst), DMA register bits `SDMA.DMA4_CSDPi[8:7]` and `SDMA.DMA4_CSDPi[15:14]`
 - Source and destination endianness, DMA register bits `SDMA.DMA4_CSDPi[21]` and `SDMA.DMA4_CSDPi[19]`
 - Write mode (posted or nonposted) and DMA register bits `SDMA.DMA4_CSDPi[17:16]`
 - Source or destination packed or nonpacked (if the ES is less than the read/write port size), DMA register bits `SDMA.DMA4_CSDPi[6]` and `SDMA.DMA4_CSDPi[13]`
- `SDMA.DMA4_CENi`: EN
- `SDMA.DMA4_CFNi`: FN per transfer block
- `SDMA.DMA4_CSSAi` and `SDMA.DMA4_CDSAi`: Source and destination start address (aligned with transfer ES)
- `SDMA.DMA4_CCRi`:
 - Read and write port addressing modes, DMA register bits `SDMA.DMA4_CCRi[13:12]` and `SDMA.DMA4_CCRi[15:14]`
 - Priority bit for both read and write ports, DMA register bits `SDMA.DMA4_CCRi[6]` and `SDMA.DMA4_CCRi[26]`
 - DMA request number (set to 0 for a software-triggered transfer) and DMA register bits `SDMA.DMA4_CCRi[4:0] = 0` and `SDMA.DMA4_CCRi[20:19] = 0`
- `SDMA.DMA4_CSEi`, `SDMA.DMA4_CSFi`, `SDMA.DMA4_CDEi`, and `SDMA.DMA4_CDFi`: Source and destination element and frame indexes (depending on addressing mode)

2. Start the transfer through the enable bit in the channel `SDMA.DMA4_CCRi` register and DMA register bit `SDMA.DMA4_CCRi[7]`

The example below perform a DMA transfer on channel 10 of a 240*160 picture from RAM to RAM (0x80C00000 to 0x80F00000) :

```

UWORD32 RegVal = 0;
DMA4_t *DMA4;

DMA4 = (DMA4_t *)malloc(sizeof(DMA4_t));
/* Init. parameters */
DMA4->DataType = 0x2; // DMA4_CSDPi[1:0]
DMA4->ReadPortAccessType = 0; // DMA4_CSDPi[8:7]
DMA4->WritePortAccessType = 0; // DMA4_CSDPi[15:14]
DMA4->SourceEndiansim = 0; // DMA4_CSDPi[21]
DMA4->DestinationEndianness = 0; // DMA4_CSDPi[19]
DMA4->WriteMode = 0; // DMA4_CSDPi[17:16]
DMA4->SourcePacked = 0; // DMA4_CSDPi[6]
DMA4->DestinationPacked = 0; // DMA4_CSDPi[13]
DMA4->NumberOfElementPerFrame = 240; // DMA4_CENi
DMA4->NumberOfFramePerTransferBlock = 160; // DMA4_CFNi
DMA4->SourceStartAddress = 0x80C00000; // DMA4_CSSAi
DMA4->DestinationStartAddress = 0x80F00000; // DMA4_CDSAi
DMA4->SourceElementIndex = 1; // DMA4_CSEi
DMA4->SourceFrameIndex = 1; // DMA4_CSFi
DMA4->DestinationElementIndex = 1; // DMA4_CDEi
DMA4->DestinationFrameIndex = 1; // DMA4_CDFi
DMA4->ReadPortAccessMode = 1; // DMA4_CCRi[13:12]
DMA4->WritePortAccessMode = 1; // DMA4_CCRi[15:14]
DMA4->ReadPriority = 0; // DMA4_CCRi[6]

```

```

DMA4->WritePriority = 0; // DMA4_CCRi[23]
DMA4->ReadRequestNumber = 0; // DMA4_CCRi[4:0]
DMA4->WriteRequestNumber = 0; // DMA4_CCRi[20:19]

/* 1) Configure the transfer parameters in the logical DMA registers */
/*-----*/
/* a) Set the data type CSDP[1:0], the Read/Write Port access type CSDP[8:7]/[15:14], the
Source/dest endiansim CSDP[21]/CSDP[19], write mode
CSDP[17:16], source/dest packed or non-packed CSDP[6]/CSDP[13]*/
// Read CSDP
RegVal = DMA4_CSDP_CH10;

// Build reg
RegVal = ((RegVal & ~ 0x3) | DMA4->DataType );
RegVal = ((RegVal & ~(0x3 << 7)) | (DMA4->ReadPortAccessType << 7));
RegVal = ((RegVal & ~(0x3 << 14)) | (DMA4->WritePortAccessType << 14));
RegVal = ((RegVal & ~(0x1 << 21)) | (DMA4->SourceEndiansim << 21));
RegVal = ((RegVal & ~(0x1 << 19)) | (DMA4->DestinationEndianism << 19));
RegVal = ((RegVal & ~(0x3 << 16)) | (DMA4->WriteMode << 16));
RegVal = ((RegVal & ~(0x1 << 6)) | (DMA4->SourcePacked << 6));
RegVal = ((RegVal & ~(0x1 << 13)) | (DMA4->DestinationPacked << 13));

// Write CSDP
DMA4_CSDP_CH10 = RegVal;

/* b) Set the number of element per frame CEN[23:0]*/
DMA4_CEN_CH10 = DMA4->NumberOfElementPerFrame;

/* c) Set the number of frame per block CFN[15:0]*/

// Read CCR
RegVal = DMA4_CCR_CH10;

// Build reg
RegVal = ((RegVal & ~(0x3 << 12)) | (DMA4->ReadPortAccessMode << 12));
RegVal = ((RegVal & ~(0x3 << 14)) | (DMA4->WritePortAccessMode << 14));
RegVal = ((RegVal & ~(0x1 << 6)) | (DMA4->ReadPriority << 6));
RegVal = ((RegVal & ~(0x1 << 26)) | (DMA4->WritePriority << 26));
RegVal&= 0xFFCFFFE0 ;

// Write CCR
DMA4_CCR_CH10 = RegVal;

/* f)- Set the source element index CSEI[15:0]*/
DMA4_CSEI_CH10 = DMA4->SourceElementIndex;

/* - Set the source frame index CSFI[15:0]*/
DMA4_CSFI_CH10 = DMA4->SourceFrameIndex ;

/* - Set the destination element index CDEI[15:0]*/
DMA4_CDEI_CH10 = DMA4->DestinationElementIndex;

/* - Set the destination frame index CDFI[31:0]*/
DMA4_CDFI_CH10 = DMA4->DestinationFrameIndex;

/* 2) Start the DMA transfer by Setting the enable bit CCR[7]=1 */
/*-----*/
//write enable bit
DMA4_CCR_CH10 |= 1 << 7; /* start */

```

7.5.3 Hardware-Synchronized Transfer

To monitor a hardware synchronized DMA transfer, initialize the SDMA.DMA4_CDACi register before the software enable.

To configure an LCh to synchronize by element, packet, frame, or block, the frame synchronization SDMA.DMA4_CCRi[5] FS bit and the block synchronization SDMA.DMA4_CCRi[18] BS bit register must be programmed. For all the following synchronized transfers (element, packet, frame or block synchronized transfers) User must set first : SDMA.DMA4_CCRi[24] SEL_SRC_DST_SYNC to 1 when the source triggers on the DMA request and SDMA.DMA4_CCRi[24] SEL_SRC_DST_SYNC to 0 when the Destination triggers on the DMA request. Note: User must take care when setting the SDMA.DMA4_CCRi[23] PREFETCH bit it is in conjunction with SDMA.DMA4_CCRi[24] SEL_SRC_DST_SYNC bit .

- To configure an LCh to transfer one element per DMA request:
 1. Set the number of DMA request associated to the current LCH in the SDMA.DMA4_CCRi[20:19] SYNCHRO_CONTROL_UPPER and SDMA.DMA4_CCRi[4:0] SYNCHRO bit field.
 2. Set the data type, also referenced as element size (ES), in the SDMA.DMA4_CSDPi[1:0] DATA_TYPE bit field.
 3. Set the Read Port access type (single or burst access) in the SDMA.DMA4_CSDPi[8:7] SRC_BURST_EN bit field.
 4. Set the Write Port access type (single or burst access) in the SDMA.DMA4_CSDPi[15:14] DST_BURST_EN bit field.
 5. Set the Read Port addressing mode in the SDMA.DMA4_CCRi[13:12] SRC_AMODE bit field.
 6. Set the Write Port addressing mode in the SDMA.DMA4_CCRi[15:14] DST_AMODE bit field.
 7. Set the Read start address in the SDMA.DMA4_CSSAi[31:0] SRC_START_ADRS bit field.
 8. Set the Write start address in the SDMA.DMA4_CDSAi[31:0] DST_START_ADRS bit field.
 9. Set both FS and BS to 0 in SDMA.DMA4_CCRi[5] FS and SDMA.DMA4_CCRi[18] BS.
 10. Set to 1 the channel enable bit SDMA.DMA4_CCRi[7] EN bit.
- To configure an LCh to transfer one frame per DMA request:
 1. Set the number of DMA request associated to the current LCH in the SDMA.DMA4_CCRi[20:19] SYNCHRO_CONTROL_UPPER and SDMA.DMA4_CCRi[4:0] SYNCHRO bit field.
 2. Set the data type, also referenced as element size (ES), in the SDMA.DMA4_CSDPi[1:0] DATA_TYPE bit field.
 3. Set the number of element per frame in the SDMA.DMA4_CENi[23:0] CHANNEL_ELMNT_NBR bit field.
 4. Set the Read Port access type (single or burst access) in the SDMA.DMA4_CSDPi[8:7] SRC_BURST_EN bit field.
 5. Set the Write Port access type (single or burst access) in the SDMA.DMA4_CSDPi[15:14] DST_BURST_EN bit field.
 6. Set the Read Port addressing mode in the SDMA.DMA4_CCRi[13:12] SRC_AMODE bit field.
 7. Set the Write Port addressing mode in the SDMA.DMA4_CCRi[15:14] DST_AMODE bit field.
 8. Set the Read start address in the SDMA.DMA4_CSSAi[31:0] SRC_START_ADRS bit field.
 9. Set the Write start address in the SDMA.DMA4_CDSAi[31:0] DST_START_ADRS bit field.
 10. Set FS to 1 and BS to 0 respectively in SDMA.DMA4_CCRi[5] FS and SDMA.DMA4_CCRi[18] BS.
 11. Set to 1 the channel enable bit SDMA.DMA4_CCRi[7] EN bit.
- To configure an LCh to transfer one block per DMA request:
 1. Set the number of DMA request associated to the current LCH in the SDMA.DMA4_CCRi[20:19] SYNCHRO_CONTROL_UPPER and SDMA.DMA4_CCRi[4:0] SYNCHRO bit field.
 2. Set the data type, also referenced as element size (ES), in the SDMA.DMA4_CSDPi[1:0] DATA_TYPE bit field.
 3. Set the number of element per frame in the SDMA.DMA4_CENi[23:0] CHANNEL_ELMNT_NBR bit field.
 4. Set in the SDMA.DMA4_CFNi[15:0] CHANNEL_FRAME_NBR bit field the number of frame (transfers), to take place before the LCH is disabled.
 5. Set the Read Port access type (single or burst access) in the SDMA.DMA4_CSDPi[8:7] SRC_BURST_EN bit field.
 6. Set the Write Port access type (single or burst access) in the SDMA.DMA4_CSDPi[15:14]

DST_BURST_EN bit field.

7. Set the Read Port addressing mode in the SDMA.DMA4_CCRi[13:12] SRC_AMODE bit field.
8. Set the Write Port addressing mode in the SDMA.DMA4_CCRi[15:14] DST_AMODE bit field.
9. Set the Read start address in the SDMA.DMA4_CSSAi[31:0] SRC_START_ADRS bit field.
10. Set the Write start address in the SDMA.DMA4_CDSAi[31:0] DST_START_ADRS bit field.
11. Set FS to 0 and BS to 1 respectively in SDMA.DMA4_CCRi[5] FS and SDMA.DMA4_CCRi[18] BS.
12. Set to 1 the channel enable bit SDMA.DMA4_CCRi[7] EN bit.
 - To configure an LCh to transfer one packet per DMA request:
 1. Set the number of DMA request associated to the current LCH in the SDMA.DMA4_CCRi[20:19] SYNCHRO_CONTROL_UPPER and SDMA.DMA4_CCRi[4:0] SYNCHRO bit field.
 2. Set the data type, also referenced as element size (ES), in the SDMA.DMA4_CSDPi[1:0] DATA_TYPE bit field.
 3. Set the number of element per packet to transfer: If the packet requestor is in the source, set SDMA.DMA4_CCR.Sel_Src_Dst_Sync to 1 and set the packet element number in the SDMA.DMA4_CSFli register; else, if the packet requestor is in the destination, set the SDMA.DMA4_CCRi[24] SEL_SRC_DST_SYNC to 0 and set the packet element number in the SDMA.DMA4_CDFli register.
 4. Set the number of element per frame in the SDMA.DMA4_CENi[23:0] CHANNEL_ELMNT_NBR bit field.
 5. Set in the SDMA.DMA4_CFNi[15:0] CHANNEL_FRAME_NBR bit field the number of frame (transfers), to take place before the LCH is disabled.
 6. Set the element number in the packet in the SDMA.DMA4_CSFli[15:0] PKT_ELNT_NBR, if constant addressing or post-incremented addressing modes are used in the source side. However, the number of elements in the packet is set in the SDMA.DMA4_CDFli[15:0] PKT_ELNT_NBR if constant addressing mode is used in the destination side.
 7. Set the Read Port access type (single or burst access) in the SDMA.DMA4_CSDPi[8:7] SRC_BURST_EN bit field.
 8. Set the Write Port access type (single or burst access) in the SDMA.DMA4_CSDPi[15:14] DST_BURST_EN bit field.
 9. Set the Read Port addressing mode in the SDMA.DMA4_CCRi[13:12] SRC_AMODE bit field.
 10. Set the Write Port addressing mode in the SDMA.DMA4_CCRi[15:14] DST_AMODE bit field.
 11. Set the Read start address in the SDMA.DMA4_CSSAi[31:0] SRC_START_ADRS bit field.
 12. Set the Write start address in the SDMA.DMA4_CDSAi[31:0] DST_START_ADRS bit field.
 13. Set FS to 1 and BS to 1 respectively in SDMA.DMA4_CCRi[5] FS and SDMA.DMA4_CCRi[18] BS.
 14. Set to 1 the channel enable bit SDMA.DMA4_CCRi[7] EN bit.

NOTE: It is possible to stop a transfer by disabling the channel. This is done by resetting the ENABLE bit in the SDMA.DMA4_CCRi register.

7.5.4 Synchronized Transfer Monitoring Using CDAC

The SDMA.DMA4_CDACi register is writable and non-initialized (value undefined). It can be initialized to monitor a transfer by applying the following programming model:

1. Write 0 in the SDMA.DMA4_CDACi
2. Enable the channel.
3. If timeout occurs, read SDMA.DMA4_CDACi
4. If SDMA.DMA4_CDACi != SDMA.DMA4_CDACi reset value:

Then transfer starts. User can then rely on SDMA.DMA4_CCENi and SDMA.DMA4_CCFNi element and frame counters.

Else, if SDMA.DMA4_CDACi = SDMA.DMA4_CDACi reset value:
Then transfer does not start.

7.5.5 Concurrent Software and Hardware Synchronization

This section describes thread allocation only, not the entire transfer. Because synchronized transfers are latency critical, you must allocate a thread on the synchronized target side at least.

Even for multiple concurrent channels, thread reservation guarantees that as soon as an HW DMA request comes in, the read/write scheduler finds available thread(s) to initiate a channel schedule and issue a read/write transaction.

Consider these six concurrent channels:

- Channels 0/1/2/3 are dedicated to memory-memory transfer: they are software triggered and not synchronized.
 - Channel 4 is dedicated to memory→peripheral transfer, hardware triggered, and synchronized on the write side.
 - Channel 5 is dedicated to peripheral→memory transfer, hardware triggered, and synchronized on the read side.
1. Allow thread reservation for priority channel 4 and channel 5:
Reserve one thread (Read ThreadID 0) on the read port: Set `SDMA.DMA4_GCR[13:12] = 0x1`.
Reserve one thread (Write ThreadID 0) on the write port: Set `SDMA.DMA4_GCR[13:12] = 0x1`.
 2. Specify channel priority:
Channel 4 is a write high priority channel: Set `SDMA.DMA4_CCRi[26] = 1`.
Channel 5 is a read high priority channel: Set `SDMA.DMA4_CCRi[6] = 1`.

7.5.6 Chained Transfer

A chained DMA transfer can be programmed as follows:

1. Configure the transfer parameters for each logical DMA channel in the chain as in step 1 for either the synchronized or non-synchronized transfers above.
2. For each channel in the chain, configure the `SDMA.DMA4_CLNK_CTRLi` register as follows:
 - Next logical DMA channel number (for a looping chained transfer link last channel to first channel number), in DMA register bits `SDMA.DMA4_CLNK_CTRLi[4:0]`.
 - Include the logical channel to the chain and enable link by setting the DMA register bit `SDMA.DMA4_CLNK_CTRLi[15]`.
 - For a non-looping chain, the last logical channel in the chain must have the DMA register bit `SDMA.DMA4_CLNK_CTRLi[15]` set to 0 to indicate the end of the chain.
3. Enable the transfer via the enable bit in the first logical channel DMA register bit `SDMA.DMA4_CCRi[7]`. All other channels in the chain must be configured as disabled. Each channel is enabled automatically in turn when the previous logical channel transfer completes. A non-synchronized transfer starts immediately; a hardware-synchronized transfer starts when the DMA request line corresponding to the first DMA channel in the chain is asserted.

To stop a looping chained transfer, disable the `NEXTLCH_ID` bit, DMA register bit `SDMA.DMA4_CLNK_CTRLi[15]`(`ENABLE_LNK` bit set to 0x0), of the final channel transfer.

In the RAM to RAM copy example, to copy in loop it's possible to link channel 10 on itself. The following line can be added in the channel configuration :

```
/* g) Set link for loop */
DMA4_CLNK_CTRL_CH10 = 0x0000800A;
```

7.5.7 90° Clockwise Image Rotation

The 90° clockwise image rotation example described in [Section 7.4.3, Addressing Modes](#), can be programmed as follows:

1. Configure the transfer parameters in the logical DMA channel registers:
 - `SDMA.DMA4_CSDPi`:
 - Transfer ES = 32-bit (32 bpp), DMA register bits `SDMA.DMA4_CSDPi[1:0]`
 - Read and write port access types = maximum burst size supported by memory device, DMA register bits `SDMA.DMA4_CSDPi[8:7]` and `SDMA.DMA4_CSDPi[15:14]`

- Source and destination endianness, DMA register bits SDMA.DMA4_CSDPi[21] and SDMA.DMA4_CSDPi[19]
- Write mode = posted with last element nonposted, DMA register bits SDMA.DMA4_CSDPi[17:16]
- Source and destination packed = Yes (although destination writes will not benefit because EI>1), DMA register bits SDMA.DMA4_CSDPi[6] and SDMA.DMA4_CSDPi[13]
- SDMA.DMA4_CENi: EN = 240
- SDMA.DMA4_CFNi: FN per transfer block = 160
- SDMA.DMA4_CSSAi: Source start address = 0x100000
- SDMA.DMA4_CDSAi: destination start address = 0x20013E
- SDMA.DMA4_CCRi:
 - Read and write port addressing modes = double-index addressing mode for both or post-increment addressing on source and double-index addressing on destination, DMA register bits SDMA.DMA4_CCRi[13:12] and SDMA.DMA4_CCRi[15:14]
 - Low or high priority, DMA register bit SDMA.DMA4_CCRi[6]
 - DMA request number = 0 (for software-triggered transfer), DMA register bits SDMA.DMA4_CCRi[4:0] and SDMA.DMA4_CCRi[20:19]
- SDMA.DMA4_CSEi: Source EI = 1
- SDMA.DMA4_CSFi: Source frame index = 1
- SDMA.DMA4_CDEi: destination EI = 637
- SDMA.DMA4_CDFi: destination frame index = -152967

2. Start the transfer via the enable bit in the channel SDMA.DMA4_CCRi register.

Below are the parameters to perform this rotation from 0x80C00000 RAM address to 0x80F00000, with the same code as in [Section 7.5.2](#):

```

/* Init. parameters */
DMA4->DataType = 0x2; // DMA4_CSDPi[1:0]
DMA4->ReadPortAccessType = 0x3; // DMA4_CSDPi[8:7]
DMA4->WritePortAccessType = 0x3; // DMA4_CSDPi[15:14]
DMA4->SourceEndiansim = 0; // DMA4_CSDPi[21]
DMA4->DestinationEndianness = 0; // DMA4_CSDPi[19]
DMA4->WriteMode = 0x2; // DMA4_CSDPi[17:16]
DMA4->SourcePacked = 0x1; // DMA4_CSDPi[6]
DMA4->DestinationPacked = 0x1; // DMA4_CSDPi[13]
DMA4->NumberOfElementPerFrame = 240; // DMA4_CENi
DMA4->NumberOfFramePerTransferBlock = 160; // DMA4_CFNi
DMA4->SourceStartAddress = 0x80C00000; // DMA4_CSSAi
DMA4->DestinationStartAddress = 0x80F00000; // DMA4_CDSAi
DMA4->SourceElementIndex = 1; // DMA4_CSEi
DMA4->SourceFrameIndex = 1; // DMA4_CSFi
DMA4->DestinationElementIndex = 637; // DMA4_CDEi
DMA4->DestinationFrameIndex = -152967; // DMA4_CDFi
DMA4->ReadPortAccessMode = 0x3; // DMA4_CCRi[13:12]
DMA4->WritePortAccessMode = 0x3; // DMA4_CCRi[15:14]
DMA4->ReadPriority = 0; // DMA4_CCRi[6]
DMA4->WritePriority = 0; // DMA4_CCRi[23]
DMA4->ReadRequestNumber = 0; // DMA4_CCRi[4:0]
DMA4->WriteRequestNumber = 0; // DMA4_CCRi[20:19]
    
```

7.5.8 Graphic Operations

- Transparent copy:
 - 1. Set the SDMA.DMA4_CCRi[17] Transparent_Copy_Enable bit field to 1.
 - 2. Set the SDMA.DMA4_CCRi[16] Constant_Fill_Enable bit field to 0.
 - 3. Set the value of key the color in the SDMA.DMA4_COLORi[15:0] color_key bit field.

To perform this graphic operation, the following lines can be added to the example of [Section 7.5.2](#)

```

DMA4_CCR_CH10 &= ~(0x1 << 16);
DMA4_CCR_CH10 |= 0x1 << 17;
DMA4_COLOR_CH10 = 0x00000003;
    
```

- Solid Color fill:

- 1. Set the SDMA.DMA4_CCRi[16] Constant_Fill_Enable bit field to 1.
 - 2. Set the SDMA.DMA4_CCRi[17] Transparent_Copy_Enable bit field to 0.
 - 3. Set the value of key the color in the DMA4_COLORi[15:0] solid_color bit field.
- To perform this graphic operation, the following lines can be added to the example of [Section 7.5.2](#)

```
DMA4_CCR_CH10 &= ~(0x1 << 17);
DMA4_CCR_CH10 |= 0x1 << 16;
DMA4_COLOR_CH10 = 0x00000003;
```

7.6 SDMA Use Cases and Tips

7.6.1 Camcorder Use Case: How to Configure SDMA to Handle Transfers With McBSP2 and MMC to External DRAM

7.6.1.1 Introduction

In this use case, the SDMA manages:

- The audio stream between the McBSP and the external DRAM
- The audio stream between the external DRAM and the MMC buffer
- The video stream between the external DRAM and the MMC buffer

The following sections describe how to configure the SDMA controller with MMC and McBSP in this use case.

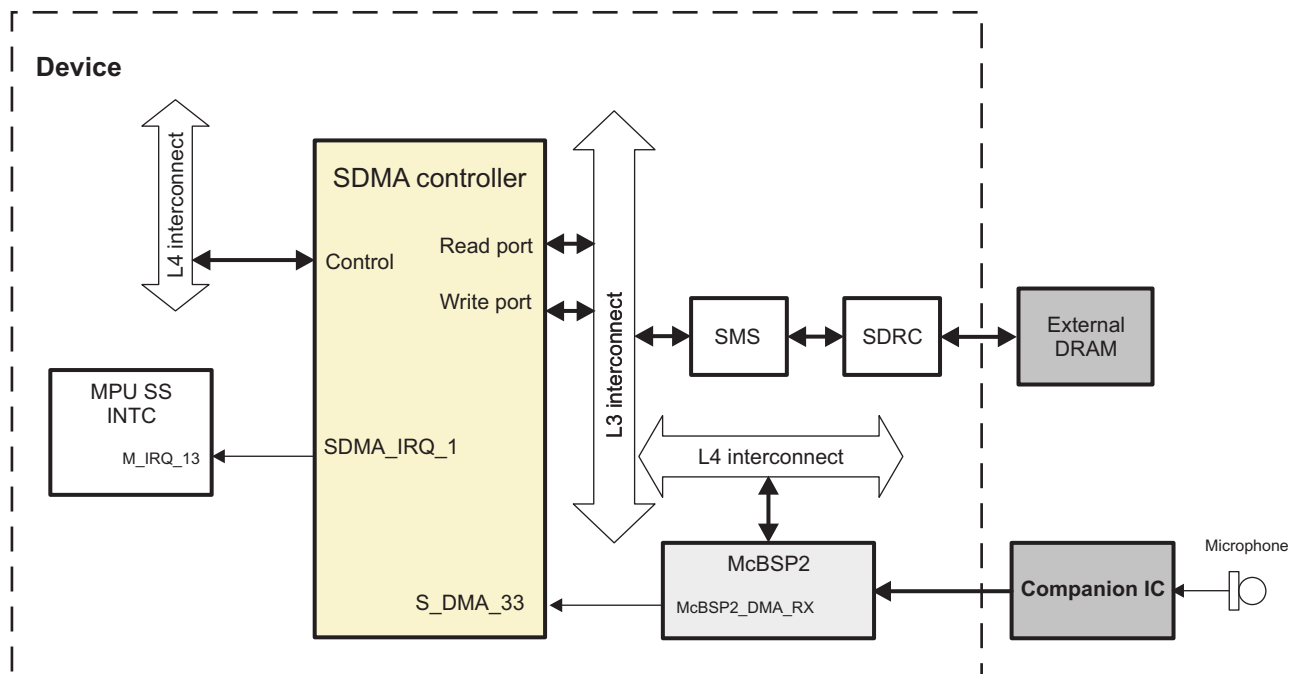

7.6.1.2 SDMA Configuration to Transfer Data Between the McBSP and External DRAM

7.6.1.2.1 Overview

The SDMA gets data from the McBSP_DRR register and copies it into three rolling buffers in the external DRAM.

[Figure 7-13](#) is an overview of the audio path.

Figure 7-13. Overview

dma_F98-001

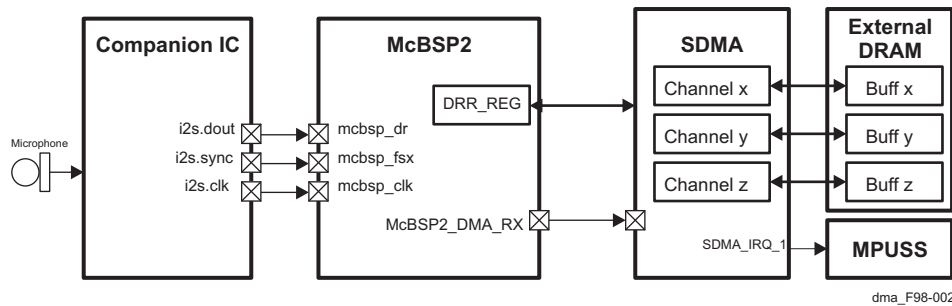

For the camcorder use case, the DMA transfer data format is:

- Frame size = 2048 x 32 bits
- Three DMA channels to manage three transfers to three memory buffers
- Interrupt generated at the end of each frame transfer
- Transfer triggered by McBSP2

7.6.1.2.2 Environment

The DMA accesses MCBSP2_DRR_REG through the interconnect and receives a DMA request from this McBSP module for driving transfers. The DMA accesses the external DRAM through the interconnect. The McBSP is directly connected to the companion IC device. Figure 7-14 shows the environment of this scenario.

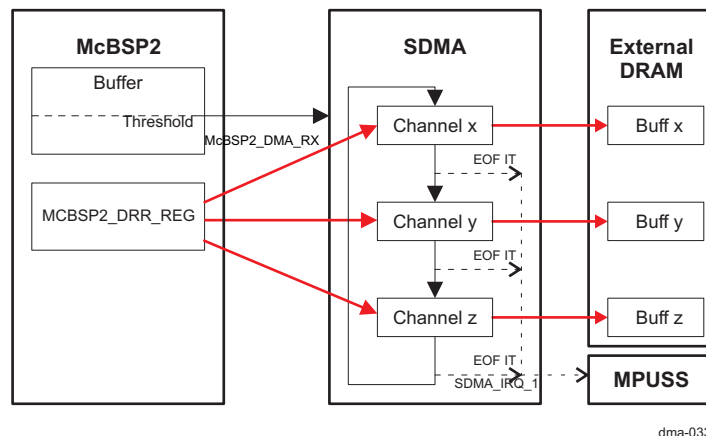

Figure 7-14. Environment

7.6.1.2.3 Data Path

The transfer is started when the DMA transfer is enabled and the MCBSP2_DMA_REQ is asserted (that is, when the McBSP FIFO threshold is reached). The DMA starts copying the first frame into the first memory buffer. When a whole frame has been transferred (2048 data), an interrupt is asserted to the MPU, and then the second channel is enabled and fills the second buffer, and so on. Figure 7-15 shows the data flow.

Figure 7-15. Data Flow

7.6.1.2.4 Programming Flow

To establish a configuration for the DMA transfers, the following points have been considered.

The MCBSP2_DRR_REG register is 32 bits wide, but in the camcorder use case, only the 16 LSBs are used (monophonic 16-bit-wide audio channel).

The McBSP receives data in a FIFO buffer. As long as the occupied locations level in this read buffer is greater than or equal to the threshold value + 1, the DMA request is asserted. After transferring the configured (THRSH1_REG value + 1) number of words, the receive DMA request is deasserted and then reasserted when the conditions are met again. Therefore, the DMA can receive at least threshold value data, with a threshold maximum value = 1280 elements = size of McBSP2 FIFO.

The frame synchronization transfer mode of the SDMA can be used with McBSP for frames with a size equal to the threshold. In the use case, however, the audio data frame is equal to 2048 elements, which is greater than the maximum transfer length possible with the McBSP.

Because the SDMA cannot be configured in frame synchronization mode, packet synchronization mode must be used. This mode enables to specify the maximum size of a transfer and to divide a frame into as many packet as needed. It is then possible to configure a frame of n elements and generate an interrupt at the end-of-frame transfer, while the transfer is segmented into packets.

The management of the three memory buffers is done by configuring three DMA channels linked between themselves: channel x is linked to channel y, channel y is linked to channel z, and channel z is linked to channel x. The three channels have the same configuration, except for the destination address, which corresponds to the three buffer addresses. Channels 11, 12, and 13 are used. Each channel generates the end-of-frame interrupts on the L1 interrupt line of the SDMA, to warn the MPU of the end of a frame transfer.

With these considerations, the DMA register of the three channels (i = 11, 12, and 13) is configured as follows:

1. Channel source destination parameters: [DMA4_CSDPi](#)

- [DMA4_CSDPi\[1:0\]](#) DATA_TYPE = 0x1: Read 16-bit elements from the McBSP_DRR_REG register.
- [DMA4_CSDPi\[5:2\]](#) RD_ADD_TRSLT = 0: Not useful
- [DMA4_CSDPi\[6\]](#) SRC_PACKED = 0x0: Cannot pack source data
- [DMA4_CSDPi\[8:7\]](#) SRC_BURST_EN = 0x0: Cannot burst source
- [DMA4_CSDPi\[12:9\]](#) WR_ADD_TRSLT = 0: Undefined
- [DMA4_CSDPi\[13\]](#) DST_PACKED = 0x1: Pack two 16-bit elements in one 32-bit packet to optimize transfer.
- [DMA4_CSDPi\[15:14\]](#) DST_BURST_EN = 0x3: Burst at 16x32-bit
- [DMA4_CSDPi\[17:16\]](#) WRITE_MODE = 0x1: Write posted
- [DMA4_CSDPi\[18\]](#) DST_ENDIAN_LOCK = 0x0: Endianness adapt
- [DMA4_CSDPi\[19\]](#) DST_ENDIAN = 0x0: Little endian type at destination
- [DMA4_CSDPi\[20\]](#) SRC_ENDIAN_LOCK = 0x0: Endianness adapt
- [DMA4_CSDPi\[21\]](#) SRC_ENDIAN = 0x0: Little endian type at source
- [DMA4_CSDPi\[31:22\]](#) RESERVED = 0x0: For future compatibility

2. Channel control register: [DMA4_CCRi](#)

- [DMA4_CCRi\[4:0\]](#) SYNCHRO_CONTROL = DmaReq & 0x1F = 0x2: 5 first bits of McBSP2_DMA_RX
- [DMA4_CCRi\[5\]](#) FS = 1: Packet mode with BS = 0x1
- [DMA4_CCRi\[6\]](#) READ_PRIORITY = 0x0: Low priority on read side
- [DMA4_CCRi\[7\]](#) ENABLE = 0x0: The logical channel is disabled.
- [DMA4_CCRi\[8\]](#) SUSPEND_SENSITIVE = 0
- [DMA4_CCRi\[9\]](#) RD_ACTIVE: Read status, read-only access
- [DMA4_CCRi\[10\]](#) WR_ACTIVE: Write status, read-only access
- [DMA4_CCRi\[11\]](#) RESERVED = 0: Write 0s for future compatibility.
- [DMA4_CCRi\[13:12\]](#) SRC_AMODE = 0x0: Constant address mode; DMA always reads McBSP2_DRR_REG.
- [DMA4_CCRi\[15:14\]](#) DST_AMODE = 0x1: Post-incremented address mode
- [DMA4_CCRi\[16\]](#) CONST_FILL_ENABLE = 0x0: Constant fill mode is disabled.
- [DMA4_CCRi\[17\]](#) TRANSPARENT_COPY_ENABLE = 0x0: Transparent copy mode is disabled.
- [DMA4_CCRi\[18\]](#) BS = 0x1: Packet mode with FS = 0x1
- [DMA4_CCRi\[20:19\]](#) SYNCHRO_CONTROL_UPPER = 0x1: Two MSBs of McBSP2_DMA_RX
- [DMA4_CCRi\[22\]](#) SUPERVISOR = 0x0: Supervisor mode is disabled.
- [DMA4_CCRi\[23\]](#) PREFETCH = 0x0: Prefetch mode is disabled, cannot prefetch a constant addressing source.
- [DMA4_CCRi\[24\]](#) SEL_SRC_DST_SYNC = 0x1: Transfer is triggered by the source. The packet

- element number is specified in the DMA4_CSFI register.
 - [DMA4_CCRi\[25\]](#) BUFFERING_DISABLE = 0x0
 - [DMA4_CCRi\[26\]](#) WRITE_PRIORITY = 0x0: Channel has low priority on Write side during the arbitration process.
 - [DMA4_CCRi\[31:27\]](#) RESERVED = 0x0: Write 0s for future compatibility.
3. Channel parameters: [DMA4_CENi](#), [DMA4_CFNi](#), [DMA4_CSSAi](#), [DMA4_CDSAi](#), [DMA4_CSEi](#), [DMA4_CSF](#), [DMA4_CDEi](#)
- [DMA4_CENi\[23:0\]](#) CHANNEL_ELMNT_NBR = 2048: 2048 elements
 - [DMA4_CFNi\[15:0\]](#) CHANNEL_FRAME_NBR = 1: One frame
 - [DMA4_CSSAi\[31:0\]](#) SRC_START_ADRS = 0x49022000: Channel source start address = MCBSP2_DRR_REG
 - [DMA4_CDSAi\[31:0\]](#) DST_START_ADRS= X, Y or Z: Channel destination start address in external DRAM, where X, Y, and Z represent the addresses of the three buffers
 - [DMA4_CSEi\[31:0\]](#) CHANNEL_SRC_ELMNT_INDEX = 1: Channel source element index
 - [DMA4_CSF\[15:0\]](#) 16BIT_PKT_ELNT_NBR = 0x80: 16-bit Packet size = MCBSP_FIFO_THRESHOLD + 1
 - [DMA4_CDEi\[15:0\]](#) CHANNEL_DST_ELMNT_INDEX = 0x1: Channel destination element index
4. Channel linking: [DMA4_CLNK_CTRLi](#)
- [DMA4_CLNK_CTRL11\[31:0\]](#) = 0x0000800C: Channel 11 is linked to channel 12.
 - [DMA4_CLNK_CTRL12\[31:0\]](#) = 0x0000800D: Channel 12 is linked to channel 13.
 - [DMA4_CLNK_CTRL13\[31:0\]](#) = 0x0000800B: Channel 13 is linked to channel 11.
5. Interrupt management: [DMA4_CICRi](#) and [DMA4_IRQENABLE_Lj](#)
- [DMA4_CICRi\[31:0\]](#) = 0x00000008: Enables the end of frame interrupt and disables others (the value of these registers is unknown after a reset; it is necessary to clear other bits)
 - [DMA4_IRQENABLE_L1\[31:0\]](#) = 0x00022800; interrupts of channels 11, 12, and 13 are unmasked on IRQ line L1.
6. Launch transfer: [DMA4_CCRi\[7\]](#) ENABLE = 0x1: Enables the three channels, starting with channel 13, then 12, and finally 11; the last one triggers the others.

[Table 7-9](#) lists the registers of DMA channel 11 after a first transfer.

Table 7-9. Registers Print

| Register Name | Address | Value | Value Description |
|-------------------|------------|------------|--|
| DMA4_IRQENABLE_L1 | 0x4805601c | 0x00022800 | Interrupts of channels 11, 12, and 13 are unmasked on IRQ line L1. |
| DMA4_CICR11 | 0x480564a8 | 0x00000008 | End-of-frame interrupt enabled |
| DMA4_CCR11 | 0x480564a0 | 0x010c40a2 | Channel control register |
| DMA4_CSDP11 | 0x480564b0 | 0x0001e001 | Channel source destination parameters |
| DMA4_CEN11 | 0x480564b4 | 0x00000800 | Channel element number |
| DMA4_CFN11 | 0x480564b8 | 0x00000001 | Channel frame number |
| DMA4_CSSA11 | 0x480564bc | 0x49022000 | Channel source start address |
| DMA4_CDSA11 | 0x480564c0 | 0x81e00000 | Channel destination start address |
| DMA4_CSF11 | 0x480564c8 | 0x00000080 | Packet size |
| DMA4_CSAC11 | 0x480564d4 | 0x49022000 | Source address counter (read only) |
| DMA4_CDAC11 | 0x480564d8 | 0x81e01000 | Destination address counter (read only) |
| DMA4_CCEN11 | 0x480564dc | 0x00000800 | Channel current transferred element number in the current frame (read only) |
| DMA4_CCFN11 | 0x480564e0 | 0x00000001 | Channel current transferred frame number in the current transfer (read only) |

Table 7-9. Registers Print (continued)

| Register Name | Address | Value | Value Description |
|------------------|------------|------------|---|
| DMA4_CLNK_CTRL11 | 0x480564a4 | 0x0000800C | Channel link control register: Link to channel 12 |

Channels 12 and 13 have a similar configuration; only the destination address and channel link change.

7.6.1.3 SDMA Configuration to Transfer Data Between MMC and External DRAM

7.6.1.3.1 Overview

The SDMA gets data from the MMC.MMCHS_DATA register and copies it into the external DRAM. The SDMA accesses the MMCHS_DATA through the interconnect and receives a DMA request from the MMC module for driving transfers. The DMA accesses the external DRAM through the interconnect. The transfer is started when the DMA transfer is enabled and the MMC1_DMA_REQ is asserted (that is, when the MMC buffer is ready).

Figure 7-16 is an overview of the path.

Figure 7-16. Overview

108-031

For the camcorder use case, the DMA transfer data format is:

- Frame size = 4096 x 32 bits
- packet size = 512 x 32 bits (512 elements ready in MMC when a DMA request is asserted)
- DMA channel to manage the transfer
- Interrupt generated at the end of each frame transfer
- Transfer triggered by MMC

7.6.1.3.2 Programming Flow

To establish a configuration for the DMA transfers, the following points have been considered.

The MMCHS_DATA register is 32 bits wide.

The SDMA is configured in packet synchronization mode. This mode enables to specify the transfer of any size frame and then to divide the frame into as many packet as needed. It is therefore possible to configure a frame of n elements and generate an interrupt at the end-of-frame transfer, while the transfer is segmented into packets.

The MMC puts its received data into a 1K-byte ping-pong buffer. When 512 x 32 bits are ready in this buffer, the DMA request is asserted. Then the DMA controller transfers the defined amount of elements divided into packets of 512 x 32-bit element (PKT_ELNT_NBR) transfers.

In the use case, the size of the transfer is set at 4096 x 32 bits, chosen after performance benches.

With these considerations, the DMA register of channel i is configured as follows:

1. Channel source destination parameters: [DMA4_CSDPi](#)

- [DMA4_CSDPi](#)[1:0] DATA_TYPE = 0x2: Read 32-bit elements from the MMCHS_DATA register.
- [DMA4_CSDPi](#)[5:2] RESERVED: Write 0s for future compatibility. Read returns 0.
- [DMA4_CSDPi](#)[6] SRC_PACKED = 0x0: Cannot pack source data
- [DMA4_CSDPi](#)[8:7] SRC_BURST_EN = 0x0: Cannot burst source
- [DMA4_CSDPi](#)[12:9] RESERVED: Write 0s for future compatibility. Read returns 0.
- [DMA4_CSDPi](#)[13] DST_PACKED = 0x0: No packing
- [DMA4_CSDPi](#)[15:14] DST_BURST_EN = 0x3: Burst at 16x32 bits
- [DMA4_CSDPi](#)[17:16] WRITE_MODE = 0x1: Write posted
- [DMA4_CSDPi](#)[18] DST_ENDIAN_LOCK = 0x0: Endianness adapt
- [DMA4_CSDPi](#)[19] DST_ENDIAN = 0x0: Little Endian type at destination
- [DMA4_CSDPi](#)[20] SRC_ENDIAN_LOCK = 0x0: Endianness adapt
- [DMA4_CSDPi](#)[21] SRC_ENDIAN = 0x0: Little endian type at source
- [DMA4_CSDPi](#)[31:22] RESERVED = 0x0: For future compatibility

2. Channel control register: [DMA4_CCRi](#)

- [DMA4_CCRi](#)[4:0] SYNCHRO_CONTROL = DmaReq & 0x1F = 0x1E: 5 first bits of MMC1_DMA_RX(62)
- [DMA4_CCRi](#)[5] FS = 1: Packet mode with BS = 0x1
- [DMA4_CCRi](#)[6] READ_PRIORITY = 0x0: Low priority on read side
- [DMA4_CCRi](#)[7] ENABLE = 0x0: The logical channel is disabled.
- [DMA4_CCRi](#)[8] SUSPEND_SENSITIVE = 0
- [DMA4_CCRi](#)[9] RD_ACTIVE: Read status, read-only access
- [DMA4_CCRi](#)[10] WR_ACTIVE: Write status, read-only access
- [DMA4_CCRi](#)[11] RESERVED = 0: Write 0s for future compatibility.
- [DMA4_CCRi](#)[13:12] SRC_AMODE = 0x0: Constant address mode; DMA always reads the MMCHS_DATA.
- [DMA4_CCRi](#)[15:14] DST_AMODE = 0x1: Post-incremented address mode
- [DMA4_CCRi](#)[16] CONST_FILL_ENABLE = 0x0: Constant fill mode is disabled.
- [DMA4_CCRi](#)[17] TRANSPARENT_COPY_ENABLE = 0x0: Transparent copy mode is disabled.
- [DMA4_CCRi](#)[18] BS = 0x1: Packet mode with FS = 0x1
- [DMA4_CCRi](#)[20:19] SYNCHRO_CONTROL_UPPER = 0x1: Two MSB of MMC1_DMA_RX(62)
- [DMA4_CCRi](#)[22] SUPERVISOR = 0x0: Supervisor mode is disabled.
- [DMA4_CCRi](#)[23] PREFETCH = 0x0: Prefetch mode is disabled; cannot prefetch a constant addressing source.
- [DMA4_CCRi](#)[24] SEL_SRC_DST_SYNC = 0x1: Transfer is triggered by the source. The packet element number is specified in the DMA4_CSF i register.
- [DMA4_CCRi](#)[25] BUFFERING_DISABLE = 0x0
- [DMA4_CCRi](#)[26] WRITE_PRIORITY = 0x0: Channel has low priority on write side during the arbitration process.
- [DMA4_CCRi](#)[31:27] RESERVED = 0x0: Write 0s for future compatibility.

3. Channel parameters: [DMA4_CENi](#), [DMA4_CFNi](#), [DMA4_CSSAi](#), [DMA4_CDSAi](#), [DMA4_CSEi](#), [DMA4_CSF \$i\$](#) , [DMA4_CDEi](#)

- [DMA4_CENi](#)[23:0] CHANNEL_ELMNT_NBR = 4096: 4096 elements
- [DMA4_CFNi](#)[15:0] CHANNEL_FRAME_NBR = 1: One frame
- [DMA4_CSSAi](#)[31:0] SRC_START_ADRS = 0x4809c120: Channel source start address = MMCHS_DATA
- [DMA4_CDSAi](#)[31:0] DST_START_ADRS = X: Channel destination start address in external DRAM
- [DMA4_CSEi](#)[31:0] CHANNEL_SRC_ELMNT_INDEX = 1: Channel source element index

- DMA4_CSF_i[15:0] 16BIT_PKT_ELNT_NBR = 0x200: Packet size = number odd data available in MMC after DMA req
 - DMA4_CDE_i[15:0] CHANNEL_DST_ELMNT_INDEX = 0x1: Channel destination element Index
4. Interrupt management: [DMA4_CICR_i](#) and [DMA4_IRQENABLE_L_j](#)
- [DMA4_CICR_i](#)[31:0] = 0x00000008: Enables the end-of-frame interrupt and disables others (the value of these registers is unknown after a reset; it is necessary to clear other bits)
 - DMA4_IRQENABLE_L0[31:0] = 0xi: Interrupt of channel i is unmasked on IRQ line L0.
5. Launch transfer: [DMA4_CCR_i](#)[7] ENABLE = 0x1: Enables the channel

[Table 7-10](#) lists the DMA channel 2 registers after a first transfer.

Table 7-10. Registers Print

| Register Name | Address | Value | Value Description |
|-------------------|------------|------------|--|
| DMA4_IRQENABLE_L0 | 0x48056018 | 0x00000003 | Interrupt of channel 2 is unmasked on IRQ line L0 |
| DMA4_CICR2 | 0x48056148 | 0x00000008 | End-of-frame interrupt enabled |
| DMA4_CCR2 | 0x48056140 | 0x010c403e | Channel control register |
| DMA4_CSDP2 | 0x48056150 | 0x0001c003 | Channel source destination parameters |

| DMA4_CFN2 | 0x48056158 | 0x00000001 | Channel frame number |
| DMA4_CSSA2 | 0x4805615c | 0x4809c120 | Channel source start address |
| DMA4_CDSA2 | 0x48056160 | 0x8071aafc | Channel destination start address |
| DMA4_CSF12 | 0x48056168 | 0x00000080 | Packet size |
| DMA4_CSAC2 | 0x48056174 | 0x49022000 | Source address counter (read only) |
| DMA4_CDAC2 | 0x48056178 | 0x8071acfc | Destination address counter (read only) |
| DMA4_CCEN2 | 0x4805617c | 0x00000080 | Channel current transferred element number in the current frame (read only) |
| DMA4_CCFN12 | 0x48056180 | 0x00000000 | Channel current transferred frame number in the current transfer (read only) |
| DMA4_CLNK_CTRL2 | 0x48056144 | 0x00000000 | Channel link control register: No link |

7.7 SDMA Registers Manual

This section provides a global view of the memory mapping as seen from the MPU for SDMA. [Table 7-11](#) show the DMA register base address.

7.7.1 SDMA Instance Summary

Table 7-11. SDMA Instances Summary

| Module Name | Base Address | Size |
|-------------|--------------|----------|
| SDMA | 0x4805 6000 | 4K bytes |

7.7.2 SDMA Register Summary

[Table 7-12](#) lists all DMA4 controller registers and their physical addresses. [Table 7-13](#) through [Table 7-66](#) describe the individual register bits.

Index *i* represents the logical channel number (*i* = 0 to 31). The offset address for some registers is calculated from channel *c* number. For example, register SDMA.DMA4_CCR10 (channel 10) has an offset address of $10 \times 0x60 = 0x3C0$, and so a physical address of $0x4800 A080 + 0x3C0 = 0x4800 A440$.

Index *j* represents the interrupt line number (*j* = 0 to 3) The offset address for some registers is calculated from channel *c* number. For example, register SDMA.DMA4_IRQSTATUS_L3 (line 3) has an offset address of $3 \times 0x4 = 0xC$, and so a physical address of $0x4800 A008 + 0xC = 0x4800 A014$.

Table 7-12. SDMA Register Summary

| Register Name | Type | Register Width (Bits) | Address Offset | SDMA Physical Address |
|--------------------|------|-----------------------|----------------------------------|----------------------------------|

7.7.3 SDMA Register Description

This section describes the registers used in the DMA4 controller.

NOTE: Some registers have no reset value (marked with -) because of hardware implementation in memory. Software must ensure the correct programming of these registers, if needed.

The shadow registers are used to read run time registers such as CCEN, CCFN, CDAC, or CSAC. Typically, when accessed in 8-bit or 16-bit access for two consecutive accesses, the value of the previous registers may change. This shadow register is used to hold the whole value to allow the next access to recover the remaining 24 bits or 16 bits.

The CSAC, CDAC, CCEN, and CCFN registers must be written or read in a way that enables the LSByte; otherwise, the shadow registers do not update the register.

There is no issue for 32-bit read-write transactions. For 16-bit transactions, read or write the LSByte first to enable the register update.

Table 7-13 through Table 7-66 describe the DMA register bits.

Table 7-13. DMA4_REVISION

| RESERVED | | | | | | | | | | | | | | | | MIDLEMODE | RESERVED | CLOCKACTIVITY | RESERVED | EMUFREE | SIDLEMODE | RESERVED | SOFTRESET | AUTOIDLE | | | | | | | |

| Bits | Field Name | Description | Type | Reset |
|-------|------------|---|------|---------|
| 31:14 | RESERVED | Write 0s for future compatibility, Reads return 0 | RW | 0x00000 |
| 13:12 | MIDLEMODE | Read write power management, standby/wait control 0x0: Force-standby: MStandby is asserted only when all the DMA channels are disabled 0x1: No-Standby: MStandby is never asserted 0x2: Smart-Standby: MStandby is asserted if at least one of the following two conditions is satisfied: 1. All the channels are disabled, OR 2. There is no non-synchronized channel enabled AND [if hardware synchronized channel is enabled, then no DMA request input is asserted and no requests are pending to be serviced.] 0x3: reserved for second smart-standby mode if needed | RW | 0x0 |
| 11:10 | RESERVED | Reserved for clocks activities extension | RW | 0x0 |

| Bits | Field Name | Description | Type | Reset |
|------|---------------|---|------|-------|
| 9:8 | CLOCKACTIVITY | Clocks activities during wake-up Bit 8: OCP interface clock 0 OCP clock can be switched-off Bit 9: Functional clock 0 Functional clock can be switched-off | R | 0x0 |
| 7:6 | RESERVED | Reserved. Write 0s for future compatibility. Read returns 0. | RW | 0x0 |
| 5 | EMUFREE | Enable sensitivity to MSuspend 0x0: DMA4 freezes its internal logic upon MSuspend assertion 0x1: DMA4 ignores the MSuspend input | RW | 0x0 |
| 4:3 | SIDLEMODE | Configuration port power management, Idle req/ack control 0x0: Force-idle. An idle request is acknowledged unconditionally 0x1: No-idle. An idle request is never acknowledged 0x2: Smart-idle. Idle acknowledge is given by DMA4 if all of the conditions are true: 1. All the channels are disabled. 2. If hardware synchronized channel is enabled, then no DMA request input is asserted and no requests are pending to be serviced. 3. All transactions are completed on all the DMA ports. 4. No interrupts are pending to be serviced. 0x3: reserved - do not use. | RW | 0x0 |
| 2 | RESERVED | Write 0s for future compatibility, Reads return 0 | RW | 0x0 |
| 1 | SOFTRESET | Software reset. Set this bit to 1 to trigger a module reset. The bit is automatically reset by the hardware. During reads, it always returns 0. 0x0: No effect 0x1: Reset | RW | 0x0 |
| 0 | AUTOIDLE | Internal OCP clock gating strategy 0x0: OCP clock is free running 0x1: Automatic OCP clock gating strategy is applied, based on the OCP interface activity. | RW | 0x0 |

|-------|------------------|---|------|-------|
| 31:24 | RESERVED | Reserved. Write 0s for future compatibility. Read returns 0. | RW | 0x00 |
| 23:16 | ARBITRATION_RATE | Arbitration switching rate between prioritized and regular channel queues | RW | 0x01 |

| Bits | Field Name | Description | Type | Reset |
|-------|------------------------|--|------|-------|
| 15:14 | HI_LO_FIFO_BUDGET | <p>Allow to have a separate Global FIFO budget for high and low priority channels.</p> <p>For Hi priority Channel: (Per_channel_Maximum FIFO depth + 1) x Number of active High priority Channel =< High Budget FIFO</p> <p>For Low priority channel: (Per_channel_Maximum FIFO depth + 1) x Number of active Low priority Channel =< Low Budget FIFO</p> <p>0x0: no fixed budget for neither higher nor lower priority channel</p> <p>0x1: 75% of FIFO for low priority and 25% for high priority channels</p> <p>0x2: 25% of FIFO for low priority and 75% for high priority channels</p> <p>0x3: 50% of FIFO for low priority and 50% for high priority channels</p> | RW | 0x0 |
| 13:12 | HI_THREAD_RESERVED | <p>Allow thread reservation for high priority channel on both read and write ports.</p> <p>0x0: No ThreadID is reserved on the Read Port for high priority channels. No ThreadID is reserved on the Write Port for high priority channels.</p> <p>0x1: Read Port ThreadID 0 is reserved for high priority channels. Write Port ThreadID 0 is reserved for high priority channels.</p> <p>0x2: Read port ThreadID 0 and ThreadID 1 are reserved for high priority channels. Write Port ThreadID 0 is reserved for high priority channels.</p> <p>0x3: Read PortThreadID 0, ThreadID 1 and ThreadID 2 are reserved for high priority channels. Write Port ThreadID 0 is reserved for high priority channels.</p> | RW | 0x0 |
| 11:8 | RESERVED | Reserved. Write 0s for future compatibility. Read returns 0. | RW | 0x0 |
| 7:0 | MAX_CHANNEL_FIFO_DEPTH | <p>Maximum FIFO depth allocated to one logical channel. Maximum FIFO depth can not be 0x0. It should be at least 0x1 or greater. Note that If channel limit is less than destination burst size enough data will not be accumulated in the data FIFO and it will never be sent out on the WR port. The burst size should be less than the FIFO limit specified in this bit field.</p> | RW | 0x10 |

| Bits | Field Name | Description | Type | Reset |
|-------|-----------------------|---|------|-------|
| 31:27 | RESERVED | Reserved. Write 0s for future compatibility. Read returns 0. | RW | 0x00 |
| 26 | WRITE_PRIORITY | Channel priority on the Write side 0x0: Channel has low priority on the Write side during the arbitration process 0x1: Channel has high priority on Write sided during the arbitration process | RW | 0x0 |
| 25 | BUFFERING_DISABLE | This bit allows to disable the default buffering functionality when transfer is source synchronized. 0x0: buffering is enable across element/packet when source is synchronized to element, packet, frame or blocks 0x1: buffering is disabled across element/packet when source is synchronized to element, packet, frame or blocks | RW | 0x- |
| 24 | SEL_SRC_DST_SYNC | Specifies that element, packet, frame or block transfer (depending on CCR.bs and CCR.fs) is triggered by the source or the destination on the DMA request 0x0: Transfer is triggered by the destination. If synch on packet the packet element number is specified in the CDFI register 0x1: Transfer is triggered by the source. If synchronized on packet the packet element number is specified in the CSFI register | RW | 0x- |
| 23 | PREFETCH | Enables the prefetch mode 0x0: Prefetch mode is disabled. When Sel_Src_Dst_Sync=1 transfers are buffered and pipelined between DMA requests 0x1: Prefetch mode is enabled. Prefetch mode is active only when destination is synchronized. It is SW user responsibility not to have at the same time Prefetch=1 when Sel_Src_Dst_Sync=1. This mode is not supported | RW | 0x0 |
| 22 | SUPERVISOR | Enables the supervisor mode 0x0: Supervisor mode is disabled 0x1: Supervisor mode is enabled | RW | 0x0 |
| 21 | RESERVED | Reserved for non-GP devices | RW | 0x0 |
| 20:19 | SYNCHRO_CONTROL_UPPER | Channel Synchronization control upper (used in conjunction with the 5 bits of synchro channel DMA4_CCRi[4:0]) Used in conjunction, as two msb, with the five bits of the synchro channel bit field. | RW | 0x0 |

| Bits | Field Name | Description | Type | Reset |
|-------|-------------------------|---|------|-------|
| 18 | BS | Block synchronization This bit used with the fs to see how the DMA request is serviced in a synchronized transfer | RW | 0x- |
| 17 | TRANSPARENT_COPY_ENABLE | Transparent copy enable 0x0: Transparent copy mode is disabled 0x1: Transparent copy mode is enabled | RW | 0x- |
| 16 | CONST_FILL_ENABLE | Constant fill enable 0x0: Constant fill mode is disabled 0x1: Constant fill mode is enabled | RW | 0x0 |
| 15:14 | DST_AMODE | Selects the addressing mode on the Write Port of a channel. 0x0: Constant address mode 0x1: Post-incremented address mode 0x2: Single index address mode 0x3: Double index address mode | RW | 0x- |
| 13:12 | SRC_AMODE | Selects the addressing mode on the Read Port of a channel. 0x0: Constant address mode 0x1: Post-incremented address mode 0x2: Single index address mode 0x3: Double index address mode | RW | 0x- |
| 11 | RESERVED | Reserved. Write 0s for future compatibility. Read returns 0. | RW | 0x0 |
| 10 | WR_ACTIVE | Indicates if the channel write context is active or not 0x0: Channel is not active on the write port 0x1: Channel is active on the write port | R | 0x0 |
| 9 | RD_ACTIVE | Indicates if the channel read context is active or not 0x0: Channel is not active on the read port 0x1: Channel is currently active on the read port | R | 0x0 |
| 8 | SUSPEND_SENSITIVE | Logical channel suspend enable bit 0x0: The channel ignores the MSuspend even if EMUFree is set to 0. 0x1: If EMUFree is set to 0 and MSuspend comes in then all current OCP services (single transaction or burst transaction as specified in the corresponding CSDP register) have to be completed before stopping processing any more transactions | RW | 0x0 |
| 7 | ENABLE | Logical channel enable. It is SW responsibility to clear the CSR register and the IRQSTATUS bit for the different interrupt lines before enabling the channel. 0x0: The logical channel is disabled 0x1: The logical channel is enabled | RW | 0x0 |
| 6 | READ_PRIORITY | Channel priority on the read side 0x0: Channel has low priority on the Read side during the arbitration process 0x1: Channel has high priority on read sided during the arbitration process | RW | 0x0 |
| 5 | FS | Frame synchronization This bit used with the BS to see how the DMA request is serviced in a synchronized transfer FS=0 and BS=0: An element is transferred once a DMA request is made. FS=0 and BS=1: An entire block is transferred once a DMA request is made. FS=1 and BS=0: An entire frame is transferred once a DMA request is made. FS=1 and BS=1: A packet is transferred once a DMA request is made. All these different transfers can be interleaved on the port with other DMA requests. | RW | 0x- |

| Bits | Field Name | Description | Type | Reset |
|------|-----------------|---|------|-------|
| 4:0 | SYNCHRO_CONTROL | Channel synchronization control This bit field used with the second_level_synchro_control_upper (as two msb) 0000000 : Is reserved for non synchronized LCH transfer xxxxxxx (from 1 to 127) There are 127 possible DMA request to assign to any LCH. Note: The channel synchronization control registers are 1-based. For example, to enable the S_DMA_1 request, SYNCHRO_CONTROL bits (formed by DMA_CCRi[20:19] and DMA4_CCRi[4:0]) must be set to 0x2 (DMA request number + 1). | RW | 0x0 |

Interrupt Controller (INTC)

This chapter describes in detail the MPU subsystem interrupt controller (MPU_INTC) module used in the stand-alone processor.

NOTE: This chapter gives information about all modules and features in the high-tier device. See Chapter 1, *Device Family* section, to check availability of modules and features. Ensure that interrupts of unavailable modules and features are masked in MPU subsystem.

| Topic | Page |

| 8.2 Interrupt Controller Environment | 865 |
| 8.3 MPU Subsystem INTCPS Integration | 866 |
| 8.4 Interrupt Controller Functional Description | 869 |
| 8.5 Interrupt Basic Programming Model | 874 |
| 8.6 Interrupt Controller Registers | 882 |

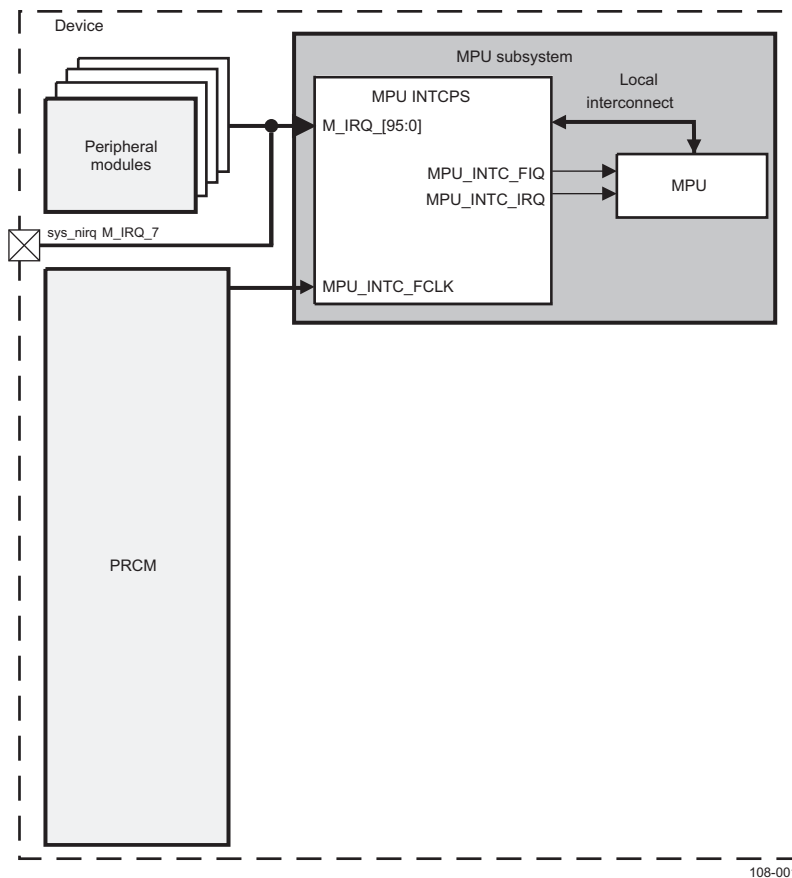

8.1 Interrupt Controller Overview

The device has one interrupt controller (INTC) module, the MPU subsystem INTC (INTCPS). This module handles all MPU-related events, using Priority Threshold and Security Features. It communicates with the ARM Cortex-A8™ processor using a private local interconnect, and runs at half the speed of the processor.

NOTE: Some features may not be available or supported in your particular device. For more information, see Chapter 1, the *Device Family* section, and your device-specific data manual.

Figure 8-1 shows the internal interrupt scheme.

Figure 8-1. Interrupt Controller Highlight

8.2 Interrupt Controller Environment

The INTC can handle two types of interrupts originating from an external device:

- sys_nirq interrupt inputs:

The MPU INTC handles external interrupts through a dedicated sys_nirq interrupt line that connects the INTC module with a TPS65950 power IC. An interrupt can generate a system wake-up event.

If the system is idle and the external interrupt is masked, the interrupt cannot wake up the system. Like other interrupt lines, the external interrupt is active at low level and is acknowledged by the software according to the common programming model.

- GPIO interrupt inputs:

External devices can also use GPIO modules to generate interrupts to the MPU. There are six dedicated interrupt lines to the MPU INTC. One interrupt line is associated with each GPIO module. Each GPIO module can generate a single interrupt whenever there is at least one event in any one of the configured 32 GPIO inputs. For more information about GPIO features, see the *General-Purpose Interface* chapter.

Figure 8-2 shows the relationship between the device and external interrupts.

Figure 8-2. Interrupts from External Devices

The features specific to INTCPS are:

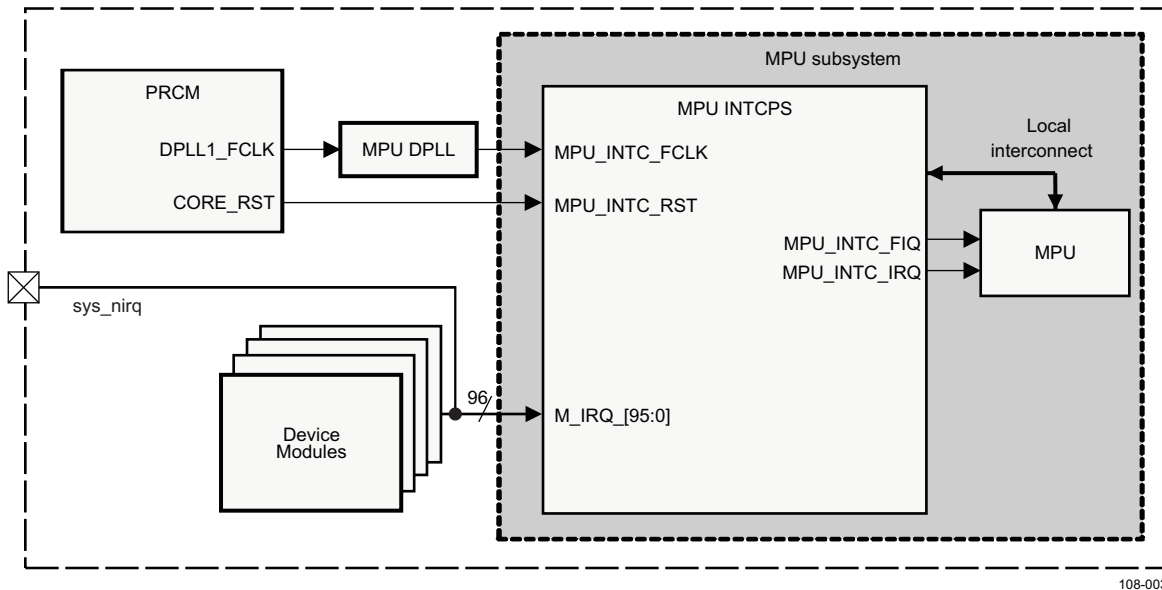

- Up to 96 level-sensitive interrupt inputs
- Individual priority (up to 64) for each interrupt input
- Interrupt lines connected to internal module interrupts
- One incoming interrupt line from an external device

8.3 MPU Subsystem INTCPS Integration

The INTCPS module is the interface between incoming interrupts and the two interrupt inputs of the MPU. It can handle up to 96 request inputs that can be configured as MPU FIQ or IRQ interrupt requests.

Figure 8-3 shows the integration of the INTCPS in the MPU subsystem.

Figure 8-3. MPU Subsystem INTCPS Integration

The MPU subsystem INTCPS is directly connected to the MPU by an MPU peripheral port. Consequently, the MPU subsystem INTCPS is accessible and visible only by the MPU.

8.3.1 Clocking, Reset, and Power Management Scheme

8.3.1.1 MPU Subsystem INTC Clocks

The MPU subsystem INTCPS runs at half the rate of the MPU functional clock (see the *MPU Subsystem* chapter).

The interface clock used for register access runs at the rate of the interconnect bus clock (equal to the rate of the MPU interface clock; see the *Power, Reset, and Clock Management* chapter).

The synchronizer clock allows external asynchronous interrupts to be resynchronized before they are masked.

Table 8-1 lists the MPU subsystem INTC clock rates.

Table 8-1. MPU Subsystem INTC Clock Rates

| Clock | Frequency | Name | Comments |
|--------------|---------------|--|------------------------------|
| Functional | ARM_FCLK | MPU_INTC_FCLK | Source is the MPU DPLL. |
| Interface | ARM_FCLK | MPU_INTC_ICLK | Source is the PRCM module. |
| Synchronizer | MPU_INTC_FCLK | Synchronizer clock (module internal clock) | Source is the MPU_INTC_FCLK. |

8.3.1.2 Hardware and Software Reset

Table 8-2 lists the MPU subsystem INTC resets.

Table 8-2. Hardware and Software Reset

| Type | Name | Source | Activation | Domain |
|----------|-----------|---|-------------|-------------------|
| Hardware | CORE_RST | PRCM | Active low | CORE |
| Software | SOFTRESET | MPU_INTC.INTCPS_SYSCONFIG[1] SOFTRESET bit | Active at 1 | MPU INTC internal |

8.3.1.3 Power Management

The MPU subsystem INTC belongs to the CORE power domain. As part of CORE power domain, it is sensitive to a CORE_RST issued by the PRCM. For more information about the CORE power domain implementation and CORE_RST signal, see the *Power, Reset, and Clock Management* chapter.

The MPU INTC clocks come from the MPU DPLL. For more information about these clocks control, see the *MPU Subsystem* chapter.

8.3.2 Interrupt Request Lines

Table 8-3 lists the incoming and outgoing interrupt lines of the INTCPS.

Table 8-3. Interrupt Lines Incoming and Outgoing

| Type | Number | Name | Mapping | Comments |
|---------------------------|----------|--------------|---------------|---|
| Interrupt request inputs | Up to 96 | M_IRQ_[95:0] | See Table 8-4 | Inputs to INTCPS module, source from various modules. |
| Interrupt request outputs | 2 | MPU_INTC_FIQ | MPU_INTC_FIQ | Outgoing to MPU Fast Interrupt |
| | | MPU_INTC_IRQ | MPU_INTC_IRQ | Outgoing to MPU Normal Interrupt |

NOTE: Interrupt request signals are active at low level.

This section gives information about all modules and features in the high-tier device. See Chapter 1, *Device Family* section, to check availability of modules and features. Ensure that interrupts of unavailable modules and features are masked in MPU subsystem.

Table 8-4 lists interrupt mappings to the MPU subsystem.

8.4 Interrupt Controller Functional Description

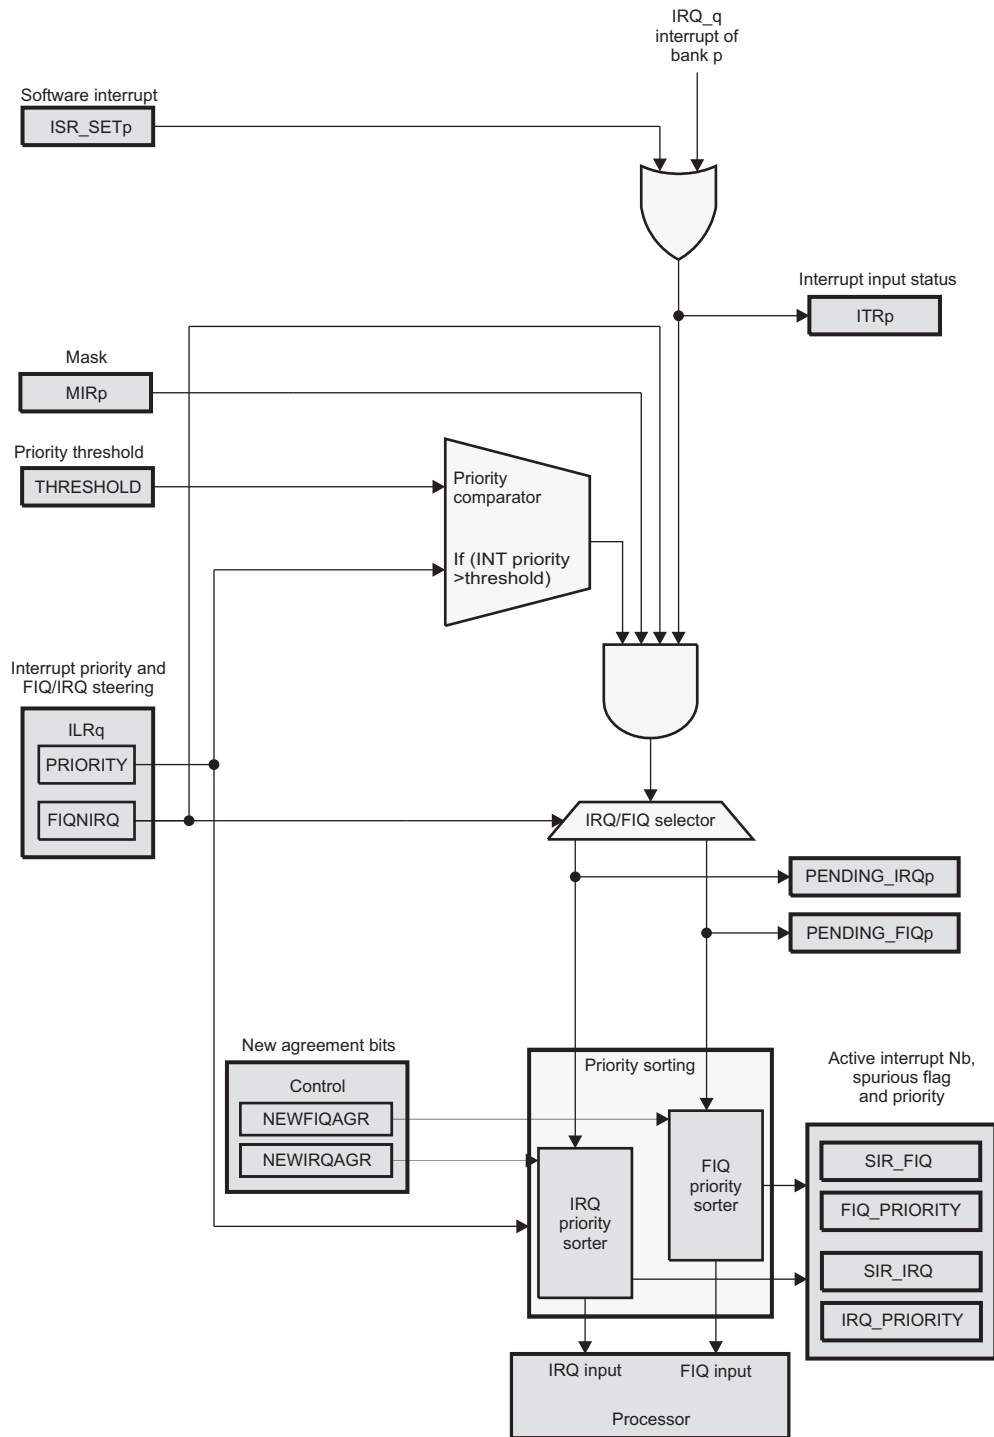

The main features of the INTCPS are:

- Individual priority (up to 64 levels) for each interrupt input
- Ability for each interrupt to be steered to either FIQ or IRQ
- Independent priority sorting for FIQ and IRQ; FIQ sorting is processed concurrently with IRQ sorting.
- Priority masking: Interrupts can be masked based on the priority threshold register.
- Atomic bit set and clear capability for interrupt mask and software interrupt registers
- For high-security (HS) devices only:
 - Global interrupt mask
 - Protection for secure interrupts
- Power-management and wake-up support
- Auto-idle power-saving support

The INTCPS processes incoming interrupts by masking and priority sorting, then it generates the interrupt requests to the MPU.

[Figure 8-4](#) shows the top-level view of the interrupt processing.

Figure 8-4. Top-Level Block Diagram

intc-004

- (1) Public Mask = $SICR[3]$ PUBLICINHIBIT bit OR ($SICR[2]$ AUTOINHIBIT bit AND $SICR[0]$ SSMFIQSTATUS bit)
- (2) The $SCRn$ forces the interrupt priority to 0 (highest).
- (3) The $SCRn$ forces the interrupt to FIQ.
- (4) The comparator output is TRUE only if the interrupt priority is higher than the threshold register priority. The highest priority is 0x0; the lowest priority is 0x3F (63).

8.4.1 Interrupt Processing

8.4.1.1 Input Selection

The INTCPS supports only level-sensitive incoming interrupt detection. A peripheral asserting an interrupt maintains it until software has handled the interrupt and instructed the peripheral to de-assert the interrupt.

A software interrupt is generated if the corresponding bit in the MPU_INTC.INTCPS_ISR_SETn register is set (register bank number: $n = [0,2]$ for the MPU subsystem INTCPS, 96 incoming interrupt lines are supported). The software interrupt clears when the corresponding bit in the MPU_INTC.INTCPS_ISR_CLEARn register is written. Typical use of this feature is software debugging.

8.4.1.2 Masking

8.4.1.2.1 Individual Masking

Detection of interrupts on each incoming interrupt line can be enabled or disabled independently by the MPU_INTC.INTCPS_MIRn interrupt mask register. In response to an unmasked incoming interrupt, the INTCPS can generate one of two types of interrupt requests to the processor:

- IRQ: low-priority interrupt request
- FIQ: fast interrupt request

The type of interrupt request is determined by the MPU_INTC.INTCPS_ILRm[0] FIQNIRQ bit ($m = [0,95]$).

The current incoming interrupt status before masking is readable from the MPU_INTC.INTCPS_ITRn register. After masking and IRQ/FIQ selection, and before priority sorting is done, the interrupt status is readable from the MPU_INTC.INTCPS_PENDING_IRQn and MPU_INTC.INTCPS_PENDING_FIQn registers.

8.4.1.2.2 Global Masking (HS Devices Only)

Software may use global masking for security purposes, but this feature must be used with care. To determine if a HS version of your device is available and for more information on HS devices, please refer to your device-specific data manual.

8.4.1.2.3 Priority Masking

To enable faster processing of high-priority interrupts, a programmable priority masking threshold is provided (the MPU_INTC.INTCPS_THRESHOLD[7:0] PRIORITYTHRESHOLD field). This priority threshold allows preemption by higher priority interrupts; all interrupts of lower or equal priority than the threshold are masked. However, priority 0 can never be masked by this threshold; a priority threshold of 0 is treated the same way as priority 1.

PRIORITY and PRIORITYTHRESHOLD fields values can be set between 0x0 and 0x3F; 0x0 is the highest priority and 0x3F is the lowest priority.

When priority masking is not necessary, a priority threshold value of 0xFF disables the priority threshold mechanism. This value is also the reset default for backward compatibility with previous versions of the INTCPS.

8.4.1.3 Priority Sorting

A priority level (0 being the highest) is assigned to each incoming interrupt line. Both the priority level and the interrupt request type are configured by the MPU_INTC.INTCPS_ILRm register. If more than one incoming interrupt with the same priority level and interrupt request type occur simultaneously, the highest-numbered interrupt is serviced first.

When one or more unmasked incoming interrupts are detected, the INTCPS separates between IRQ and FIQ using the corresponding MPU_INTC.INTCPS_ILRm[0] FIQNIRQ bit. The result is placed in INTCPS_PENDING_IRQn or INTCPS_PENDING_FIQn

If no other interrupts are currently being processed, INTCPS asserts IRQ/FIQ and starts the priority computation. Priority sorting for IRQ and FIQ can execute in parallel.

Each IRQ/FIQ priority sorter determines the highest priority interrupt number. Each priority number is placed in the corresponding MPU_INTC.INTCPS_SIR_IRQ[6:0] ACTIVEIRQ field or MPU_INTC.INTCPS_SIR_FIQ[6:0] ACTIVEFIQ field. The value is preserved until the corresponding MPU_INTC.INTCPS_CONTROL NEWIRQAGR or NEWFIQAGR bit is set.

Once the interrupting peripheral device has been serviced and the incoming interrupt de-asserted, the user must write to the appropriate NEWIRQAGR or NEWFIQAGR bit to indicate to the INTCPS the interrupt has been handled. If there are any pending unmasked incoming interrupts for this interrupt request type, the INTCPS restarts the appropriate priority sorter; otherwise, the IRQ or FIQ interrupt line is de-asserted.

8.4.2 Secure Interrupts (HS Devices Only)

To determine if a HS version of your device is available and for more information on HS devices, please refer to your device-specific data manual.

8.4.3 Register Protection

If the MPU_INTC.INTCPS_PROTECTION[0] PROTECTION bit is set, access to the INTCPS registers is restricted to the supervisor mode. Access to the MPU_INTC.INTCPS_PROTECTION register is always restricted to privileged mode.

8.4.4 Module Power Saving

The INTCPS provides an auto-idle function in its three clock domains:

- Interface clock
- Functional clock
- Synchronizer clock

The interface clock auto-idle power-saving mode is enabled if the MPU_INTC.INTCPS_SYSCONFIG[0] AUTOIDLE bit is set to 1. When this mode is enabled and there is no activity on the bus interface, the interface clock is disabled internally to the module, thus reducing power consumption. When there is new activity on the bus interface, the interface clock restarts without any latency penalty. After reset, this mode is disabled, by default.

The functional clock auto-idle power-saving mode is enabled if the MPU_INTC.INTCPS_IDLE[0] FUNCIDLE bit is set to 0. When this mode is enabled and there is no active interrupt (IRQ or FIQ interrupt being processed or generated) or no pending incoming interrupt, the functional clock is disabled internally to the module, thus reducing power consumption. When a new unmasked incoming interrupt is detected, the functional clock restarts and the INTCPS processes the interrupt. If this mode is disabled, the interrupt latency is reduced by one cycle. After reset, this mode is enabled, by default.

The synchronizer clock allows external asynchronous interrupts to be resynchronized before they are masked. The synchronizer input clock has an auto-idle power-saving mode enabled if the MPU_INTC.INTCPS_IDLE[1] TURBO bit is set to 1. If the auto-idle mode is enabled, the standby power is reduced, but the IRQ or FIQ interrupt latency increases from four to six functional clock cycles. This feature can be enabled dynamically according to the requirements of the device. After reset, this mode is disabled, by default.

To ensure optimal power consumption, INTC_INIT_REGISTER1[0] INIT1 and INTC_INIT_REGISTER2[1] INIT2 bits must be set to 1 during initialization.

8.4.5 Interrupt Latency

The IRQ/FIQ interrupt generation takes four INTCPS functional clock cycles (plus or minus one cycle) if the MPU_INTC.INTCPS_IDLE[1] TURBO bit is set to 0. If the TURBO bit is set to 1, the interrupt generation takes six cycles, but power consumption is reduced while waiting for an interrupt.

These latencies can be reduced by one cycle by disabling functional clock auto-idle (MPU_INTC.INTCPS_IDLE[0] FUNCIDLE bit set to 1), but power consumption is increased, so the benefit is minimal. For information about power saving, see [Section 8.4.4](#).

To minimize interrupt latency when an unmasked interrupt occurs, the IRQ or FIQ interrupt is generated before priority sorting completion. The priority sorting takes 10 functional clock cycles, which is less than the minimum number of cycles required for the MPU to switch to the interrupt context after reception of the IRQ or FIQ event.

Any read of the MPU_INTC.INTCPS_SIR_IRQ or MPU_INTC.INTCPS_SIR_FIQ register during the priority sorting process stalls until priority sorting is complete and the relevant register is updated. However, the delay between the interrupt request being generated and the interrupt service routine being executed is such that priority sorting always completes before the MPU_INTC.INTCPS_SIR_IRQ or MPU_INTC.INTCPS_SIR_FIQ register is read.

8.5 Interrupt Basic Programming Model

8.5.1 Initialization Sequence

1. Program the MPU_INTC.INTCPS_SYSCONFIG register: If necessary, enable the interface clock autogating by setting the AUTOIDLE bit.
2. Program the MPU_INTC.INTCPS_IDLE register: If necessary, disable functional clock autogating or enable synchronizer autogating by setting the FUNCIDLE bit or TURBO bit accordingly.
3. Program the MPU_INTC.INTCPS_ILRm register for each interrupt line: Assign a priority level and set the FIQNFIQ bit for an FIQ interrupt (by default, interrupts are mapped to IRQ and priority is 0x0 [highest]).
4. Program the MPU_INTC.INTCPS_MIRn register: Enable interrupts (by default, all interrupt lines are masked).

NOTE: To program the MPU_INTC.INTCPS_MIRn register, the MPU_INTC.INTCPS_MIR_SETn and MPU_INTC.INTCPS_MIR_CLEARn registers are provided to facilitate the masking, even if it is possible for backward-compatibility to write directly to the MPU_INTC.INTCPS_MIRn register.

8.5.2 MPU INTC Processing Sequence

After the MPU_INTC.INTCPS_MIRn and MPU_INTC.INTCPS_ILRm registers are configured to enable and assign priorities to incoming interrupts, the interrupt is processed as explained in the following subsections.

IRQ and FIQ processing sequences are quite similar, the differences for the FIQ sequence are shown after a '/' character in **bold** characters in the text or the code below.

1. One or more unmasked incoming interrupts (M_IRQ_n signals) are received and IRQ or FIQ outputs (MPU_INTC_IRQ/**FIQ**) are not currently asserted.
2. If the MPU_INTC.INTCPS_ILRm[0] FIQNIRQ bit is set to 0, the MPU_INTC_IRQ output signal is generated. If the FIQNIRQ bit is set to 1, the MPU_INTC_FIQ output signal is generated.
3. The INTC performs the priority sorting and updates the MPU_INTC.INTCPS_SIR_IRQ[6:0] ACTIVEIRQ/**MPU_INTC.INTCPS_SIR_FIQ[6:0] ACTIVEFIQ** field with the current interrupt number.
4. During priority sorting, if the IRQ/**FIQ** is enabled at the host processor side, the host processor automatically saves the current context and executes the ISR as follows:

NOTE: The ARM host processor automatically performs the following actions in pseudo code.

```

LR = PC + 4                /* return link                */
SPSR = CPSR                /* Save CPSR before execution */
CPSR[5] = 0                /* Execute in ARM state      */
CPSR[7] = 1                /* Disable IRQ                */
CPSR[8] = 1                /* Disable Imprecise Data Aborts */
CPSR[9] = CP15_reg1_EEbit  /* Endianness on exception entry */
if interrupt == IRQ then
    CPSR[4:0] = 0b10010    /* Enter IRQ mode            */
    if high vectors configured then

```

```

        PC = 0xFFFF0018
    else
        PC = 0x00000018          /* execute interrupt vector      */
else if interrupt == FIQ then
    CPSR[4:0] = 0b10001        /* Enter FIQ mode              */
    CPSR[6] = 1                /* Disable FIQ                  */
    if high vectors configured then
        PC = 0xFFFF001C
    else
        PC = 0x0000001C        /* execute interrupt vector      */
end if

```

5. The ISR saves the remaining context, identifies the interrupt source by reading the **ACTIVEIRQ/ACTIVEFIQ** field, and jumps to the relevant subroutine handler as follows:

CAUTION

The code in steps 5 and 7 is an assembly code compatible with ARM architecture V6 and V7. This code is developed for the Texas Instruments Code Composer Studio tool set. It is a draft version, only tested on an emulated environment.

    MRS R11, SPSR                    ; Save the SPSR into R11

    ; Get the number of the highest priority active IRQ/FIQ
    LDR R10, INTCPS_SIR_IRQ_ADDR/INTCPS_SIR_FIQ_ADDR
    LDR R10, [R10]                    ; Get the INTCPS_SIR_IRQ/INTCPS_SIR_FIQ register
    AND R10, R10, #ACTIVEIRQ_MASK     ; Apply the mask to get the active IRQ number

    ; Jump to relevant subroutine handler
    LDR PC, [PC, R10, lsl #2]         ; PC base address points this instruction + 8
    NOP                                ; To index the table by the PC

    ; Table of handler start addresses
    .word IRQ0handler ;For IRQ0 of BANK0
    .word IRQ1handler
    .word IRQ2handler

```

6. The subroutine handler executes code specific to the peripheral generating the interrupt by handling the event and de-asserting the interrupt condition at the peripheral side.

```

; IRQ0 subroutine
IRQ0handler:

    ; Save working registers
    STMFD SP!, {R0-R1}

    ; Now read-modify-write the peripheral module status register
    ; to de-assert the M_IRQ_0 interrupt signal

    ; De-Assert the peripheral interrupt
    MOV R0, #0x7                      ; Mask for 3 flags
    LDR R1, MODULE0_STATUS_REG_ADDR   ; Get the address of the module Status Register
    STR R0, [R1]                       ; Clear the 3 flags

    ; Restore working registers

```

```
LDMFD SP!, {R0-R1}
```

```
; Jump to the end part of the ISR
B IRQ_ISR_end/FIQ_ISR_end
```

7. After the return of the subroutine, the ISR sets the **NEWIRQAGR/NEWFIQAGR** bit to enable the processing of subsequent pending IRQs/**FIQs** and to restore ARM context in the following code. Because the writes are posted on an Interconnect bus, to be sure that the preceding writes are done before enabling IRQs/**FIQs**, a Data Synchronization Barrier is used. This operation ensure that the IRQ/**FIQ** line is de-asserted before IRQ/**FIQ** enabling. After that, the INTC processes any other pending interrupts or de-asserts the MPU_INTC_IRQ/**MPU_INTC_FIQ** signal if there is no interrupt.

```
; INTCPS_CONTROL register address
INTCPS_CONTROL_ADDR .word 0x48200048
```

```
; NEWIRQAGR/NEWFIQAGR bit mask to set only the NEWIRQAGR/NEWFIQAGR bit
NEWIRQAGR_MASK/NEWFIQAGR_MASK .equ 0x01/0x02
```

```
IRQ_ISR_end/FIQ_ISR_end:
```

```
; Allow new IRQs/FIQs at INTC side
; The INTCPS_CONTROL register is a write only register so no need to write back others bits
MOV R0, #NEWIRQAGR_MASK/NEWFIQAGR_MASK ; Get the NEWIRQAGR/NEWFIQAGR bit position
LDR R1, INTCPS_CONTROL_ADDR
STR R0, [R1] ; Write the NEWIRQAGR/NEWFIQAGR bit to allow new IRQs/FIQs
```

```
; Data Synchronization Barrier
MOV R0, #0
MCR P15, #0, R0, C7, C10, #4
```

```
; restore critical context
MSR SPSR, R11 ; Restore the SPSR from R11
LDMFD SP!, {R0-R12, LR} ; Restore working registers and Link register
```

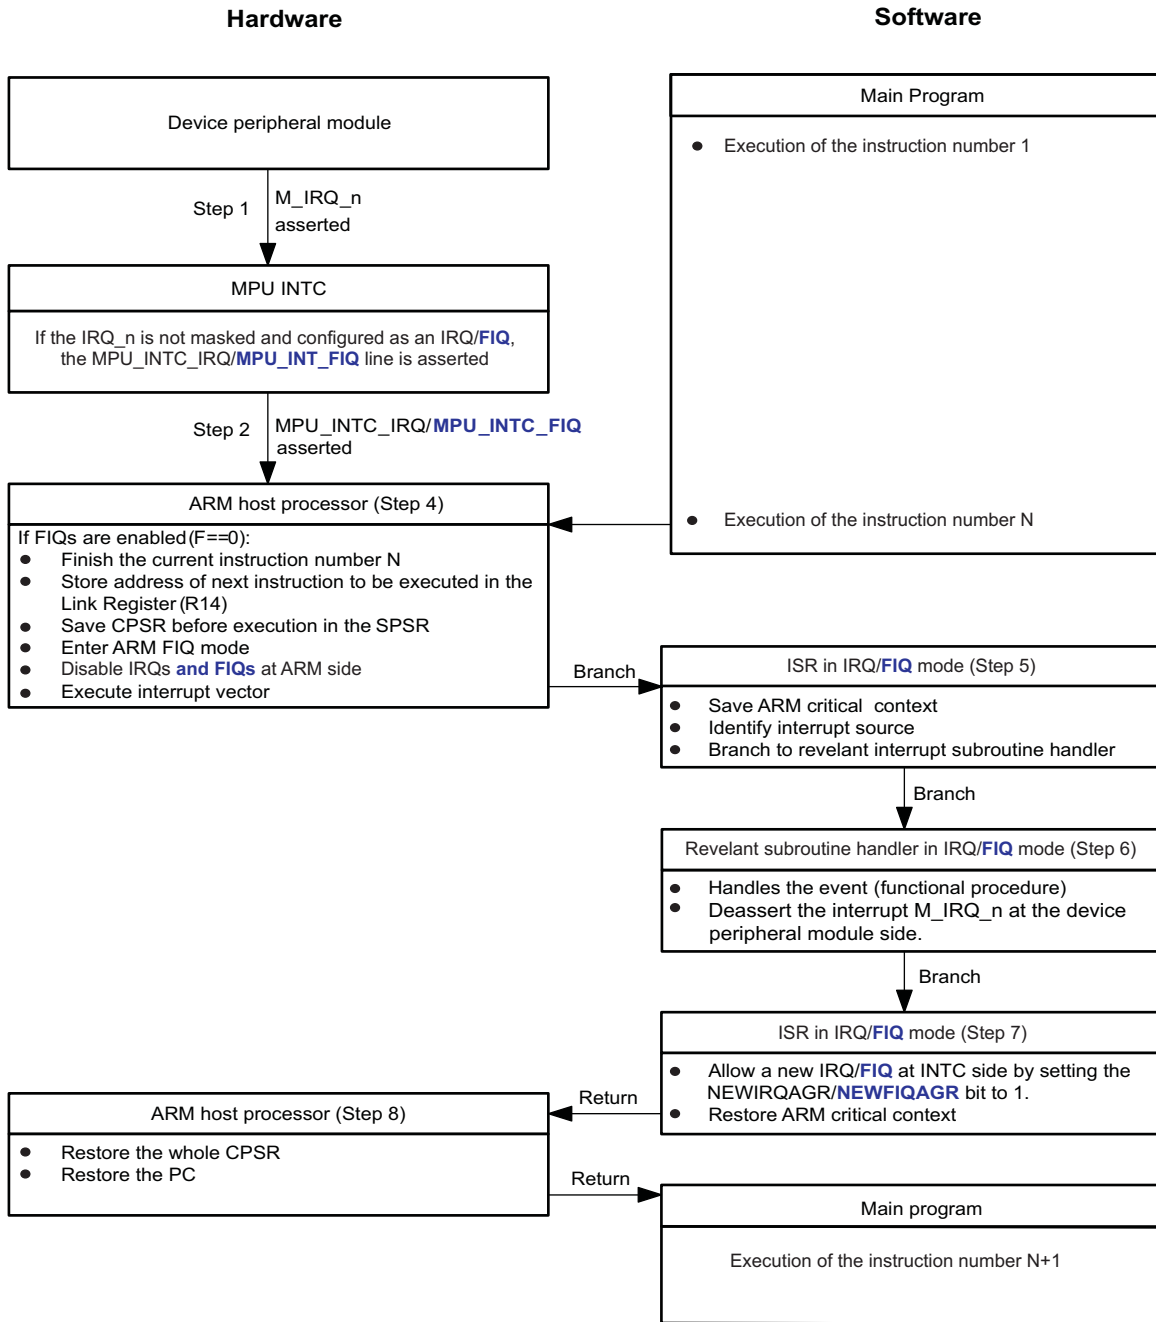

```
; Return after handling the interrupt
SUBS PC, LR, #4
```

8. After the ISR return, the ARM automatically restores its context as follows:

```
CPSR = SPSR
PC = LR
```

Figure 8-5 shows the IRQ/**FIQ** processing sequence from the originating device peripheral module to the main program interruption.

Figure 8-5. IRQ/FIQ Processing Sequence

108-005

NOTE: The differences between the IRQ and the FIQ sequence are highlighted in blue and bold characters.

The priority sorting mechanism is frozen during an interrupt processing sequence. If an interrupt condition occurs during this time, the interrupt is not lost. It is sorted when the NEWIRQAGR/NEWFIQAGR bit is set (priority sorting is reactivated).

8.5.3 MPU INTC Preemptive Processing Sequence

Preemptive interrupts, also called nested interrupts, can reduce the latencies for higher priority interrupts. A preemptive ISR can be suspended by a higher priority interrupt. Thus, the higher priority interrupt can be served immediately.

Nested interrupts must be used carefully to avoid using corrupted data. Programmers must save corruptible registers and enable IRQ or FIQ at ARM side.

IRQ and FIQ processing sequences are quite similar, the differences for the FIQ sequence are shown after a '/' character in **bold** characters in the text or the code below.

To enable IRQ/**FIQ** preemption by higher priority IRQs/**FIQs**, programers can follow this procedure to write the ISR:

At the beginning of an IRQ/**FIQ** ISR:

1. Save the ARM critical context registers.
2. Save the MPU_INTC.INTCPS_THRESHOLD PRIORITYTHRESHOLD field before modifying it.
3. Read the active interrupt priority in the MPU_INTC.INTCPS_IRQ_PRIORITY IRQPRIORITY / **MPU_INTC.INTCPS_FIQ_PRIORITY FIQPRIORITY** field and write it to the PRIORITYTHRESHOLD⁽¹⁾ field.
4. Read the active interrupt number in the MPU_INTC.INTCPS_SIR_IRQ[6:0] ACTIVEIRQ / **MPU_INTC.INTCPS_SIR_FIQ[6:0] ACTIVEFIQ** field to identify the interrupt source.
5. Write 1 to the appropriate MPU_INTC.INTCPS_CONTROL NEWIRQAGR and ⁽²⁾ **NEWFIQAGR** bit while an interrupt is still processing to allow only higher priority interrupts to preempt.
6. Because the writes are posted on an Interconnect bus, to be sure that the preceding writes are done before enabling IRQs/**FIQs**, a Data Synchronization Barrier is used. This operation ensure that the IRQ line is de-asserted before IRQ/**FIQ** enabling.
7. Enable IRQ/**FIQ** at ARM side.
8. Jump to the relevant subroutine handler.

The sample code below shows the previous steps:

CAUTION

The code below is an assembly code compatible with ARM architecture V6 and V7. This code is developed for the Texas Instruments Code Composer Studio tool set. It is a draft version, only tested on an emulated environment.

```

; bit field mask to get only the bit field
ACTIVEPRIO_MASK .equ 0x3F

_IRQ_ISR:
; Step 1 : Save the critical context
STMFD SP!, {R0-R12, LR}           ; Save working registers
MRS R11, SPSR                     ; Save the SPSR into R11

; Step 2 : Save the INTCPS_THRESHOLD register into R12
LDR R0, INTCPS_THRESHOLD_ADDR
LDR R12, [R0]

; Step 3 : Get the priority of the highest priority active IRQ

```

- ⁽¹⁾ The priority-threshold mechanism is enabled automatically when writing a priority in the range of 0x00 to 0x3F while reading it from the IRQPRIORITY and FIQPRIORITY fields. Writing a value of 0xFF (reset default) disables the priority-threshold mechanism. Values between 0x3F and 0xFF must not be used. When the hardware-priority threshold is in use, the priorities of interrupts selected as FIQ or IRQ become linked; otherwise, they are independent. When they are linked, all FIQ priorities must be set higher than all IRQ priorities to maintain the relative priority of FIQ over IRQ.
- ⁽²⁾ When handling FIQs using the priority-threshold mechanism, both NEWFIQAGR and NEWIRQAGR bits must be written at the same time to ensure that the new priority threshold is applied while an IRQ sort is in progress. This IRQ will not have been seen by the ARM, as it will have been masked on entry to the FIQ ISR. However, the source of the IRQ remains active and it is finally processed when the priority threshold falls to a priority sufficiently low to allow it to be processed. The precaution of writing to New FIQ Agreement is not required during an IRQ ISR, as FIQ sorting is not affected (providing all FIQ priorities are higher than all IRQ priorities).

```

LDR R1, INTCPS_IRQ_PRIORITY_ADDR/INTCPS_FIQ_PRIORITY_ADDR
LDR R1, [R1] ; Get the INTCPS_IRQ_PRIORITY/INTCPS_FIQ_PRIORITY register
AND R1, R1, #ACTIVEPRIO_MASK ; Apply the mask to get the priority of the IRQ
STR R1, [R0] ; Write it to the INTCPS_THRESHOLD register

; Step 4 : Get the number of the highest priority active IRQ
LDR R10, INTCPS_SIR_IRQ_ADDR/INTCPS_SIR_FIQ_ADDR
LDR R10, [R10] ; Get the INTCPS_SIR_IRQ/INTCPS_SIR_FIQ register
AND R10, R10, #ACTIVEIRQ_MASK ; Apply the mask to get the active IRQ number

; Step 5 : Allow new IRQs and FIQs at INTC side
MOV R0, #0x1/0x3 ; Get the NEWIRQAGR and NEWFIQAGR bit position
LDR R1, INTCPS_CONTROL_ADDR
STR R0, [R1] ; Write the NEWIRQAGR and NEWFIQAGR bit

; Step 6 : Data Synchronization Barrier
MOV R0, #0
MCR P15, #0, R0, C7, C10, #4

; Step 7 : Read-modify-write the CPSR to enable IRQs/FIQs at ARM side
MRS R0, CPSR ; Read the status register
BIC R0, R0, #0x80/0x40 ; Clear the I/F bit
MSR CPSR, R0 ; Write it back to enable IRQs

; Step 8 : Jump to relevant subroutine handler
LDR PC, [PC, R10, lsl #2] ; PC base address points this instruction + 8
NOP ; To index the table by the PC

; Table of handler start addresses
.word IRQ0handler ;IRQ0 BANK0
.word IRQ1handler
.word IRQ2handler

```

After the return of the relevant IRQ/FIQ subroutine handle :

1. Disable IRQs/FIQs at ARM side.
2. Restore the MPU_INTC.INTCPS_THRESHOLD PRIORITYTHRESHOLD field.
3. Restore the ARM critical context registers.

The sample code below shows the three previous steps:

CAUTION

The code below is an assembly code compatible with ARM architecture V6 and V7. This code is developed for the Texas Instruments Code Composer Studio tool set. It is a draft version, only tested on an emulated environment.

IRQ_ISR_end:

```

; Step 1 : Read-modify-write the CPSR to disable IRQs/FIQs at ARM side
MRS R0, CPSR ; Read the CPSR
ORR R0, R0, #0x80/0x40 ; Set the I/F bit
MSR CPSR, R0 ; Write it back to disable IRQs

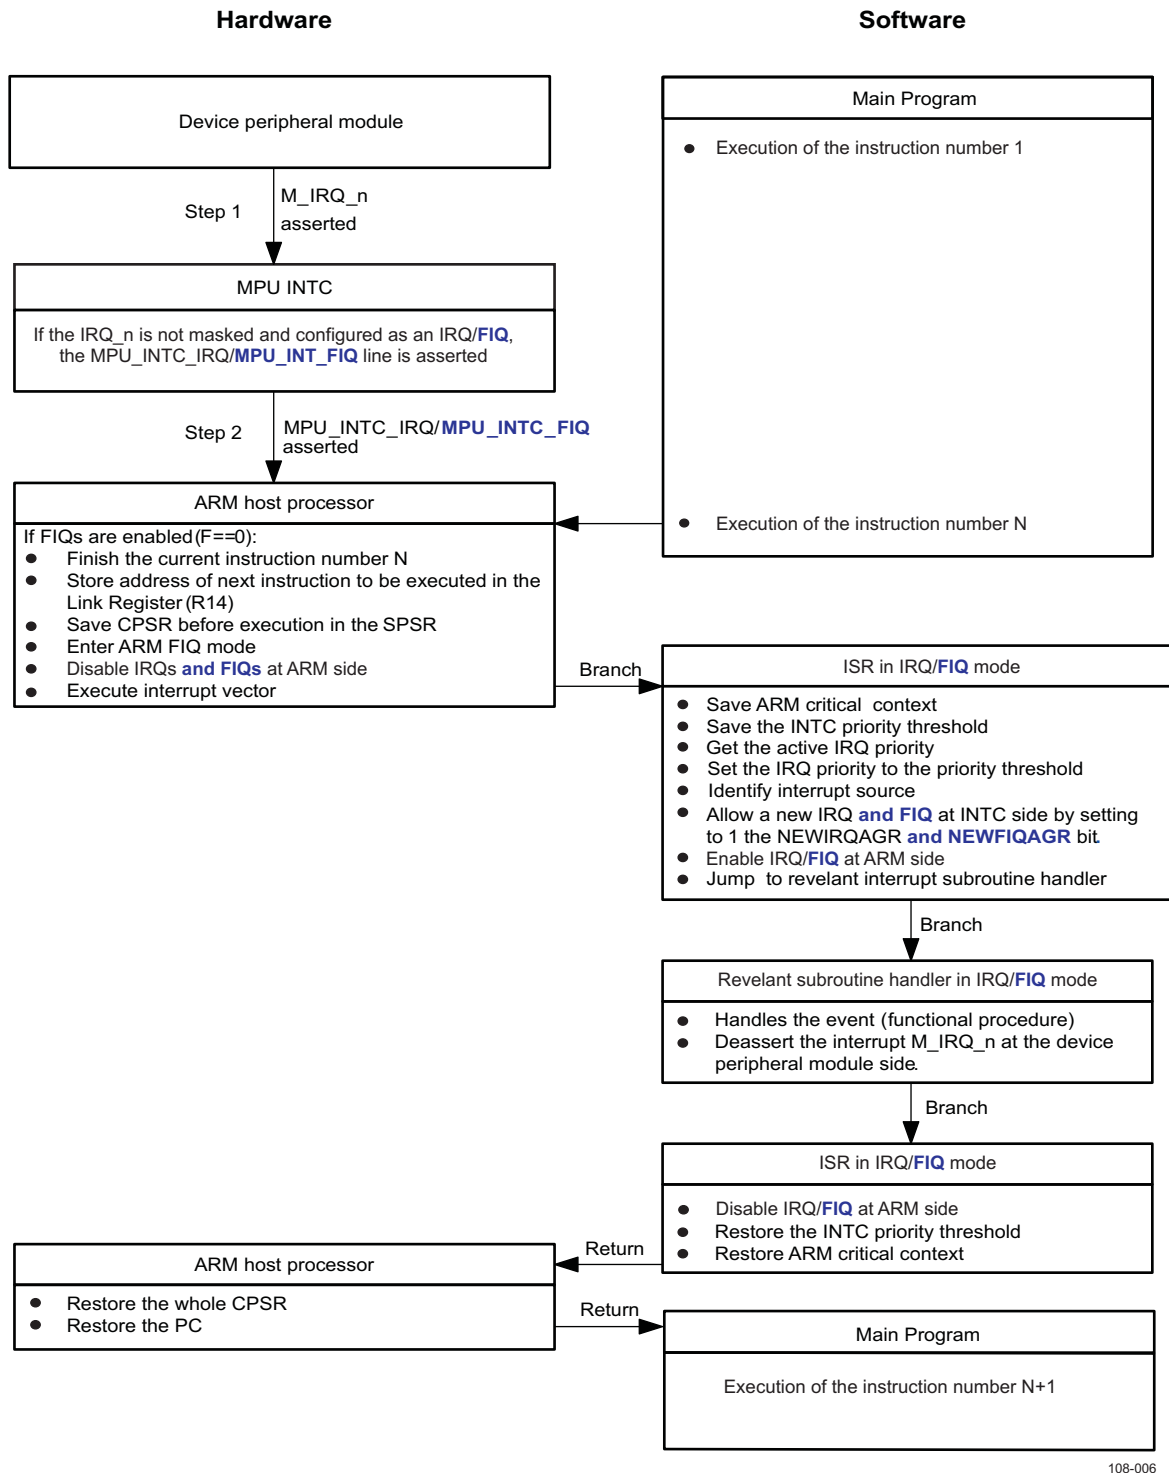

; Step 2 : Restore the INTCPS_THRESHOLD register from R12
LDR R0, INTCPS_THRESHOLD_ADDR
STR R12, [R0]

; Step 3 : Restore critical context
MSR SPSR, R11 ; Restore the SPSR from R11
LDMFD SP!, {R0-R12, LR} ; Restore working registers and Link register

; Return after handling the interrupt
SUBS PC, LR, #4

```

Figure 8-6 shows the nested IRQ/FIQ processing sequence from the originating device peripheral module to the main program interruption.

Figure 8-6. Nested IRQ/FIQ Sequence

NOTE: The differences between the IRQ and the FIQ sequence are highlighted in blue and bold characters.

8.5.4 MPU INTC Spurious Interrupt Handling

The spurious flag indicates whether the result of the sorting (a window of 10 INTC functional clock cycles after the interrupt assertion) is invalid. The sorting is invalid if:

- The interrupt that triggered the sorting is no longer active during the sorting.
- A change in the mask has affected the result during the sorting time.

As a result, the values in the MPU_INTC.INTCPS_MIRn, MPU_INTC.INTCPS_ILRm, or MPU_INTC.INTCPS_MIR_SETn registers must not be changed while the corresponding interrupt is asserted. If these registers are changed within the 10-cycle window after the interrupt assertion, only the active interrupt input that triggered the sort can be masked before its turn in the sort. The resulting values of the following registers become invalid:

- MPU_INTC.INTCPS_SIR_IRQ
- MPU_INTC.INTCPS_SIR_FIQ
- MPU_INTC.INTCPS_IRQ_PRIORITY
- MPU_INTC.INTCPS_FIQ_PRIORITY

This condition is detected for both IRQ and FIQ, and the invalid status is flagged across the SPURIOUSIRQFLAG (see Note 1) and SPURIOUSFIQFLAG (see Note 2) bit fields in the SIR and PRIORITY registers. A 0 indicates valid and a 1 indicates invalid interrupt number and priority. The invalid indication can be tested in software as a false register value.

NOTE:

1. The MPU_INTC.INTCPS_SIR_IRQ[31:7] SPURIOUSIRQFLAG field is a copy of the MPU_INTC.INTCPS_IRQ_PRIORITY[31:7] SPURIOUSIRQFLAG field.
 2. The MPU_INTC.INTCPS_SIR_FIQ[31:7] SPURIOUSFIQFLAG field is a copy of the MPU_INTC.INTCPS_FIQ_PRIORITY[31:7] SPURIOUSFIQFLAG field.
-

8.6 Interrupt Controller Registers

Table 8-5 lists the base address and address space for the INTC.

Table 8-5. INTC Instance Summary

| Module Name | Base Address | Size |
|-------------|--------------|----------|
| MPU INTC | 0x4820 0000 | 4K bytes |

8.6.1 Register Mapping Summary

CAUTION

MPU INTC registers are limited to 32-bit and 16-bit data accesses. 8-bit is not allowed and can corrupt register content.

In Section 8.6.2, each register from MPU_INTC.INTCPS_ITR_n to MPU_INTC.INTCPS_PENDING_FIQ_n contains 32 bits, 1 bit for each interrupt (in ascending order: bit 0 of the MPU_INTC.INTCPS_ITR₀ register applies to interrupt line 0; bit 0 of the MPU_INTC.INTCPS_ITR₁ register applies to interrupt line 32).

Table 8-6. MPU INTC Register Summary

| Register Name | Type | Register Width (Bits) | Address Offset | MPU INTC Physical Address | Section |

| Bits | Field Name | Description | Type | Reset |
|------|------------|--|------|------------|
| 31:1 | Reserved | Read returns reset value. | R | 0x00000000 |
| 0 | RESETDONE | Internal reset monitoring Read 0x0: Internal module reset is ongoing. Read 0x1: Reset complete | R | - |

8.6.2.3 INTCPS_SIR_IRQ

Table 8-10. INTCPS_SIR_IRQ

| | | | |
|-------------------------|---|-----------------|----------|
| Address Offset | 0x040 | | |
| Physical Address | 0x4820 0040 | Instance | MPU INTC |
| Description | This register supplies the currently active IRQ interrupt number. | | |
| Type | R | | |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|-----------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|-----------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| SPURIOUSIRQFLAG | | | | | | | | | | | | | | | | ACTIVEIRQ | | | | | | | | | | | | | | | |

| Bits | Field Name | Description | Type | Reset |
|------|-----------------|-------------------|------|------------|
| 31:7 | SPURIOUSIRQFLAG | Spurious IRQ flag | R | 0x1FFFFFFF |
| 6:0 | ACTIVEIRQ | Active IRQ number | R | 0x00 |

8.6.2.4 INTCPS_SIR_FIQ

Table 8-11. INTCPS_SIR_FIQ

| | | | |
|-------------------------|---|-----------------|----------|
| Address Offset | 0x044 | | |
| Physical Address | 0x4820 0044 | Instance | MPU INTC |
| Description | This register supplies the currently active FIQ interrupt number. | | |
| Type | R | | |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|-----------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|-----------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| SPURIOUSFIQFLAG | | | | | | | | | | | | | | | | ACTIVEFIQ | | | | | | | | | | | | | | | |

| Bits | Field Name | Description | Type | Reset |
|------|-----------------|-------------------|------|------------|
| 31:7 | SPURIOUSFIQFLAG | Spurious FIQ flag | R | 0x1FFFFFFF |
| 6:0 | ACTIVEFIQ | Active FIQ number | R | 0x00 |

8.6.2.5 INTCPS_CONTROL

Table 8-12. INTCPS_CONTROL

| | | | |
|-------------------------|--|-----------------|----------|
| Address Offset | 0x048 | | |
| Physical Address | 0x4820 0048 | Instance | MPU INTC |
| Description | This register contains the new interrupt agreement bits. | | |
| Type | RW | | |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|-----------|-----------|---|---|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|---|------|------------|
| 31:1 | Reserved | Write 0s for future compatibility. Read returns reset value. | R | 0x00000000 |
| 0 | PROTECTION | Protection mode 0x0: Protection mode is disabled (default). 0x1: Protection mode is enabled. When enabled, all the MPU INTC registers are accessible only in privileged mode. | RW | 0 |

8.6.2.7 INTCPS_IDLE

Table 8-14. INTCPS_IDLE

| | | | |
|-------------------------|---|-----------------|----------|
| Address Offset | 0x050 | | |
| Physical Address | 0x4820 0050 | Instance | MPU INTC |
| Description | This register controls the functional clock auto-idle and the synchronizer clock auto-gating. | | |
| Type | RW | | |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|-------|----------|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Reserved | | | | | | | | | | | | | | | | TURBO | FUNCIDLE | | | | | | | | | | | | | | |

| Bits | Field Name | Description | Type | Reset |
|------|------------|--|------|------------|
| 31:2 | Reserved | Write 0s for future compatibility. Read returns reset value. | R | 0x00000000 |
| 1 | TURBO | Input synchronizer clock auto-gating 0x0: Input synchronizer clock is free-running (default). 0x1: Input synchronizer clock is auto-gated based on interrupt input activity. | RW | 0 |
| 0 | FUNCIDLE | Functional clock idle mode 0x0: Functional clock gating strategy is applied (default). 0x1: Functional clock is free-running. | RW | 0 |

8.6.2.8 INTCPS_IRQ_PRIORITY

Table 8-15. INTCPS_IRQ_PRIORITY

| | | | |
|-------------------------|---|-----------------|----------|
| Address Offset | 0x060 | | |
| Physical Address | 0x4820 0060 | Instance | MPU INTC |
| Description | This register supplies the currently active IRQ priority level. | | |
| Type | R | | |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|-----------------|----|----|----|----|----|----|----|----|----|----|----|----|----|-------------|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|

| Bits | Field Name | Description | Type | Reset |
|------|------------|---|------|------------|
| 31:2 | Reserved | Write 0s for future compatibility. Read returns reset value. | R | 0x00000000 |
| 1 | INIT2 | For optimal power consumption, this bit must be set to 1 during initialization. | RW | 0 |
| 0 | Reserved | For optimal power consumption keep default value of 0 for this bit. | R | 0 |

Memory Subsystem

This chapter describes the memory subsystem.

| Topic | Page |
|--|------|
| 9.1 General-Purpose Memory Controller (GPMC) | 896 |
| 9.2 SDRAM Controller (SDRC) Subsystem | 1015 |
| 9.3 On-Chip Memory (OCM) Subsystem | 1122 |
| 9.4 Revision History | 1127 |

9.1 General-Purpose Memory Controller (GPMC)

9.1.1 General-Purpose Memory Controller Overview

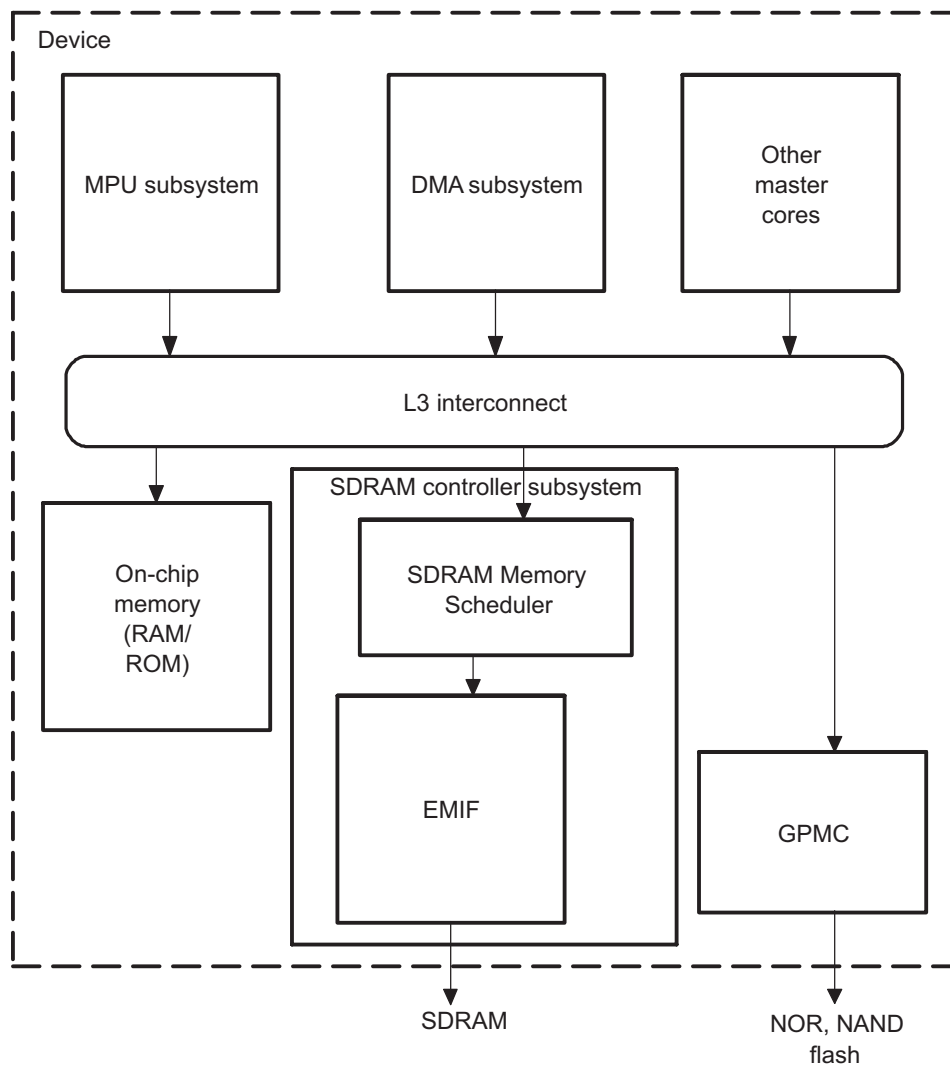

The general-purpose memory controller (GPMC) is dedicated to interfacing external memory devices:

- Asynchronous SRAM-like memories and application-specific integrated circuit (ASIC) devices
- Asynchronous, synchronous, and page mode (only available in non-muxed mode) burst NOR flash devices
- NAND flash
- Pseudo-SRAM devices

NOTE: Page mode is only available in non-muxed mode. The non-muxed mode is described in this chapter even though its use is very limited (address space limited to 2 KBytes).

Figure 9-1 shows the environment of the GPMC.

Figure 9-1. GPMC Environment

gpmc-001

9.1.1.1 GPMC Features

The GPMC is a 16-bit external memory controller. The GPMC data access engine provides a flexible programming model for communication with all standard memories. The GPMC supports various accesses:

- Asynchronous read/write access
- Asynchronous read page access (4, 8, 16 Word16)
- Synchronous read/write access
- Synchronous read/write burst access without wrap capability (4, 8, 16 Word16)
- Synchronous read/write burst access with wrap capability (4, 8, 16 Word16)
- Address/data-multiplexed access
- Little- and big-endian access

The GPMC can communicate with a wide range of external devices:

- External asynchronous or synchronous 8-bit wide memory or device
- External asynchronous or synchronous 16-bit wide memory or device
- External 16-bit nonmultiplexed device with limited address range (2 Kbytes)
- External 16-bit address/data-multiplexed NOR flash device
- External 8-bit and 16-bit NAND flash device
- External 16-bit pseudo SRAM (pSRAM) device

The GPMC supports up to eight chip-select regions of programmable size, and programmable base addresses in a total address space of 1 Gbyte.

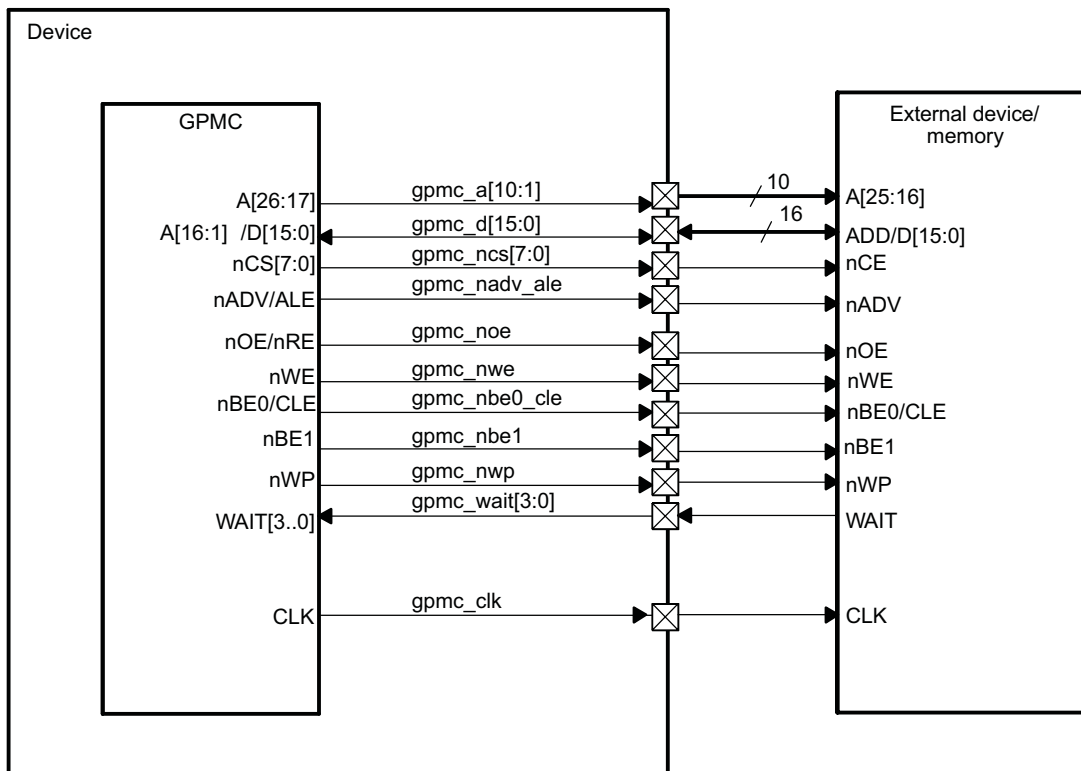

NOTE: Some features may not be available or supported in your particular device. For more information, see Chapter 1, the *Device Family* section, and your device-specific data manual.

9.1.2 GPMC Environment

Figure 9-2 and Figure 9-3 show two GPMC external connection options:

- GPMC to 16-bit address/data-multiplexed memory
 Figure 9-2 shows a connection between the GPMC and a 16-bit synchronous address/data-multiplexed external memory device.
- GPMC to 16-bit NAND device
 Figure 9-3 shows a connection between the GPMC and a 16-bit NAND device.

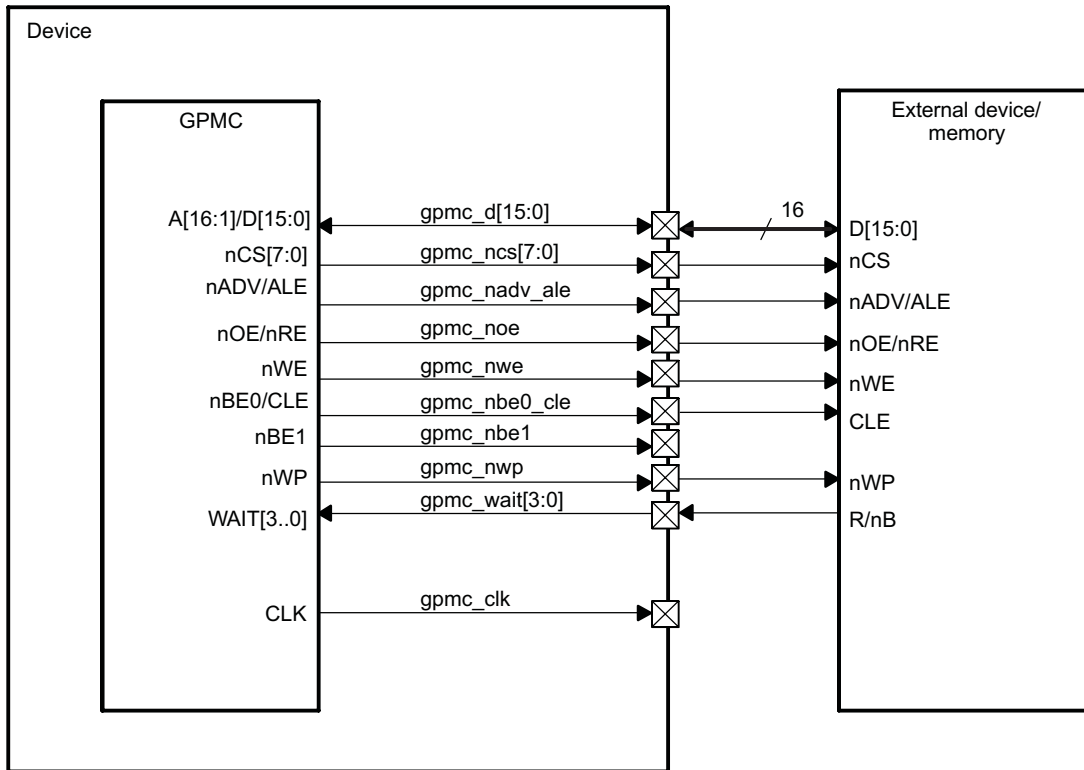

Figure 9-2. GPMC to 16-Bit Address/Data-Multiplexed Memory

gpmc-002

NOTE: The device does not provide the A0 byte address line required for random-byte addressable 8-bit wide device interfacing (for multiplexed and nonmultiplexed protocol). Hence, an 8-bit device must be connected to the D[7:0] / gpmc_d[7:0] data bus (rather than D[15:8] / gpmc_d[15:8]) of the GPMC controller. This limits the use of 8-bit wide device interfacing to byte-alias access.

Figure 9-3. GPMC to 16-Bit NAND Device

gpmc-003

NOTE: An 8-bit NAND must be connected to the D[7:0] data bus of the GPMC.

Table 9-1 lists the GPMC subsystem I/O pins.

Table 9-1. GPMC I/O Description

| Pin Name | I/O | Description |
|----------------|-----|---|
| gpmc_a[10:1] | O | Address |
| gpmc_d[15:0] | I/O | Data |
| gpmc_ncs[7:0] | O | Chip-selects (active low) |
| gpmc_clk | I/O | Clock ⁽¹⁾ |
| gpmc_nadv_ale | O | Address valid (active low). Also used as address latch enable (active high) for NAND protocol memories. |
| gpmc_noe_nre | O | Output enable (active low). Also used as read enable (active low) for NAND protocol memories. |
| gpmc_nwe | O | Write enable (active low) |
| gpmc_nbe0_cle | O | Lower-byte enable (active low). Also used as command latch enable for NAND protocol memories. |

| gpmc_d[0] | A1/D0 | D0 | D0 | D0 |

Enabling the GPMC.GPMC_CONFIG[1] LIMITEDADDRESS bit forces A[26:11] to 1 on the GPMC I/O side. Thus, only devices with 2 Kbytes of addressing space can be accessed using gpmc_a[10:1].

With all device types, the GPMC does not drive unnecessary address lines. They stay at their reset value of 0x00.

Address mapping supports address/data-multiplexed 16-bit wide devices:

- To minimize the number of IC pins required for the external memory connection, the NOR flash memory controller supports multiplexed address and data memory devices without adding logic externally.
- Multiplexing mode can be selected through the GPMC.GPMC_CONFIG1_i[9] MUXADDDATA bit (I = 0 to 7).
- Asynchronous page mode is not supported for multiplexed address and data devices.

9.1.3 GPMC Integration

9.1.3.1 Description

Figure 9-4 shows how the GPMC interacts with other modules in the processor.

Figure 9-4. GPMC Integration in the Processor

gpmc-004

9.1.3.2 Clocking, Reset, and Power Management Scheme

9.1.3.2.1 Clocking

The GPMC use a single clock, GPMC_FCLK, which comes internally from the power, reset, and clock-management (PRCM) module and runs at the L3 interconnect frequency. Its source is the PRCM module, CORE_L3_ICLK output. CORE_L3_ICLK belongs to the L3 interconnect clock domain.

For details, see the *Power, Reset, and Clock Management* chapter.

GPMC_CLK is the external clock provided to the attached synchronous memory or device. The GPMC_CLK clock frequency is the GPMC_FCLK clock frequency divided by 1, 2, 3, or 4, depending on the GPMC.GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER bit field (where I = 0 to 7).

NOTE: When the GPMC is configured for synchronous mode, the GPMC_CLK signal (which is an output) must also be set as an input (CONTROL.CONTROL_PADCONF_GPMC_NCS7[24] INPUTENABLE1 = 1). GPMC_CLK is looped back through the output and input buffers of the corresponding GPMC_CLK pad at the device boundary. The looped-back clock is used to synchronize the sampling of the memory signals.

9.1.3.2.2 Hardware Reset

A global reset of the GPMC occurs through activation of the CORE_RSTRET signal (CORE power domain) controlled by the Power, Reset and Clock Management module (see the *Power, Reset, and Clock Management* chapter).

The CORE_RSTRET signal is activated during IC global power-on and global warm reset, and it resets the controller state machine and configuration registers.

9.1.3.2.3 Software Reset

GPMC modules can be reset under software control through the GPMC.GPMC_SYSCONFIG[1] SOFTRESET bit. When software reset bit is set, all registers and the finite state-machine (FSM) are reset immediately and unconditionally. The GPMC_SYSSTATUS[0] RESETDONE bit can be polled to check reset status.

9.1.3.2.4 Power Domain, Power Saving, and Reset Management

GPMC power is supplied by the CORE power domain, and GPMC power management complies with system power-management guidelines.

The GPMC reduces power consumption through auto-idle mode and the idle request/acknowledge process, both of which are configurable:

- Dynamic auto-idle (configurable through the GPMC.GPMC_SYSCONFIG[0] AUTOIDLE bit): To reduce power consumption, the GPMC internally disables the functional clock when no requests are pending and no accesses are ongoing.
- Idle request/acknowledge (one of three idle modes configurable through the GPMC.GPMC_SYSCONFIG[4:3] IDLEMODE field):
 - Force-idle: Immediately on receiving an idle request from the PRCM module, the GPMC sends an idle request/acknowledge to let the PRCM module correctly cut the GPMC source clock.
 - No-idle: The GPMC never goes to idle mode.
 - Smart-idle (strongly recommended): The GPMC goes to idle mode when all ongoing transactions are complete.

For detailed information about power management, see the *Power, Reset, and Clock Management* chapter.

9.1.3.2.5 Hardware Requests

The GPMC uses two hardware requests as shown in [Figure 9-4](#) :

- One interrupt request goes from GPMC (GPMC_IRQ) to the microprocessor unit (MPU) subsystem : M_IRQ_20.
- One DMA request goes from GPMC (GPMC_DMA_REQ) to the system DMA (sDMA) : S_DMA_3.

9.1.3.3 GPMC Address and Data Bus

The current application supports GPMC connection to address/data-multiplexed memory and a NAND device. Connection to a nonmultiplexed address/data memory is supported with an address range of only 2 Kbytes.

Depending on the GPMC configuration on each chip-select, address and data-bus lines that are not required for a particular access protocol are not updated (changed from current value) and are not sampled when input (input data bus).

The current application supports GPMC connection to address/data-multiplexed memory, address/data-nonmultiplexed memory with limited address (2 Kbytes), and a NAND device:

- When the GPMC.GPMC_CONFIG[1] LIMITEDADDRESS bit is set to 1, only gpmc_a[10:1] address lines are used. This limits the memory support to 2K-byte addressable memories.
- For address/data-multiplexed NOR devices, the address is multiplexed on the data bus.
- 8-bit wide NOR devices do not use GPMC I/O: gpmc_d[15:8] for data (they are used for address if needed).
- 16-bit wide NAND devices do not use GPMC I/O: gpmc_a[10:1].
- 8-bit wide NAND devices do not use GPMC I/O: gpmc_a[10:1] and GPMC I/O: gpmc_d[15:8].

CAUTION

Before trying to access a chip-select configured with a nonmultiplexed protocol, set the LIMITEDADDRESS bit control.

9.1.3.3.1 GPMC I/O Configuration Setting (In Default Pinout Mode 0)

NOTE: In this section, the I in GPMC_CONFIG1_i stands for the GPMC chip-select I where I = 0 to 7.

The address/data-nonmultiplexed device, which is limited to a 2K-byte address range, is selected by programming the following register fields:

- GPMC.GPMC_CONFIG1_i[11:10] DEVICETYPE field = 0x00
- GPMC.GPMC_CONFIG1_i[9] MUXADDDATA bit = 0
- GPMC.GPMC_CONFIG[1] LIMITEDADDRESS bit = 1

NOTE: The LIMITEDADDRESS field applies only to address/data-nonmultiplexed devices; it has no effect on other device types (address/data-multiplexed, NAND).

To select the address/data-multiplexed device, program the following register fields:

- GPMC.GPMC_CONFIG1_i[11:10] DEVICETYPE field = 0b00
- GPMC.GPMC_CONFIG1_i[9] MUXADDDATA bit = 1

To select the NAND device, program the following register field:

- GPMC.GPMC_CONFIG1_i[11:10] DEVICETYPE field = 0b10
- GPMC.GPMC_CONFIG1_i[9] MUXADDDATA bit = 0

9.1.3.3.2 GPMC CS0 Default Configuration at IC Reset

To ensure a correct external boot with a GPMC access from IC reset time on CS0, several external pins are sampled:

- The sys_boot[4:0] pins (device boundary) define the sequence of interfaces and devices to use for booting.
- The sys_boot[5] pin defines which group of booting sequences is preferred: memory booting (sys_boot[5] = 0) or peripheral booting (sys_boot[5] = 1).
- Three additional pins are used to configure reset values in the GPMC.GPMC_CONFIG1_i register (where I = 0):
 - The bootwaiten input pin (GPMC boundary) enables the monitoring on chip-select 0 of the WAIT pin at IC reset release time for read accesses. The input pin is used to configure the GPMC.GPMC_CONFIG1_i[22] WAITREADMONITORING bit (where I = 0). Its value comes from the BOOT_WAIT_ENABLE signal generated by the system control module (SCM). When sys_boot[5:0] = 0b111111, the BOOT_WAIT_ENABLE signal is activated, causing the wait pin to be monitored for read access.
 - The bootdevicesize input pin (GPMC boundary) defines the size of the attached device on chip-select 0 and is used to configure the GPMC.GPMC_CONFIG1_i[13:12] DEVICESIZE bits (where I = 0). A BOOT_DEVICE_SIZE signal is propagated from the SCM. Its value is fixed at 0x1 at IC reset, causing a 16-bit wide external memory to be used.
 - The cs0muxdevice input pin (GPMC boundary) selects whether the attached device to chip-select 0 is a multiplexed address and data device or not. The input pin is used to configure the GPMC.GPMC_CONFIG1_i[9] MUXADDDATA bit (where I = 0). A CS0_MUX_DEVICE signal is propagated from the SCM. Its value is fixed at 0x1 at IC reset, causing the attached device to be address/data-multiplexed.
 - The waitselectpin input pin selects the WAIT signal at IC reset release time between WAIT0 input pin or WAIT1 input pin. At IC reset release time, these two pins have different polarity.

CAUTION

Using the internal boot code, the entire CS0 configuration can be modified before the first CS0 access. This modification of internal boot code is necessary for two external devices:

- NAND device attached to CS0
- Nonmultiplexed 2 Kbyte address range device attached to CS0

At reset time, the IC may boot from the internal ROM or from the memory attached to the GPMC chip-select 0. This selection is made outside the GPMC.

Reset values of the timing control parameters are defined to cope with direct boot on address and data multiplexed NOR Flash device, on non-multiplexed NOR Flash device or on any asynchronous device with large timing margins assuming a low GPMC_FCLK frequency (for example, 19.2Mhz) at boot time.

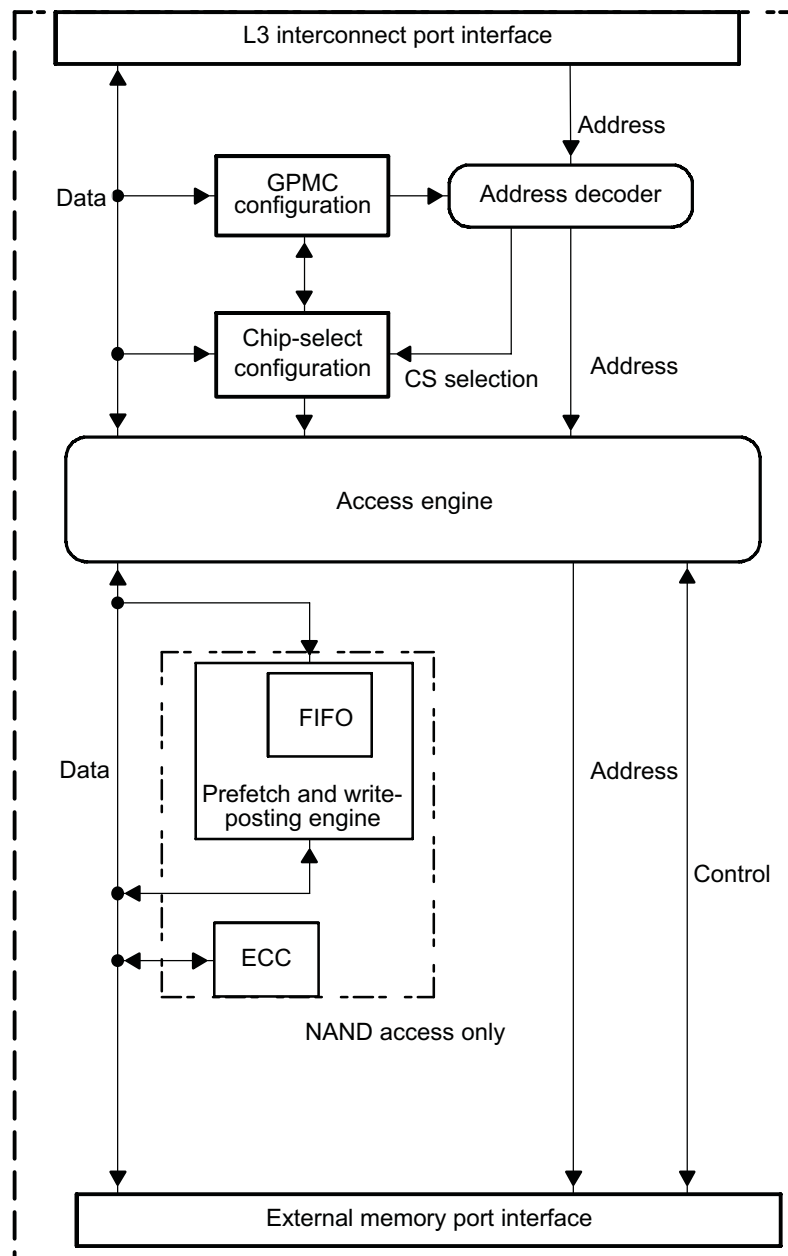

9.1.4 GPMC Functional Description

9.1.4.1 Description

As Figure 9-5 shows, the GPMC consists of six blocks:

- L3 interconnect port interface
- Address decoder, GPMC configuration, and chip-select configuration register file
- Access engine
- Prefetch and write-posting engine
- Error correction code engine (ECC)
- External device/memory port interface

Figure 9-5. GPMC Functional Diagram

gpmc-005

The GPMC can access various external devices through the L3 Interconnect. The flexible programming model allows a wide range of attached device types and access schemes.

Based on the programmed configuration bit fields stored in the GPMC registers, the GPMC is able to generate all control signals timing depending on the attached device and access type.

Given the chip-select decoding and its associated configuration registers, the GPMC selects the appropriate device type control signals timing.

9.1.4.2 L3 Interconnect Interface

The GPMC L3 interconnect interface is a pipelined interface including an 8 × 32-bit word write buffer.

Any device system host can issue external access requests through the GPMC.

The device system can issue the following requests through this interface:

- One 8-bit / 16-bit / 32-bit interconnect access (read/write)
- Two incrementing 32-bit interconnect accesses (read/write)
- Two wrapped 32-bit interconnect accesses (read/write)
- Four incrementing 32-bit interconnect accesses (read/write)
- Four wrapped 32-bit interconnect accesses (read/write)
- Eight incrementing 32-bit interconnect accesses (read/write)
- Eight wrapped 32-bit interconnect accesses (read/write)

Only linear burst transactions are supported; interleaved burst transactions are not supported. Only power-of-two-length precise bursts 2 × 32, 4 × 32, or 8 × 32 with the burst base address aligned on the total burst size are supported (this limitation applies to incrementing bursts only).

This interface also provides one interrupt and one DMA request line, for specific event control.

It is recommended to program the ATTACHEDDEVICEPAGELENGTH field (GPMC_CONFIG1_i[24:23]) according to the effective attached device page length and to enable WRAPBURST bit (GPMC_CONFIG1_i[31]) if the attached device supports wrapping burst.

However, it is possible to emulate wrapping burst on a non-wrapping memory by providing relevant addresses within the page or splitting transactions. Bursts larger than the memory page length are chopped into multiple bursts transactions. Due to the alignment requirements, a page boundary is never crossed.

9.1.4.3 Address Decoder, GPMC Configuration, and Chip-Select Configuration Register File

Address-decoding logic selects for chip-selects according to the address request and the content of the chip-select base address register file, which includes a set of global GPMC configuration registers and eight sets of chip-select configuration registers.

The GPMC configuration register file is memory-mapped and can be read or written with byte, 16-bit word, or 32-bit word accesses. The register file should be configured as a noncacheable, nonbufferable region to prevent any desynchronization between host execution (write request) and the completion of register configuration (write completed with register updated). [Section 9.1.7](#) of this chapter provides the GPMC register locations. For the map of GPMC memory locations, see the *Memory Mapping* chapter.

After the chip-select is configured, the access engine accesses the external device, drives the external interface control signals, and applies the interface protocol based on user-defined timing parameters and settings.

9.1.4.4 Error Correction Code Engine (ECC)

The GPMC includes an ECC calculation engine that allows ECC calculation during data read or data program (write) operations. Two ECC algorithms are available depending on GPMC_ECC_CONFIG[16] ECCALGORITHM settings: Hamming code or BCH code (Bose-Chaudhuri-Hocquenghem).

The GPMC does not directly handle the error code correction itself. During writes, the GPMC computes parity bits. During reads, the GPMC provides enough information for the processor to correct errors without reading the data buffer all over again.

The Hamming code ECC is based on a 2-dimensional (row and column) bit parity accumulation. This parity accumulation is either accomplished on the programmed number of bytes or Word16s read from the memory device, or written to the memory device in stream mode.

Because the ECC engine includes only one accumulation context, it can be allocated to only one chip-select at a time through the GPMC.GPMC_ECC_CONFIG[3:1] ECCCS bit field.

Refer to [Section 9.1.5.14.3](#), for more information on ECC Calculation.

9.1.4.5 Prefetch and Write-Posting Engine

The prefetch and write-posting engine is a simplified embedded-access requester that presents requests to the access engine on a user-defined chip-select target. The access engine interleaves these requests with any request coming from the L3 interface; as a default the prefetch and write-posting engine has the lowest priority.

The prefetch and write-posting engine is dedicated to data-stream access (as opposed to random data access); thus, it is primarily dedicated to NAND support. The engine does not include an address generator; the request is limited to chip-select target identification. It includes a 64-byte FIFO associated with a DMA request synchronization line, for optimal DMA-based use.

For more information about prefetch and write-posting engine programming, see [Section 9.1.5.14.4](#), *Prefetch and Write-Posting Engine*.

9.1.4.6 External Device/Memory Port Interface

The external port interface controls all address, data, and control signals required for communication with GPMC-supported devices and memories.

9.1.5 GPMC Basic Programming Model

The GPMC basic programming model offers maximum flexibility to support various access protocols for each of the eight configurable chip-selects. Use optimal chip-select settings, based on the characteristics of the external device:

- Different protocols can be selected to support generic asynchronous or synchronous random-access devices (NOR flash, SRAM) or to support specific NAND devices.
- The address and the data bus can be multiplexed on the same external bus.
- Read and write access can be independently defined as asynchronous or synchronous.
- System requests (byte, Word16, burst) are performed through single or multiple accesses. External access profiles (single, multiple with optimized burst length, native- or emulated-wrap) are based on external device characteristics (supported protocol, bus width, data buffer size, native-wrap support).
- System burst read or write requests are synchronous-burst (multiple-read or multiple-write). When neither burst nor page mode is supported by external memory or ASIC devices, system burst read or write requests are translated to successive single synchronous or asynchronous accesses (single reads or single writes). 8-bit wide devices are supported only in single-synchronous or asynchronous read or write mode.
- To simulate a programmable internal-wait state, an external wait pin can be monitored to dynamically control external access at the beginning (initial access time) of and during a burst access.

Each control signal is controlled independently for each chip-select. The internal functional clock of the GPMC (GPMC_FCLK) is used as a time reference to specify the following:

- Read- and write-access duration
- Most GPMC external interface control-signal assertion and deassertion times
- Data-capture time during read access
- External wait-pin monitoring time
- Duration of idle time between accesses, when required

9.1.5.1 Chip-Select Base Address and Region Size Configuration

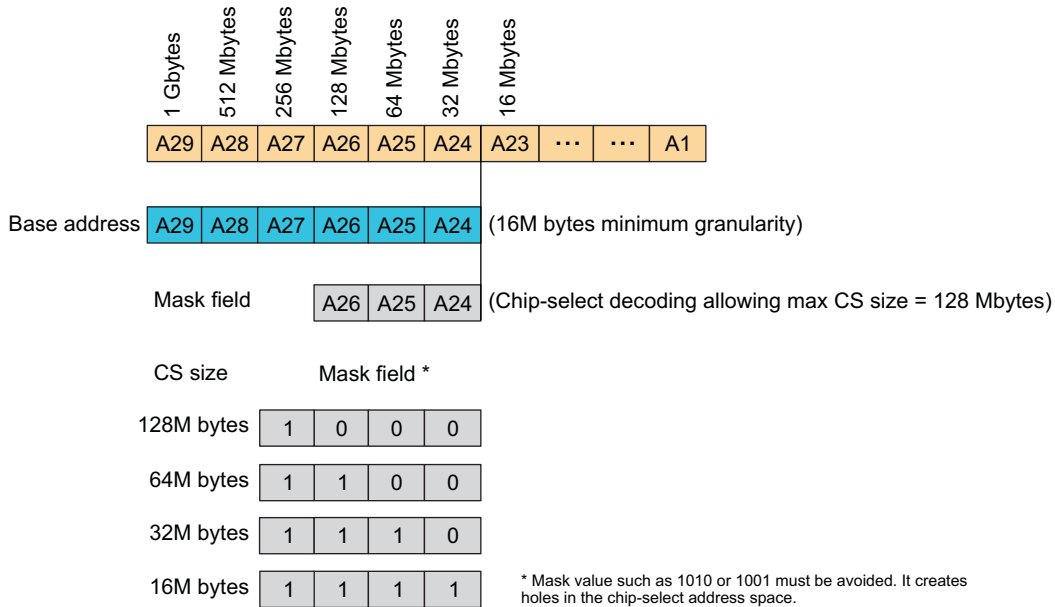

Any external memory or ASIC device attached to the GPMC external interface can be accessed by any device system host within the GPMC 1 Gbyte contiguous address space. For details, see the *Memory Mapping* chapter.

The GPMC 1 Gbyte address space can be divided into a maximum of eight chip-select regions with programmable base address and programmable CS size. The CS size is programmable from 16 MBytes to 256 MBytes (must be a power-of-2) and is defined by the mask field. Attached memory smaller than the programmed CS region size is accessed through the entire CS region (aliasing).

Each chip-select has a 6-bit base address encoding and a 4-bit decoding mask, which must be programmed according to the following rules:

- The programmed chip-select region base address must be aligned on the chip-select region size address boundary and is limited to a power-of-2 address value. During access decoding, the register base address value is used for address comparison with the address-bit line mapping as described in [Figure 9-6](#) (with A0 as the device system byte-address line). Base address is programmed through the GPMC_CONFIG7_i[5:0] BASEADDRESS bit field
- The register mask is used to exclude some address lines from the decoding. A register mask bit field set to 0 suppresses the associated address line from the address comparison (incoming address bit line is don't care). The register mask value must be limited to the subsequent value, based on the desired chip-select region size. Any other value has an undefined result. When multiple chip-select regions with overlapping addresses are enabled concurrently, access to these chip-select regions is cancelled and a GPMC access error is posted. The mask field is programmed through the GPMC_CONFIG7_i[11:8] MASKADDRESS bit field.

Figure 9-6. Chip-Select Address Mapping and Decoding Mask

gpmc-006

Chip-select configuration (base and mask address or any protocol and timing settings) must be performed while the associated chip-select is disabled through the GPMC.GPMC_CONFIG7_i[6] CSVALID bit (where I stands for the GPMC chip-select value, I = 0 to 7). In addition, a chip-select configuration can only be disabled if there is no ongoing access to that chip-select. This requires activity monitoring of the prefetch or write-posting engine if the engine is active on the chip-select. Also, the write buffer state must be monitored to wait for any posted write completion to the chip-select.

Conversely, before trying to access a chip-select, software must ensure that the chip-select is enabled. To account for prefetch engine effects, after the chip-select-enable instruction, an NOP instruction (equivalent to 64 bits) must be executed before the chip-select is accessed.

Any access attempted to a nonvalid GPMC address region (CSVALID disabled or address decoding outside a valid chip-select region) is not propagated to the external interface and a GPMC access error is posted. In case of chip-selects overlapping, an error is generated and no access will occur on either chip-select.

Chip-select 0 is the only chip-select region enabled after either a power-up or a GPMC reset.

CAUTION

Although the GPMC interface can drive up to 8 chip-selects, the frequency specified for this interface is for a specific load. If this load is exceeded, the maximum frequency cannot be reached. One solution is to implement a board with buffers, to allow the slowest device to maintain the total load on the lines at the value specified in your device-specific data manual. To have access to the device-specific data manual, please contact your TI representative.

9.1.5.2 Access Protocol Configuration

9.1.5.2.1 Supported Devices

The access protocol of each chip-select can be independently specified through the GPMC.GPMC_CONFIG1_i[11:10] DEVICETYPE parameter (where I =0 to 7) for:

- Random-access synchronous or asynchronous memory like NOR flash, SRAM
- NAND flash asynchronous devices

NOTE: NAND flash interfacing requires the parameter settings of generic chip-select 0. For more information about the NAND flash GPMC basic programming model and NAND support, see [Section 9.1.5.14, NAND Device Basic Programming Model](#), and [Section 9.1.5.14.1, NAND Memory Device in Byte or Word 16 Stream Mode](#).

9.1.5.2.2 Access Size Adaptation and Device Width

Each chip-select can be independently configured through the GPMC.GPMC_CONFIG1_i[13:12] DEVICESIZE field (I = 0 to 7) to interface with a 16-bit wide device or an 8-bit wide device. System requests with data width greater than the external device data bus width are split into successive accesses according to both the external device data-bus width and little-endian data organization.

NOTE: The processor does not provide the A0 byte address line required for random-byte addressable 8-bit wide device interfacing (for both multiplexed and nonmultiplexed protocol). It limits the use of 8-bit wide device interfacing to byte-alias accesses. This limitation is not applicable to NAND device interfacing (8-bit wide or 16-bit wide devices).

9.1.5.2.3 Address/Data-Multiplexing Interface

For random synchronous or asynchronous memory interfacing (DEVICETYPE = 0b00), an address- and data-multiplexing protocol can be selected through the GPMC.GPMC_CONFIG1_i[9] MUXADDDATA bit (I = 0 to 7). The nADV signal must be used as the external device address latch control signal. For the associated chip-select configuration, nADV assertion and deassertion time and nOE assertion time must be set to the appropriate value to meet the address latch setup/hold time requirements of the external device. See [Section 9.1.3, GPMC Integration](#).

NOTE: This address/data-multiplexing interface is not applicable to NAND device interfacing. NAND devices require a specific address, command, and data multiplexing protocol. See [Section 9.1.5.14, NAND Device Basic Programming Model](#).

9.1.5.2.4 Address and Data Bus

See [Section 9.1.3.3, GPMC Address and Data Bus](#).

9.1.5.2.5 Asynchronous and Synchronous Access

For each chip-select configuration, the read access can be specified as either asynchronous or synchronous access through the GPMC.GPMC_CONFIG1_i[29] READTYPE bit (I = 0 to 7). For each chip-select configuration, the write access can be specified as either synchronous or asynchronous access through the GPMC.GPMC_CONFIG1_i[27] WRITETYPE bit (I = 0 to 7).

Asynchronous and synchronous read (write) access time and related control signals are controlled through timing parameters that refer to GPMC_FCLK. The primary difference of synchronous mode is the availability of a configurable clock interface (GPMC_CLK) to control the external device. Synchronous mode also affects data-capture and wait-pin monitoring schemes in read access.

For details about asynchronous and synchronous access, see the descriptions of GPMC_CLK, RdAccessTime, WrAccessTime, and wait-pin monitoring.

For more information about timing-parameter settings, see the sample timing diagrams in this chapter.

NOTE: The address bus and nBE[1:0] are fixed for the duration of a synchronous burst read access, but they are updated for each beat of an asynchronous page-read access.

9.1.5.2.6 Page and Burst Support

Each chip-select can be configured to process system single or burst requests into successive single accesses or asynchronous page/synchronous burst accesses, with appropriate access size adaptation.

Depending on the external device page or burst capability, read and write accesses can be independently configured through the GPMC. The GPMC_CONFIG1_i[30] READMULTIPLE and GPMC_CONFIG1_i[28] WRITEMULTIPLE bits (I = 0 to 7) are associated with the READTYPE and WRITETYPE parameters.

NOTE:

- Asynchronous write page mode is not supported.
 - 8-bit wide device support is limited to nonburstable devices (READMULTIPLE and WRITEMULTIPLE are don't care).
 - Not applicable to NAND device interfacing.
-

9.1.5.2.7 System Burst Versus External Device Burst Support

The device system can issue the following requests to the GPMC:

- Byte, Word16, Word32 requests (byte enable controlled). This is always a single request from the interconnect point of view.
- Incrementing fixed-length bursts of two words, four words, and eight words
- Wrapped (critical word access first) fixed-length burst of two, four, or eight words

To process a system request with the optimal protocol, the READMULTIPLE (and READTYPE) and WRITEMULTIPLE (and WRITETYPE) parameters must be set according to the burstable capability (synchronous or asynchronous) of the attached device.

The GPMC access engine issues only fixed-length burst. The maximum length that can be issued is defined per CS by the GPMC_CONFIG1_i[24:23] ATTACHEDDEVICEPAGELENGTH field (I = 0 to 7). When the ATTACHEDDEVICEPAGELENGTH value is less than the system burst request length (including the appropriate access size adaptation according to the device width), the GPMC splits the system burst request into multiple burst beats. Within the specified 4-, 8-, or 16-word value, the ATTACHEDDEVICEPAGELENGTH field value must correspond to the maximum-length burst supported by the memory device configured in fixed-length burst mode (as opposed to continuous burst mode).

To get optimal performance from memory devices that natively support 16 Word16-length-wrapping burst capability (critical word access first), the ATTACHEDDEVICEPAGELENGTH parameter must be set to 16 words and the GPMC_CONFIG1_i[31] WRAPBURST bit (I = 0 to 7) must be set to 1. Similarly DEVICEPAGELENGTH is set to 4 and 8 for memories supporting respectively 4 and 8 Word16-length-wrapping burst.

When the memory device does not offer (or is not configured to offer) native 16 Word16-length-wrapping burst, the WRAPBURST parameter must be cleared, and the GPMC access engine emulates the wrapping burst by issuing the appropriate burst sequences according to the ATTACHEDDEVICEPAGELENGTH value.

When the memory device does not support native-wrapping burst, there is usually no difference in behavior between a fixed burst length mode and a continuous burst mode configuration (except for a potential power increase from a memory-speculative data prefetch in a continuous burst read). However, even though continuous burst mode is compatible with GPCM behavior, because the GPMC access engine issues only fixed-length burst and does not benefit from continuous burst mode, it is best to configure the memory device in fixed-length burst mode.

The memory device maximum-length burst (configured in fixed-length burst wrap or nonwrap mode) usually corresponds to the memory device data buffer size. Memory devices with a minimum of 16 half-word buffers are the most appropriate (especially with wrap support), but memory devices with smaller buffer size (4 or 8) are also supported, assuming that the GPMC_CONFIG1_i[24:23] ATTACHEDDEVICEPAGELENGTH field is set accordingly to 4 or 8 words.

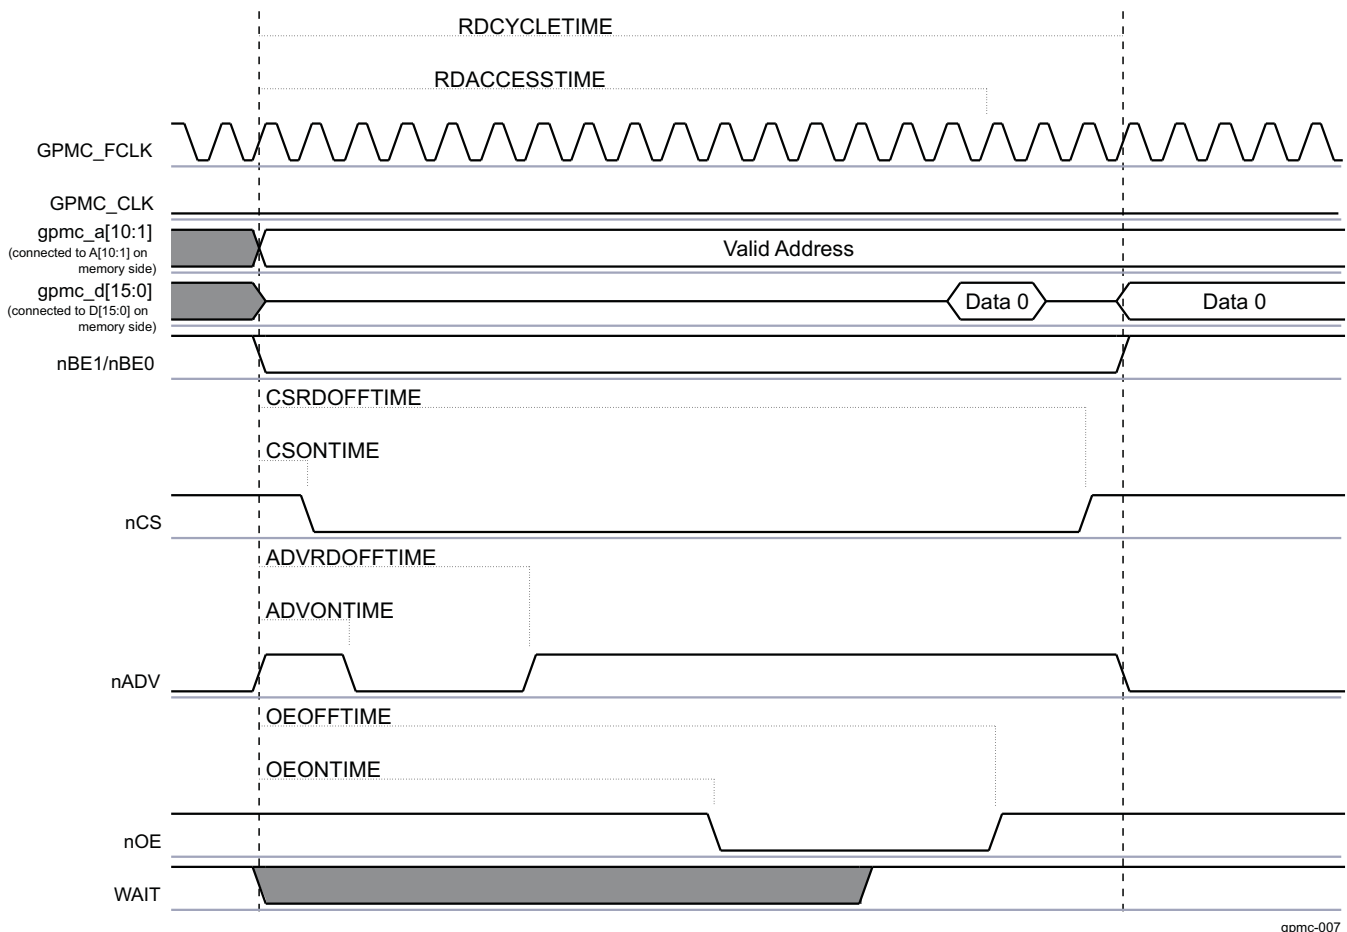

The device system issues only requests with addresses or starting addresses for nonwrapping burst requests; that is, the request size boundary is aligned. In case of an eight-word-wrapping burst, the wrapping address always occurs on the eight-words boundary. As a consequence, all words requested must be available from the memory data buffer when the buffer size is equal to or greater than the ATTACHEDDEVICEPAGELENGTH value. This usually means that data can be read from or written to the buffer at a constant rate (number of cycles between data) without wait states between data accesses. If the memory does not behave this way (nonzero wait state burstable memory), wait-pin monitoring must be enabled to dynamically control data-access completion within the burst beat.

NOTE: When the system burst request length is less than the ATTACHEDDEVICEPAGELENGTH value, the GPMC proceeds with the required accesses.

9.1.5.3 Timing Setting

The GPMC is a signal generator that offers the maximum flexibility to support various access protocols. Most of the timing parameters of the protocol access used by the GPMC to communicate with attached memories or devices are programmable on a chip-select basis. Assertion and deassertion times of control signals are defined to match the attached memory or device timing specifications and to get maximum performance during accesses. For example, the timing diagram in Figure 9-7 shows an asynchronous single-read access performed on an asynchronous device. For more information on GPMC_CLK and GPMC_FCLK refer to Section 9.1.5.3.6.

Figure 9-7. Asynchronous Single Read on a Nonmultiplexed Address/Data Device

gpmc-007

9.1.5.3.1 Read Cycle Time and Write Cycle Time (RDCYCLETIME / WRCYCLETIME)

The GPMC.GPMC_CONFIG5_i[4:0] RDCYCLETIME and GPMC.GPMC_CONFIG5_i[12:8] WRCYCLETIME fields (I = 0 to 7) define the address bus and byte enables valid times for read and write accesses. To ensure a correct duty cycle of GPMC_CLK between accesses, RDCYCLETIME and WRCYCLETIME are expressed in GPMC_FCLK cycles and must be multiples of the GPMC_CLK cycle.

When either RDCYCLETIME or WRCYCLETIME completes, if they are not already deasserted, all control signals (NCS, nADV/ALE, nOE/RE, nWE, and BE0/CLE) are deasserted to their reset values, regardless of their deassertion time parameters.

An exception to this forced deassertion occurs when a pipelined request to the same chip-select or to a different chip-select is pending. In such a case, it is not necessary to deassert a control signal with deassertion time parameters equal to the cycle-time parameter. This exception to forced deassertion prevents any unnecessary glitchy transition. This requirement also applies to BE signals, thus avoiding an unnecessary BE glitch transition when pipelining requests.

If no inactive cycles are required between successive accesses to the same or to a different chip-select (GPMC.GPMC_CONFIG6_i[7] CYCLE2CYCLESAMECSSEN = 0 or GPMC.GPMC_CONFIG6_i[6] CYCLE2CYCLEDIFFCSSEN = 0, where I = 0 to 7), and if assertion-time parameters associated with the pipelined access are equal to 0, asserted control signals (nCS, nADV/ALE, nBE0/CLE, nWE, and nOE/RE) are kept asserted. This applies to any read/write to read/write access combination.

If inactive cycles are inserted between successive accesses, that is, CYCLE2CYCLESAMECSSEN = 1 or CYCLE2CYCLEDIFFCSSEN = 1, the control signals are forced to their respective default reset values for the number of GPMC_FCLK cycles defined in CYCLE2CYCLEDELAY:

- The RDCYCLETIME and WRCYCLETIME bit fields are programmable in the GPMC.GPMC_CONFIG5_i register, I = 0 to 7.
- The RDCYCLETIME and WRCYCLETIME bit fields can be set from 0 to 31 GPMC_FCLK cycles with a granularity of 1 for GPMC.GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY set to 0.
- The RDCYCLETIME and WRCYCLETIME bit fields can be set from 0 to 62 GPMC_FCLK cycles with a granularity of 2 for GPMC.GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY set to 1.

9.1.5.3.2 nCS: Chip-Select Signal Control Assertion/Deassertion Time (CSONTIME / CSRDOFFTIME / CSWROFFTIME / CSEXTRADELAY)

The GPMC.GPMC_CONFIG2_i[3:0] CSONTIME field (where I = 0 to 7) defines the nCS signal-assertion time relative to the start access time. It is common for read and write accesses.

For a read access, the GPMC.GPMC_CONFIG2_i[12:8] CSRDOFFTIME field defines the nCS signal deassertion time relative to start access time.

For a write access, the GPMC.GPMC_CONFIG2_i[20:16] CSWROFFTIME field defines the nCS signal deassertion time relative to start access time.\

CSONTIME, CSRDOFFTIME and CSWROFFTIME parameters are applicable to synchronous and asynchronous modes. CSONTIME can be used to control an address and byte enable setup time before chip-select assertion. CSRDOFFTIME and CSWROFFTIME can be used to control an address and byte enable hold time after chip-select deassertion.

nCS signal transitions as controlled through CSONTIME, CSRDOFFTIME, and CSWROFFTIME can be delayed by half a GPMC_FCLK period by enabling the GPMC.GPMC_CONFIG2_i[7] CSEXTRADELAY bit. This half of a GPMC_FCLK period provides more granularity on the nCS assertion and deassertion time to guarantee proper setup and hold time relative to GPMC_CLK. CSEXTRADELAY is especially useful in configurations where GPMC_CLK and GPMC_FCLK have the same frequency, but can be used for all GPMC configurations. If asserted, CSEXTRADELAY applies to all parameters controlling nCS transitions.

The CSEXTRADELAY bit must be used carefully to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program the RDCYCLETIME and WRCYCLETIME bit fields to be greater than the nCS signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

9.1.5.3.3 *nADV/ALE: Address Valid/Address Latch Enable Signal Control Assertion/Deassertion Time (ADVONTIME / ADVRDOFFTIME / ADVWROFFTIME / ADVEXTRADELAY)*

The GPMC.GPMC_CONFIG3_i[3:0] ADVONTIME field (where I = 0 to 7) defines the nADV/ALE signal-assertion time relative to start access time. It is common to read and write accesses.

For a read access, the GPMC.GPMC_CONFIG3_i[12:8] ADVRDOFFTIME field defines the nADV/ALE signal-deassertion time relative to start access time.

For a write access, the GPMC.GPMC_CONFIG3_i[20:16] ADVWROFFTIME field defines the nADV/ALE signal-deassertion time relative to start access time.

ADVONTIME can be used to control an address and byte enable valid setup time control before nADV/ALE assertion. ADVRDOFFTIME and ADVWROFFTIME can be used to control an address and byte enable valid hold time control after nADV/ALE de-assertion. ADVRDOFFTIME and ADVWROFFTIME are applicable to both synchronous and asynchronous modes.

nADV/ALE signal transitions as controlled through ADVONTIME, ADVRDOFFTIME, and ADVWROFFTIME can be delayed by half a GPMC_FCLK period by enabling the GPMC.GPMC_CONFIG3_i[7] ADVEXTRADELAY bit. This half of a GPMC_FCLK period provides more granularity on nADV/ALE assertion and deassertion time to guarantee proper setup and hold time relative to GPMC_CLK. The ADVEXTRADELAY configuration parameter is especially useful in configurations where GPMC_CLK and GPMC_FCLK have the same frequency, but can be used for all GPMC configurations. If asserted, ADVEXTRADELAY applies to all parameters controlling nADV/ALE transitions.

ADVEXTRADELAY must be used carefully to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program the RDCYCLETIME and WRCYCLETIME bit fields to be greater than nADV/ALE signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

Refer to [Section 9.1.5.14](#) for more details on ADVONTIME, ADVRDOFFTIME and ADVWROFFTIME usage for CLE and ALE (Command / Address Latch Enable) usage for a NAND Flash interface.

9.1.5.3.4 *nOE/nRE: Output Enable / Read Enable Signal Control Assertion / Deassertion Time (OEONTIME / OEOFFTIME / OEEXTRADELAY)*

The GPMC.GPMC_CONFIG4_i[3:0] OEONTIME field (where I = 0 to 7) defines the nOE/nRE signal assertion time relative to start access time. It is applicable only to read accesses.

The GPMC.GPMC_CONFIG4_i[12:8] OEOFFTIME field defines the nOE/nRE signal deassertion time relative to start access time. It is applicable only to read accesses.

OEONTIME and OEOFFTIME parameters are applicable to synchronous and asynchronous modes. OEONTIME can be used to control an address and byte enable valid setup time control before nOE/nRE assertion. OEOFFTIME can be used to control an address and byte enable valid hold time control after nOE/nRE assertion.

The nOE/nRE signal transitions as controlled through OEONTIME, and OEOFFTIME can be delayed by half a GPMC_FCLK period by enabling the GPMC.GPMC_CONFIG4_i[7] OEEXTRADELAY bit. This half of a GPMC_FCLK period provides more granularity on nOE/nRE assertion and deassertion time to guaranty proper setup and hold time relative to GPMC_CLK. If asserted, OEEXTRADELAY applies to all parameters controlling nOE/nRE transitions.

OEEXTRADELAY must be used carefully, to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program RDCYCLETIME and WRCYCLETIME to be greater than nOE/nRE signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

nOE/nRE is not asserted during a write cycle.

NOTE: When the GPMC generates a read access to an address-/data-multiplexed device, it drives the address bus until nOE assertion time.

9.1.5.3.5 *nWE: Write Enable Signal Control Assertion / Deassertion Time (WEONTIME / WEOFFTIME /*

WEEXTRADELAY)

The GPMC.GPMC_CONFIG4_i[19:16] WEONTIME field (where I = 0 to 7) defines the nWE signal-assertion time relative to start access time. It applies only to write accesses.

The GPMC.GPMC_CONFIG4_i[28:24] WEOFFTIME field defines the nWE signal-deassertion time relative to start access time. It applies only to write accesses.

WEONTIME can be used to control an address and byte enable valid setup time control before nWE assertion. WEOFFTIME can be used to control an address and byte enable valid hold time control after nWE assertion.

nWE signal transitions as controlled through WEONTIME, and WEOFFTIME can be delayed by half a GPMC_FCLK period by enabling the GPMC.GPMC_CONFIG4_i[23] WEEXTRADELAY bit. This half of a GPMC_FCLK period provides more granularity on nWE assertion and deassertion time to guaranty proper setup and hold time relative to GPMC_CLK. If asserted, WEEXTRADELAY applies to all parameters controlling nWE transitions.

The WEEXTRADELAY bit must be used carefully to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program the WRCYCLETIME bit field to be greater than the nWE signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

nWE is not asserted during a read cycle.

9.1.5.3.6 GPMC_CLK

GPMC_CLK is the external clock provided to the attached synchronous memory or device.

- The GPMC_CLK clock frequency is the GPMC_FCLK functional clock frequency divided by 1, 2, 3, or 4, depending on the GPMC.GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER bit field (where I = 0 to 7), with a guaranteed 50-percent duty cycle.
- The GPMC_CLK clock is only activated when the access in progress is defined as synchronous (read or write access).
- The GPMC.GPMC_CONFIG1_i[26:25] CLKACTIVATIONTIME field (I = 0 to 7) defines the number of GPMC_FCLK cycles from start access time to GPMC_CLK activation.
- The GPMC_CLK clock is stopped when cycle time completes and is asserted low between accesses.
- The GPMC_CLK clock is kept low when access is defined as asynchronous.
- When cycle time completes, the GPMC_CLK may be high because of the GPMCFCLKDIVIDER bit field. To ensure correct stoppage of the GPMC_CLK clock within the 50-percent required duty cycle, it is the user's responsibility to extend the RDCYCLETIME or WRCYCLETIME value.
- When the GPMC is configured for synchronous mode, the GPMC_CLK signal (which is an output) must also be set as an input (CONTROL.CONTROL_PADCONF_GPMC_NCS7[24] INPUTENABLE1 = 1). GPMC_CLK is looped back through the output and input buffers of the corresponding GPMC_CLK pad at the device boundary. The looped-back clock is used to synchronize the sampling of the memory signals.

NOTE: To ensure a correct external clock cycle, the following rules must be applied:

- (RDCYCLETIME CLKACTIVATIONTIME) must be a multiple of (GPMCFCLKDIVIDER + 1).
 - The PAGEBURSTACCESSTIME value must be a multiple of (GPMCFCLKDIVIDER + 1).
-

9.1.5.3.7 GPMC_CLK and Control Signals Setup and Hold

Control-signal transition (assertion and deassertion) setup and hold values with respect to the GPMC_CLK edge can be controlled in the following ways:

- For the GPMC_CLK signal, the GPMC.GPMC_CONFIG1_i[26:25] CLKACTIVATIONTIME field (I = 0 to 7) allows setup and hold control of control-signal assertion time.
- The use of a divided GPMC_CLK allows setup and hold control of control-signal assertion and deassertion times.

- When GPMC_CLK runs at the GPMC_FCLK frequency so that GPMC_CLK edge and control-signal transitions refer to the same GPMC_FCLK edge, the control-signal transitions can be delayed by half of a GPMC_FCLK period to provide minimum setup and hold times. This half-GPMC_FCLK delay is enabled with the CSEXTRADelay, ADVEXTRADelay, OEEXTRADelay, or WEEXTRADelay parameter. This delay must be used carefully to prevent control-signal overlap between successive accesses to different chip-selects. This implies that the RDCYCLETIME and WRCYCLETIME are greater than the last control-signal deassertion time, including the extra half-GPMC_FCLK cycle.

9.1.5.3.8 Access Time (RDACCESSTIME / WRACCESSTIME)

The read access time and write access time durations can be programmed independently allowing nOE and GPMC data capture timing parameters to be independent of nWE and memory device data capture timing parameters.

RDACCESSTIME is programmed in the GPMC.GPMC_CONFIG5_i[20:16] bit field (I = 0 to 7).

WRACCESSTIME is programmed in the GPMC.GPMC_CONFIG6_i[28:24] bit field (I = 0 to 7).

RDACCESSTIME and WRACCESSTIME can be set from 0 to 31 GPMC_FCLK cycles with a granularity of one (GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY = 0).

RDACCESSTIME and WRACCESSTIME can be set from 0 to 62 GPMC_FCLK cycles with a granularity of two (GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY = 1).

9.1.5.3.8.1 Access Time on Read Access

In asynchronous read mode, for single and paged accesses, RDACCESSTIME field (I = 0 to 7) defines the number of GPMC_FCLK cycles from start access time to the GPMC_FCLK rising edge used for the first data capture. RDACCESSTIME must be programmed to the rounded greater GPMC_FCLK cycle value of the read access time of the attached memory device.

In synchronous read mode, for single or burst accesses, RDACCESSTIME defines the number of GPMC_FCLK cycles from start access time to the GPMC_FCLK rising edge corresponding to the GPMC_CLK rising edge used for the first data capture.

GPMC_CLK which is sent to the memory device for synchronization with the GPMC controller, is internally retimed to correctly latch the returned data. RDCYCLETIME must be greater than RDACCESSTIME in order to let the GPMC latch the last return data using the internally retimed GPMC_CLK.

The external WAIT signal can be used in conjunction with RDACCESSTIME to control the effective GPMC data-capture GPMC_FCLK edge on read access in both asynchronous mode and synchronous mode. For details about wait monitoring, see [Section 9.1.5.4](#).

9.1.5.3.8.2 Access Time on Write Access

In asynchronous write mode, the GPMC_CONFIG6_i[28:24] WRACCESSTIME timing parameter is not used to define the effective write access time. Instead, it is used as a WAIT invalid timing window, and must be set to a correct value so that the gpmc_wait pin is at a valid state two GPMC_CLK cycles before WRACCESSTIME completes. For details about wait monitoring, see [Section 9.1.5.4](#).

In synchronous write mode, for single or burst accesses, WRACCESSTIME defines the number of GPMC_FCLK cycles from start access time to the GPMC_CLK rising edge used by the memory device for the first data capture.

The external WAIT signal can be used in conjunction with WRACCESSTIME to control the effective memory device data capture GPMC_CLK edge for a synchronous write access. For details about wait monitoring, see [Section 9.1.5.4](#).

9.1.5.3.9 Page Burst Access Time (PAGEBURSTACCESSTIME)

PAGEBURSTACCESSTIME is programmed in the GPMC.GPMC_CONFIG5_i[27:24] bit field (I = 0 to 7).

PAGEBURSTACCESSTIME can be set from 0 to 15 GPMC_FCLK cycles with a granularity of one (GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY set to 0), or from 0 to 30 GPMC_FCLK cycles with a granularity of two (TIMEPARAGRANULARITY set to 1).

9.1.5.3.9.1 Page Burst Access Time on Read Access

In asynchronous page read mode, the delay between successive word captures in a page is controlled through the PAGEBURSTACCESSTIME bit field. The PAGEBURSTACCESSTIME parameter must be programmed to the rounded greater GPMC_FCLK cycle value of the read access time of the attached device.

In synchronous burst read mode, the delay between successive word captures in a burst is controlled through the PAGEBURSTACCESSTIME field.

The external WAIT signal can be used in conjunction with PAGEBURSTACCESSTIME to control the effective GPMC data capture GPMC_FCLK edge on read access. For details about wait monitoring, see [Section 9.1.5.4](#).

9.1.5.3.9.2 Page Burst Access Time on Write Access

Asynchronous page write mode is not supported. PAGEBURSTACCESSTIME is irrelevant in this case.

In synchronous burst write mode, PAGEBURSTACCESSTIME controls the delay between successive memory device word captures in a burst.

The external WAIT signal can be used in conjunction with PAGEBURSTACCESSTIME to control the effective memory-device data capture GPMC_CLK edge in synchronous write mode. For details about wait monitoring, see [Section 9.1.5.4](#).

9.1.5.3.10 Bus Keeping Support

At the end-cycle time of a read access, if no other access is pending, the GPMC drives the bus with the last data read after RDCYCLETIME completion time to prevent bus floating and reduce power consumption.

After a write access, if no other access is pending, the GPMC keeps driving the data bus after WRCYCLETIME completes with the same data to prevent bus floating and power consumption.

9.1.5.4 WAIT Pin Monitoring Control

GPMC access time can be dynamically controlled using an external gpmc_wait pin when the external device access time is not deterministic and cannot be defined and controlled only using the GPMC internal RDACCESSTIME, WRACCESSTIME and PAGEBURSTACCESSTIME wait state generator.

The GPMC four input wait pins: gpmc_wait3, gpmc_wait2, gpmc_wait1, and gpmc_wait0. These four pins allow direct plugin and control of external devices with different wait-pin polarity. They also allow the overlap of wait-pin assertion from different devices without affecting access to devices for which the wait pin is not asserted.

- The GPMC.GPMC_CONFIG1_i[17:16] WAITPINSELECT field (i = 0 to 7) selects which input gpmc_wait pin is used for the device attached to the corresponding chip-select.
- The polarity of the wait pin is defined through the WAITxPINPOLARITY bit of the GPMC.GPMC_CONFIG register. A wait pin configured to be active low means that low level on the WAIT signal indicates that the data is not ready and that the data bus is invalid. When WAIT is inactive, data is valid.

The GPMC access engine can be configured by CS to monitor the wait pin of the external memory device or not, based on the access type: read or write.

- The GPMC.GPMC_CONFIG1_i[22] WAITREADMONITORING bit defines whether the wait pin should be monitored during read accesses or not.
- The GPMC.GPMC_CONFIG1_i[21] WAITWRITEMONITORING bit defines whether the wait pin should be monitored during write accesses or not.

The GPMC access engine can be configured to monitor the wait pin of the external memory device asynchronously or synchronously with the GPMC_CLK clock, depending on the access type: synchronous or asynchronous (the GPMC.GPMC_CONFIG1_i[29] READTYPE and GPMC.GPMC_CONFIG1_i[27] WRITETYPE bits).

9.1.5.4.1 Wait Monitoring During an Asynchronous Read Access

When wait-pin monitoring is enabled for read accesses (WAITREADMONITORING), the effective access time is a logical AND combination of the RDACCESSTIME timing completion and the wait-deasserted state.

During asynchronous read accesses with wait-pin monitoring enabled, the wait pin must be at a valid level (asserted or deasserted) for at least two GPMC clock cycles before RDACCESSTIME completes, to ensure correct dynamic access-time control through wait-pin monitoring. The advance pipelining of the two GPMC clock cycles is the result of the internal synchronization requirements for the WAIT signal.

In this context, RDACCESSTIME is used as a WAIT invalid timing window and is set to such a value that the wait pin is at a valid state two GPMC clock cycles before RDACCESSTIME completes.

Similarly, during a multiple-access cycle (for example, asynchronous read page mode), the effective access time is a logical AND combination of PAGEBURSTACCESSTIME timing completion and the wait-deasserted state. Wait-monitoring pipelining is also applicable to multiple accesses (access within a page).

- WAIT monitored as active freezes the CYCLETIME counter. For an access within a page, when the CYCLETIME counter is by definition in a lock state, WAIT monitored as asserted extends the current access time in the page. Control signals are kept in their current state. The data bus is considered invalid, and no data are captured during this clock cycle.
- WAIT monitored as inactive unfreezes the CYCLETIME counter. For an access within a page, when the CYCLETIME counter is by definition in a lock state, WAIT monitored as inactive completes the current access time and starts the next access phase in the page. The data bus is considered valid, and data are captured during this clock cycle. In case of a single access or if this was the last access in a multiple-access cycle, all signals are controlled according to their related control timing value and according to the CYCLETIME counter status.

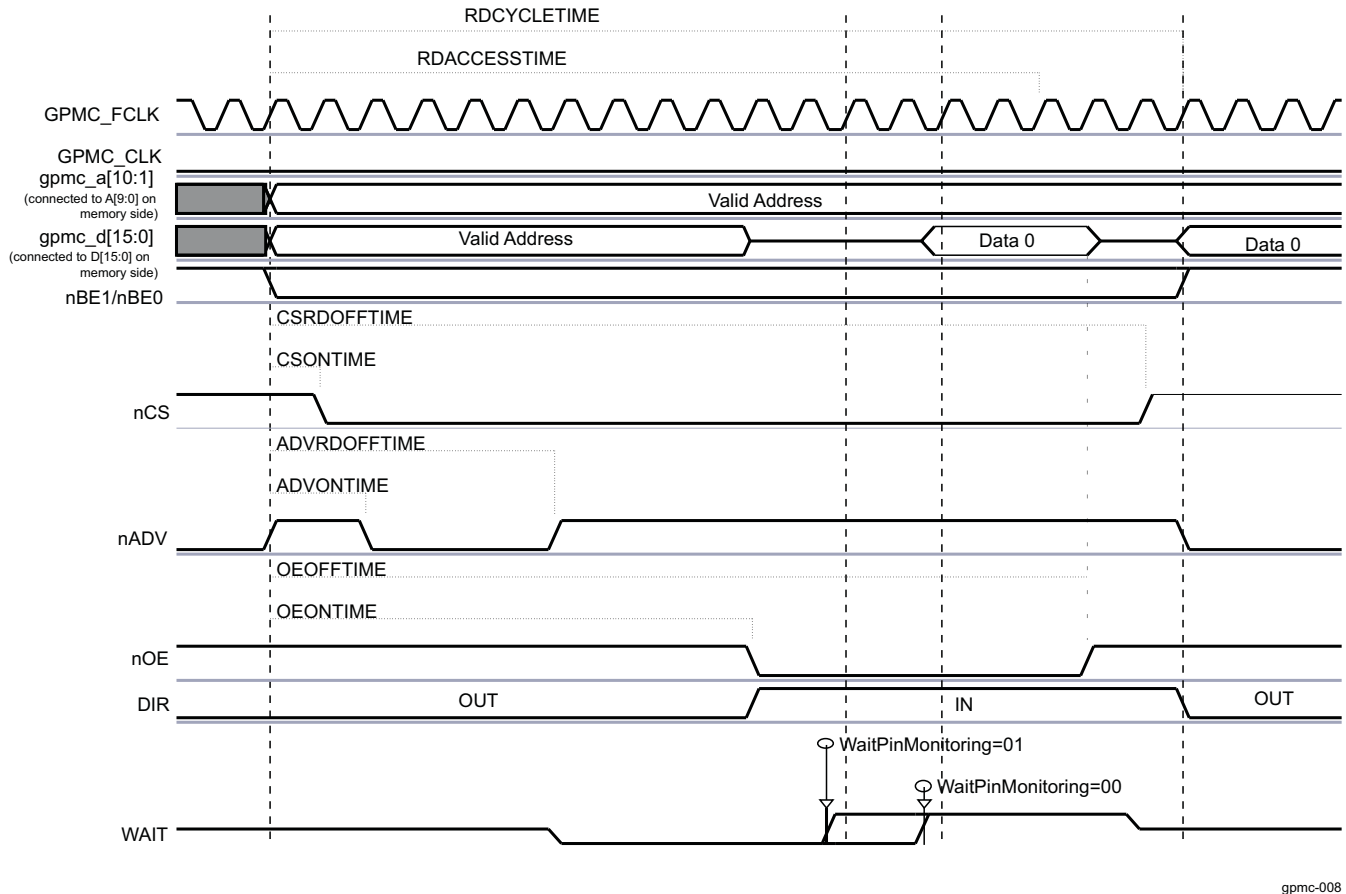

When a delay larger than two GPMC clocks must be observed between wait-pin deactivation time and data valid time (including the required GPMC and the device data setup time), an extra delay can be added between wait-pin deassertion time detection and effective data-capture time and the effective unlock of the CYCLETIME counter. This extra delay can be programmed in the GPMC.GPMC_CONFIG1_[19:18] WAITMONITORINGTIME field (I = 0 to 7).

NOTE:

- The WAITMONITORINGTIME parameter does not delay the wait-pin active or inactive detection, nor does it modify the two GPMC clocks pipelined detection delay.
 - This extra delay is expressed as a number of GPMC_CLK clock cycles, even though the access is defined as asynchronous, and no GPMC_CLK clock is provided to the external device. Still, GPMCFCLKDIVIDER is used as a divider for the GPMC clock, so it must be programmed to define the correct WAITMONITORINGTIME delay.
-

Figure 9-8 shows wait behavior during an asynchronous single read access.

Figure 9-8. Wait Behavior During an Asynchronous Single Read Access (GPMCFCLKDivider = 1)

NOTE: The WAIT signal is active low. WAITMONITORINGTIME = 00, 01.

9.1.5.4.2 Wait Monitoring During an Asynchronous Write Access

When wait-pin monitoring is enabled for write accesses (GPMC.GPMC_CONFIG1_i[21] WAITWRITEMONITORING bit = 0x1), the WAIT-invalid timing window is defined by the WRACCESSTIME field. WRACCESSTIME must be set so that the wait pin is at a valid state two GPMC clock cycles before WRACCESSTIME completes. The advance pipelining of the two GPMC clock cycles is the result of the internal synchronization requirements for the WAIT signal.

- WAIT monitored as active freezes the CYCLETIME counter. This informs the GPMC that the data bus is not captured by the external device. The control signals are kept in their current state. The data bus still drives the data.
- WAIT monitored as inactive unfreezes the CYCLETIME counter. This informs that the data bus is correctly captured by the external device. All signals, including the data bus, are controlled according to their related control timing value and to the CYCLETIME counter status.

When a delay larger than two GPMC clock cycles must be observed between wait-pin deassertion time and the effective data write into the external device (including the required GPMC data setup time and the device data setup time), an extra delay can be added between wait-pin deassertion time detection and effective data write time into the external device and the effective unfreezing of the CYCLETIME counter. This extra delay can be programmed in the GPMC.GPMC_CONFIG1_i[19:18] WAITMONITORINGTIME fields (I = 0 to 7).

NOTE:

- The WAITMONITORINGTIME parameter does not delay the wait-pin assertion or deassertion detection, nor does it modify the two GPMC clock cycles pipelined detection delay.
- This extra delay is expressed as a number of GPMC_CLK clock cycles, even though the access is defined as synchronous, and even though no clock is provided to the external device. Still, GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER is used as a divider for the GPMC clock and so it must be programmed to define the correct WAITMONITORINGTIME delay.

9.1.5.4.3 Wait Monitoring During a Synchronous Read Access

During synchronous accesses with wait-pin monitoring enabled, the wait pin is captured synchronously with GPMC_CLK, using the rising edge of this clock.

The WAIT signal can be programmed to apply to the same clock cycle it is captured in. Alternatively, it can be sampled one or two GPMC_CLK cycles ahead of the clock cycle it applies to. This pipelining is applicable to the entire burst access, and to all data phase in the burst access. This WAIT pipelining depth is programmed in the GPMC.GPMC_CONFIG1_i[19:18] WAITMONITORINGTIME field (where $l = 0$ to 7), and is expressed as a number of GPMC_CLK clock cycles.

In synchronous mode, when wait-pin monitoring is enabled (GPMC.GPMC_CONFIG1_i[22] WAITREADMONITORING bit), the effective access time is a logical AND combination of the RDACCESSTIME timing completion and the WAIT deasserted-state detection.

Depending on the programmed WAITMONITORINGTIME value, the wait pin should be at a valid level, either asserted or deasserted:

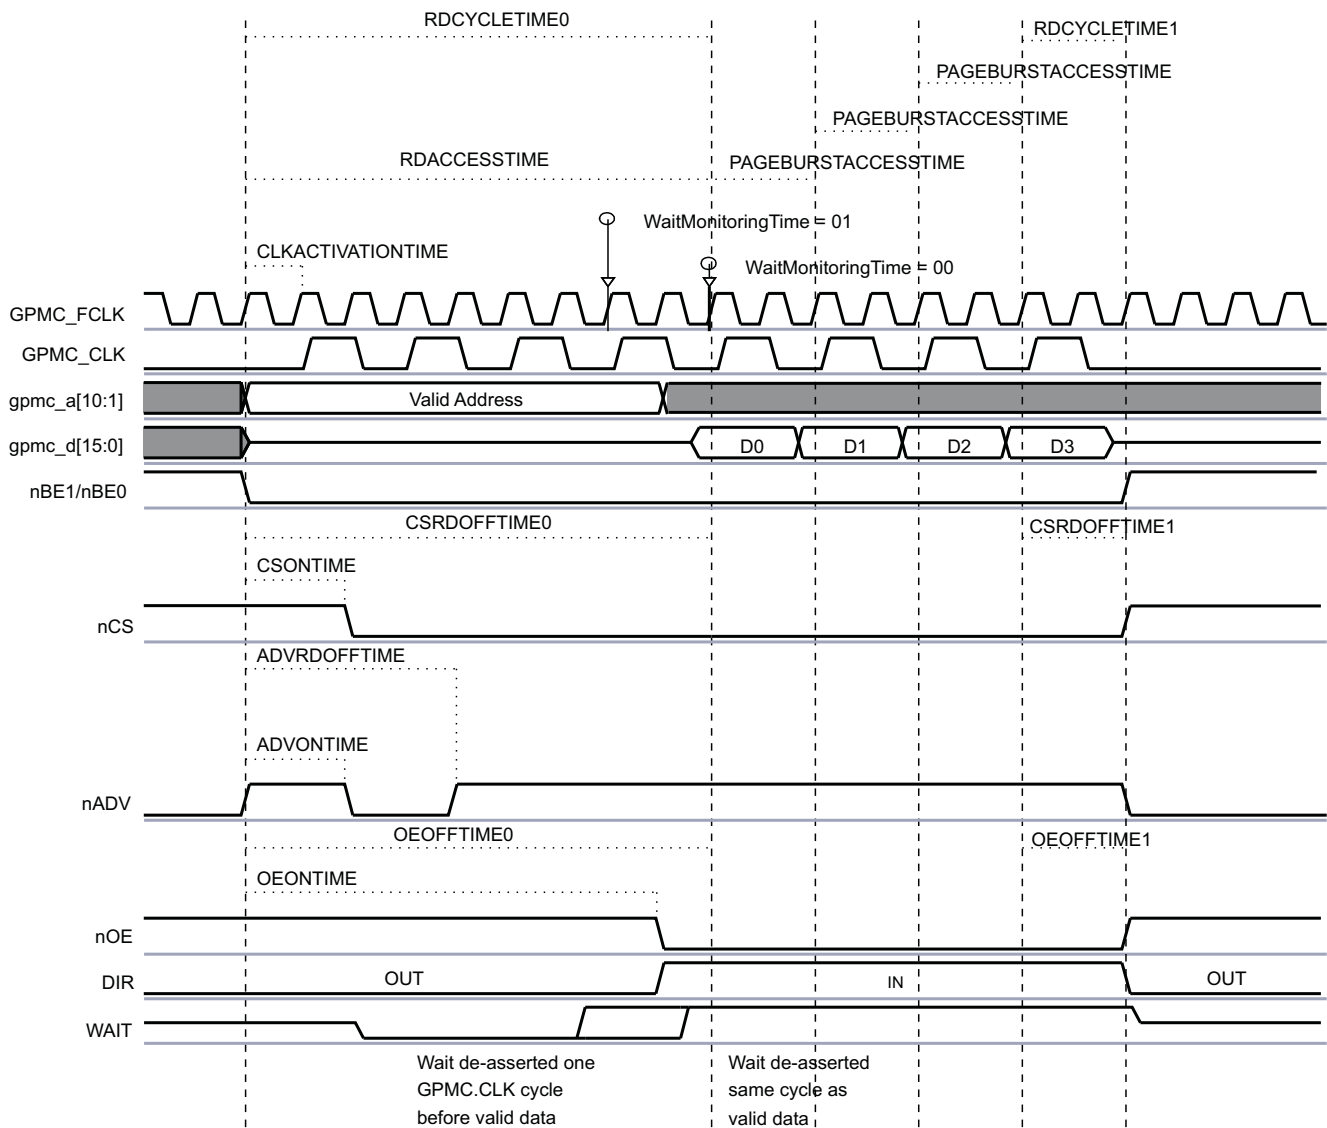

- In the same clock cycle the data is valid if WAITMONITORINGTIME = 0 (at RDACCESSTIME completion)
- In the WAITMONITORINGTIME \times (GPMCFCLKDIVIDER + 1) GPMC_FCLK clock cycles before RDACCESSTIME completion if WAITMONITORINGTIME \neq 0

Similarly, during a multiple-access cycle (burst mode), the effective access time is a logical AND combination of PAGEBURSTACCESSTIME timing completion and the wait-inactive state. The Wait pipelining depth programming applies to the whole burst access.

- WAIT monitored as active freezes the CYCLETIME counter. For an access within a burst (when the CYCLETIME counter is by definition in a lock state), WAIT monitored as active extends the current access time in the burst. Control signals are kept in their current state. The data bus is considered invalid, and no data are captured during this clock cycle.
- WAIT monitored as inactive unfreezes the CYCLETIME counter. For an access within a burst (when the CYCLETIME counter is by definition in lock state), WAIT monitored as inactive completes the current access time and starts the next access phase in the burst. The data bus is considered valid, and data are captured during this clock cycle. In a single access or if this was the last access in a multiple-access cycle, all signals are controlled according to their relative control timing value and the CYCLETIME counter status.

Figure 9-9 shows wait behavior during a synchronous read burst access.

Figure 9-9. Wait Behavior During a Synchronous Read Burst Access

gpmc-009

NOTE: The WAIT signal is active low. WAITMONITORINGTIME = 00, 01.

9.1.5.4.4 Wait Monitoring During a Synchronous Write Access

During synchronous accesses with wait-pin monitoring enabled (the WAITWRITEMONITORING bit), the wait pin is captured synchronously with GPMC_CLK, using the rising edge of this clock.

If enabled, external wait-pin monitoring can be used in combination with WRACCESSTIME to control the effective memory device GPMC_CLK capture edge.

Wait-monitoring pipelining depth is similar to synchronous read access:

- At WRACCESSTIME completion if WAITMONITORINGTIME = 0
- The WAITMONITORINGTIME × (GPMCFCLKDIVIDER + 1) GPMC_FCLK cycles before WRACCESSTIME completion if WAITMONITORINGTIME ≠ 0.

Wait-monitoring pipelining definition applies to whole burst accesses:

- WAIT monitored as active freezes the CYCLETIME counter. For accesses within a burst, when the CYCLETIME counter is by definition in a lock state, WAIT monitored as active indicates that the data bus is not being captured by the external device. Control signals are kept in their current state. The data bus is kept in its current state.
- WAIT monitored as inactive unfreezes the CYCLETIME counter. For accesses within a burst, when the CYCLETIME counter is by definition in a lock state, WAIT monitored as inactive indicates the effective data capture of the bus by the external device and starts the next access of the burst. In case of a single access or if this was the last access in a multiple access cycle, all signals, including the data bus, are controlled according to their related control timing value and the CYCLETIME counter status.

NOTE: Wait monitoring is supported for all configurations except for GPMC_CONFIG1_i[19:18] WAITMONITORINGTIME = 0x 0 (where I = 0 to 7) for write bursts with a clock divider of 1 or 2 (GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER field equal to 0x0 or 0x1 respectively).

9.1.5.4.5 WAIT with NAND Device

For details about the use of the wait pin for communication with a NAND flash external device, see [Section 9.1.5.14.2, NAND Device-Ready Pin](#).

9.1.5.4.6 Idle Cycle Control between Successive Accesses

9.1.5.4.6.1 Bus Turnaround (BUSTURNAROUND)

To prevent data-bus contention, an access that follows a read access to a slow memory/device (that is, control the nCS/nOE de-assertion to data bus in high-impedance delay) must be delayed.

The bus turnaround is a time-out counter starting after nCS or nOE de-assertion time (whichever occurs first) and delays the next access start-cycle time. It is programmed through the GPMC.GPMC_CONFIG6_i[3:0] BUSTURNAROUND bit field (where I = 0 to 7).

After a read access to a chip-select with a non zero BUSTURNAROUND, the next access is delayed until the BUSTURNAROUND delay completes, if the next access is one of the following:

- A write access to any chip-select (same or different from the chip-select data was read from)
- A read access to a different chip-select from the chip-select data was read access from
- A read or write access to a chip-select associated with an address/data-multiplexed device

Another way to prevent bus contention is to define an earlier nCS or nOE deassertion time for slow devices or to extend the value of RDCYCLETIME. Doing this prevents bus contention, but affects all accesses of this specific chip-select.

9.1.5.4.6.2 Idle Cycles Between Accesses to Same Chip-Select (CYCLE2CYCLESAMECSSEN, CYCLE2CYCLEDELAY)

Some devices require a minimum chip-select signal inactive time between accesses. The GPMC.GPMC_CONFIG6_i[7] CYCLE2CYCLESAMECSSEN bit (I = 0 to 7) enables insertion of a minimum number of GPMC_FCLK cycles, defined by the GPMC.GPMC_CONFIG6_i[11:8] CYCLE2CYCLEDELAY field, between successive accesses of any type (read or write) to the same chip-select.

If CYCLE2CYCLESAMECSSEN is enabled, any subsequent access to the same chip-select is delayed until its CYCLE2CYCLEDELAY completes. The CYCLE2CYCLEDELAY counter starts when CSRDOFFTIME/CSWROFFTIME completes.

The same applies to successive accesses occurring during Word32 or burst accesses split into successive single accesses when the single-access mode is used (GPMC_CONFIG1_i[30] READMULTIPLE = 0 or GPMC_CONFIG1_i[28] WRITEMULTIPLE = 0).

All control signals are kept in their default states during these idle GPMC_FCLK cycles. This prevents back-to-back accesses to the same chip-select without idle cycles between accesses.

9.1.5.4.6.3 Idle Cycles Between Accesses to Different Chip-Select (CYCLE2CYCLEDIFFCSEN, CYCLE2CYCLEDELAY)

Because of the pipelined behavior of the system, successive accesses to different chip-selects can occur back-to-back with no idle cycles between accesses. Depending on the control signals (nCS, nADV/ALE, nBE0/CLE, nOE/RE, nWE) assertion and de-assertion timing parameters and on the IC timing parameters, some control signals assertion times may overlap between the successive accesses to different CS. Similarly, some control signals (WE, OE/RE) may not respect required transition times.

To work around the overlapping and to observe the required control-signal transitions, a minimum of CYCLE2CYCLEDELAY inactive cycles is inserted between the access being initiated to this chip-select and the previous access ending for a different chip-select. This applies to any type of access (read or write).

If GPMC_CONFIG6_i[6] CYCLE2CYCLEDIFFCSEN is enabled, the chip-select access is delayed until CYCLE2CYCLEDELAY cycles have expired since the end of a previous access to a different chip-select. CYCLE2CYCLEDELAY count starts at CSRDOFFTIME/CSWROFFTIME completion. All control signals are kept inactive during the idle GPMC_FCLK cycles.

NOTE: CYCLE2CYCLESAMECSEN and CYCLE2CYCLEDIFFCSEN should be set in GPMC_CONFIG6_i registers to respectively get idle cycles inserted between accesses on this chip-select and after accesses to a different chip-select.

The CYCLE2CYCLEDELAY delay runs in parallel with the BUSTURNAROUND delay. It should be noted that BUSTURNAROUND is a timing parameter defined for the ending chip-select access, whereas CYCLE2CYCLEDELAY is a timing parameter defined for the starting chip-select access. The effective minimum delay between successive accesses is based on the larger delay timing parameter and on access type combination, since bus turnaround does not apply to all access types. See [Section 9.1.5.4.6.1](#) for more details on bus turnaround.

[Table 9-3](#) describes the configuration required for idle cycle insertion.

Table 9-3. Idle Cycle Insertion Configuration

| 1st Access Type | BUSTURN AROUND Timing Parameter | Second Access Type | Chip-Select | Add/Data Multiplexed | CYCLE2 CYCLE SAMECSEN Parameter | CYCLE2 CYCLE DIFFCSEN Parameter | Idle Cycle Insertion Between the Two Accesses |
|-----------------|---------------------------------|--------------------|-------------|----------------------|---------------------------------|---------------------------------|--|
| R/W | = 0 | R/W | Any | Any | 0 | x | No idle cycles are inserted if the two accesses are well pipelined. |
| R | > 0 | R | Same | Nonmuxed | x | 0 | No idle cycles are inserted if the two accesses are well pipelined. |
| R | > 0 | R | Different | Nonmuxed | 0 | 0 | BTA cycles are inserted. |
| R | > 0 | R/W | Any | Muxed | 0 | 0 | BTA cycles are inserted. |
| R | > 0 | W | Any | Any | 0 | 0 | BTA cycles are inserted. |
| W | > 0 | R/W | Any | Any | 0 | 0 | No idle cycles are inserted if the two accesses are well pipelined. |
| R/W | = 0 | R/W | Same | Any | 1 | x | CYCLE2CYCLEDELAY cycles are inserted. |
| R/W | = 0 | R/W | Different | Any | x | 1 | CYCLE2CYCLEDELAY cycles are inserted. |
| R/W | > 0 | R/W | Same | Any | 1 | x | CYCLE2CYCLEDELAY cycles are inserted. If BTA idle cycles already apply on these two back-to-back accesses, the effective delay is max (BUSTURNAROUND, CYCLE2CYCLEDELAY). |

Table 9-3. Idle Cycle Insertion Configuration (continued)

| 1st Access Type | BUSTURN AROUND Timing Parameter | Second Access Type | Chip-Select | Add/Data Multiplexed | CYCLE2 CYCLE SAMECSEN Parameter | CYCLE2 CYCLE DIFFCSEN Parameter | Idle Cycle Insertion Between the Two Accesses |
|-----------------|---------------------------------|--------------------|-------------|----------------------|---------------------------------|---------------------------------|--|
| R/W | > 0 | R/W | Different | Any | x | 1 | CYCLE2CYCLEDELAY cycles are inserted. If BTA idle cycles already apply on these two back-to-back accesses, the effective delay is maximum (BUSTURNAROUND, CYCLE2CYCLEDELAY). |

9.1.5.4.7 Slow Device Support (TIMEPARAGRANULARITY Parameter)

All access-timing parameters can be multiplied by 2 by setting the GPMC.GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY bit (where I stands for the GPMC chip-select value, I = 0 to 7). Increasing all access timing parameters allows support of slow devices.

9.1.5.5 gpmc_io_dir Pin

The gpmc_io_dir pin is used to control I/O direction on the GPMC data bus gpmc_d[15:0]. Depending on top-level pad multiplexing, this signal can be output and used externally to the processor, if required.

The gpmc_io_dir pin is low during transmit (OUT) and high during receive (IN).

For write accesses, the gpmc_io_dir pin stays OUT from start-cycle time to end-cycle time.

For read accesses, the gpmc_io_dir pin goes from OUT to IN at nOE assertion time and stays IN until:

- BUSTURNAROUND is enabled:
 - The gpmc_io_dir pin goes from IN to OUT at end-cycle time plus programmable bus turnaround time.
- BUSTURNAROUND is disabled:
 - After an asynchronous read access, the gpmc_io_dir pin goes from IN to OUT at RDACCESSTIME + 1 GPMC_FCLK cycle or when RDCYCLETIME completes, whichever occurs last.
 - After a synchronous read access, the gpmc_io_dir pin goes from IN to OUT at RDACCESSTIME + 2 GPMC_FCLK cycles or when RDCYCLETIME completes, whichever occurs last.

Because of the bus-keeping feature of the GPMC, after a read or write access and with no other accesses pending, the default value of the gpmc_io_dir pin is OUT (see [Section 9.1.5.3.10, Bus Keeping Support](#)).

To prevent unnecessary toggling, the gpmc_io_dir pin stays IN between two successive read accesses to a nonmultiplexed device (address mapping supports nonmultiplexed 16-bit wide devices with limited address (2 Kbytes)).

[Figure 9-10](#) shows address mapping in nonmultiplexed mode with a limited address range (A[10:1]).

9.1.5.6 Reset

No reset signal is sent to the external memory device by the GPMC. The PRCM specifications provide more information about external-device reset.

The PRCM module provides an input pin, global_rst_n, to the GPMC:

- The global_rst_n pin is activated during processor's warm reset and cold reset.
- The global_rst_n pin initializes the internal state-machine and the internal configuration registers.

9.1.5.7 Write Protect (nWP)

When connected to the attached memory device, the WRITE PROTECT signal can enable or disable the lockdown function of the attached memory.

The gpmc_nwp output pin value is controlled through the GPMC.GPMC_CONFIG[4] WRITEPROTECT bit, which is common to all CS.

9.1.5.8 Byte Enable (nBE1/nBE0)

BYTE ENABLE signals (nBE1/nBE0) are:

- Valid (asserted or nonasserted according to the incoming system request) from access start to access completion for asynchronous and synchronous single accesses
- Asserted low from access start to access completion for asynchronous and synchronous multiple read accesses
- Valid (asserted or nonasserted, according to the incoming system request) synchronously to each written data for synchronous multiple write accesses

9.1.5.9 Asynchronous Access Description

In asynchronous operations:

- GPMC_CLK is not provided outside the GPMC.
- GPMC_CLK is kept low.

9.1.5.9.1 Asynchronous Single Read

9.1.5.9.1.1 Asynchronous Single Read Operation on a Nonmultiplexed Device

Figure 9-10 shows an asynchronous single read operation on a nonmultiplexed device.

Figure 9-10. Asynchronous Single Read on an Address/Data-Nonmultiplexed Device

gpmc-010

In the following section *I* stands for the chip-select number, *I* = 0 to 7.

- GPMC.GPMC_CONFIG[1] LIMITEDADDRESS set to 1 (A26-A11 are not modified during an external memory access)
- GPMC.GPMC_CONFIG1_i register settings:
 - GPMC_CONFIG1_i[30] READMULTIPLE bit at 0 (read single access)
 - GPMC_CONFIG1_i[29] READTYPE bit at 0 (asynchronous read)
 - GPMC_CONFIG1_i[9] MUXADDDATA bit at 0 (non multiplexed device)
- Chip-select signal nCS:
 - nCS assertion time is controlled by the GPMC_CONFIG2_i[3:0] CS ONTIME field. It controls the address setup time to nCS assertion.
 - nCS deassertion time is controlled by the GPMC_CONFIG2_i[12:8] CSRD OFFTIME field. It controls the address hold time from nCS deassertion.
- Address valid signal nADV:
 - nADV assertion time is controlled by the GPMC_CONFIG3_i[3:0] ADV ONTIME field.
 - nADV deassertion time is controlled by the GPMC_CONFIG3_i[12:8] ADV RD OFFTIME field.

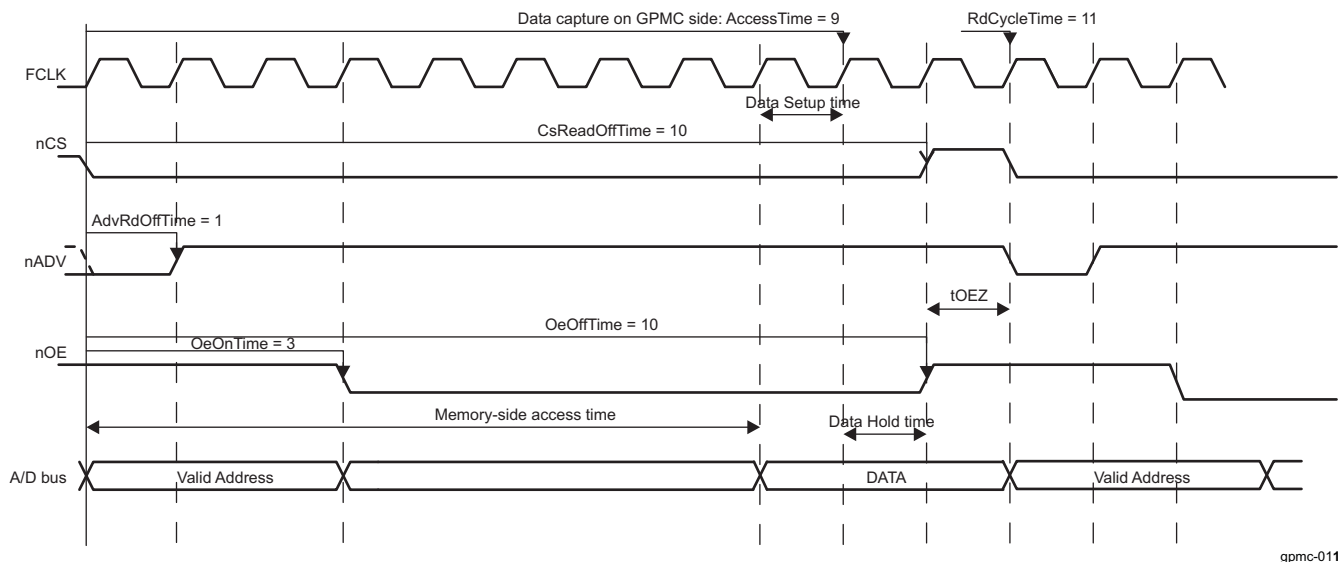

- Output enable signal nOE:
 - nOE assertion indicates a read cycle.
 - nOE assertion time is controlled by the GPMC_CONFIG4_i[3:0] OEONTIME field.
 - nOE deassertion time is controlled by the GPMC_CONFIG4_i[12:8] OEOFFTIME field.
- Read data is latched when RDACCESSTIME completes. Access time is defined in the GPMC.GPMC_CONFIG5_i[20:16] RDACCESSTIME field.
- The end of the access is defined by the RDCYCLETIME parameter. The read cycle time is defined in the GPMC.GPMC_CONFIG5_i[4:0] RDCYCLETIME field.
- Direction signal DIR: DIR goes from OUT to IN at the same time that nOE is asserted.

After a read operation, if no other access (read or write) is pending, the data bus is driven with the previous read value. See [Section 9.1.5.3.10, Bus Keeping Support](#) for more details.

9.1.5.9.1.2 Asynchronous Single-Read Operation on an Address/Data Multiplexed Device

Figure 9-11 shows an asynchronous single read operation on an address/data-multiplexed device.

Figure 9-11. Asynchronous Single Read on an Address/Data-Multiplexed Device

gpmc-011

When the GPMC generates a read access to an address/data-multiplexed device, it drives the address bus until nOE assertion time. For details, see [Section 9.1.5.2.3, Address/Data-Multiplexing Interface](#).

GPMC.GPMC_CONFIG1_i register settings (I = 0 to 7):

- READMULTIPLE bit at 0 (read single access)
- READTYPE bit at 0 (read asynchronous)
- MUXADDDATA bit at 1 (address/data-multiplexed device)

Address bits ([16:1] from a GPMC perspective, [15:0] from an external device perspective) are placed on the address/data bus, and the remaining address bits [25:16] are placed on the address bus. The address phase ends at nOE assertion, when the DIR signal goes from OUT to IN.

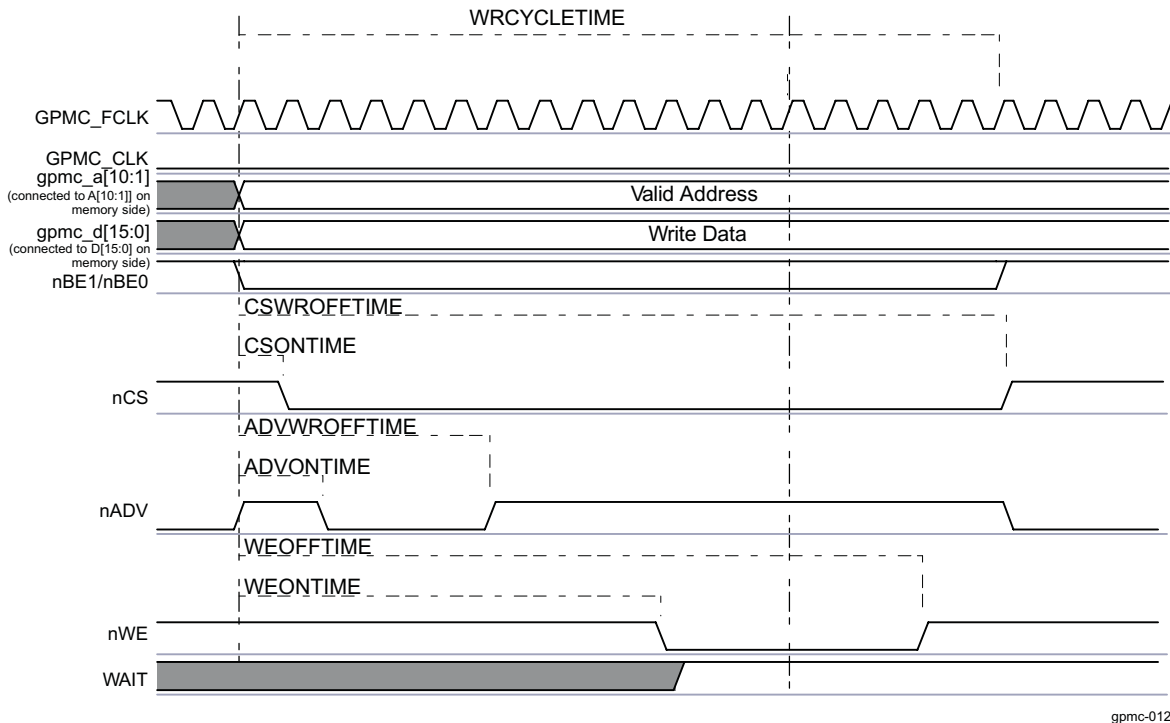

The nCS, nADV, nOE, and DIR signals are controlled in the same way as nonmultiplexed accesses.

9.1.5.9.2 Asynchronous Single Write

9.1.5.9.2.1 Asynchronous Single Write Operation on a Nonmultiplexed Device

Figure 9-12 shows an asynchronous single write operation on a nonmultiplexed device.

Figure 9-12. Asynchronous Single Write on an Address/Data-Nonmultiplexed Device

In the following section *l* stands for the chip-select number, $l = 0$ to 7.

- GPMC.GPMC_CONFIG[1] LIMITEDADDRESS set to 1 (A26-A11 are not modified during an external memory access)
- GPMC.GPMC_CONFIG1_i register settings:
 - WRITEMULTIPLE bit at 0 (write single access)
 - WRITETYPE bit at 0 (write asynchronous)
 - MUXADDDATA bit at 0 (nonaddress/data-multiplexed device)
- Chip-select signal nCS:
 - nCS assertion time is controlled by the GPMC.GPMC_CONFIG2_i[3:0] CSONTIME field and ensures address setup time to nCS assertion.
 - nCS deassertion time is controlled by the GPMC.GPMC_CONFIG2_i[20:16] CSWROFFTIME field and ensures address hold time to nCS deassertion.
- Address valid signal nADV:
 - nADV assertion time is controlled by the GPMC.GPMC_CONFIG3_i[3:0] ADVONTIME field.
 - nADV deassertion time is controlled by the GPMC.GPMC_CONFIG3_i[20:16] ADVWROFFTIME field.

Address and data are driven on their corresponding buses at start-of-cycle time.

- Write enable signal nWE:
 - nWE assertion indicates a write cycle.
 - nWE assertion time is controlled by the GPMC.GPMC_CONFIG4_i[19:16] WEONTIME field.
 - nWE deassertion time is controlled by the GPMC.GPMC_CONFIG4_i[28:24] WEOFFTIME field.
- Direction signal DIR:
 - DIR signal is OUT during the entire access.

- The end of the access is defined by the WRCYCLETIME parameter.
This write-cycle time is defined in the GPMC.GPMC_CONFIG5_i[12:8] WRCYCLETIME field.

After a write operation, if no other access (read or write) is pending, the data bus keeps its previous value. See [Section 9.1.5.3.10, Bus Keeping Support](#).

In the GPMC, when a 16-bit wide device is attached to the controller, a Word32 write access is split into two Word16 write accesses. For more information about GPMC access size and type adaptation, see [Section 9.1.5.2.7, System Burst Versus External Device Burst Support](#).

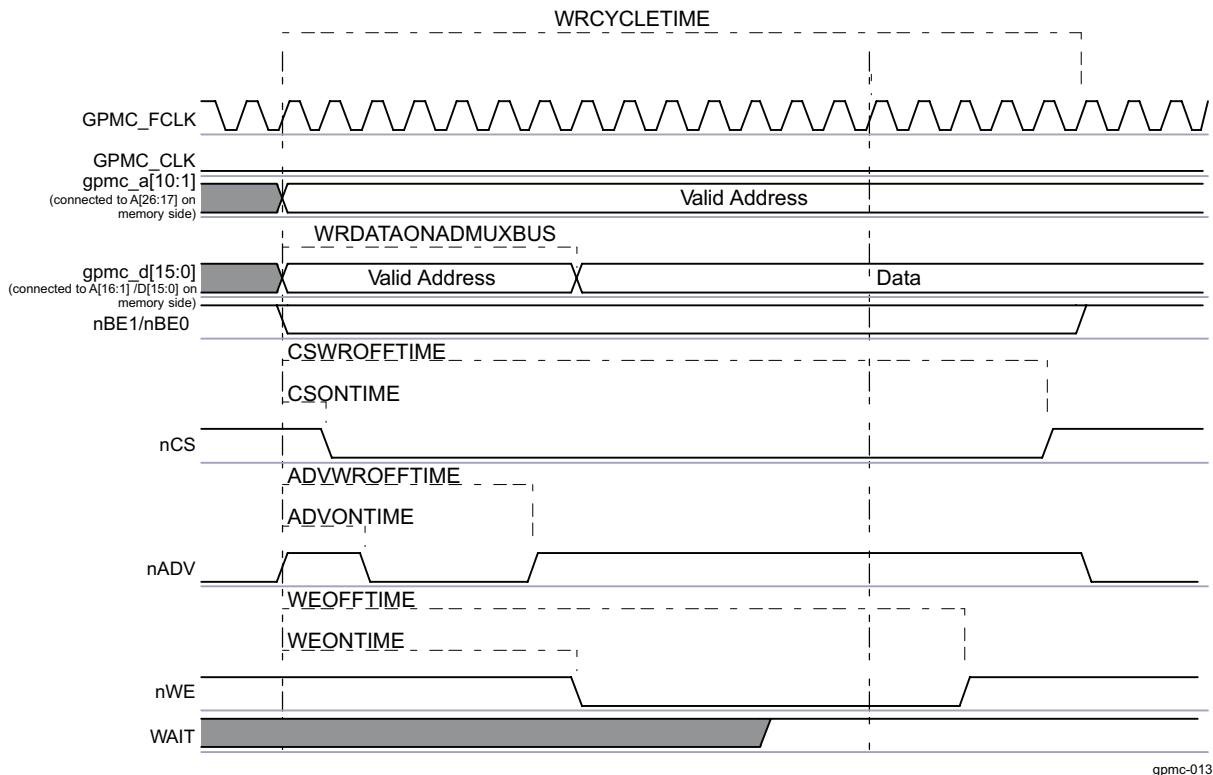

Between two successive accesses, if an nCS pulse is needed:

- The GPMC.GPMC_CONFIG6_i[11:8] CYCLE2CYCLEDELAY field can be programmed with GPMC.GPMC_CONFIG6_i[7] CYCLE2CYCLESAMECSSEN enabled.
- The CSWROFFTIME and CSONTIME parameters also allow a chip-select pulse, but this affects all other types of access.

9.1.5.9.2.2 Asynchronous Single Write Operation on an Address/Data-Multiplexed Device

Figure 9-13 shows an asynchronous single write operation on an address/data-multiplexed device.

Figure 9-13. Asynchronous Single Write on an Address/Data-Multiplexed Device

When the GPMC generates a write access to an address/data-multiplexed device, it drives the address on the address/data muxed bus until WRDATAONADMUXBUS time, and then it drives the data. For more information, see [Section 9.1.5.2.3, Address/Data-Multiplexing Interface](#).

GPMC.GPMC_CONFIG1_i register settings (I = 0 to 7):

- WRITEMULTIPLE bit at 0 (write single access)
- WRITETYPE bit at 0 (write asynchronous)
- MUXADDDATA bit at 1 (address/data-multiplexed device)

Address bits [16:1] are placed on the address/data bus at the start of cycle time, and the remaining address bits [26:17] are placed on the address bus.

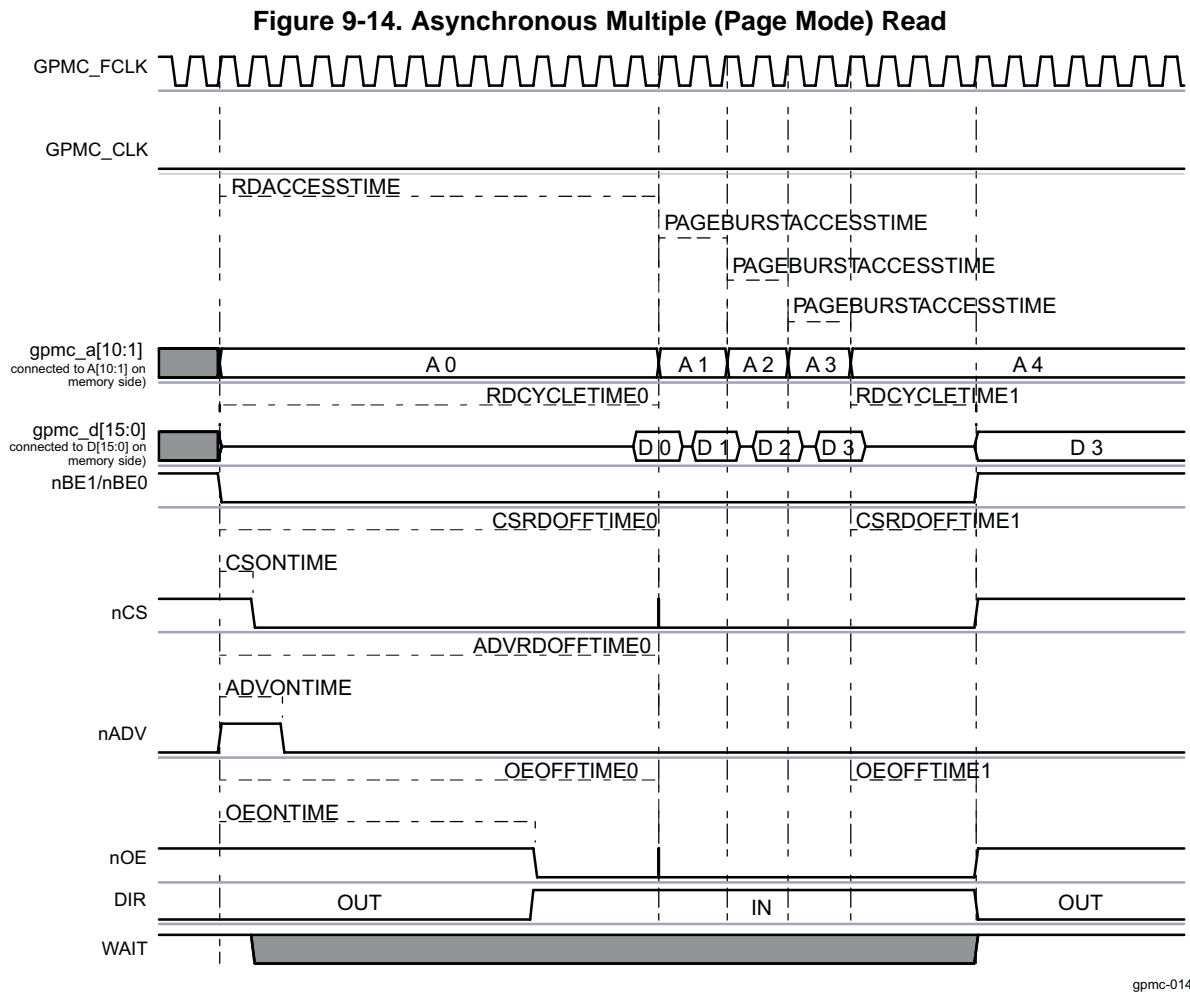

The nCS, nADV, and nWE signals are controlled in the same way as nonmultiplexed accesses.

Data is driven on the address/data bus at a GPMC_CONFIG6_[19:16] WRDATAONADMUXBUS time.

NOTE: Write multiple access in asynchronous mode is not supported. If WRITEMULTIPLE is enabled with WRITETYPE as asynchronous, the GPMC processes single asynchronous accesses.

9.1.5.9.3 Asynchronous Multiple (Page Mode) Read

Figure 9-14 shows an asynchronous multiple read operation.

NOTE: The WAIT signal is active low.

In the following section I stands for the chip-select number, I = 0 to 7.

For read access with GPMC.GPMC_CONFIG1_i register settings:

- READMULTIPLE bit at 1 (read multiple access)
- READTYPE bit at 0 (read asynchronous)
- MUXADDDATA bit at 0 (non-address/data-multiplexed device). The page mode is not supported by address/data-multiplexed devices.

In Figure 9-14, two Word32 read host accesses on the GPMC configured with READMULTIPLE = 1, READTYPE = 0, and MUXADDDATA = 0 are merged into one multiple-read access (page mode of four Word16) on the attached device.

When RDACCESSTIME completes, control-signal timings are frozen during the multiple data transactions, corresponding to PAGEBURSTACCESSTIME multiplied by the number of remaining data transactions.

- Chip-select signal nCS:
 - nCS assertion time is controlled by the GPMC.GPMC_CONFIG2_i[3:0] CSONTIME field and ensures the address setup time to nCS assertion.
 - nCS deassertion time is controlled by the GPMC.GPMC_CONFIG2_i[12:8] CSRDOFFTIME field and ensures the address hold time to nCS deassertion.
- Address valid signal nADV:
 - nADV assertion time is controlled by the GPMC.GPMC_CONFIG3_i[3:0] ADVONTIME field.
 - nADV deassertion time is controlled by the GPMC.GPMC_CONFIG3_i[12:8] ADVRDOFFTIME field.
- Output enable signal nOE:
 - nOE assertion indicates a read cycle.
 - nOE assertion time is controlled by the GPMC.GPMC_CONFIG4_i[3:0] OEONTIME field.
 - nOE deassertion time is controlled by the GPMC.GPMC_CONFIG4_i[12:8] OEOFFTIME field.
- Initial latency for the first read data is controlled by the RDACCESSTIME parameter. The access time is defined in the GPMC.GPMC_CONFIG5_i[20:16] RDACCESSTIME field.

During consecutive accesses, the GPMC increments the address after each data read completes.

- Delay between successive read data in the page is controlled by the PAGEBURSTACCESSTIME parameter:
 - This timing is defined in the GPMC.GPMC_CONFIG5_i[27:24] PAGEBURSTACCESSTIME field.
 - Depending on the device page length, the GPMC can control device page crossing during a burst request and insert initial RDACCESSTIME latency. Note that page crossing is only possible with a new burst access, meaning a new initial access phase is initiated.
- Total access time (RDCYCLETIME) corresponds to RDACCESSTIME plus the address hold time starting from the nCS deassertion plus the time from RDACCESSTIME to CSRDOFFTIME.
 - The read cycle time is defined in the GPMC.GPMC_CONFIG5_i[4:0] RDCYCLETIME field.
 - In [Figure 9-14](#), the RDCYCLETIME programmed value equals RDCYCLETIME0 (before paged accesses) + RDCYCLETIME1 (after paged accesses).
- Direction signal DIR:
 - DIR goes from OUT to IN at the same time as nOE assertion time.

After a read operation, if no other access (read or write) is pending, the data bus is driven with the previous read value. See [Section 9.1.5.3.10](#), *Bus Keeping Support*.

9.1.5.10 Synchronous Access

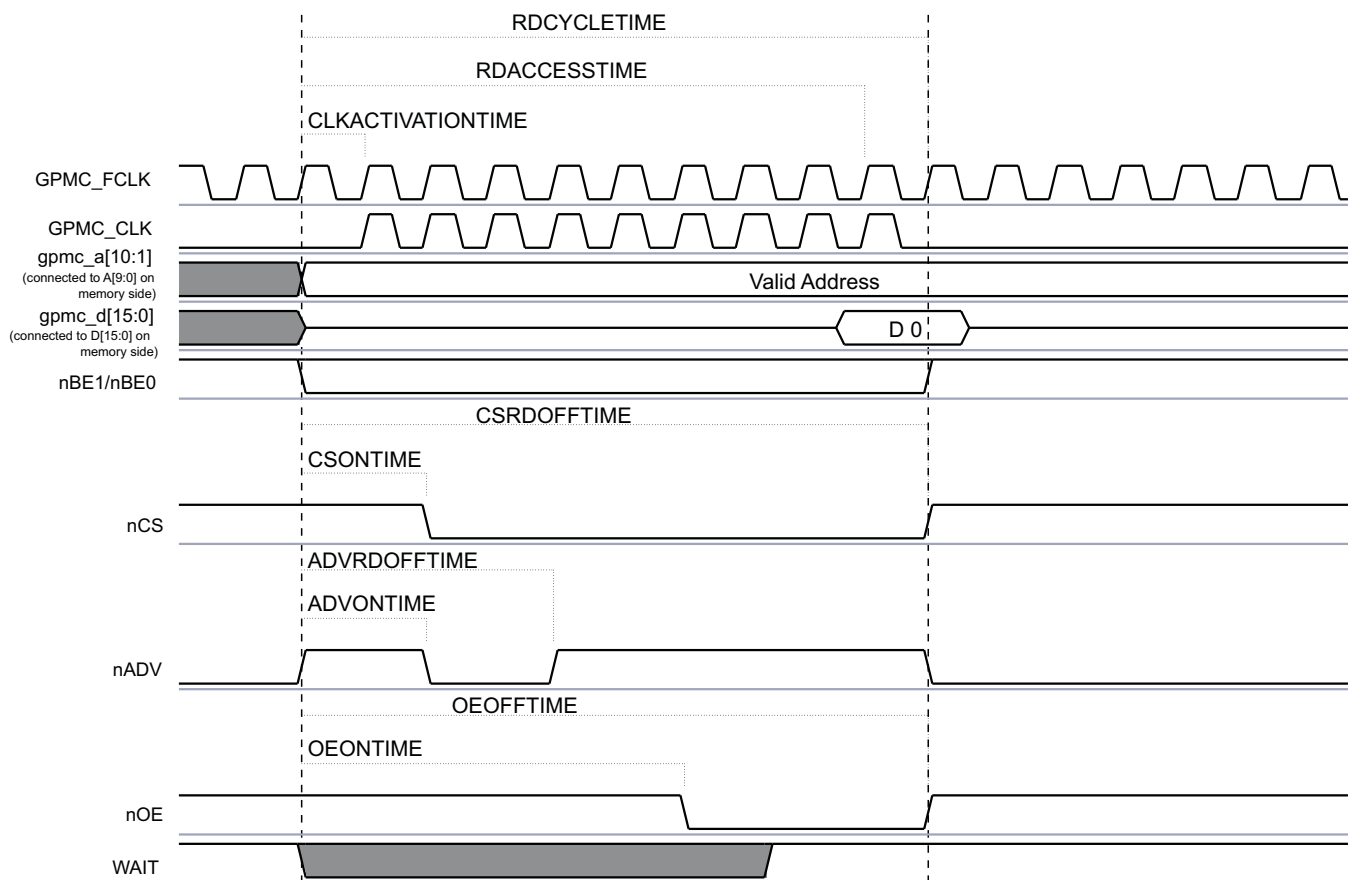

In synchronous operations:

- The GPMC_CLK clock is provided outside the GPMC when accessing the memory device.
- The GPMC_CLK clock is derived from the GPMC_FCLK clock using the GPMC.GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER field (where I = 0 to 7).
- The GPMC.GPMC_CONFIG1_i[26:25] CLKACTIVATIONTIME field specifies that the GPMC_CLK is provided outside the GPMC 0, 1, or 2 GPMC_FCLK cycles after start access time until CycleTime completes.
- When the GPMC is configured for synchronous mode, the GPMC_CLK signal (which is an output) must also be set as an input (CONTROL.CONTROL_PADCONF_GPMC_NCS7[24] INPUTENABLE1 = 1). GPMC_CLK is looped back through the output and input buffers of the corresponding GPMC_CLK pad at the device boundary. The looped-back clock is used to synchronize the sampling of the memory signals.

9.1.5.10.1 Synchronous Single Read

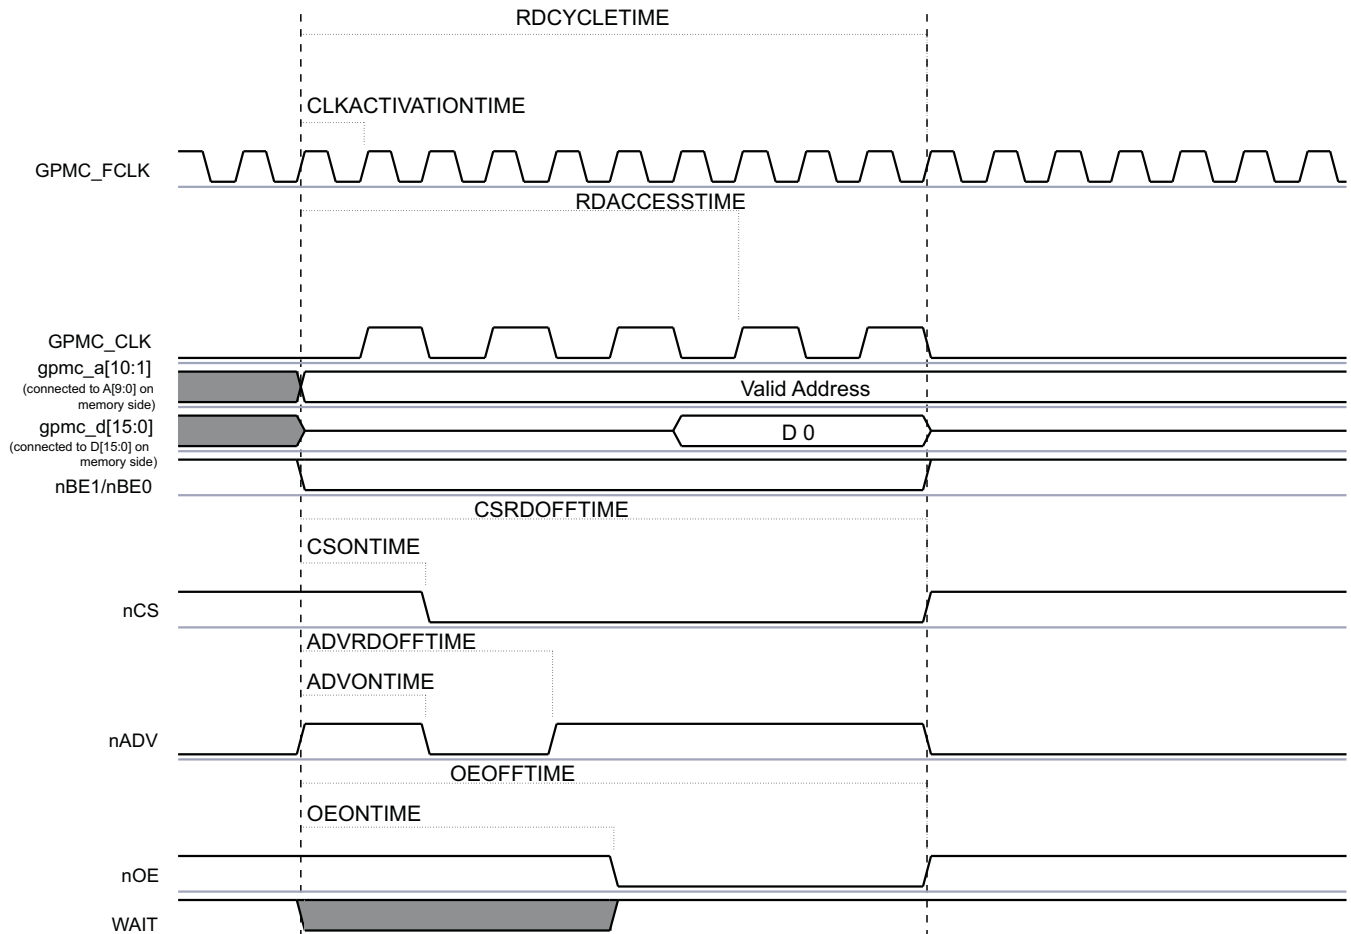

Figure 9-15 and Figure 9-16 show a synchronous single-read operation with GPMCFCLKDIVIDER equal to 0 and 1, respectively.

Figure 9-15. Synchronous Single Read (GPMCFCLKDIVIDER = 0)

gpmc-015

Figure 9-16. Synchronous Single Read (GPMCFCLKDIVIDER = 1)

gpmc-016

In the following section *I* stands for the chip-select number, *I* = 0 to 7.

- GPMC.GPMC_CONFIG1_*i* register settings:
 - READMULTIPLE bit at 0 (read single access)
 - READTYPE bit at 1 (read synchronous)
 - MUXADDDATA bit at 0 (non-address/data-multiplexed device)
- Chip-select signal nCS:
 - nCS assertion time is controlled by the GPMC.GPMC_CONFIG2_*i*[3:0] CSOFTIME field and ensures address setup time to nCS assertion.
 - nCS deassertion time is controlled by the GPMC.GPMC_CONFIG2_*i*[12:8] CSRDOFFTIME field and ensures address hold time to nCS deassertion.
- Address valid signal nADV:
 - nADV assertion time is controlled by the GPMC.GPMC_CONFIG3_*i*[3:0] ADVONTIME field.
 - nADV deassertion time is controlled by the GPMC.GPMC_CONFIG3_*i*[12:8] ADVRDOFFTIME field.
- Output enable signal nOE:
 - nOE assertion indicates a read cycle.
 - nOE assertion time is controlled by the GPMC.GPMC_CONFIG4_*i*[3:0] OEONTIME field.
 - nOE deassertion time is controlled by the GPMC.GPMC_CONFIG4_*i*[12:8] OEOFFTIME field.
- Initial latency for the first read data is controlled by GPMC.GPMC_CONFIG5_*i*[20:16]

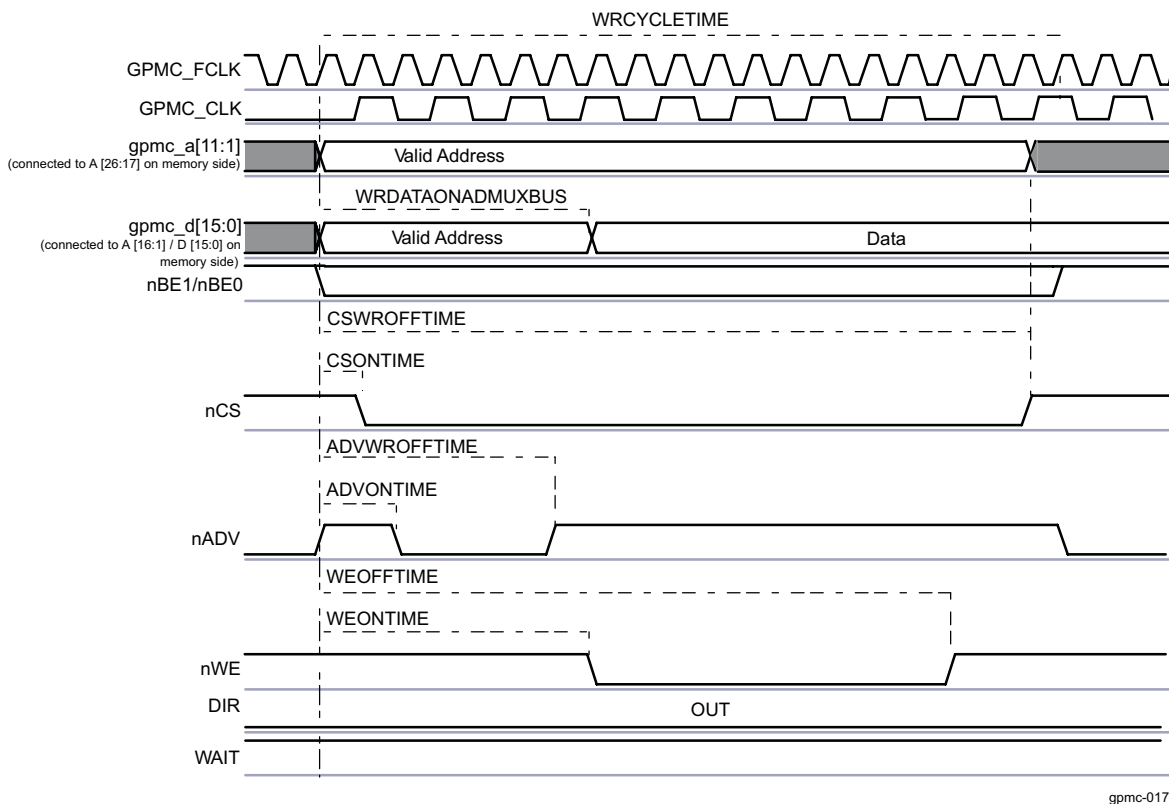

RDACCESSTIME or by monitoring the WAIT signal.

- Total access time (GPMC.GPMC_CONFIG5_i[4:0] RDCYCLETIME) corresponds to RDACCESSTIME plus the address hold time from nCS deassertion, plus time from RDACCESSTIME to CSWROFFTIME.
- Direction signal DIR:
DIR goes from OUT to IN at the same time as nOE assertion.

After a read operation, if no other access (read or write) is pending, the data bus is driven with the previous read value. See [Section 9.1.5.3.10, Bus Keeping Support](#).

9.1.5.10.2 Synchronous Single Write

Figure 9-17. Synchronous Single Write on an Address/Data-Multiplexed Device

NOTE: The WAIT signal is active low.

When the GPMC generates a write access to an address/data-multiplexed device, it drives the data bus until WRDATAONADMUXBUS time (GPMC_CONFIG6_i[19:16]).

The GPMC.GPMC_CONFIG1_i register settings (I = 0 to 7) are as follows:

- WRITEMULTIPLE bit at 0 (write single access)
- WRITETYPE bit at 1 (write synchronous)
- MUXADDDATA bit at 1 (address/data-multiplexed device)

Address bits [16:1] are placed on the address/data bus at cycle-start time, and the remaining address bits [26:17] are placed on the address bus.

The address phase ends at WRDATAONADMUXBUS.

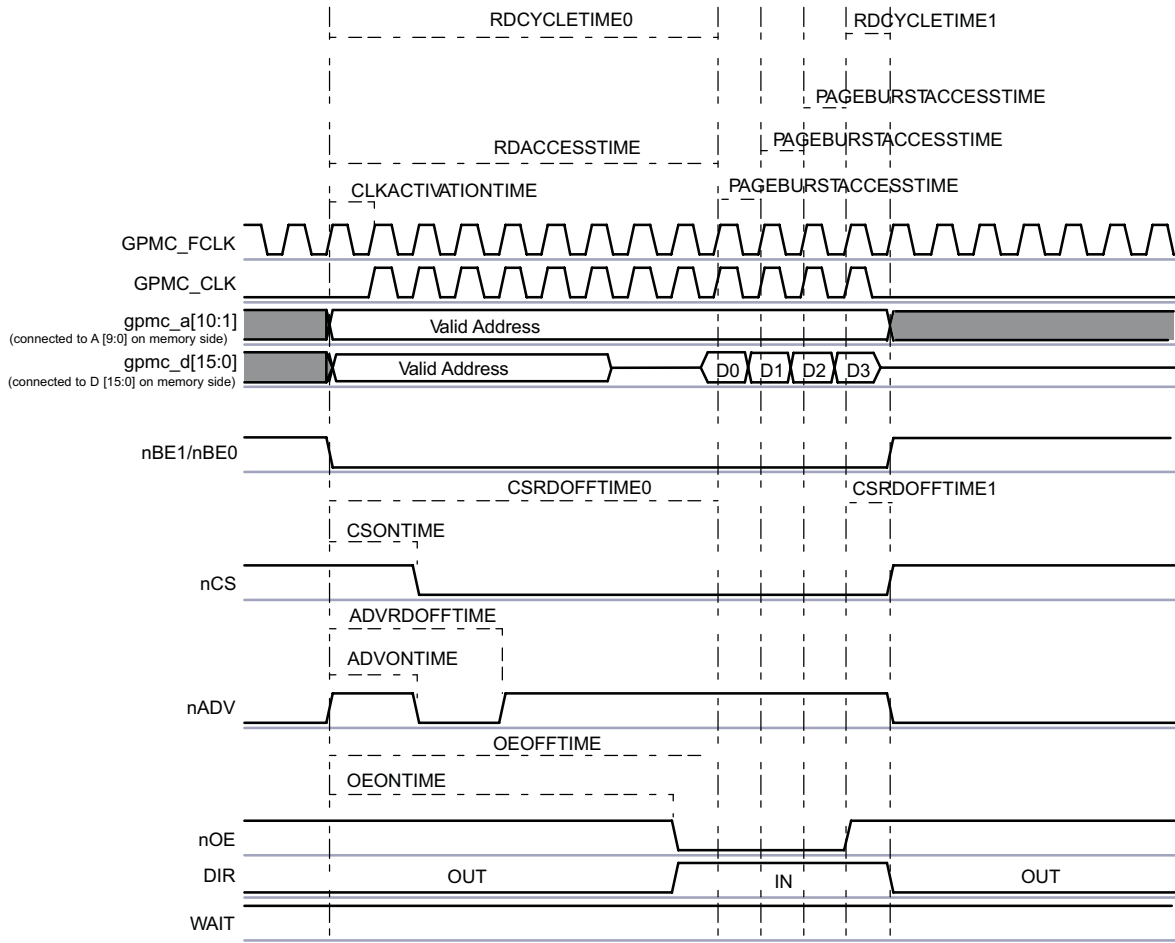

The nCS, nADV, and nWE signals are controlled in the same way as nonmultiplexed accesses.

First data of the burst is driven on the address/data bus at WRDATAONADMUXBUS time.

9.1.5.10.3 Synchronous Multiple (Burst) Read (4-, 8-, 16-Word 16 Burst with Wraparound Capability)

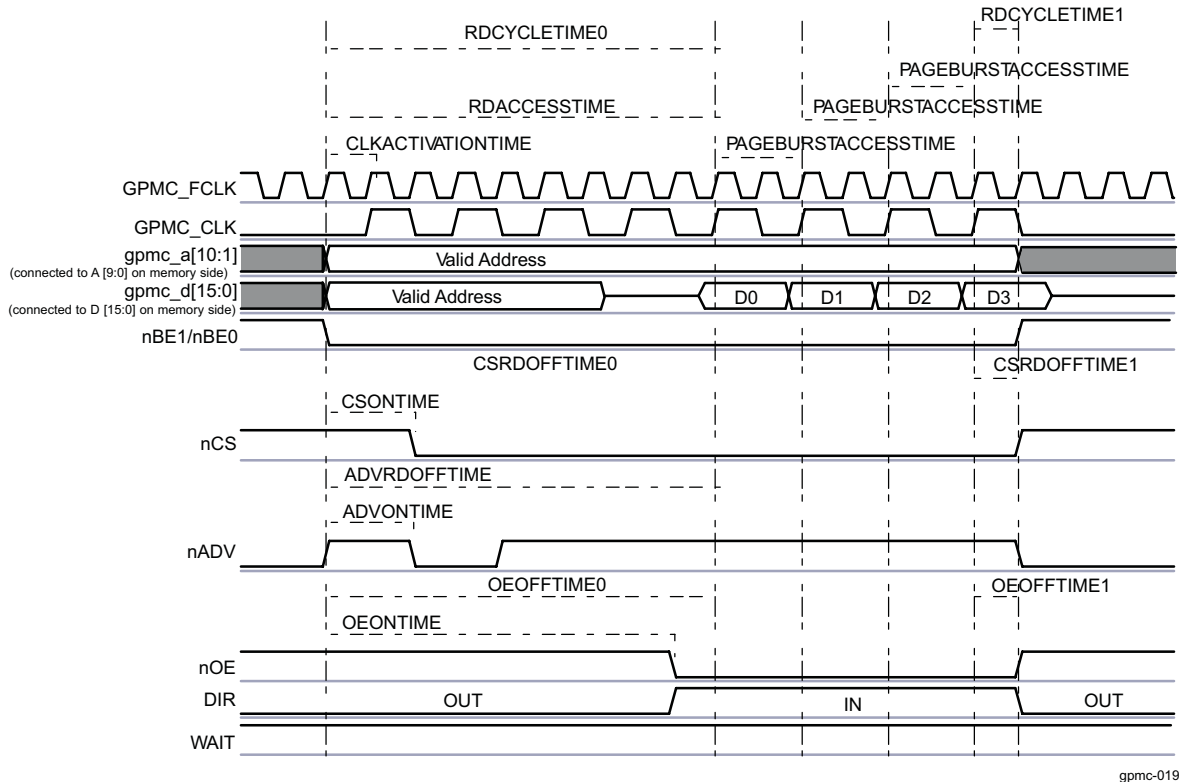

Figure 9-18 and Figure 9-19 show a synchronous multiple read operation with GPMCFCLKDivider equal to 0 and 1, respectively.

Figure 9-18. Synchronous Multiple (Burst) Read (GPMCFCLKDIVIDER = 0)

gpmc-018

NOTE: The WAIT signal is active low.

Figure 9-19. Synchronous Multiple (Burst) Read (GPMCFCLKDIVIDER = 1)

NOTE: The WAIT signal is active low.

In the following section I stands for the chip-select number, I = 0 to 7.

- GPMC.GPMC_CONFIG1_i register settings:
 - READMULTIPLE bit at 1 (read multiple access)
 - READTYPE bit at 1 (read synchronous)
 - MUXADDDATA bit at 0 (nonaddress/data-multiplexed device)

When RDACCESSTIME completes, control-signal timings are frozen during the multiple data transactions, corresponding to PAGEBURSTACCESSTIME multiplied by the number of remaining data transactions.

- Chip-select signal nCS:
 - nCS assertion time is controlled by the GPMC.GPMC_CONFIG2_i[3:0] CSONTIME field and ensures address setup time to nCS assertion.
 - nCS deassertion time is controlled by the GPMC.GPMC_CONFIG2_i[12:8] CSRDOFFTIME field and ensures address hold time to nCS deassertion.
- Address valid signal nADV:
 - nADV assertion time is controlled by the GPMC.GPMC_CONFIG3_i[3:0] ADVONTIME field.
 - nADV deassertion time is controlled by the GPMC.GPMC_CONFIG3_i[12:8] ADVRDOFFTIME field.
- Output enable signal nOE:
 - nOE assertion indicates a read cycle.
 - nOE assertion time is controlled by the GPMC.GPMC_CONFIG4_i[3:0] OEONTIME field.
 - nOE deassertion time is controlled by the GPMC.GPMC_CONFIG4_i[12:8] OEOFFTIME field.
- Initial latency for the first read data is controlled by GPMC.GPMC_CONFIG5_i[20:16] RDACCESSTIME or by monitoring the WAIT signal.
- Successive read data are provided by the memory device each one or two GPMC_CLK cycles. The PAGEBURSTACCESSTIME parameter must be set accordingly with GPMCFCLKDIVIDER and the memory-device internal configuration.

gpmc-019

Depending on the device page length, the GPMC can control device page crossing during a new burst request and purposely insert initial latency.

- Total access time (RDCYCLETIME) corresponds to RDACCESSTIME plus the address hold time from nCS deassertion, plus the time from RDACCESSTIME to CSRDOFFTIME.
 - RDCYCLETIME is defined in the GPMC.GPMC_CONFIG5_i register.
 - In Figure 9-19, the RDCYCLETIME programmed value equals RDCYCLETIME0 + RDCYCLETIME1.
- Direction signal DIR:
 - DIR goes from OUT to IN at the same time as nOE assertion.

After a read operation, if no other access (read or write) is pending, the data bus is driven with the previous read value. See Section 9.1.5.3.10, *Bus Keeping Support*.

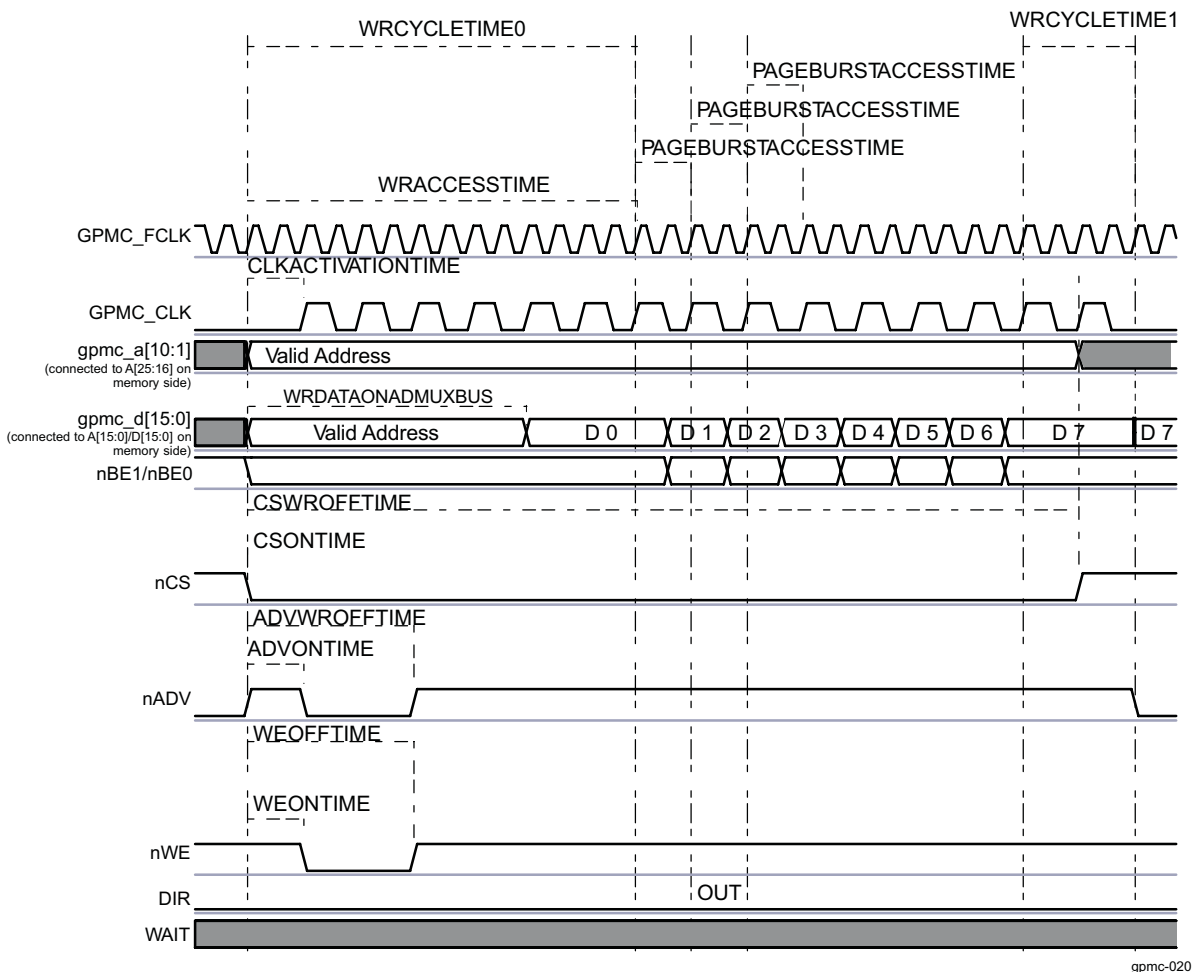

- Burst wraparound
 - The GPMC.GPMC_CONFIG1_i[31] WRAPBURST bit allows a 4-, 8-, or 16-Word16 linear burst access to wrap within its burst-length boundary.

9.1.5.10.4 Synchronous Multiple (Burst) Write

Burst write mode provides synchronous single or consecutive accesses.

Figure 9-20 shows a synchronous multiple (burst) write.

Figure 9-20. Synchronous Multiple (Burst) Write

NOTE: The WAIT signal is active low.

In the following section I stands for the chip-select number, I = 0 to 7.

- GPMC.GPMC_CONFIG1_i register settings:
 - WRITEMULTIPLE bit at 1 (write multiple access)
 - WRITETYPE bit at 1 (write synchronous)
 - MUXADDDATA bit at 1 (address/data-multiplexed device)

When WRACCESSTIME completes, control-signal timings are frozen during the multiple data transactions, corresponding to the PAGEBURSTACCESSTIME multiplied by the number of remaining data transactions.

- Chip-select signal nCS:
 - nCS assertion time is controlled by the GPMC.GPMC_CONFIG2_i[3:0] CSONTIME field and ensures address setup time to nCS assertion.
 - nCS deassertion time controlled by the GPMC.GPMC_CONFIG2_i[20:16] CSWROFFTIME field and ensures address hold time to nCS deassertion.
- Address valid signal nADV:
 - nADV assertion time is controlled by the GPMC.GPMC_CONFIG3_i[3:0] ADVONTIME field.
 - nADV deassertion time is controlled by the GPMC.GPMC_CONFIG3_i[20:16] ADVWROFFTIME field.
- Write enable signal nWE:
 - nWE assertion indicates a write cycle.
 - nWE assertion time is controlled by the GPMC.GPMC_CONFIG4_i[19:16] WEONTIME field.
 - nWE deassertion time is controlled by the GPMC.GPMC_CONFIG4_i[28:24] WEOFFTIME field.

NOTE: The nWE falling edge must not be used to control the time when the burst first data is driven in the address / data bus because some new devices require the nWE signal at low during the address phase.

- First write data is driven by the GPMC at WRDATAONADMUXBUS (GPMC_CONFIG6_i[19:16]), when in address/data mux configuration. The next write data of the burst is driven on the bus at WRACCESSTIME + 1 during PAGEBURSTACCESSTIME GPMC_FCLK cycles. The last data of the synchronous burst write is driven until WRCYCLETIME completes.
 - WRACCESSTIME is defined in the GPMC.GPMC_CONFIG5_i register.
 - The PAGEBURSTACCESSTIME parameter must be set accordingly with GPMCFCLKDIVIDER and the memory-device internal configuration.
- Total access time (WRCYCLETIME) corresponds to WRACCESSTIME plus the address hold time from nCS deassertion, plus time from WRACCESSTIME to CSWROFFTIME.
 - WRCYCLETIME is defined in the GPMC.GPMC_CONFIG5_i register.
 - In [Figure 9-20](#), the WRCYCLETIME programmed value equals WRCYCLETIME0 + WRCYCLETIME1.
- Direction signal DIR:
 - DIR is OUT during the entire access.

After a write operation, if no other access (read or write) is pending, the data bus keeps the previous value. See [Section 9.1.5.3.10, Bus Keeping Support](#).

[Figure 9-21](#) shows the same synchronous burst write access when the chip-select is configured in address/data-multiplexed mode.

Figure 9-21. Synchronous Multiple Write (Burst Write) in Address/Data-Multiplexed Mode

The first data of the burst is driven on the a/d bus at GPMC_CONFIG6_i[19:16] WRDATAONADMUXBUS.

9.1.5.11 pSRAM Basic Programming Model

pSRAM devices are SRAM-pin-compatible low-power memories that contain a self-refreshed DRAM memory array. These devices can be accessed by the GPMC with the GPMC.GPMC_CONFIG1_i[11:10] DEVICETYPE field (I = 0 to 7).

The pSRAM devices support the following operations:

- Asynchronous single read
- Asynchronous page read
- Asynchronous single write
- Synchronous single read and write
- Synchronous burst read
- Synchronous burst write

pSRAM devices must be powered up and initialized in a predefined manner according to the specifications of the attached device.

pSRAM devices can be programmed to use either mode: fixed or variable latency. pSRAM devices can either automatically schedule autorefresh operations, which force the GPMC to use its WAIT signal capability when read or write operations occur during an internal self-refresh operation, or pSRAM devices automatically include the autorefresh operation in the access time. These devices do not require additional WAIT signal capability or a minimum nCS high pulse width between consecutive accesses to ensure that the correct internal refresh operation is scheduled.

In both pSRAM cases, the GPMC configuration for this chip-select must be set according to the specifications of the attached device.

9.1.5.12 Error Handling

When an error occurs in the GPMC, the error information is stored in the GPMC.GPMC_ERR_TYPE register and the address of the illegal access is stored in the GPMC.GPMC_ERR_ADDRESS register. The GPMC only keeps the first error abort information until the GPMC.GPMC_ERR_TYPE register is reset. Subsequent accesses that cause errors are not logged until the error is cleared by hardware with the GPMC.GPMC_ERR_TYPE[0] ERRORVALID bit.

- **ERRORNOTSUPPADD** occurs when an incoming system request address decoding does not match any valid chip-select region, or if two chip-select regions are defined as overlapped, or if a register file access is tried outside the valid address range of 1 Kbyte.
- **ERRORNOTSUPPMCMD** occurs when an unsupported command request is decoded at the L3 interconnect interface.
- **ERRORTIMEOUT**: A time-out mechanism prevents the system from hanging. The start value of the 9-bit time-out counter is defined in the GPMC.GPMC_TIMEOUT_CONTROL register and enabled with the GPMC.GPMC_TIMEOUT_CONTROL[0] TIMEOUTENABLE bit. When enabled, the counter starts at start-cycle time until it reaches 0 and data is not responded to from memory, then a time-out error occurs. When data are sent from memory, this counter is reset to its start value. With multiple accesses (asynchronous page mode or synchronous burst mode), the counter is reset to its start value for each data access within the burst.

The GPMC does not generate interrupts on these errors. True abort to the MPU or interrupt generation is handled at interconnect level.

9.1.5.13 Boot Configuration

See [Section 9.1.3.3.2, GPMC CS0 Default Configuration at IC Reset](#).

9.1.5.14 NAND Device Basic Programming Model

NAND (8-bit and 16-bit) memory devices using a classical NAND asynchronous address/data-multiplexing scheme can be supported on any chip-select with the appropriate asynchronous configuration settings.

As for any other type of memory compatible with the GPMC interface, accesses to a chip-select allocated to a NAND device can be interleaved with accesses to chip-selects allocated to other external devices. This interleaved capability limits the system to chip enable don't care NAND devices since the chip-select allocated to the NAND device has to be de-asserted if accesses to other chip-selects are requested.

9.1.5.14.1 NAND Memory Device in Byte or Word16 Stream Mode

NAND devices require correct command and address programming before data array read or write accesses. The GPMC does not include specific hardware to translate a random address system request into a NAND-specific multiphase access. In that sense, GPMC NAND support, as opposed to random memory-map device support, is data-stream-oriented (byte or Word16).

The GPMC NAND programming model relies on a software driver for address and command formatting with the correct data address pointer value according to the block and page structure. Because of NAND structure and protocol interface diversity, the GPMC does not support automatic command and address phase programming, and software drivers must access the NAND device ID to ensure that correct command and address formatting are used for the identified device.

NAND device data read and write accesses are achieved through an asynchronous read or write access. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Any chip-select region can be qualified as a NAND region to constrain the nADV/ALE signal as Address Latch Enable (ALE active high, default state value at low) during address program access, and the nBE0/CLE signal as Command Latch Enable (CLE active high, default state value at low) during command program access. GPMC address lines are not used (the previous value is not changed) during NAND access.

9.1.5.14.1.1 Chip-Select Configuration for NAND Interfacing in Byte or Word Stream Mode

The GPMC.GPMC_CONFIG7_i register (where I = 0 to 7) associated with a NAND device region interfaced in byte or word stream mode can be initialized with a minimum size of 16 Mbytes, because any address location in the chip-select memory region can be used to access a NAND data array. The NAND Flash protocol specifies an address sequence where address bits are passed through the data bus in a series of write accesses with the ALE pin asserted. After this address phase, all operations are streamed and the system requests address is irrelevant.

CAUTION

To allow correct command, address, and data-access controls, the GPMC.GPMC_CONFIG1_i register associated with a NAND device region must be initialized in asynchronous read and write modes with the parameters shown in [Table 9-4](#). Failure to comply with these settings corrupts the NAND interface protocol.

Table 9-4. Chip-Select Configuration for NAND Interfacing

| Bit Field | Register | Value | Comments |
|--------------------------|-----------------------------------|--------------|--|
| WRAPBURST | GPMC_CONFIG1_i[31] ⁽¹⁾ | 0 | No wrap |
| READMULTIPLE | GPMC_CONFIG1_i[30] | 0 | Single access |
| READTYPE | GPMC_CONFIG1_i[29] | 0 | Asynchronous mode |
| WRITEMULTIPLE | GPMC_CONFIG1_i[28] | 0 | Single access |
| WRITETYPE | GPMC_CONFIG1_i[27] | 0 | Asynchronous mode |
| CLKACTIVATIONTIME | GPMC_CONFIG1_i[26:25] | 00 | |
| ATTACHEDDEVICEPAGELENGTH | GPMC_CONFIG1_i[24:23] | Don't care | Single-access mode |
| WAITREADMONITORING | GPMC_CONFIG1_i[22] | 0 | Wait not monitored by GPMC access engine |
| WAITWRITEMONITORING | GPMC_CONFIG1_i[21] | 0 | Wait not monitored by GPMC access engine |
| WAITMONITORINGTIME | GPMC_CONFIG1_i[19:18] | Don't care | Wait not monitored by GPMC access engine |
| WAITPINSELECT | GPMC_CONFIG1_i[17:16] | | Select which wait is monitored by edge detectors |
| DEVICESIZE | GPMC_CONFIG1_i[13:12] | 0b00 or 0b01 | 8- or 16-bit interface |
| DEVICETYPE | GPMC_CONFIG1_i[11:10] | 0b10 | NAND device in stream mode |
| MUXADDDATA | GPMC_CONFIG1_i[9] | 0 | Nonmultiplexed mode |
| TIMEPARAGRANULARITY | GPMC_CONFIG1_i[4] | 0 | Timing achieved with best GPMC clock granularity |
| GPMCFCLKDIVIDER | GPMC_CONFIG1_i[1:0] | Don't care | Asynchronous mode |

⁽¹⁾ I = 0 to 7

The GPMC.GPMC_CONFIG1_i to GPMC.GPMC_CONFIG4_i register (where I = 0 to 7) associated with a NAND device region must be initialized with the correct control-signal timing value according to the NAND device timing parameters.

9.1.5.14.1.2 NAND Device Command and Address Phase Control

NAND devices require multiple address programming phases. The CPU software driver is responsible for issuing the correct number of command and address program accesses, according to the device command set and the device address-mapping scheme.

NAND device-command and address-phase programming is achieved through write requests to the GPMC.GPMC_NAND_COMMAND_i and GPMC.GPMC_NAND_ADDRESS_i register locations (I = 0 to 7) with the correct command and address values. These locations are mapped in the associated chip-select register region. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Command and address values are not latched during the access and cannot be read back at the register location.

- Only write accesses must be issued to these locations, but the GPMC does not discard any read access. Accessing a NAND device with nOE and CLE or ALE asserted (read access) can produce undefined results.
- Write accesses to the GPMC.GPMC_NAND_COMMAND_i register location and to the GPMC.GPMC_NAND_ADDRESS_i register location must be posted for faster operations (I = 0 to 7). The GPMC.GPMC_CONFIG[0] NANDFORCEPOSTEDWRITE bit enables write accesses to these locations as posted, even if they are defined as nonposted.

A write buffer is used to store write transaction information before the external device is accessed:

- Up to eight consecutive posted write accesses can be accepted and stored in the write buffer.
- For nonposted write, the pipeline is one deep.
- An GPMC.GPMC_STATUS[0] EMPTYWRITEBUFFERSTATUS bit stores the empty status of the write buffer.

GPMC.GPMC_NAND_COMMAND_i and GPMC.GPMC_NAND_ADDRESS_i (I = 0 to 7) are Word32 locations, which means any Word32 or Word16 access is split into 4- or 2-byte accesses if an 8-bit wide NAND device is attached. For multiple-command phase or multiple-address phase, the software driver can use Word32 or Word16 access to these registers, but it must account for the splitting and little-endian ordering scheme. When only one byte command or address phase is required, only byte write access to GPMC.GPMC_NAND_COMMAND_i and GPMC.GPMC_NAND_ADDRESS_i can be used, and any of the four byte locations of the registers are valid.

The same applies to a GPMC.GPMC_NAND_COMMAND_i and a GPMC.GPMC_NAND_ADDRESS_i (I = 0 to 7) Word32 write access to a 16-bit wide NAND device (split into two Word16 accesses). In the case of a Word16 write access, the MSByte of the Word16 value must be set according to the NAND device requirement (usually 0). Either Word16 location or any one of the four byte locations of the registers is valid.

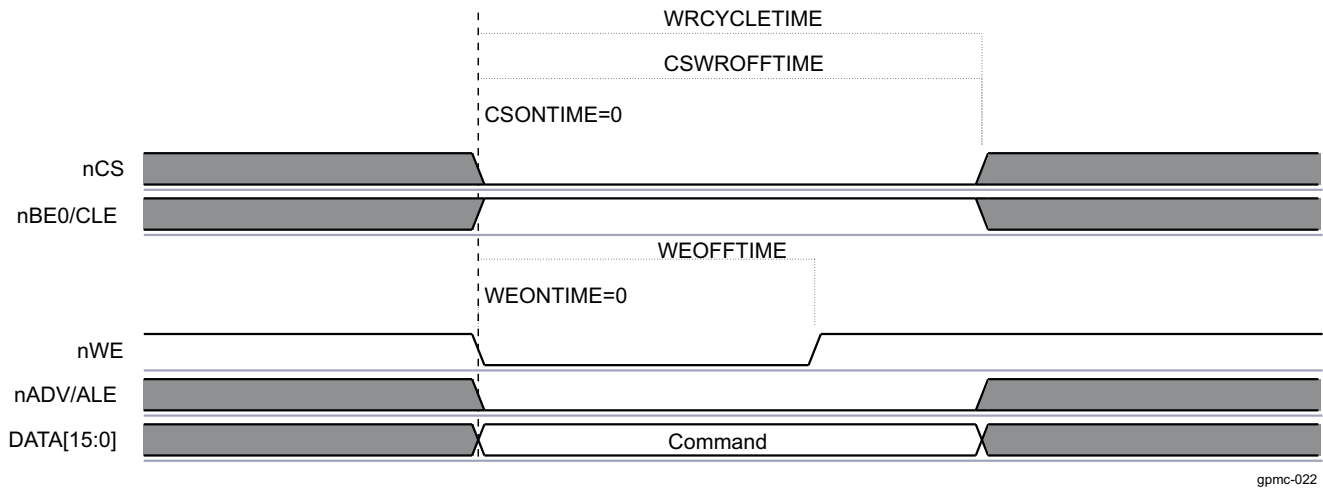

9.1.5.14.1.3 Command Latch Cycle

Writing data at the GPMC.GPMC_NAND_COMMAND_i location (I = 0 to 7) places the data as the NAND command value on the bus, using a regular asynchronous write access.

- nCE is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- CLE is controlled by the ADVONTIME and ADVWROFFTIME timing parameters.
- nWE is controlled by the WEONTIME and WEOFFTIME timing parameters.
- ALE and nRE (nOE) are maintained inactive.

Figure 9-22 shows the NAND command latch cycle.

Figure 9-22. NAND Command Latch Cycle

gpmc-022

NOTE: CLE is shared with the nBE0 output signal and has an inverted polarity from BE0. The NAND qualifier deals with this. During the asynchronous NAND data access cycle, nBE0 (also nBE1) must not toggle, because it is shared with CLE.

NAND Flash memories do not use byte enable signals at all.

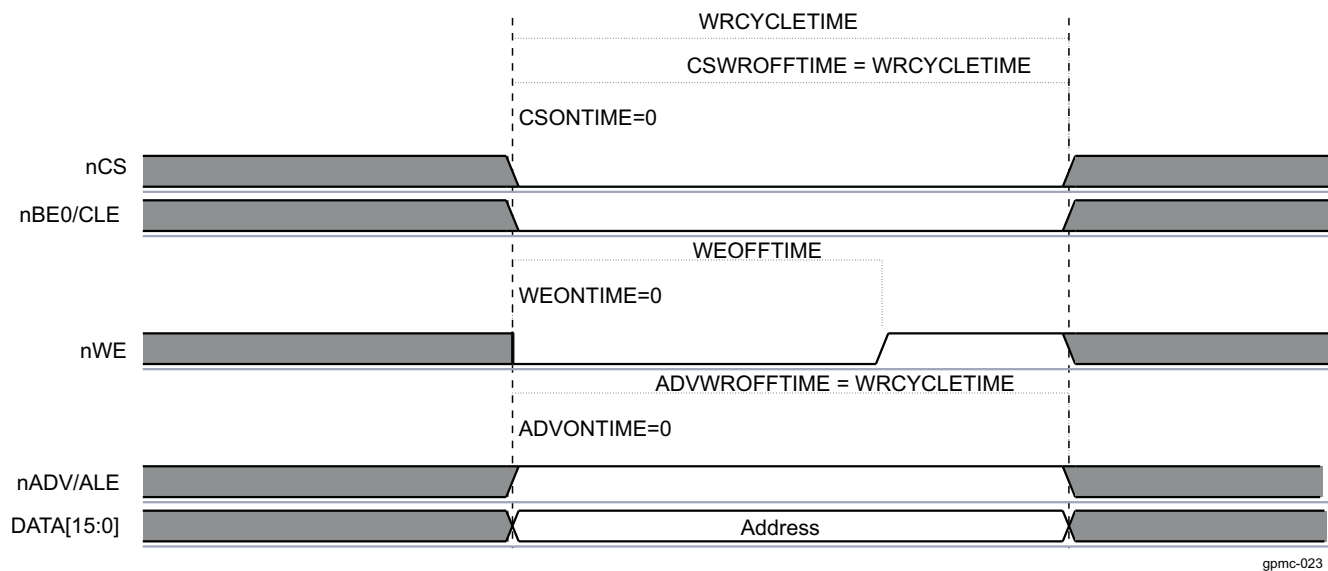

9.1.5.14.1.4 Address Latch Cycle

Writing data at the GPMC.GPMC_NAND_ADDRESS_i location (i = 0 to 7) places the data as the NAND partial address value on the bus, using a regular asynchronous write access.

- nCS is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- ALE is controlled by the ADVONTIME and ADVWROFFTIME timing parameters.
- nWE is controlled by the WEONTIME and WEOFFTIME timing parameters.
- CLE and nRE (nOE) are maintained inactive.

Figure 9-23 shows the NAND address latch cycle.

Figure 9-23. NAND Address Latch Cycle

NOTE: ALE is shared with the nADV output signal and has an inverted polarity from ADV. The NAND qualifier deals with this. During the asynchronous NAND data access cycle, ALE is kept stable.

9.1.5.14.1.5 NAND Device Data Read and Write Phase Control in Stream Mode

NAND device data read and write accesses are achieved through a read or write request to the chip-select-associated memory region at any address location in the region or through a read or write request to the GPMC.GPMC_NAND_DATA_i location (I = 0 to 7) mapped in the chip-select-associated control register region. GPMC.GPMC_NAND_DATA_i is not a true register, but an address location to enable nRE or nWE signal control. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

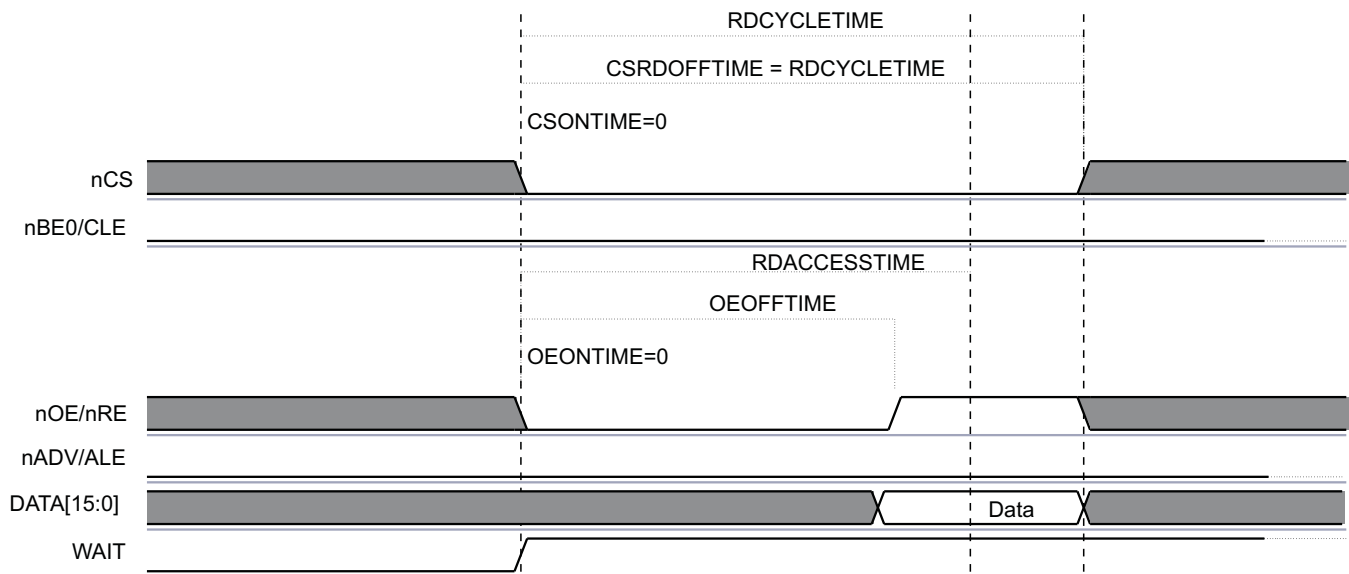

Reading data from the GPMC.GPMC_NAND_DATA_i location or from any location in the associated chip-select memory region activates an asynchronous read access.

- nCS is controlled by the CSONTIME and CSRDOFFTIME timing parameters.
- nRE is controlled by the OEONTIME and OEOFFTIME timing parameters.
- To take advantage of nRE high-to-data invalid minimum timing value, the RDACCESSTIME can be set so that data are effectively captured after nRE deassertion. This allows optimization of NAND read access cycle time completion. For optimal timing parameter settings, see the NAND device and processor IC timing parameters.

ALE, CLE, and nWE are maintained inactive.

Figure 9-24 shows the NAND data read cycle.

Figure 9-24. NAND Data Read Cycle

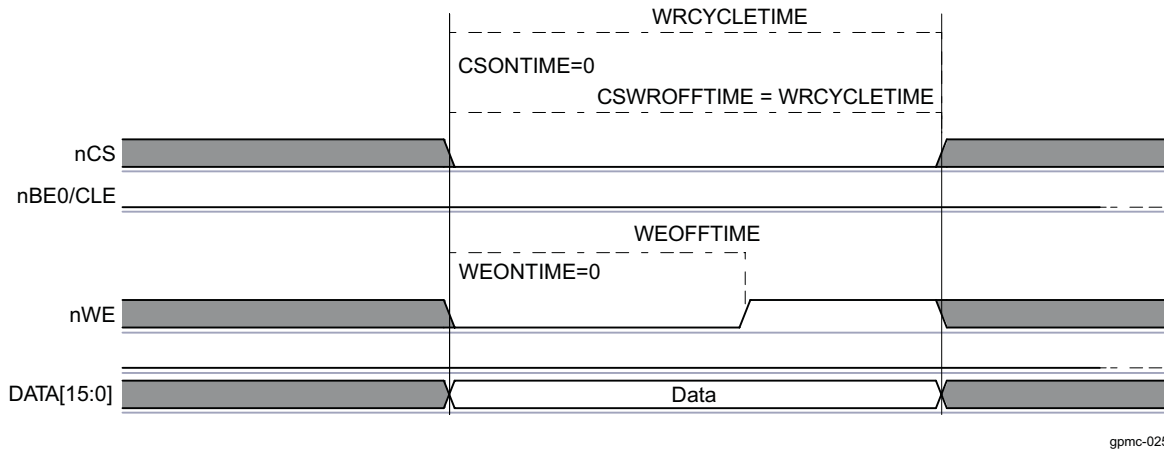

gpmc-024

Writing data to the GPMC.GPMC_NAND_DATA_i location or to any location in the associated chip-select memory region activates an asynchronous write access.

- nCS is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- nWE is controlled by the WEONTIME and WEOFFTIME timing parameters.
- ALE, CLE, and nRE (nOE) are maintained inactive.

Figure 9-25 shows the NAND data write cycle.

Figure 9-25. NAND Data Write Cycle

9.1.5.14.1.6 NAND Device General Chip-Select Timing Control Requirement

For most NAND devices, read data access time is dominated by nCS-to-data-valid timing and has faster nRE-to-data-valid timing. Successive accesses with nCS deassertions between accesses are affected by this timing constraint. Because accesses to a NAND device can be interleaved with other chip-select accesses, there is no certainty that nCS always stays low between two accesses to the same chip-select. Moreover, an nCS deassertion time between the same chip-select NAND accesses is likely to be required as follows: the nCS deassertion requires programming $CYCLETIME$ and $RDACCESSTIME$ according to the nCS-to-data-valid critical timing.

To get full performance from NAND read and write accesses, the prefetch engine can dynamically reduce $RDCYCLETIME$, $WRCYCLETIME$, $RDACCESSTIME$, $WRACCESSTIME$, $CSRDOFFTIME$, $CSWROFFTIME$, $ADVRDOFFTIME$, $ADVWROFFTIME$, $OEOFFTIME$, and $WEOFFTIME$ on back-to-back NAND accesses (to the same memory) and suppress the minimum nCS high pulse width between accesses. For more information about optimal prefetch engine access, see [Section 9.1.5.14.4, Prefetch and Write-Posting Engine](#).

Some NAND devices require minimum write-to-read idle time, especially for device-status read accesses following status-read command programming (write access). If such write-to-read transactions are used, a minimum nCS high pulse width must be set. For this, $CYCLE2CYCLESAMECSEN$ and $CYCLE2CYCLEDELAY$ must be set according to the appropriate timing requirement to prevent any timing violation.

NAND devices usually have an important nRE high to data bus in tristate mode. This requires a bus turnaround setting ($BUSTURNAROUND = 1$), so that the next access to a different chip-select is delayed until the $BUSTURNAROUND$ delay completes. Back-to-back NAND read accesses to the same NAND Flash are not affected by the programmed bus turnaround delay.

9.1.5.14.1.7 Read and Write Access Size Adaptation

9.1.5.14.1.7.1 8-bit Wide NAND Device

Host Word16 and Word32 read and write access requests to a chip-select associated with an 8-bit wide NAND device are split into successive read and write byte accesses to the NAND memory device. Byte access is ordered according to little-endian organization. A NAND 8-bit wide device must be interfaced on the D0D7 interface bus lane. GPMC data accesses are justified on this bus lane when the chip-select is associated with an 8-bit wide NAND device.

9.1.5.14.1.7.2 16-bit Wide NAND Device

Host Word32 read and write access requests to a chip-select associated with a 16-bit wide NAND device are split into successive read and write Word16 accesses to the NAND memory device. Word16 access is ordered according to little-endian organization.

Host byte read and write access requests to a 16-bit wide NAND device are completed as 16-bit accesses on the device itself, because there is no byte-addressing capability on 16-bit wide NAND devices. This means that the NAND device address pointer is incremented on a Word16 basis and not on a byte basis. For a read access, only the requested byte is given back to the host, but the remaining byte is not stored or saved by the GPMC, and the next byte or Word16 read access gets the next Word16 NAND location. For a write access, the invalid byte part of the Word16 is driven to FF, and the next byte or Word16 write access programs the next Word16 NAND location.

Generally, byte access to a 16-bit wide NAND device should be avoided, especially when ECC calculation is enabled. 8-bit or 16-bit ECC-based computations are corrupted by a byte read to a 16-bit wide NAND device, because the nonrequested byte is considered invalid on a read access (not captured on the external data bus; FF is fed to the ECC engine) and is set to FF on a write access.

Host requests (read/write) issued in the chip-select memory region are translated in successive single or split accesses (read/write) to the attached device. Therefore, incrementing 32-bit burst requests are translated in multiple 32-bit sequential accesses following the access adaptation of the 32-bit to 8- or 16-bit device.

9.1.5.14.2 NAND Device-Ready Pin

The NAND memory device provides a ready pin to indicate data availability after a block/page opening and to indicate that data programming is complete. The ready pin can be connected to one of the four WAIT GPMC input pins; data read accesses must not be tried when the ready pin is sampled inactive (device is not ready) even if the associated chip-select WAITREADMONITORING bit field is set. The duration of the NAND device busy state after the block/page opening is so long (up to 50 s) that accesses occurring when the ready pin is sampled inactive can stall GPMC access and eventually cause a system time-out.

NOTE: If a read access to a NAND flash is done using the wait monitoring mode, the device is blocked during a page opening, and so is the GPMC. If the correct settings are used, other chip-selects can be used while the memory processes the page opening command.

To avoid a time-out caused by a block/page opening delay in NAND flash, disable the wait pin monitoring for read and write accesses (that is, set the GPMC.GPMC_CONFIG1_I[21] WAITWRITEMONITORING and GPMC.GPMC_CONFIG1_I[22] WAITREADMONITORING bits to 0, where I = 0 to 7), and use one of the following methods instead:

- Use software to poll the WAITnSTATUS bit (n = 0 to 3) of the GPMC_STATUS register.
- Configure an interrupt that is generated on the WAIT signal change (through the GPMC.GPMC_IRQENABLE register bits[11:8]).

Even if the READWAITMONITORING bit is not set, the external memory nR/B pin status is captured in the programmed WAIT bit in the GPMC_STATUS register.

The READWAITMONITORING bit method must be used for other memories than NAND flash, if they require the use of a WAIT signal.

9.1.5.14.2.1 Ready Pin Monitored by Software Polling

The ready signal state can be monitored through the GPMC.GPMC_STATUS WAITxSTATUS bit (x = 0 to 3). The software must monitor the ready pin only when the signal is declared valid. Refer to the NAND device timing parameters to set the correct software temporization to monitor ready only after the invalid window is complete from the last read command written to the NAND device.

9.1.5.14.2.2 Ready Pin Monitored by Hardware Interrupt

Each gpmc_wait input pin can generate an interrupt when a wait-to-no-wait transition is detected. Depending on whether the GPMC.GPMC_CONFIG WAITxPINPOLARITY bits (x = 0 to 3) is active low or active high, the wait-to-no-wait transition is a low-to-high external WAIT signal transition or a high-to-low external WAIT signal transition, respectively.

The wait transition pin detector must be cleared before any transition detection. This is done by writing 1 to the WAITxEDGEDETECTIONSTATUS bit (x = 0 to 3) of the GPMC.GPMC_IRQSTATUS register according to the gpmc_wait pin used for the NAND device-ready signal monitoring. To detect a wait-to-no-wait transition, the transition detector requires a wait active time detection of a minimum of two GPMC_FCLK cycles. Software must incorporate precautions to clear the wait transition pin detector before wait (busy) time completes.

A wait-to-no-wait transition detection can issue a GPMC interrupt if the WAITxEDGEDETECTIONENABLE bit in the GPMC.GPMC_IRQENABLE register is set and if the WAITxEDGEDETECTIONSTATUS bit field in the GPMC.GPMC_IRQSTATUS register is set.

The WAITMONITORINGTIME field does not affect wait-to-no-wait transition time detection.

It is also possible to poll the WAITxEDGEDETECTIONSTATUS bit field in the GPMC.GPMC_IRQSTATUS register according to the gpmc_wait pin used for the NAND device ready signal monitoring.

9.1.5.14.3 ECC Calculator

The General Purpose Memory Controller includes an Error Code Correction (ECC) calculator circuitry that enables on the fly ECC calculation during data read or data program (that is, write) operations.

The user can choose from two different algorithms with different error correction capabilities, Hamming code (for 1-bit error code correction) and BCH code (for 4- or 8-bit error correction) through the GPMC_ECC_CONFIG[16] ECCALGORITHM bit. Only one ECC context can be active at any given time through the GPMC_ECC_CONFIG[3:1] ECCCS bit. Even if two CS use different ECC algorithms, one the Hamming code and the other a BCH code, they must define separate ECC contexts because some of the ECC registers are common to all types of algorithms.

9.1.5.14.3.1 Hamming Code

All references to Error Code Correction (ECC) in this subsection refer to the 1-bit error correction Hamming code.

The ECC is based on a two-dimensional (row and column) bit parity accumulation known as Hamming Code. The parity accumulation is done for a programmed number of bytes or Word16 read from the memory device or written to the memory device in stream mode.

There is no automatic error detection or correction, and it is the software NAND driver responsibility to read the multiple ECC calculation results, compare them to the expected code value, and take the appropriate corrective actions according to the error handling strategy (ECC storage in spare byte, error correction on read, block invalidation).

The ECC engine includes a single accumulation context. It can be allocated to a single designated chip-select at a time and parallel computations on different chip-selects are not possible. Since it is allocated to a single chip-select, the ECC computation is not affected by interleaved GPMC accesses to other chip-selects and devices. The ECC accumulation is sequentially processed in the order of data read from or written to the memory on the designated chip-select. The ECC engine does not differentiate read accesses from write accesses and does not differentiate data from command or status information. It is the software responsibility to make sure only relevant data are passed to the NAND flash memory while the ECC computation engine is active.

The starting NAND page location must be programmed first, followed by an ECC accumulation context reset with an ECC enabling, if required. The NAND device accesses discussed in the following sections must be limited to data read or write until the specified number of ECC calculations is completed.

9.1.5.14.3.1.1 ECC Result Register and ECC Computation Accumulation Size

The GPMC includes up to nine ECC result registers (GPMC.GPMC_ECCj_RESULT, $j = 1$ to 9) to store ECC computation results when the specified number of bytes or Word16s has been computed.

The ECC result registers are used sequentially; one ECC result is stored in one ECC result register on the list, the next ECC result is stored in the next ECC result register on the list, and so forth, until the last ECC computation. The GPMC.GPMC_ECCj_RESULT register value is valid only when the programmed number of bytes or Word16s has been accumulated, which means that the same number of bytes or Word16s has been read from or written to the NAND device in sequence.

The GPMC.GPMC_ECC_CONTROL[3:0] ECCPOINTER field must be set to the correct value to select the ECC result register to be used first in the list for the incoming ECC computation process. The ECCPointer can be read to determine which ECC register is used in the next ECC result storage for the ongoing ECC computation. The GPMC.GPMC_ECCj_RESULT register value ($j = 1$ to 9) can be considered valid when ECCPOINTER equals $j + 1$. When GPMC.GPMC_ECCj_RESULT (where $j = 9$) is updated, ECCPOINTER is frozen at 10, and ECC computing is stopped (ECCENABLE = 0).

The ECC accumulator must be reset before any ECC computation accumulation process. The GPMC.GPMC_ECC_CONTROL[8] ECCCLEAR bit must be set to 1 (nonpersistent bit) to clear the accumulator and all ECC result registers.

For each ECC result (each GPMC.GPMC_ECCj_RESULT register, $j = 1$ to 9), the number of bytes or Word16s used for ECC computing accumulation can be selected from between two programmable values.

The ECCjRESULTSIZES bits ($j = 1$ to 9) in the GPMC.GPMC_ECC_SIZE_CONFIG register select which programmable size value (ECCSIZE0 or ECCSIZE1) must be used for this ECC result (stored in GPMC.GPMC_ECCj_RESULT).

The ECCSIZE0 and ECCSIZE1 fields allow selection of the number of bytes or Word16s used for ECC computation accumulation. Any even values from 2 to 512 are allowed.

Flexibility in the number of ECCs computed and the number of bytes or Word16s used in the successive ECC computations enables different NAND page error-correction strategies. Usually based on 256 or 512 bytes and on 128 or 256 Word16, the number of ECC results required is a function of the NAND device page size. Specific ECC accumulation size can be used when computing the ECC on the NAND spare byte.

For example, with a 2 Kbyte data page 8-bit wide NAND device, eight ECCs accumulated on 256 bytes can be computed and added to one extra ECC computed on the 24 spare bytes area where the eight ECC results used for comparison and correction with the computed data page ECC are stored. The GPMC then provides nine GPMC.GPMC_ECCj_RESULT registers (j) to store the results. In this case, ECCSIZE0 is set to 256, and ECCSIZE1 is set to 24; the ECC[1:8]RESULTSIZES bits are set to 0, and the ECC9RESULTSIZES bit is set to 1.

9.1.5.14.3.1.2 ECC Enabling

The GPMC.GPMC_ECC_CONFIG[3:0] ECCCS field selects the allocated chip-select. The GPMC.GPMC_ECC_CONFIG[0] ECCENABLE bit enables ECC computation on the next detected read or write access to the selected chip-select.

The ECCPOINTER, ECCCLEAR, ECCSIZE, ECCjRESULTSIZES (where $j = 1$ to 9), ECC16B, and ECCCS fields must not be changed or cleared while an ECC computation is in progress.

The ECC accumulator and ECC result register must not be changed or cleared while an ECC computation is in progress.

Table 9-5 describes the ECC enable settings.

Table 9-5. ECC Enable Settings

| Bit Field | Register | Value | Comments |
|-----------|------------------|-------|---|
| ECCCS | GPMC_ECC_CONFIG | 0-7 | Selects the chip-select where ECC is computed |
| ECC16B | GPMC_ECC_CONFIG | 0/1 | Selects column number for ECC calculation |
| ECCCLEAR | GPMC_ECC_CONTROL | 0-7 | Clears all ECC result registers |

Table 9-5. ECC Enable Settings (continued)

| Bit Field | Register | Value | Comments |
|----------------------------------|----------------------|-----------|---|
| ECCPOINTER | GPMC_ECC_CONTROL | 0-7 | A write to this bit field selects the ECC result register where the first ECC computation is stored. Set to 1 by default. |
| ECSSIZE1 | GPMC_ECC_SIZE_CONFIG | 0x00-0xFF | Defines ECSSIZE1 |
| ECSSIZE0 | GPMC_ECC_SIZE_CONFIG | 0x00-0xFF | Defines ECSSIZE0 |
| ECCkRESULTSIZ (j from 1 to 9) | GPMC_ECC_SIZE_CONFIG | 0/1 | Selects the size of ECCn result register |
| ECCENABLE | GPMC_ECC_CONFIG | 1 | Enables the ECC computation |

9.1.5.14.3.1.3 ECC Computation

The ECC algorithm is a multiple parity bit accumulation computed on the odd and even bit streams extracted from the byte or Word 16 streams. The parity accumulation is split into row and column accumulations, as shown in Figure 9-26 and Figure 9-27. The intermediate row and column parities are used to compute the upper level row and column parities. Only the final computation of each parity bit is used for ECC comparison and correction.

P1o = bit7 XOR bit5 XOR bit3 XOR bit1 on each byte of the data stream

P1e = bit6 XOR bit4 XOR bit2 XOR bit0 on each byte of the data stream

P2o = bit7 XOR bit6 XOR bit3 XOR bit2 on each byte of the data stream

P2e = bit5 XOR bit4 XOR bit1 XOR bit0 on each byte of the data stream

P4o = bit7 XOR bit6 XOR bit5 XOR bit4 on each byte of the data stream

P4e = bit3 XOR bit2 XOR bit1 XOR bit0 on each byte of the data stream

Each column parity bit is XORed with the previous accumulated value.

Figure 9-26. Hamming Code Accumulation Algorithm (1/2)

gpmc-026

For line parities, the bits of each new data are XORed together, and line parity bits are computed as described below:

P8e = row0 XOR row2 XOR row4 XOR XOR row254

P8o = row1 XOR row3 XOR row5 XOR XOR row255

P16e = row0 XOR row1 XOR row4 XOR row5 XOR XOR row252 XOR row 253

P16o = row2 XOR row3 XOR row6 XOR row7 XOR XOR row254 XOR row 255

Figure 9-27. Hamming Code Accumulation Algorithm (2/2)

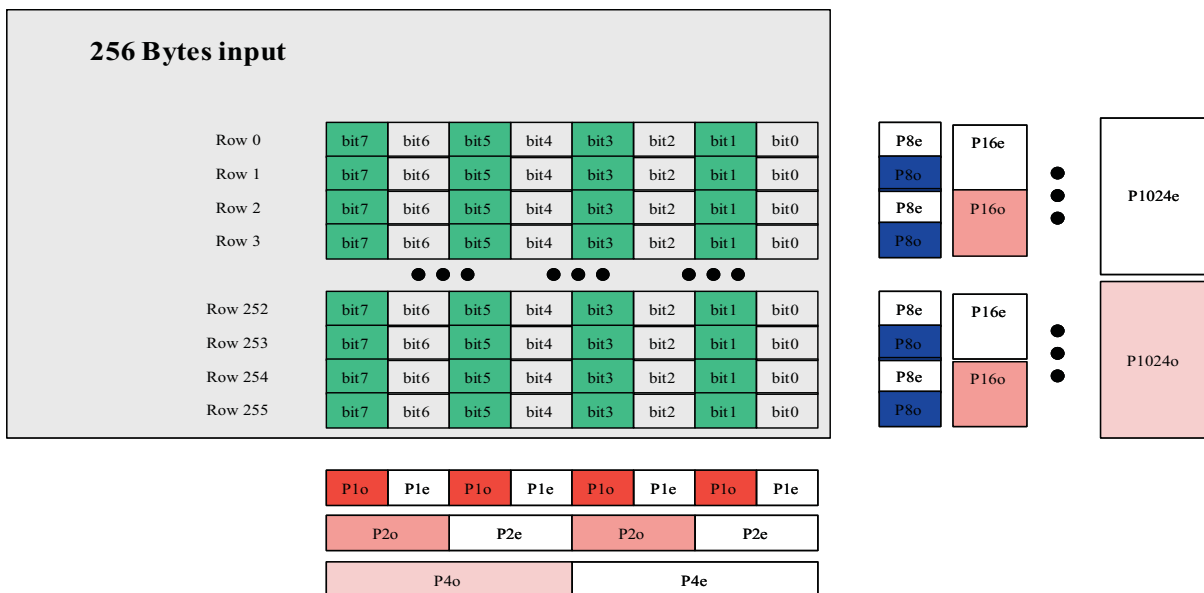

gpmc-027

Unused parity bits in the result registers are set to 0.

Figure 9-28 shows ECC computation for a 256-byte data stream (read or write). The result includes six column parity bits (P1o-P2o-P4o for odd parities, and P1e-P2e-P4e for even parities) and sixteen row parity bits (P8o-P16o-P32o--P1024o for odd parities, and P8e-P16e-P32e--P1024e for even parities).

Figure 9-28. ECC Computation for a 256-Byte Data Stream (Read or Write)

gpmc-028

Figure 9-29 shows ECC computation for a 512-byte data stream (read or write). The result includes six column parity bits (P1o-P2o-P4o for odd parities, and P1e-P2e-P4e for even parities) and eighteen row parity bits (P8o-P16o-P32o--P1024o- - P2048o for odd parities, and P8e-P16e-P32e--P1024e- P2048e for even parities).

Figure 9-29. ECC Computation for a 512-Byte Data Stream (Read or Write)

gpmc-029

For a 2 Kbytes page, four 512 bytes ECC calculations plus one for the spare area are required. Results are stored in the GPMC_ECCj_RESULT registers ($j = 1$ to 9).

9.1.5.14.3.1.4 ECC Comparison and Correction

To detect an error, the computed ECC result must be XORed with the parity value stored in the spare area of the accessed page.

- If the result of this logical XOR is all 0s, no error is detected and the read data is correct.
- If every second bit in the parity result is a 1, one bit is corrupted and is located at bit address (P2048o, P1024o, P512o, P256o, P128o, P64o, P32o, P16o, P8o, P4o, P2o, P1o). The software must correct the corresponding bit.
- If only one bit in the parity result is 1, it is an ECC error and the read data is correct.

9.1.5.14.3.1.5 ECC Calculation Based on 8-Bit Word

The 8-bit based ECC computation is used for 8-bit wide NAND device interfacing.

The 8-bit based ECC computation can be used for 16-bit wide NAND device interfacing to get backward compatibility on the error-handling strategy used with 8-bit wide NAND devices. In this case, the 16-bit wide data read from or written to the NAND device is fragmented into 2 bytes. According to little-endian access, the least significant bit (LSB) of the 16-bit wide data is ordered first in the byte stream used for 8-bit based ECC computation.

9.1.5.14.3.1.6 ECC Calculation Based on 16-Bit Word

ECC computation based on a 16-bit word is used for 16-bit wide NAND device interfacing. This ECC computation is not supported when interfacing an 8-bit wide NAND device, and the GPMC.GPMC_ECC_CONFIG[7] ECC16B bit must be set to 0 when interfacing an 8-bit wide NAND device.

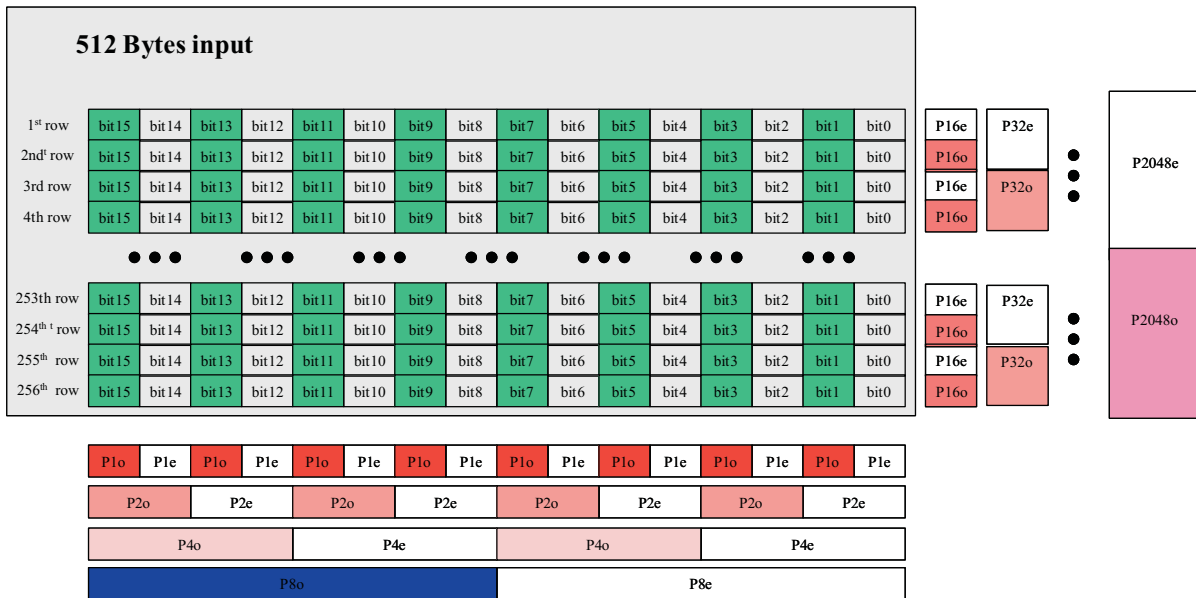

The parity computation based on 16-bit words affects the row and column parity mapping. The main difference is that the odd and even parity bits P8o and P8e are computed on rows for an 8-bit based ECC while there are computed on columns for a 16-bit based ECC. [Figure 9-30](#) and [Figure 9-31](#) show a 128 Word 16 ECC computation scheme and a 256 Word 16 ECC computation scheme.

9.1.5.14.3.2 BCH Code

All references to Error Code Correction (ECC) in this subsection refer to the 4- or 8-bit error correction BCH code.

9.1.5.14.3.2.1 Requirements

1. Read and write accesses to a NAND flash take place by whole pages, in a predetermined sequence: first the data byte page itself, then some spare bytes, including the BCH ECC (and other information). The NAND IC can cache a full page, including spares, for read and write accesses. Typical page write sequence:
 - Sequential write to NAND cache of main data + spare data, for a page. ECC is calculated on the fly. Calculated ECC may be inserted on the fly in the spares, or replaced by dummy accesses.

- When the calculated ECC is replaced by dummy accesses, it must be written to the cache in a second, separate phase. The ECC module is disabled during that time.
 - NAND writes its cache line (page) to the array.
- Typical page read sequence:
- Sequential read of a page. ECC is calculated on the fly.
 - ECC module buffers status determines the presence of errors.
2. Accesses to several memories may be interleaved by the GPMC, but only one of those memories can be a NAND using the BCH engine at a time; in other words, only one BCH calculation (for example, for a single page) can be on-going at any time. Note also that the sequential nature of NAND accesses guarantees that the data is always written / read out in the same order. BCH-relevant accesses are selected by the GPMCs chip-select.
The BCH module has the capacity to store all remainders internally. After the page start, an internal counter is used to detect the 512-byte sector boundaries. On those boundaries, the current remainder is stored and the divider reset for the next calculation. At the end of the page, the BCH module contains all remainders.
 3. Each page may hold up to 4 Kbytes of data, spare bytes not included. This means up to 8 × 512-byte BCH messages. Since all the data is written / read out first, followed by the BCH ECC, this means that the BCH engine must be able to hold 8 104-bit remainders or syndromes (or smaller, 52-bit ones) at the same time.
 4. NAND access cycles hold 8 or 16 bits of data each (1 or 2 bytes); Each NAND cycle takes at least 4 cycles of the GPMCs internal clock. This means the NAND flash timing parameters must define a RDCYCLETIME and a WRCYCLETIME of at least 4 clock cycles after optimization when using the BCH calculator.
 5. The spare area is assumed to be large enough to hold the BCH ECC, that is, to have at least a message of 13 bytes available per 512-byte sector of data. The zone of unused spare area by the ECC may or may not be protected by the same ECC scheme, by extending the BCH message beyond 512 bytes (maximum codeword is 1023-byte long, ECC included, which leaves a lot of space to cover some spares bytes).

9.1.5.14.3.2.2 Memory-Mapping of the BCH Codeword

BCH encoding considers a block of data to protect as a polynomial message M(x). In our standard case, 512 bytes of data (that is, 2¹² bits = 4096 bits) are seen as a polynomial of degree 2¹² - 1 = 4095, with parameters ranging from M0 to M4095. For 512 bytes of data, 52 bits are required for 4-bit error correction, and 104 bits are required for 8-bit error correction. The ECC is a remainder polynomial R(x) of degree 103 (or 51, depending on the selected mode). The complete codeword C(x) is the concatenation of M(x) and R(x) as shown in [Table 9-6](#).

Table 9-6. Flattened BCH Codeword Mapping (512 Bytes + 104 Bits)

| | Message M(x) | | | ECC R(x) | | |
|------------|--------------|-----|----|----------|-----|----|
| Bit number | M4095 | ... | M0 | R103 | ... | R0 |

If the message is extended by the addition of spare bytes to be protected by the same ECC, the principle is still valid. For example, a 3-byte extension of the message gives a polynomial message M(x) of degree ((512 + 3) * 8) - 1 = 4119, for a total of 3+13 = 16 spare bytes of spare, all protected as part of the same codeword.

The message and the ECC bits are manipulated and mapped in the GPMC byte-oriented system. The ECC bits are stored in GPMC_BCH_RESULT0_i, GPMC_BCH_RESULT1_i, GPMC_BCH_RESULT2_i, and GPMC_BCH_RESULT3_i (where I = 0 to 7).

9.1.5.14.3.2.2.1 Memory-Mapping of the Data Message

The data message mapping shall follow the following rules:

- Bit endianness within a byte is little-endian, that is, the bytes LS bit is also the lowest-degree polynomial parameter: a byte b7-b0 (with b0 the LS bit) represents a segment of polynomial b7 * x⁽⁷⁺ⁱ⁾ + b6 * x⁽⁶⁺ⁱ⁾ + ... + b0 * xⁱ

- The message is mapped in the NAND starting with the highest-order parameters, that is, in the lowest addresses of a NAND page.
- Byte endianness within the NANDs 16-bit words is big endian. This means that the same message mapped in 8- and 16-bit memories has the same content at the same byte address.

NOTE: The BCH module has no visibility over actual addresses. The most important point is the sequence of data word the BCH sees. However, the NAND page is always scanned incrementally in read and write accesses, and this produces the mapping patterns described below.

The following tables represent the mapping of the same 512-byte vector (typically a BCH message) in the NANDs memory space. Note that the byte 'address' is only an offset modulo 512 (0x200), since the same page may contain several contiguous 512-byte sectors (BCH blocks). The LSB and MSB are respectively the bits M0 and M(2¹²-1) of the codeword mapping given above. In both cases the data vectors are aligned, that is, their boundaries coincide with the RAMs data word boundaries.

Table 9-7. Aligned Message Byte Mapping in 8-bit NAND

| Byte offset | 8-bit word |
|-------------|------------------------|
| 0x000 | (msb) Byte 511 (0x1FF) |
| 0x001 | Byte 510 (0x1FE) |
| ... | ... |
| 0x1FF | Byte 0 (0x0) (lsb) |

Table 9-8. Aligned Message Byte Mapping in 16-bit NAND

| Byte offset | 16-bit words MSB | 16-bit words LSB |
|-------------|------------------|------------------------|
| 0x000 | Byte 510 (0x1FE) | (msb) Byte 511 (0x1FF) |
| 0x002 | Byte 508 (0x1FC) | Byte 509 (0x1FD) |
| ... | ... | ... |
| 0x1FE | Byte 0 (0x0) | (lsb) Byte 1 (0x1) |

The following tables show the mapping in memory of arbitrarily-sized messages, starting on access (byte or 16-bit word) boundaries for more clarity. Note that message may actually start and stop on arbitrary nibbles. A nibble is a 4-bit entity. The unused nibbles are not discarded, and they can still be used by the BCH module, but as part of the next message section (for example, on another sectors ECC).

Table 9-9. Aligned Nibble Mapping of Message in 8-bit NAND

| Byte offset | 8-bit word | |
|-------------|-------------------------------|-------------------------------|
| | 4-bit most significant Nibble | 4-bit less significant Nibble |
| 1 | (msb) Nibble S-1 | Nibble S-2 |
| 2 | Nibble S-3 | Nibble S-4 |
| ... | ... | ... |
| S/2 - 2 | Nibble 3 | Nibble 2 |
| S/2 - 1 | Nibble 1 | Nibble 0 (lsb) |

Table 9-10. Misaligned Nibble Mapping of Message in 8-bit NAND

| Byte offset | 8-bit word | | |
|---------------|-------------------------------|--|-------------------------------|
| | 4-bit most significant Nibble | | 4-bit less significant Nibble |
| 1 | (msb) Nibble S-1 | | Nibble S-2 |
| 2 | Nibble S-3 | | Nibble S-4 |
| ... | ... | | ... |
| $(S+1)/2 - 2$ | Nibble 2 | | Nibble 1 |
| $(S+1)/2 - 1$ | Nibble 0 (lsb) | | |

Table 9-11. Aligned Nibble Mapping of Message in 16-bit NAND

| Byte offset | 16-bit word | | | |
|-------------|-------------------------------|----------------|-------------------------------|------------|
| | 4-bit most significant Nibble | | 4-bit less significant Nibble | |
| 0 | Nibble S-3 | Nibble S-4 | (msb) Nibble S-1 | Nibble S-2 |
| 2 | Nibble S-7 | Nibble S-8 | Nibble S-5 | Nibble S-6 |
| ... | ... | ... | ... | ... |
| $S/2 - 4$ | Nibble 5 | Nibble 4 | Nibble 7 | Nibble 6 |
| $S/2 - 2$ | Nibble 1 | Nibble 0 (lsb) | Nibble 3 | Nibble 2 |

Table 9-12. Misaligned Nibble Mapping of Message in 16-bit NAND (1 Unused Nibble)

| Byte offset | 16-bit word | | | |
|---------------|-------------------------------|------------|-------------------------------|------------|
| | 4-bit most significant Nibble | | 4-bit less significant Nibble | |
| 0 | Nibble S-3 | Nibble S-4 | (msb) Nibble S-1 | Nibble S-2 |
| 2 | Nibble S-7 | Nibble S-8 | Nibble S-5 | Nibble S-6 |
| ... | ... | ... | ... | ... |
| $(S+1)/2 - 4$ | Nibble 4 | Nibble 3 | Nibble 6 | Nibble 5 |
| $(S+1)/2 - 2$ | Nibble 0 (lsb) | | Nibble 2 | Nibble 1 |

Table 9-13. Misaligned Nibble Mapping of Message in 16-bit NAND (2 Unused Nibbles)

| Byte offset | 16-bit word | | | |
|---------------|-------------------------------|------------|-------------------------------|----------------|
| | 4-bit most significant Nibble | | 4-bit less significant Nibble | |
| 0 | Nibble S-3 | Nibble S-4 | (msb) Nibble S-1 | Nibble S-2 |
| 2 | Nibble S-7 | Nibble S-8 | Nibble S-5 | Nibble S-6 |
| ... | ... | ... | ... | ... |
| $(S+2)/2 - 4$ | Nibble 3 | Nibble 2 | Nibble 5 | Nibble 4 |
| $(S+2)/2 - 2$ | | | Nibble 1 | Nibble 0 (lsb) |

Table 9-14. Misaligned Nibble Mapping of Message in 16-bit NAND (3 Unused Nibbles)

| Byte offset | 16-bit word | | | |
|---------------|-------------------------------|------------|-------------------------------|------------|
| | 4-bit most significant Nibble | | 4-bit less significant Nibble | |
| 0 | Nibble S-3 | Nibble S-4 | (msb) Nibble S-1 | Nibble S-2 |
| 2 | Nibble S-7 | Nibble S-8 | Nibble S-5 | Nibble S-6 |
| ... | ... | ... | ... | ... |
| $(S+3)/2 - 4$ | Nibble 2 | Nibble 1 | Nibble 4 | Nibble 3 |
| $(S+3)/2 - 2$ | | | Nibble 0 (lsb) | |

Note that many other cases exist than the ones represented above, for example, where the message does not start on a word boundary.

9.1.5.14.3.2.2 Memory-Mapping of the ECC

The ECC (or remainder) is presented by the BCH module as a single 104-bit (or 52-bit), little-endian vector. It is up to the software to fetch those 13 bytes (or 6 ½ bytes) from the modules interface, then store them to the NANDs spare area (page write) or to an intermediate buffer for comparison with the stored ECC (page read). There are no constraints on the ECC mapping inside the spare area: it is a software controlled operation.

However, it is advised to maintain a coherence in the respective formats of the message or the ECC remainder once they have been read out of the NAND. The error correction algorithm works from the complete codeword (concatenated message and remainder) once an error as been detected. The creation of this codeword should be made as straightforward as possible.

There are cases where the same NAND access contains both data and the ECC protecting that data. This is the case when the data/ECC boundary (which can be on any nibble) does not coincide with an access boundary. The ECC is calculated on-the-fly following the write. In that case, the write must also contain part of the ECC because it is impossible to insert the ECC on-the-fly. Instead:

- During the initial page write (BCH encoding), the ECC is replaced by dummy bits. The BCH encoder is by definition turned OFF during the ECC section, so the BCH result is unmodified.
- During a second phase, the ECC is written to the correct location, next to the actual data.
- The completed line buffer is then written to the NAND array.

9.1.5.14.3.2.3 Wrapping Modes

For a given wrapping mode, the module automatically goes through a specific number of sections, as data is being fed into the module. For each section, the BCH core can be enabled (in which case the data is fed to the BCH divider) or not (in which case the BCH simply counts to the end of the section). When enabled, the data is added to the ongoing calculation for a given sector number (for example, number 0).

Wrapping modes are described below. To get a better understanding and see the real-life read and write sequences implemented with each mode, see [Section 9.1.5.14.3.2.3](#).

For each mode:

- a sequence describes the mode in pseudo-language, with for each section the size and the buffer used for ECC processing (if ON). The programmable lengths are size, size0 and size1.
- a checksum condition is given. If the checksum condition is not respected for a given mode, the modules behavior is unpredictable. S is the number of sectors in the page; size0 and size1 are the section sizes programmed for the mode, in nibbles.

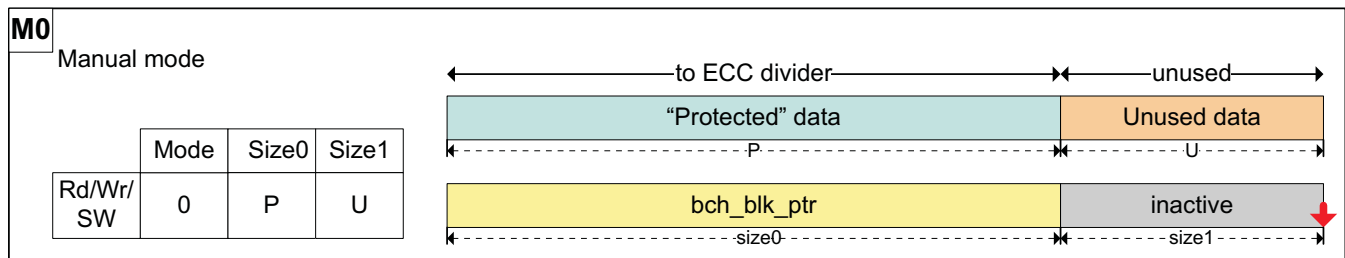

Note that wrapping modes 8, 9, 10, and 11 insert a 1-nibble padding where the BCH processing is OFF. This is intended for t = 4 ECC, where ECC is 6 ½ bytes long and the ECC area is expected to include (at least) 1 unused nibble to remain byte-aligned.

9.1.5.14.3.2.4 Manual Mode (0x0)

This mode is intended for short sequences, added manually to a given buffer through the software data port input. A complete page may be built out of several such sequences.

To process an arbitrary sequence of 4-bit nibbles, accesses to the software data port shall be made, containing the appropriate data. If the sequence end does not coincide with an access boundary (for example, to process 5 nibbles = 20 bits in 16-bit access mode) and those nibbles need to be skipped, a number of unused nibbles shall be programmed in size1 (in the same example: 5 nibbles to process + 3 to discard = 8 nibbles = exactly 2 x 16-bit accesses: we must program size0 = 5, size1 = 3).

NOTE: In the following figures size and size0 are the same parameter.

Figure 9-32. Manual Mode Sequence and Mapping

gpmc-032

Section processing sequence:

- One time with buffer
 - size0 nibbles of data, processing ON
 - size1 nibbles of unused data, processing OFF

Checksum: size0 + size1 nibbles must fit in a whole number of accesses.

9.1.5.14.3.2.2.5 Mode 0x1

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
 - size0 nibbles spare, processing ON
 - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = S - (size0 + size1)

9.1.5.14.3.2.2.6 Mode 0xA (10)

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
 - size0 nibbles spare, processing ON
 - 1 nibble pad spare, processing OFF
 - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = S - (size0 + 1 + size1)

9.1.5.14.3.2.2.7 Mode 0x2

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
 - size0 nibbles spare, processing OFF
 - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = S - (size0 + size1)

9.1.5.14.3.2.2.8 Mode 0x3

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- One time with buffer 0
 - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
 - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S - size1)

9.1.5.14.3.2.2.9 Mode 0x7

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- One time with buffer 0
 - size0 nibbles spare, processing ON
- Repeat S times (no buffer used)
 - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = size0 + (S - size1)

9.1.5.14.3.2.2.10 Mode 0x8

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- One time with buffer 0
 - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
 - 1 nibble padding spare, processing OFF
 - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S - (1+size1))

9.1.5.14.3.2.2.11 Mode 0x4

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- One time (no buffer used)
 - size0 nibbles spare, processing OFF
- Repeat with buffer 0 to S-1
 - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S - size1)

9.1.5.14.3.2.2.12 Mode 0x9

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- One time (no buffer used)
 - size0 nibbles spare, processing OFF
- Repeat with buffer 0 to S-1
 - 1 nibble padding spare, processing OFF
 - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S - (1+size1))

9.1.5.14.3.2.2.13 Mode 0x5

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
 - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
 - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = S - (size0 + size1)

9.1.5.14.3.2.2.14 Mode 0xB (11)

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
 - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
 - 1 nibble padding spare, processing OFF
 - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = S - (size0 + 1 + size1)

9.1.5.14.3.2.2.15 Mode 0x6

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
 - size0 nibbles spare, processing ON
- Repeat S times (no buffer used)
 - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = S - (size0 + size1)

9.1.5.14.3.2.3 Supported NAND Page Mappings and ECC Schemes

The following rules apply throughout the entire mapping description:

- Main data area (sectors) size is hardcoded to 512 bytes.
- Spare area size is programmable.
- All page sections (of main area data bytes, protected spare bytes, unprotected spare bytes, and ECC) are defined as explained in [Section 9.1.5.14.3.2.2.1](#).

Each one of the following sections shows a NAND page mapping example (per-sector spare mappings, pooled spare mapping, per-sector spare mapping, with ECC separated at the end of the page).

In the mapping diagrams, sections that belong to the same BCH codeword have the same color (blue or green); unprotected sections are not covered (orange) by the BCH scheme.

Below each mapping diagram, a write (encoding) and read (decoding: syndrome generation) sequence is given, with the number of the active buffers at each point in time (yellow). In the inactive zones (grey), no computing is taking place but the data counter is still active.

A table on the left summarizes the mode, size0, size1 parameters to program for respectively write and read processing of a page, with the given mapping, where :

- P is the size of spare byte section Protected by the ECC (in nibbles)
- U is the size of spare byte section Unprotected by the ECC (in nibbles)
- E is the size of the ECC itself (in nibbles)
- S is the number of Sectors per page (2 in the current diagrams)

Each time the processing of a BCH block is complete (ECC calculation for write/encoding, syndrome generation for read/decoding, indicated by red arrows), the update pointer is pulsed. Note that the processing for block 0 can be the first or the last to complete, depending on the NAND page mapping and operation (read or write). All examples show a page size of 1kByte + spares, that is, $S = 2$ sectors of 512 bytes. The same principles can be extended to larger pages by adding more sectors.

The actual BCH codeword size is used during the error location work to restrict the search range: by definition, errors can only happen in the codeword that was actually written to the NAND, and not in the mathematical codeword of $n = 2^{13} - 1 = 8191$ bits. That codeword (higher-order bits) is all-zero and implicit during computations.

The actual BCH codeword size depends on the mode, on the programmed sizes and on the sector number (all sizes in nibbles):

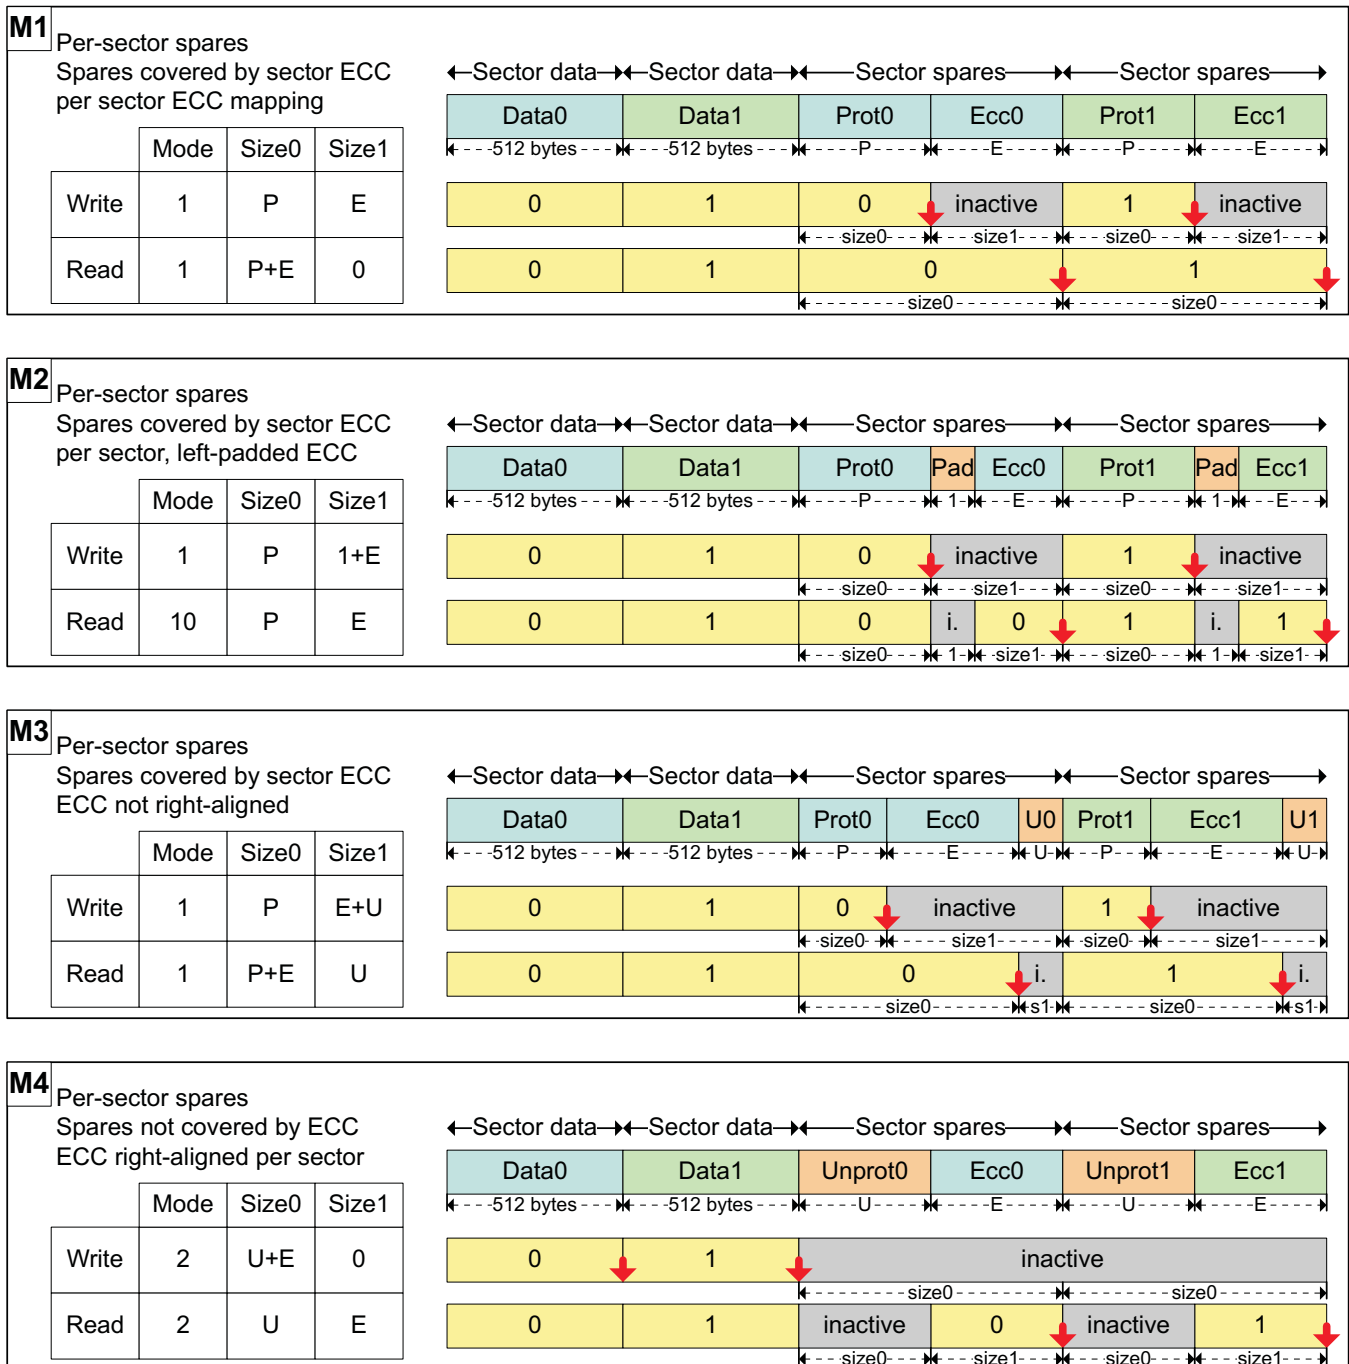

- Spares mapped and protected per sector (below: see M1-M2-M3-M9-M10):
 - all sectors: $(512) + P + E$
- Spares pooled and protected by sector 0 (below: see M5-M6):
 - sector 0 codeword: $(512) + P + E$
 - other sectors: $(512) + E$
- Unprotected spares (below: see M4-M7-M8-M11-M12):
 - all codewords $(512) + E$

9.1.5.14.3.2.3.1 Per-Sector Spare Mappings

In these schemes, each 512-byte sector of the main area has its own dedicated section of the spare area. The spare area of each sector is composed of :

- ECC, which must be located after the data it protects
- other data, which may or may not be protected by the sectors ECC

Figure 9-33. NAND Page Mapping and ECC: Per-Sector Schemes

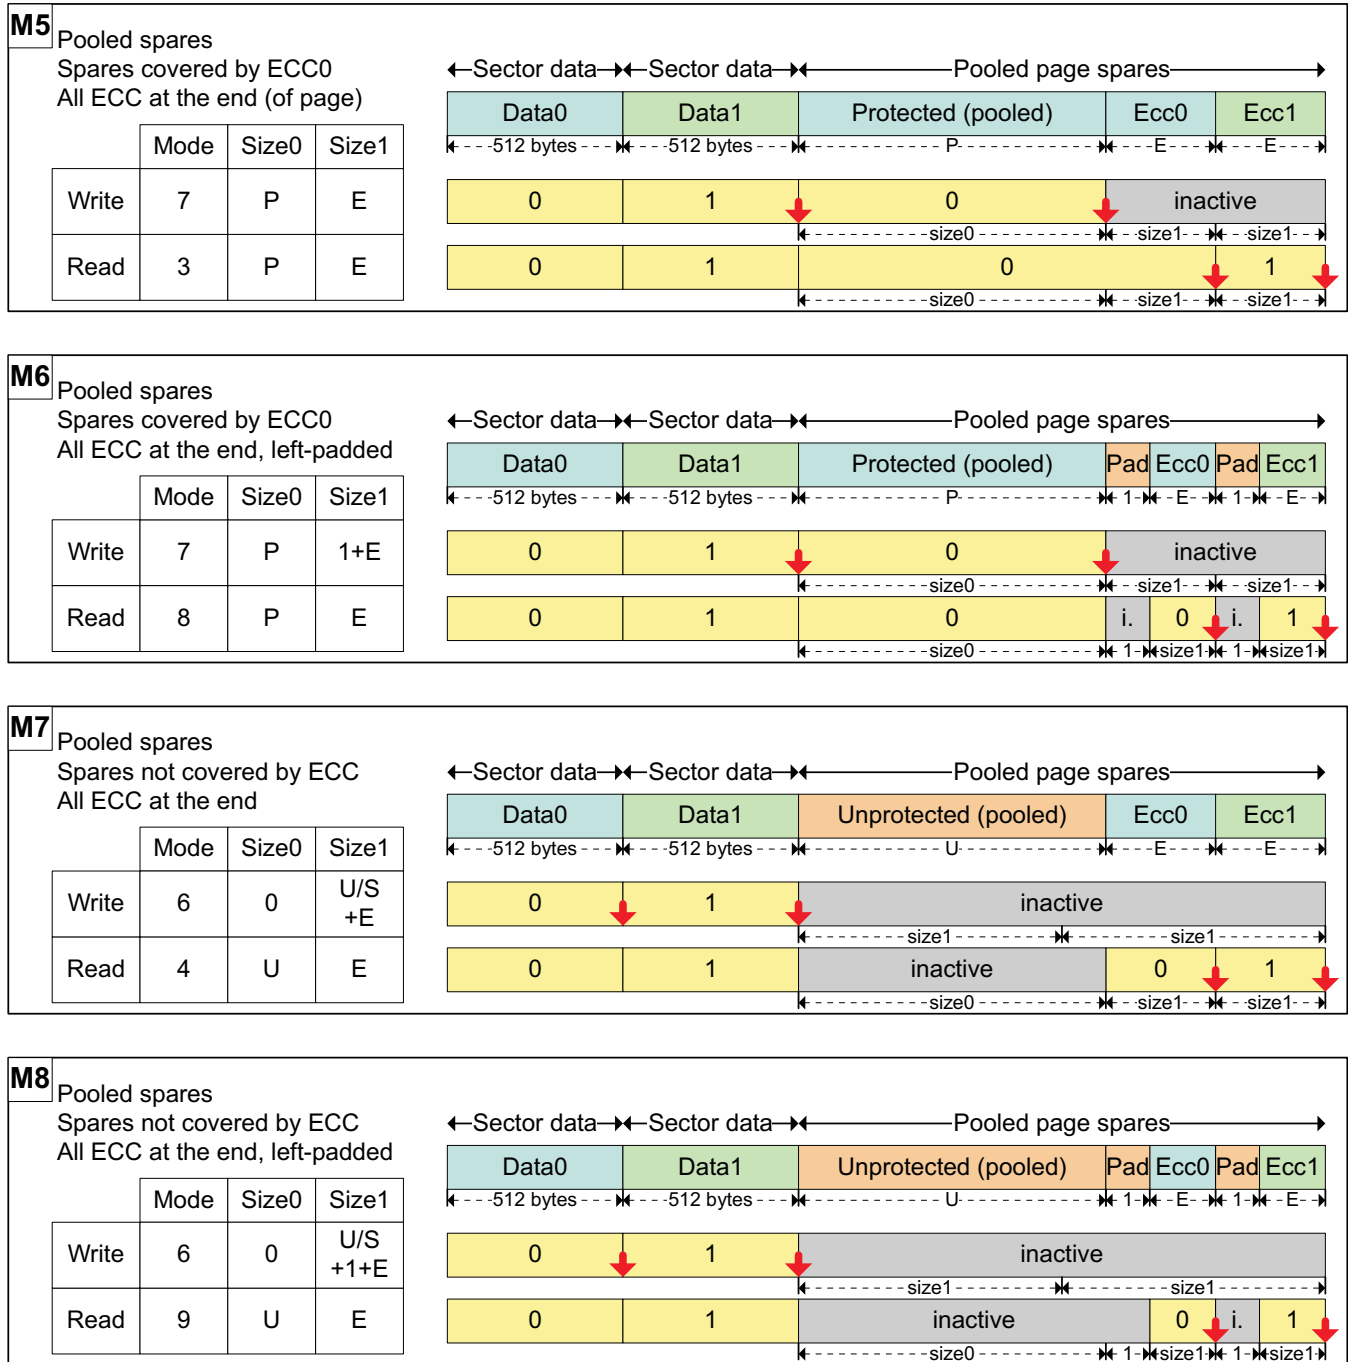

gpmc-033

9.1.5.14.3.2.3.2 Pooled Spare Mapping

In the schemes below, the spare area is pooled for the page.

- The ECC of each sector is aligned at the end of the spare area.
- The non-ECC spare data may or may not be covered by the ECC of sector 0

Figure 9-34. NAND Page Mapping and ECC: Pooled Spare Schemes

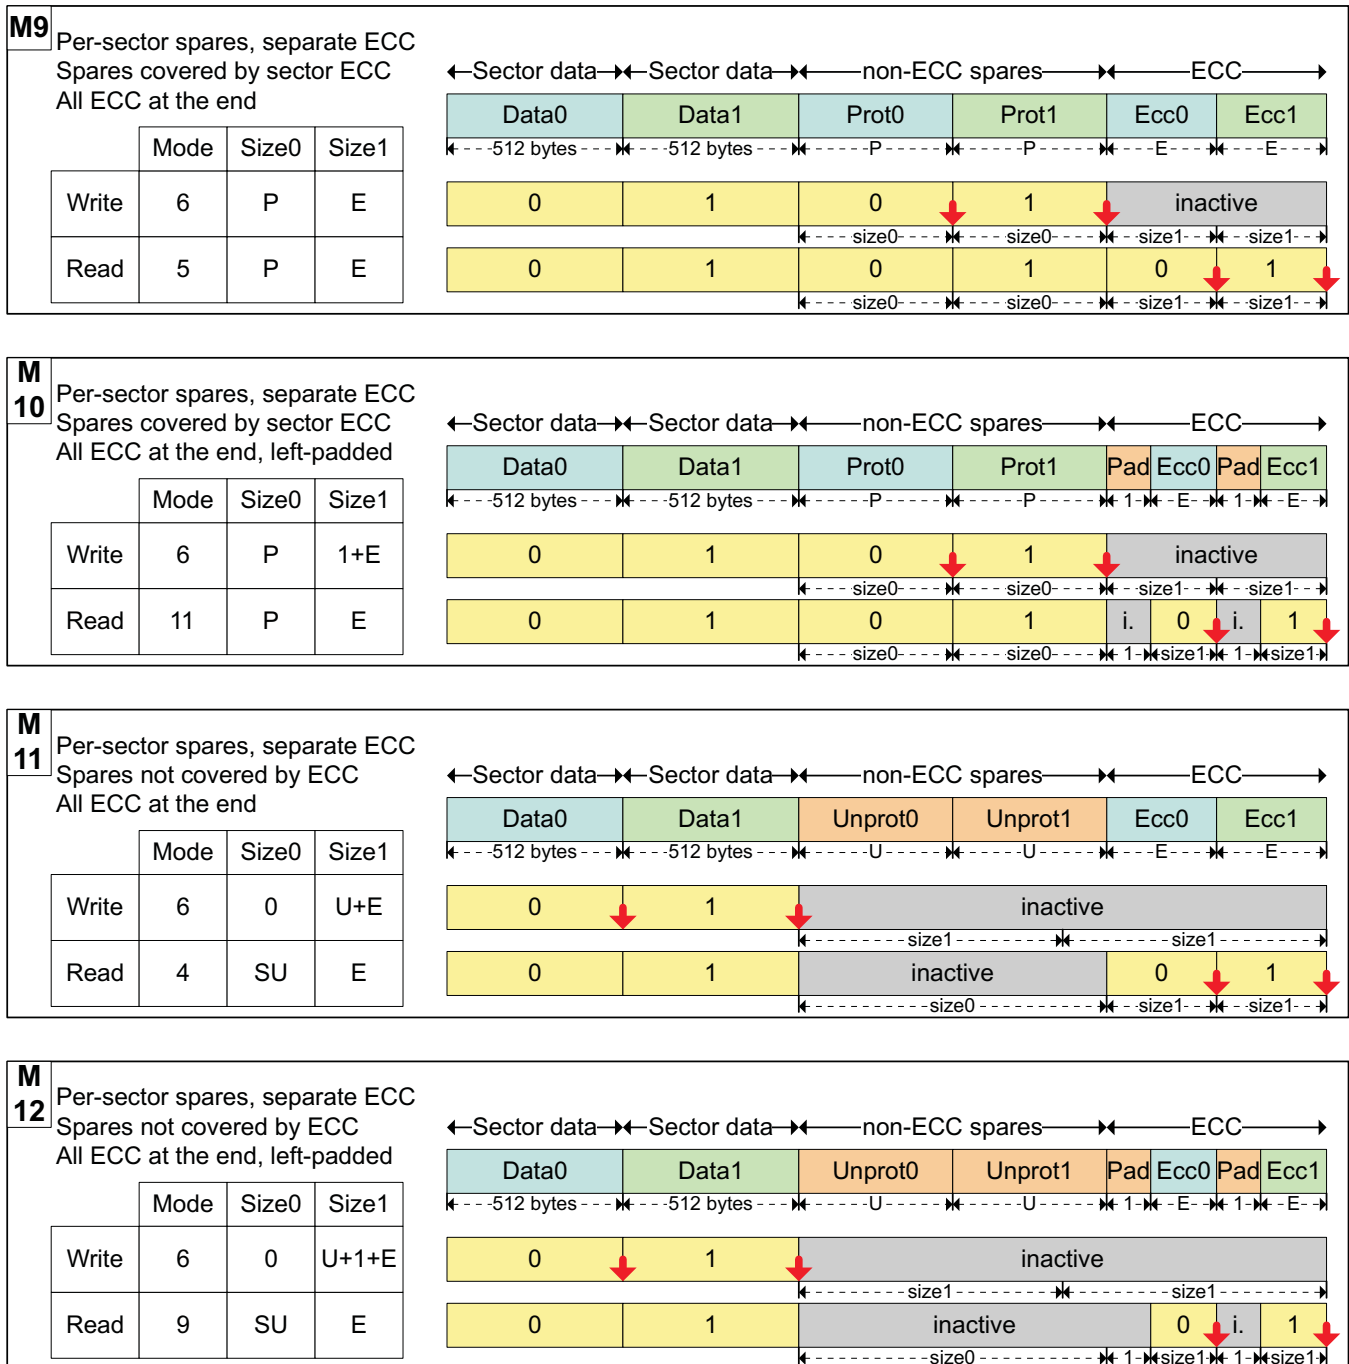

gpmc-034

9.1.5.14.3.2.3.3 Per-Sector Spare Mapping, with ECC Separated at the End of the Page

In these schemes, each 512-byte sector of the main area is associated with 2 sections of the spare area.

- ECC section, all aligned at the end of the page
- other data section, aligned before the ECCs, each of which may or may not be protected by its sectors ECC

Figure 9-35. NAND Page Mapping and ECC: Per-Sector Schemes, with Separate ECC

gpmc_035

9.1.5.14.4 Prefetch and Write-Posting Engine

NAND device data access cycles are usually much slower than the MCU system frequency; such NAND read or write accesses issued by the processor will impact the overall system performance, especially considering long read or write sequences required for NAND page loading or programming. To minimize this effect on system performance, the GPMC includes a prefetch and write-posting engine, which can be used to read from or write to any chip-select location in a buffered manner.

The prefetch and write-posting engine uses an embedded 64 bytes (32 Word16) FIFO to prefetch data

from the NAND device in read mode (prefetch mode) or to store host data to be programmed into the NAND device in write mode (write-posting mode). The FIFO draining and filling (read and write) can be controlled either by the MCU through interrupt synchronization (an interrupt is triggered whenever a programmable threshold is reached) or the sDMA through DMA request synchronization, with a programmable request byte size in both prefetch or posting mode.

The prefetch and write-posting engine includes a single memory pool. Therefore, only one mode, read or write, can be used at any given time. In other words, the prefetch and write-posting engine is a single-context engine that can be allocated to only one chip-select at a time for a read prefetch or a write-posting process.

The engine does not support atomic command and address phase programming and is limited to linear memory read or write access. In consequence, it is limited to NAND data-stream access. The engine relies on the MCU NAND software driver to control block and page opening with the correct data address pointer initialization, before the engine can read from or write to the NAND memory device.

Once started, the engine data reads and writes sequencing is solely based on FIFO location availability and until the total programmed number of bytes is read or written.

Any host-concurrent accesses to a different chip-select are correctly interleaved with ongoing engine accesses. The engine has the lowest priority access so that host accesses to a different chip-select do not suffer a large latency.

A round-robin arbitration scheme can be enabled to ensure minimum bandwidth to the prefetch and write-posting engine in the case of back-to-back direct memory requests to a different chip-select. If the GPMC.GPMC_PREFETCH_CONFIG1[23] PFPWENROUNDROBIN bit is enabled, the arbitration grants the prefetch and write posting engine access to the GPMC bus for a number of requests programmed in the GPMC.GPMC_PREFETCH_CONFIG1[19:16] PFPWWEIGHTEDPRIO field.

The prefetch and write-posting engine is dedicated to data-stream access (as opposed to random data access). The engine does not include an address generator, and the request is limited to chip-select target identification. The prefetch/write-posting engine read or write request is routed to the access engine with the chip-select destination ID. After the required arbitration phase, the access engine processes the request as a single access with the data access size equal to the device size specified in the corresponding chip-select configuration.

NOTE: The destination chip-select configuration must be set to the NAND protocol-compatible configuration for which address lines are not used (the address bus is not changed from its current value). Selecting a different chip-select configuration can produce undefined behavior.

9.1.5.14.4.1 General Basic Programming Model

The engine can be configured only if the GPMC.GPMC_PREFETCH_CONTROL[0] STARTENGINE bit is de-asserted.

The engine must be correctly configured in prefetch or write-posting mode and must be linked to a NAND chip-select before it can be started. The chip-select is linked using the GPMC.GPMC_PREFETCH_CONFIG1[26:24] ENGINECSSELECTOR field.

In both prefetch and write-posting modes, the engine respectively uses byte or Word16 access requests for an 8- or 16-bit wide NAND device attached to the linked chip-select. The FIFOTHRESHOLD and TRANSFERCOUNT fields must be programmed accordingly as a number of bytes or a number of Word16.

When the GPMC.GPMC_PREFETCH_CONFIG1[7] ENABLEENGINE bit is set, the FIFO entry on the L3 interconnect port side is accessible at any address in the associated chip-select memory region. When the ENABLEENGINE bit is set, any host access to this chip-select is rerouted to the FIFO input. Directly accessing the NAND device linked to this chip-select from the host is still possible through the GPMC.GPMC_NAND_COMMAND_i, GPMC.GPMC_NAND_ADDRESS_i, and GPMC.GPMC_NAND_DATA_i registers (where I = 0 to 7).

The FIFO entry on the L3 interconnect port can be accessed with Byte, Word16, or Word32 access size, according to little-endian format, even though the FIFO input is 32-bit wide.

The FIFO control is made easier through the use of interrupts or DMA requests associated with the FIFOTHRESHOLD bit field. The GPMC.GPMC_PREFETCH_STATUS[30:24] FIFOPointer field monitors the number of available bytes to be read in prefetch mode or the number of free empty slots which can be written in write-posting mode. The GPMC.GPMC_PREFETCH_STATUS[13:0] COUNTVALUE field monitors the number of remaining bytes to be read or written by the engine according to the TRANSFERCOUNT value. The FIFOPointer and COUNTVALUE bit fields are always expressed as a number of bytes even if a 16-bit wide NAND device is attached to the linked chip-select.

In prefetch mode, when the FIFOPointer equals 0, that is, the FIFO is empty, a host read access receives the byte last read from the FIFO as its response. In case of Word32 or Word16 read accesses, the last byte read from the FIFO is copied the required number of times to fit the requested word size. In write-posting mode, when the FIFOPointer equals 0, that is, the FIFO is full, a host write overwrites the last FIFO byte location. There is no underflow or overflow error reporting in the GPMC.

9.1.5.14.4.2 Prefetch Mode

The prefetch mode is selected when the GPMC.GPMC_PREFETCH_CONFIG1[0] ACCESSMODE bit is cleared.

The MCU NAND software driver must issue the block and page opening (READ) command with the correct data address pointer initialization before the engine can be started to read from the NAND memory device. The engine is started by asserting the GPMC.GPMC_PREFETCH_CONTROL[0] STARTENGINE bit. The STARTENGINE bit automatically clears when the prefetch process completes.

If required, the ECC calculator engine must be initialized (configured, reset, and enabled) before the prefetch engine is started, so that the ECC is correctly computed on all data read by the prefetch engine.

When the GPMC.GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE bit is cleared, the prefetch engine starts requesting data as soon as the STARTENGINE bit is set. If using this configuration, the host must monitor the NAND device-ready pin so that it only sets the STARTENGINE bit when the NAND device is in a ready state, meaning data is valid for prefetching.

When the GPMC.GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE bit is set, the prefetch engine starts requesting data when an active to inactive wait signal transition is detected. The transition detector must be cleared before any transition detection; see [Section 9.1.5.14.2.2](#). The GPMC.GPMC_PREFETCH_CONFIG1[5:4] WAITPINSELECTOR field selects which gpmc_wait pin edge detector triggers the prefetch engine in this synchronized mode.

If the STARTENGINE bit is set after the NAND address phase (page opening command), the engine is effectively started only after the actual NAND address phase completion. To prevent GPMC stall during this NAND address phase, set the STARTENGINE bit field before NAND address phase completion when in synchronized mode. The prefetch engine will start when an active to inactive wait signal transition is detected. The STARTENGINE bit is automatically cleared on prefetch process completion.

The prefetch engine issues a read request to ensure that the FIFO is always filled with as much data as acceptable, until the programmed GPMC.GPMC_PREFETCH_CONFIG2[13:0] TRANSFERCOUNT field is completed.

Table 9-15. Prefetch Mode Configuration

| Bit Field | Register | Value | Comments |
|------------------|------------------------------|--------|---|
| STARTENGINE | GPMC_PREFETCH_CONTROL[0] | 0 | Prefetch engine can be configured only if STARTENGINE is set to 0. |
| ENGINECSSELECTOR | GPMC_PREFETCH_CONFIG1[26:24] | 0 to 7 | Selects the chip-select associated with a NAND device where the prefetch engine is active. |
| ACCESSMODE | GPMC_PREFETCH_CONFIG1[0] | 0 | Selects prefetch mode |
| FIFOTHRESHOLD | GPMC_PREFETCH_CONFIG1[14:8] | | Selects the maximum number of bytes read or written by the host on DMA or interrupt request |

Table 9-15. Prefetch Mode Configuration (continued)

| Bit Field | Register | Value | Comments |
|-----------------------|------------------------------|--------|---|
| TRANSFERCOUNT | GPMC_PREFETCH_CONFIG2[13:0] | | Selects the number of bytes to be read or written by the engine to the selected chip-select |
| SYNCHROMODE | GPMC_PREFETCH_CONFIG1[3] | 0/1 | Selects when the engine starts the access to the chip-select |
| WAITPINSELECT | GPMC_PREFETCH_CONFIG1[17:16] | 0 to 3 | (If SynchroMode = 1) Selects wait pin edge detector |
| ENABLEOPTIMIZEDACCESS | GPMC_PREFETCH_CONFIG1[27] | 0/1 | See Section 9.1.5.14.4.6 . |
| CYCLEOPTIMIZATION | GPMC_PREFETCH_CONFIG1[30:28] | | |
| ENABLEENGINE | GPMC_PREFETCH_CONFIG1[7] | 1 | Engine enabled |
| STARTENGINE | GPMC_PREFETCH_CONTROL[0] | 1 | Starts the prefetch engine |

9.1.5.14.4.3 FIFO Control in Prefetch Mode

The FIFO can be drained directly by the MPU or by an sDMA channel.

In MPU draining mode, the FIFO status can be monitored through the GPMC.GPMC_PREFETCH_STATUS[30:24] FIFOPointer field or through the GPMC.GPMC_PREFETCH_STATUS[16] FIFOTHRESHOLDSTATUS bit. The FIFOPointer indicates the current number of available data to be read; FIFOTHRESHOLDSTATUS set to 1 indicates that at least FIFOTHRESHOLD bytes are available from the FIFO.

An interrupt can be triggered by the GPMC if the GPMC.GPMC_IRQENABLE[0] FIFOEVENTENABLE bit is set. The FIFO interrupt event is logged, and the GPMC.GPMC_IRQSTATUS[0] FIFOEVENTSTATUS bit is set. To clear the interrupt, the MPU must read all the available bytes, or at least enough bytes to get below the programmed FIFO threshold, and the FIFOEVENTSTATUS bit must be cleared to enable further interrupt events. The FIFOEVENTSTATUS bit must always be reset prior to asserting the FIFOEVENTENABLE bit to clear any out-of-date logged interrupt event. This interrupt generation must be enabled after enabling the STARTENGINE bit.

Prefetch completion can be monitored through the GPMC.GPMC_PREFETCH_STATUS[13:0] COUNTVALUE field. COUNTVALUE indicates the number of currently remaining data to be requested according to the TRANSFERCOUNT value. An interrupt can be triggered by the GPMC when the prefetch process is complete (that is, COUNTVALUE equals 0) if the GPMC.GPMC_IRQENABLE[1] TERMINALCOUNTEVENTENABLE bit is set. At prefetch completion, the TERMINALCOUNT interrupt event is also logged, and the GPMC.GPMC_IRQSTATUS[1] TERMINALCOUNTSTATUS bit is set. To clear the interrupt, the MPU must clear the TERMINALCOUNTSTATUS bit. The TERMINALCOUNTSTATUS bit must always be cleared prior to asserting the TERMINALCOUNTEVENTENABLE bit to clear any out-of-date logged interrupt event.

NOTE: The COUNTVALUE value is only valid when the prefetch engine is active (started), and an interrupt is only triggered when COUNTVALUE reaches 0, that is, when the prefetch engine automatically goes from an active to an inactive state.

The number of bytes to be prefetched (programmed in TRANSFERCOUNT) must be a multiple of the programmed FIFOTHRESHOLD to trigger the correct number of interrupts allowing a deterministic and transparent FIFO control. If this guideline is respected, the number of ISR accesses is always required and the FIFO is always empty after the last interrupt is triggered. In other cases, the TERMINALCOUNT interrupt must be used to read the remaining bytes in the FIFO (the number of remaining bytes being lower than the FIFOTHRESHOLD value).

In DMA draining mode, the GPMC.GPMC_PREFETCH_CONFIG1[2] DMAMODE bit must be set so that the GPMC issues a DMA hardware request when at least FIFOTHRESHOLD bytes are ready to be read from the FIFO. The DMA channel owning this DMA request must be programmed so that the number of bytes programmed in FIFOTHRESHOLD is read from the FIFO during the DMA request process. The DMA request is kept active until this number of bytes has effectively been read from the FIFO, and no other DMA request can be issued until the ongoing active request is complete.

In prefetch mode, the TERMINALCOUNT event is also a source of DMA requests if the number of bytes to be prefetched is not a multiple of FIFOTHRESHOLD, the remaining bytes in the FIFO can be read by the DMA channel using the last DMA request. This assumes that the number of remaining bytes to be read is known and controlled through the DMA channel programming model.

Any potentially active DMA request is cleared when the prefetch engine goes from inactive to active prefetch (the STARTENGINE bit is set to 1). The associated DMA channel must always be enabled by the MPU after setting the STARTENGINE bit so that the out-of-date active DMA request does not trigger spurious DMA transfers.

9.1.5.14.4.4 Write-Posting Mode

The write-posting mode is selected when the GPMC.GPMC_PREFETCH_CONFIG1[0] ACCESSMODE bit is set.

The MCU NAND software driver must issue the correct address pointer initialization command (page program) before the engine can start writing data into the NAND memory device. The engine starts when the GPMC.GPMC_PREFETCH_CONTROL[0] STARTENGINE bit is set to 1. The STARTENGINE bit clears automatically when posting completes. When all data have been written to the NAND memory device, the MCU NAND software driver must issue the second cycle program command and monitor the status for programming process completion (adding ECC handling, if required).

If used, the ECC calculator engine must be started (configured, reset, and enabled) before the posting engine is started so that the ECC parities are properly calculated on all data written by the prefetch engine to the associated chip-select.

In write-posting mode, the GPMC.GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE bit must be cleared so that posting starts as soon as the STARTENGINE bit is set and the FIFO is not empty.

If the STARTENGINE bit is set after the NAND address phase (page program command), the STARTENGINE setting is effective only after the actual NAND command completion. To prevent GPMC stall during this NAND command phase, set the STARTENGINE bit field before the NAND address completion and ensure that the associated DMA channel is enabled after the NAND address phase.

The posting engine issues a write request when valid data are available from the FIFO and until the programmed GPMC.GPMC_PREFETCH_CONFIG2[13:0] TRANSFERCOUNT accesses have been completed.

The STARTENGINE bit clears automatically when posting completes. When all data have been written to the NAND memory device, the MCU NAND software driver must issue the second cycle program command and monitor the status for programming process completion. The closing program command phase must only be issued when the full NAND page has been written into the NAND flash write buffer, including the spare area data and the ECC parities, if used.

Table 9-16. Write-Posting Mode Configuration

| Bit Field | Register | Value | Comments |
|-----------------------|------------------------------|--------|--|
| STARTENGINE | GPMC_PREFETCH_CONTROL[0] | 0 | Write-posting engine can be configured only if STARTENGINE is set to 0. |
| ENGINECSSELECTOR | GPMC_PREFETCH_CONFIG1[26:24] | 0 to 7 | Selects the chip-select associated with a NAND device where the prefetch engine is active |
| ACCESSMODE | GPMC_PREFETCH_CONFIG1[0] | 1 | Selects write-posting mode |
| FIFOTHRESHOLD | GPMC_PREFETCH_CONFIG1[14:8] | | Selects the maximum number of bytes read or written by the host on DMA or interrupt request |
| TRANSFERCOUNT | GPMC_PREFETCH_CONFIG2[13:0] | | Selects the number of bytes to be read or written by the engine from/to the selected chip-select |
| SYNCHROMODE | GPMC_PREFETCH_CONFIG1[3] | 0 | Engine starts the access to chip-select as soon as STARTENGINE is set. |
| ENABLEOPTIMIZEDACCESS | GPMC_PREFETCH_CONFIG1[27] | 0/1 | See Section 9.1.5.14.4.6 . |
| CYCLOPTIMIZATION | GPMC_PREFETCH_CONFIG1[30:28] | | |

Table 9-16. Write-Posting Mode Configuration (continued)

| Bit Field | Register | Value | Comments |
|--------------|--------------------------|-------|----------------------------|
| ENABLEENGINE | GPMC_PREFETCH_CONFIG1[7] | 1 | Engine enabled |
| STARTENGINE | GPMC_PREFETCH_CONTROL[0] | 1 | Starts the prefetch engine |

9.1.5.14.4.5 FIFO Control in Write-Posting Mode

The FIFO can be filled directly by the MPU or by an sDMA channel.

In MPU filling mode, the FIFO status can be monitored through the FIFOPINTER or through the GPMC.GPMC_PREFETCH_STATUS[16] FIFOTHRESHOLDSTATUS bit. FIFOPINTER indicates the current number of available free byte places in the FIFO, and the FIFOTHRESHOLDSTATUS bit, when set, indicates that at least FIFOTHRESHOLD free byte places are available in the FIFO.

An interrupt can be issued by the GPMC if the GPMC.GPMC_IRQENABLE[0] FIFOEVENTENABLE bit is set. When the interrupt is fired, the GPMC.GPMC_IRQSTATUS[0] FIFOEVENTSTATUS bit is set. To clear the interrupt, the MPU must write enough bytes to fill the FIFO, or enough bytes to get below the programmed threshold, and the FIFOEVENTSTATUS bit must be cleared to get further interrupt events. The FIFOEVENTSTATUS bit must always be cleared prior to asserting the FIFOEVENTENABLE bit to clear any out-of-date logged interrupt event. This interrupt must be enabled after enabling the STARTENGINE bit.

The posting completion can be monitored through the GPMC.GPMC_PREFETCH_STATUS[13:0] COUNTVALUE field. COUNTVALUE indicates the current number of remaining data to be written based on the TRANSFERCOUNT value. An interrupt is issued by the GPMC when the write-posting process completes (that is, COUNTVALUE equal to 0) if the GPMC.GPMC_IRQENABLE[1] TERMINALCOUNTEVENTENABLE bit is set. When the interrupt is fired, the GPMC.GPMC_IRQSTATUS[1] TERMINALCOUNTSTATUS bit is set. To clear the interrupt, the MPU must clear the TERMINALCOUNTSTATUS bit. The TERMINALCOUNTSTATUS bit must always be cleared prior to asserting the TERMINALCOUNTEVENTENABLE bit to clear any out-of-date logged interrupt event.

NOTE: The COUNTVALUE value is only valid if the write-posting engine is active and started, and an interrupt is only issued when COUNTVALUE reaches 0, that is, when the posting engine automatically goes from active to inactive.

In DMA filling mode, the DMAMode bit field in the GPMC.GPMC_PREFETCH_CONFIG1[2] DMAMODE bit must be set so that the GPMC issues a DMA hardware request when at least FIFOTHRESHOLD bytes-free places are available in the FIFO. The DMA channel owning this DMA request must be programmed so that a number of bytes equal to the value programmed in the FIFOTHRESHOLD bit field are written into the FIFO during the DMA access. The DMA request remains active until the associated number of bytes has effectively been written into the FIFO, and no other DMA request can be issued until the ongoing active request has been completed.

Any potentially active DMA request is cleared when the prefetch engine goes from inactive to active prefetch (STARTENGINE set to 1). The associated DMA channel must always be enabled by the MPU after setting the STARTENGINE bit so that an out-of-date active DMA request does not trigger spurious DMA transfers.

In write-posting mode, the DMA or the MPU fill the FIFO with no consideration to the associated byte enables. Any byte stored in the FIFO is written into the memory device.

9.1.5.14.4.6 Optimizing NAND Access Using the Prefetch and Write-Posting Engine

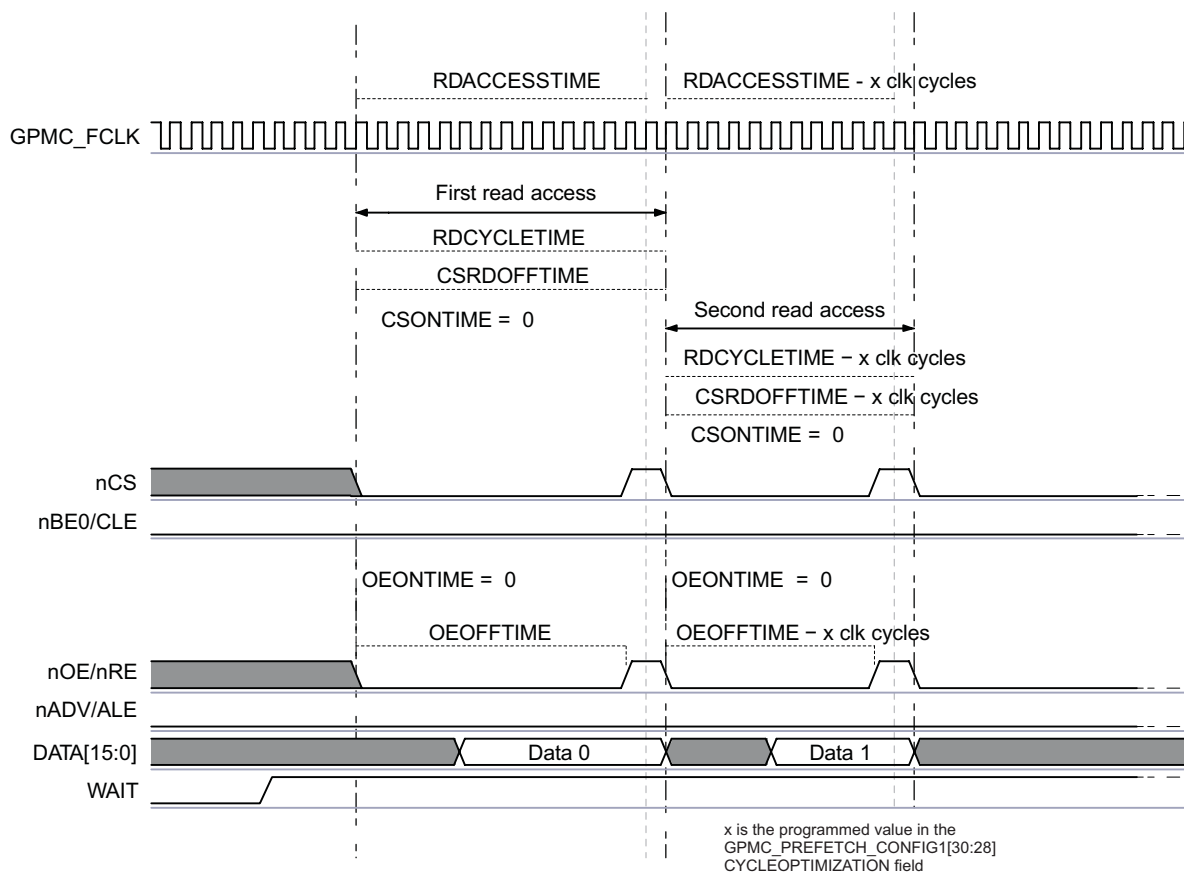

Access time to a NAND memory device can be optimized for back-to-back accesses if the associated nCS signal is not deasserted between accesses. The GPMC access engine can track prefetch engine accesses to optimize the access timing parameter programmed for the allocated chip-select, if no

accesses to other chip-selects (that is, interleaved accesses) occur. Similarly, the access engine also eliminates the CYCLE2CYCLEDELAY even if CYCLE2CYCLESAMEECSEN is set. This capability is limited to the prefetch and write-posting engine accesses, and MPU accesses to a NAND memory device (through the defined chip-select memory region or through the GPMC.GPMC_NAND_DATA_i location, $i = 0$ to 7) are never optimized.

The GPMC.GPMC_PREFETCH_CONFIG1[27] ENABLEOPTIMIZEDACCESS bit must be set to enable optimized accesses. To optimize access time, the GPMC.GPMC_PREFETCH_CONFIG1[30:28] CYCLEOPTIMIZATION field defines the number of GPMC_FCLK cycles to be suppressed from the RDCYCLETIME, WRCYCLETIME, RDACCESSTIME, WRACCESSTIME, CSOFFTIME, ADVOFFTIME, OEOFFTIME, and WEOFFTIME timing parameters.

Figure 9-36 highlights that, in the case of back-to-back accesses to the NAND flash through the prefetch engine, CYCLE2CYCLESAMEECSEN is forced to 0 when using optimized accesses. The first access uses the regular timing settings for this chip-select. All accesses after this one use settings reduced by x clock cycles, x being defined by the GPMC_PREFETCH_CONFIG1[30:28] CYCLEOPTIMIZATION field.

Figure 9-36. NAND Read Cycle Optimization Timing Description

gpmc-036

9.1.5.14.4.7 Interleaved Accesses between Prefetch and Write-Posting Engine and Other Chip-Selects

Any on-going read or write access from the prefetch and write-posting engine is completed before an access to any other chip-select can be initiated. As a default, the arbiter uses a fixed-priority algorithm, and the prefetch and write-posting engine has the lowest priority. The maximum latency added to access starting time in this case equals the RDCYCLETIME or WRCYCLETIME (optimized or not) plus the requested BUSTURNAROUND delay for bus turnaround completion programmed for the chip-select to which the NAND device is connected to.

Alternatively, a round-robin arbitration can be used to prioritize accesses to the external bus. This arbitration scheme is enabled by setting the GPMC.GPMC_PREFETCH_CONFIG1[23]

PPWENROUNDROBIN bit. When a request to another chip-select is received while the prefetch and write-posting engine is active, priority is given to the new request. The request processed thereafter is the prefetch and write-posting engine request, even if another interconnect request is passed in the mean time. The engine keeps control of the bus for an additional number of requests programmed in the GPMC.GPMC_PREFETCH_CONFIG1[19:16] PFPWWEIGHTEDPRIO bit field. Control is then passed to the direct interconnect request.

As an example, the round-robin arbitration scheme is selected with PFPWWEIGHTEDPRIO set to 0x2. Considering the prefetch and write-posting engine and the interconnect interface are always requesting access to the external interface, the GPMC grants priority to the direct interconnect access for one request. The GPMC then grants priority to the engine for three requests, and finally back to the direct interconnect access, until the arbiter is reset when one of the two initiators stops initiating requests.

9.1.6 GPMC Use Cases and Tips

9.1.6.1 How to Set GPMC Timing Parameters for Typical Accesses

9.1.6.1.1 External Memory Attached to the GPMC Module

As discussed in the introduction to this chapter, the GPMC module supports the following external memory types:

- Asynchronous or synchronous, 8-bit or 16-bit-width memory or device
- 16-bit address/data-multiplexed or not multiplexed NOR flash device
- 8- or 16-bit NAND flash device

The following examples show how to calculate GPMC timing parameters by showing a typical parameter setup for the access to be performed.

The example is based on a 512-Mb multiplexed NOR flash memory with the following characteristics:

- Manufacturer: NOR Flash
- Type: NOR flash (address/data-multiplexed mode)
- Size: 512M bits
- Data Bus: 16 bits wide
- Speed: 104 MHz clock frequency
- Read access time: 80 ns

9.1.6.1.2 Typical GPMC Setup

[Table 9-17](#) lists some of the I/Os of the GPMC module.

Table 9-17. GPMC Signals

| Signal Name | I/O | Description |
|----------------|----------|--|
| GPMC_FCLK | Internal | Functional and interface clock. Acts as the time reference. |
| gpmc_clk | I/O | External clock provided to the external device for synchronous operations |
| gpmc_a[10: 1] | O | Address |
| gpmc_d[15: 0] | I/O | Data-multiplexed with addresses A[16:1] on memory side |
| gpmc_ncs | O | Chip-select |
| gpmc_nadv_ale | O | Address valid enable |
| gpmc_noe_nre | O | Output enable (read access only) |
| gpmc_nwe | O | Write enable (write access only) |
| gpmc_wait[3:0] | I | Ready signal from memory device. Indicates when valid burst data is ready to be read |

Figure 9-37 shows the typical connection between the GPMC module and the attached NOR Flash memory.

Figure 9-37. GPMC Connection to External NOR Flash Memory

gpmc_037

The following sections demonstrate how to calculate GPMC parameters for three access types:

- Synchronous burst read
- Asynchronous read
- Asynchronous single write

9.1.6.1.2.1 GPMC Configuration for Synchronous Burst Read Access

The clock runs at 104 MHz ($f = 104 \text{ MHz}$; $T = 9,615 \text{ ns}$).

Table 9-18 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Table 9-19 shows how to calculate timings for the GPMC using the memory parameters.

Figure 9-38 shows the synchronous burst read access.

Table 9-18. Useful Timing Parameters on the Memory Side

| AC Read Characteristics on the Memory Side | Description | Duration (ns) |
|--|-----------------------------|---------------|
| tCES | nCS setup time to clock | 0 |
| tACS | Address setup time to clock | 3 |
| tIACC | Synchronous access time | 80 |

Table 9-18. Useful Timing Parameters on the Memory Side (continued)

| AC Read Characteristics on the Memory Side | Description | Duration (ns) |
|--|---|---------------|
| tBACC | Burst access time valid clock to output delay | 5,2 |
| tCEZ | Chip-select to High-Z | 7 |
| tOEZ | Output enable to High-Z | 7 |
| tAVC | nADV setup time | 6 |
| tAVD | nAVD pulse | 6 |
| tACH | Address hold time from clock | 3 |

The following terms, which describe the timing interface between the controller and its attached device, are used to calculate the timing parameters on the GPMC side:

- Read Access time (GPMC side): Time required to activate the clock + read access time requested on the memory side + data setup time required for optimal capture of a burst of data
- Data setup time (GPMC side): Ensures a good capture of a burst of data (as opposed to taking a burst of data out). One burst of data is processed in one clock cycle ($T = 9,615$ ns). The read access time between 2 bursts of data is tBACC = 5,2 ns. Therefore, data setup time is a clock period - tBACC = 4,415 ns of data setup.
- Access completion (GPMC side): (Different from page burst access time) Time required between the last burst access and access completion: nCS/nOE hold time (nCS and nOE must be released at the end of an access. These signals are held to allow the access to complete).
- Read cycle time (GPMC side): Read Access time + access completion
- Write cycle time for burst access: Not supported for NOR flash memory

Table 9-19. Calculating GPMC Timing Parameters

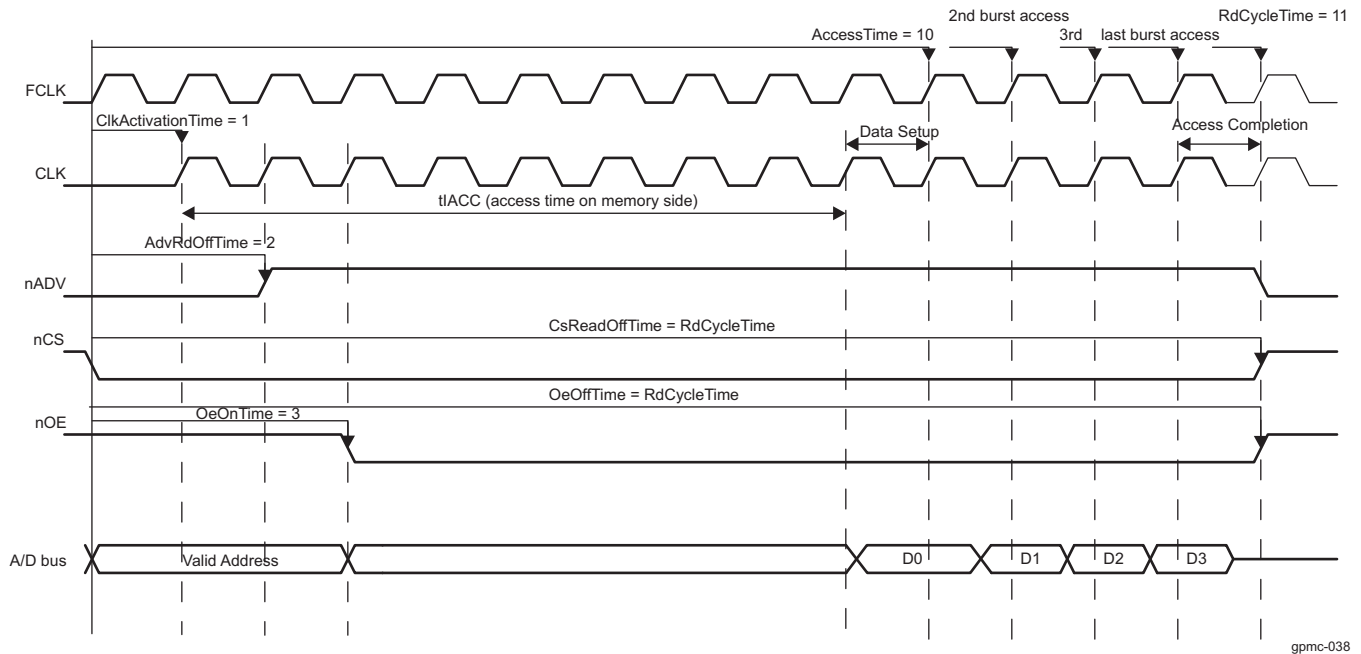

| Parameter Name on GPMC Side | Formula | Duration (ns) | Number of Clock Cycles (F = 104 MHz) | GPMC Register Configurations |
|-----------------------------|---|-----------------------------|--------------------------------------|------------------------------|
| ClkActivation Time | min (tCES, tACS) | 3 | 1 | CLKACTIVATIONTIME = 0x1 |
| RdAccessTime | roundmax (ClkActivationTime + tIACC + DataSetupTime) | 94,03: (9,615 + 80 + 4,415) | 10 : roundmax (94,03 / 9,615) | ACCESSTIME = 0x0A |
| PageBurst AccessTime | roundmax (tBACC) | roundmax (5,2) | 1 | PAGEBURSTACCESSTIME = 0x1 |
| RdCycleTime | AccessTime + max (tCEZ, tOEZ) | 101, 03: (94, 03 + 7) | 11 | RDCYCLETIME = 0x0B |
| CsOnTime | tCES | 0 | 0 | CSONTIME = 0x0 |
| CsReadOffTime | RdCycleTime | - | 11 | CSRDOFFTIME = 0x0B |
| AdvOnTime | tAVC ⁽¹⁾ | 0 | 0 | ADVONTIME = 0x0 |
| AdvRdOffTime | tAVD + tAVC ⁽²⁾ | 12 | 2 | ADVRDOFFTIME = 0x02 |
| OeOnTime ⁽³⁾ | (ClkActivationTime + tACH) < OeOnTime < (ClkActivationTime + tIACC) | - | 3 for instance. | OEONTIME = 0x3 |
| OeOffTime | RdCycleTime | - | 11 | OEOFFTIME = 0x0B |

⁽¹⁾ The external clock provided to the NOR flash is not yet available.

⁽²⁾ AdvRdOffTime - AdvOnTime = tAVD; thus, AdvRdOffTime = tAVD + AdvOnTime = tAVD + tAVC.

⁽³⁾ OeOnTime must guarantee that addresses are available. It must not exceed the availability of the first burst of data.

Figure 9-38. Synchronous Burst Read Access (Timing Parameters in Clock Cycles)

9.1.6.1.2.2 GPMC Configuration for Asynchronous Read Access

The clock runs at 104 MHz (f = 104 MHz; T = 9, 615 ns).

Table 9-20 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Table 9-21 shows how to calculate timings for the GPMC using the memory parameters.

Figure 9-39 shows the asynchronous read access.

Table 9-20. AC Characteristics for Asynchronous Read Access

| AC Read Characteristics on the Memory Side | Description | Duration (ns) |
|--|---|---------------|
| tCE | Read Access time from nCS low | 80 |
| tAAVDS | Address setup time to rising edge of nADV | 3 |
| tAVDP | nADV low time | 6 |
| tCAS | nCS setup time to nADV | 0 |
| tOE | Output enable to output valid | 6 |
| tOEZ | Output enable to High-Z | 7 |

Use the following formula to calculate the RdCycleTime parameter for this typical access:

$$RdCycleTime = RdAccessTime + AccessCompletion = RdAccessTime + 1 \text{ clock cycle} + tOEZ:$$

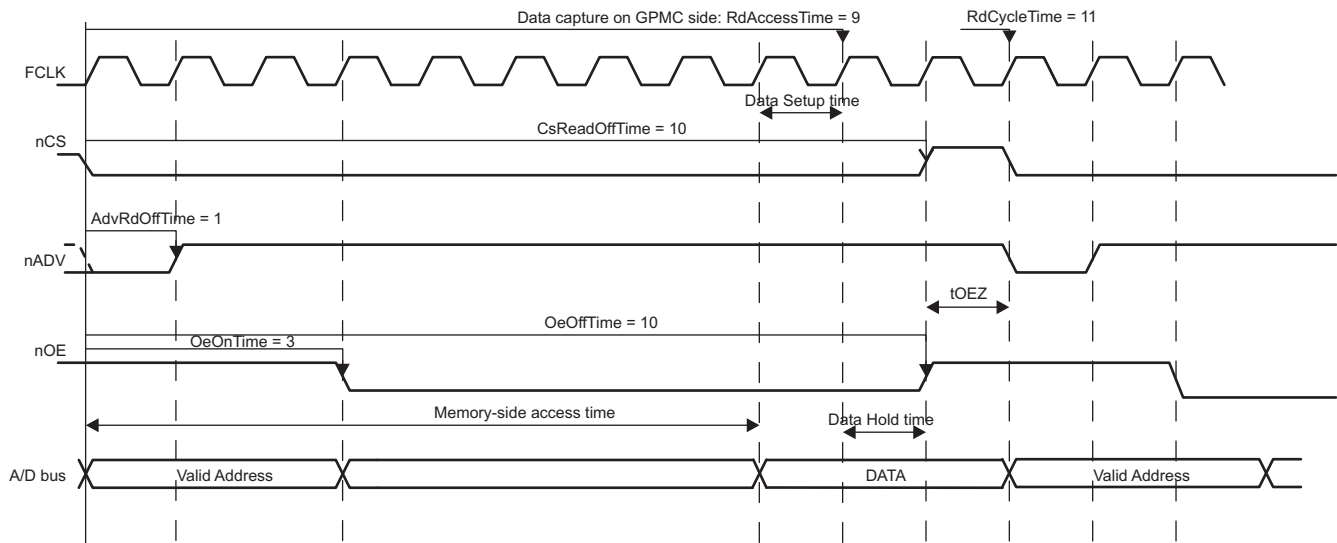

- First, on the memory side, the external memory makes the data available to the output bus. This is the memory-side read access time defined in Table 9-20: the number of clock cycles between the address capture (nADV rising edge) and the data valid on the output bus. The GPMC side requires some hold to allow the data to be captured correctly and the access to be finished.
- To read the data correctly, the GPMC must capture it with enough data setup time; the GPMC module captures the data on the next rising edge. This is access time on the GPMC side.
- There must also be a data hold time for correctly reading the data (checking that there is no nOE/nCS deassertion while reading the data). This data hold time is 1 clock cycle (AccessTime + 1).
- To complete the access, nOE/nCS signals are driven to High-Z. AccessTime + 1 + tOEZ is the read

- cycle time.
- Addresses can now be relatched and a new read cycle begun.

Table 9-21. GPMC Timing Parameters for Asynchronous Read Access

| Parameter Name on GPMC side | Formula | Duration (ns) | Number of Clock Cycles (F = 104 MHz) | GPMC Register Configurations |
|-----------------------------|---|-------------------------|--------------------------------------|------------------------------|
| ClkActivationTime | | n/a (asynchronous mode) | | |
| AccessTime | round max (tCE) | 80 | 9 | ACCESSTIME = 0x09 |
| PageBurstAccess Time | n/a (single access) | | | |
| RdCycleTime | AccessTime + 1 cycle + tOEZ | 96, 615 | 11 | RDCYCLETIME = 0x0B |
| CsOnTime | tCAS | 0 | 0 | CSONTIME = 0x0 |
| CsReadOffTime | AccessTime + 1 cycle | 89, 615 | 10 | CSRDOFFTIME = 0x0A |
| AdvOnTime | tAAVDS | 3 | 1 | ADVONTIME = 0x1 |
| AdvRdOffTime | tAAVDS + tAVDP | 9 | 1 | ADVRDOFFTIME = 0x01 |
| OeOnTime | OeOnTime >= AdvRdOffTime (multiplexed mode) | - | 3 for instance | OEONTIME = 0x3 |
| OeOffTime | AccessTime + 1 cycle | 89, 615 | 10 | OEOFFTIME = 0x0A |

Figure 9-39. Asynchronous Single Read Access (Timing Parameters in Clock Cycles)

gpmc-039

9.1.6.1.2.3 GPMC Configuration for Asynchronous Single Write Access

The clock runs at 104 MHz: (f = 104 MHz; T = 9, 615 ns).

Table 9-23 shows how to calculate timings for the GPMC using the memory parameters.

Table 9-22 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Figure 9-40 shows the synchronous burst write access.

Table 9-22. AC Characteristics for Asynchronous Single Write (Memory Side)

| AC Characteristics on the Memory Side | Description | Duration (ns) |
|---------------------------------------|-------------------|---------------|
| tWC | Write cycle time | 60 |
| tAVDP | nADV low time | 6 |
| tWP | Write pulse width | 25 |

Table 9-22. AC Characteristics for Asynchronous Single Write (Memory Side) (continued)

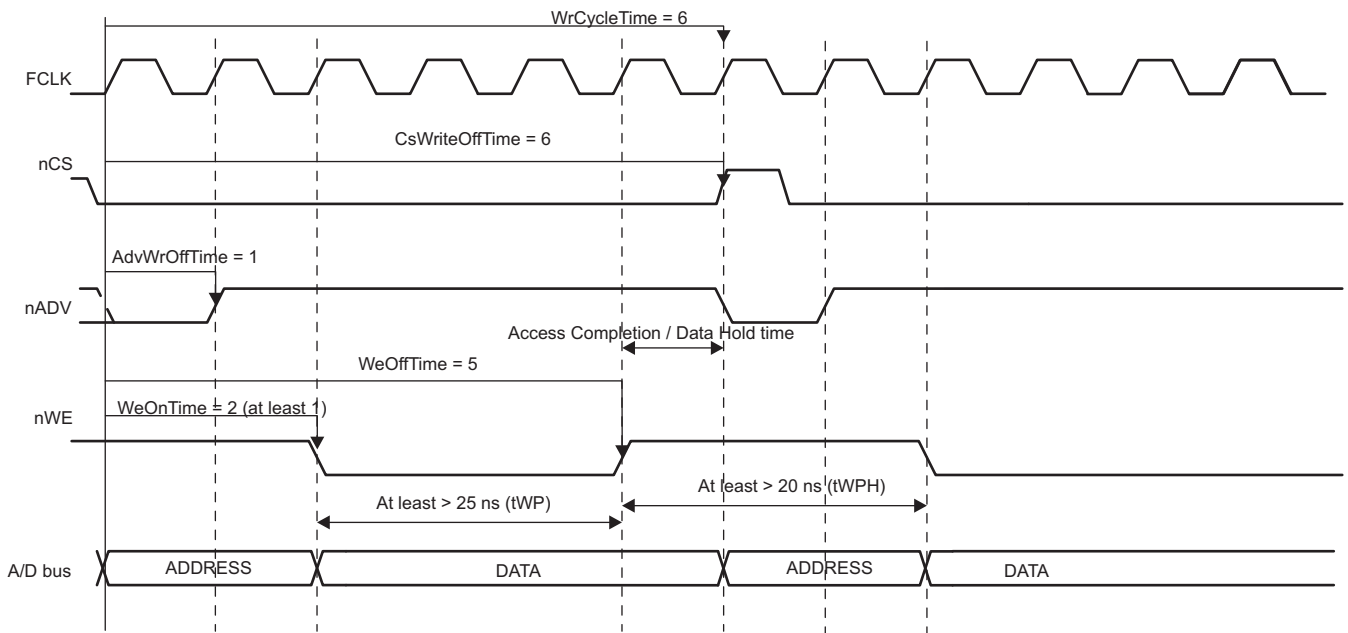

| AC Characteristics on the Memory Side | Description | Duration (ns) |
|---------------------------------------|------------------------|---------------|
| tWPH | Write pulse width high | 20 |
| tCS | nCS setup time to nWE | 3 |
| tCAS | nCS setup time to nADV | 0 |
| tAVSC | nADV setup time | 3 |

For asynchronous single write access, write cycle time is $WrCycleTime = WeOffTime + AccessCompletion = WeOffTime + 1$. For the AccessCompletion: 1 cycle is required for data hold time (nCS deassertion).

Table 9-23. GPMC Timing Parameters for Asynchronous Single Write

| Parameter Name on GPMC side | Formula | Duration (ns) | Number of Clock Cycles (F = 104 MHz) | GPMC Registers Configuration |
|-----------------------------|--|-------------------------|--------------------------------------|------------------------------|
| ClkActivationTime | | n/a (asynchronous mode) | | |
| AccessTime | Applicable only to WAITMONITORING (the value is the same as for read access) | | | |
| PageBurstAccessTime | | n/a (single access) | | |
| WrCycleTime | $WeOffTime + AccessCompletion$ | 57, 615 | 6 | WRCYCLETIME = 0x06 |
| CsOnTime | tCAS | 0 | 0 | CSONTIME = 0x0 |
| CsWrOffTime | $WeOffTime + 1$ | 57, 615 | 6 | CSWROFFTIME = 0x06 |
| AdvOnTime | tAVSC | 3 | 1 | ADVONTIME = 0x1 |
| AdvWrOffTime | $tAVSC + tAVDP$ | 9 | 1 | ADVWROFFTIME = 0x01 |
| WeOnTime | tCS | 3 | 1 | WEONTIME = 0x1 |
| WeOffTime | $tCS + tWP + tWPH$ | 48 | 5 | WEOFFTIME = 0x05 |

9.1.6.2 How to Choose a Suitable Memory to use with the GPMC

This section is intended to help the user select a suitable memory device to interface with the GPMC controller.

9.1.6.2.1 Supported Memories or Devices

NAND flash and NOR flash architectures are the two flash technologies. The GPMC supports various types of external memory or device, basically any one that supports NAND or NOR protocols:

- 8- and 16-bit width asynchronous or synchronous memory or device (8-bit: non burst device only)
- 16-bit address and data multiplexed NOR flash devices (pSRAM, OneNAND™, ...)
- 8- and 16-bit NAND flash device

NOTE: Non-multiplexed NOR flash devices are supported by the GPMC but their usage is highly limited. As only ten address pins are available on the GPMC interface, the maximum device size supported is 2KB.

9.1.6.2.1.1 Memory Pin Multiplexing

This section highlights the interfacing differences of the GPMC supported memories.

Table 9-24. Supported Memories Interfaces

| Function | 16-bit Address/Data muxed pSRAM or NOR Flash ⁽¹⁾ | OneNAND | 16-bit NAND | 8-bit NAND |
|-----------|---|---------|-------------|--------------------|
| gpmc_a10 | A26 | | | |

| gpmc_wait3 | WAIT3 | | | R/nB3 |

9.1.6.2.1.2 NAND Interface Protocol

NAND flash architecture, introduced in 1989, is a flash technology. NAND is a page-oriented memory device, i.e. read and write accesses are done by pages. NAND achieves great density by sharing common areas of the storage transistor, which creates strings of serially connected transistors (in NOR devices, each transistor stands alone). Thanks to its high density NAND is best suited to devices requiring high capacity data storage, such as pictures, music, or data files. NAND non-volatility, makes of it a good storage solution for many applications where mobility, low power, and speed are key factors. Low pin count and simple interface are other advantages of NAND.

Table 9-25 summarizes the NAND interface signals level applied to external device or memories.

Table 9-25. NAND Interface Bus Operations Summary

| Bus operation | CLE | ALE | nCE | nWE ⁽¹⁾ | nRE ⁽¹⁾ | nWP |
|-----------------------|-----|-----|------------------|--------------------|--------------------|--------------------|
| Read (cmd input) | H | L | L | RE | H | x |
| Read (add input) | L | H | L | RE | H | x |
| Write (cmd input) | H | L | L | RE | H | H |
| Write (add input) | L | H | L | RE | H | H |
| Data input | L | L | L | RE | H | H |
| Data output | L | L | L | H | FE | x |
| Busy (during read) | x | x | H ⁽²⁾ | H ⁽²⁾ | H ⁽²⁾ | x |
| Busy (during program) | x | x | x | x | x | H |
| Busy (during erase) | x | x | x | x | x | H |
| Write protect | x | x | x | x | x | L |
| Stand-by | x | x | H | x | x | H/L ⁽³⁾ |

⁽¹⁾ RE stands for rising edge, FE stands for falling edge

⁽²⁾ Can be either nCE high, or WE and nRE high.

⁽³⁾ nWP should be biased to CMOS high or CMOS low for standby

9.1.6.2.1.3 NOR Interface Protocol

NOR flash architecture, introduced in 1988, is a flash technology. Unlike NAND which is a sequential access device, NOR is directly addressable, i.e. is designed to be a random access device. NOR is best suited to devices used to store and run code or firmware, usually in small capacities. While NOR has fast read capabilities it has slow write and erase functions compared to NAND architecture.

Table 9-26 summarizes the NOR interface signals level applied to external device or memories.

Table 9-26. NOR Interface Bus Operations Summary

| Bus operation | CLK | nADV | nCS | nOE | nWE | WAIT | DQ[15:0] |
|----------------------|---------|------|-----|-----|-----|----------|----------|
| Read (asynchronous) | x | L | L | L | H | Asserted | Output |
| Read (synchronous) | Running | L | L | L | H | Driven | Output |
| Read (burst suspend) | Halted | x | L | H | H | Active | Output |
| Write | x | L | L | H | L | Asserted | Input |
| Output disable | x | x | L | H | H | Asserted | High-Z |
| Standby | x | x | H | x | x | High-Z | High-Z |

9.1.6.2.1.4 Other Technologies

Other supported device type interact with the GPMC through the NOR interface protocol.

OneNAND™ is a high density and low-power memory device. OneNAND™ is based on single- or multi-level-cell NAND core with SRAM and logic, and interfaces as a synchronous NOR Flash, plus has synchronous write capability. It reads faster than conventional NAND and write faster than conventional NOR flash. Hence, it is appropriate for both mass storage and code storage.

pSRAM stands for pseudo-static random access memory. pSRAM is a low-power memory device for mobile applications. pSRAM is based on the DRAM cell with internal refresh and address control features, and interfaces as a synchronous NOR Flash, plus has synchronous write capability.

9.1.6.2.2 GPMC Features and Settings

This section lists GPMC features and settings:

- Supported device type: up to eight NAND or NOR protocol external memories or devices
- Operating Voltage: 1.8V;
- Maximum operating frequency provided externally: up to 100MHz (single device) with an L3-clock of 100MHz. Up to 83MHz (L3-clock divided by two) with an L3-clock of 166MHz. See the device-specific Data Manual for precise information.
- Maximum GPMC addressing capability: 1 GByte divided into eight chip-selects
- Maximum supported memory size: 128 MBytes (must be a power-of-2)
- Minimum supported memory size: 16 MBytes (must be a power-of-2). Aliasing occurs when addressing smaller memories.
- Data path to external memory or device: 8- and 16-bit wide
- Burst and page access: burst of 4-8-16 Word16
- Supports bus keeping
- Supports bus turn around

9.1.7 GPMC Registers

This section provides information about the GPMC instance in this product. [Table 9-28](#) provides a summary of the GPMC registers. The remaining parts of this section describe the registers within the module instance.

Table 9-27. Instance Summary

| Module Name | Base Address | Size |
|-------------|--------------|-----------|
| GPMC | 0x6E00 0000 | 16 Mbytes |

9.1.7.1 GPMC Register Mapping Summary

| Bits | Field Name | Description | Type | Reset |
|-------|--------------------------|---|------|---------|
| 31:12 | RESERVED | Write 0s for future compatibility. Read returns 0s. | RW | 0x00000 |
| 11 | WAIT3EDGEDETECTIONSTATUS | Status of the Wait3 Edge Detection interrupt Read 0x0: A transition on WAIT3 input pin has not been detected Write 0x0: WAIT3EDGEDETECTIONSTATUS bit unchanged Read 0x1: A transition on WAIT3 input pin has been detected Write 0x1: WAIT3EDGEDETECTIONSTATUS bit is reset | RW | 0x0 |
| 10 | WAIT2EDGEDETECTIONSTATUS | Status of the Wait2 Edge Detection interrupt Read 0x0: A transition on WAIT2 input pin has not been detected Write 0x0: WAIT2EDGEDETECTIONSTATUS bit unchanged Read 0x1: A transition on WAIT2 input pin has been detected Write 0x1: WAIT2EDGEDETECTIONSTATUS bit is reset | RW | 0x0 |
| 9 | WAIT1EDGEDETECTIONSTATUS | Status of the Wait1 Edge Detection interrupt Read 0x0: A transition on WAIT1 input pin has not been detected Write 0x0: WAIT1EDGEDETECTIONSTATUS bit unchanged Read 0x1: A transition on WAIT1 input pin has been detected Write 0x1: WAIT1EDGEDETECTIONSTATUS bit is reset | RW | 0x0 |
| 8 | WAIT0EDGEDETECTIONSTATUS | Status of the Wait0 Edge Detection interrupt Read 0x0: A transition on WAIT0 input pin has not been detected Write 0x0: WAIT0EDGEDETECTIONSTATUS bit unchanged Read 0x1: A transition on WAIT0 input pin has been detected Write 0x1: WAIT0EDGEDETECTIONSTATUS bit is reset | RW | 0x0 |
| 7:2 | RESERVED | Write 0s for future compatibility. Read returns 0s. | RW | 0x00 |

| Bits | Field Name | Description | Type | Reset |
|-------------|---------------------|--|-------------|--------------|
| 1 | TERMINALCOUNTSTATUS | Status of the TerminalCountEvent interrupt Read 0x0: Indicates that CountValue is greater than 0 Write 0x0: TERMINALCOUNTSTATUS bit unchanged Read 0x1: Indicates that CountValue is equal to 0 Write 0x1: TERMINALCOUNTSTATUS bit is reset | RW | 0x0 |
| 0 | FIFOEVENTSTATUS | Status of the FIFOEvent interrupt Read 0x0: Indicates than less than FIFOThreshold bytes are available in prefetch mode and less than FIFOThreshold bytes free places are available in write-posting mode. Write 0x0: FIFOEVENTSTATUS bit unchanged Read 0x1: Indicates than at least FIFOThreshold bytes are available in prefetch mode and at least FIFOThreshold bytes free places are available in write-posting mode. Write 0x1: FIFOEVENTSTATUS bit is reset | RW | 0x0 |

9.1.7.2.4 GPMC_IRQENABLE

Table 9-32. GPMC_IRQENABLE

| | | | |
|-------------------------|--|-----------------|------|
| Address Offset | 0x0000 001C | Instance | GPMC |
| Physical Address | 0x6E00 001C | | |
| Description | The interrupt enable register allows to mask/unmask the module internal sources of interrupt, on a event-by-event basis. | | |
| Type | RW | | |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |

| Bits | Field Name | Description | Type | Reset |
|-------|----------------------|---|------|---------|
| 31:12 | RESERVED | Write 0s for future compatibility. Read returns 0s. | RW | 0x00000 |
| 11 | WAIT3PINPOLARITY | Selects the polarity of input pin WAIT3 0x0: WAIT3 active low 0x1: WAIT3 active high | RW | 0x1 |
| 10 | WAIT2PINPOLARITY | Selects the polarity of input pin WAIT2 0x0: WAIT2 active low 0x1: WAIT2 active high | RW | 0x0 |
| 9 | WAIT1PINPOLARITY | Selects the polarity of input pin WAIT1 0x0: WAIT1 active low 0x1: WAIT1 active high | RW | 0x1 |
| 8 | WAIT0PINPOLARITY | Selects the polarity of input pin WAIT0 0x0: WAIT0 active low 0x1: WAIT0 active high | RW | 0x0 |
| 7:5 | RESERVED | Write 0s for future compatibility. Read returns 0s. | RW | 0x0 |
| 4 | WRITEPROTECT | Controls the WP output pin level 0x0: WP output pin is low 0x1: WP output pin is high | RW | 0x0 |
| 3:2 | RESERVED | Write 0s for future compatibility. Read returns 0s. | RW | 0x0 |
| 1 | LIMITEDADDRESS | Limited Address device support 0x0: No effect 0x1: A26-A11 are not modified during an external memory access. | RW | 0x0 |
| 0 | NANDFORCEPOSTEDWRITE | Enables the Force Posted Write feature to NAND Cmd/Add/Data location 0x0: Disables Force Posted Write 0x1: Enables Force Posted Write | RW | 0x0 |

9.1.7.2.9 GPMC_STATUS
Table 9-37. GPMC_STATUS

| | | | |
|-------------------------|---|-----------------|------|
| Address Offset | 0x0000 0054 | Instance | GPMC |
| Physical Address | 0x6E00 0054 | | |
| Description | The status register provides global status bits of the GPMC | | |
| Type | RW | | |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|-------------|-------------|-------------|-------------|----------|----|---|---|---|---|------------------------|---|---|---|---|---|

| Bits | Field Name | Description | Type | Reset |
|-------|--------------------------|--|------|-------|
| 31 | WRAPBURST | Enables the wrapping burst capability. Must be set if the attached device is configured in wrapping burst 0x0: Synchronous wrapping burst not supported 0x1: Synchronous wrapping burst supported | RW | 0x0 |
| 30 | READMULTIPLE | Selects the read single or multiple access 0x0: Single access 0x1: Multiple access (burst if synchronous, page if asynchronous) | RW | 0x0 |
| 29 | READTYPE | Selects the read mode operation 0x0: Read Asynchronous 0x1: Read Synchronous | RW | 0x0 |
| 28 | WRITEMULTIPLE | Selects the write single or multiple access 0x0: Single access 0x1: Multiple access (burst if synchronous, considered as single if asynchronous) | RW | 0x0 |
| 27 | WRITETYPE | Selects the write mode operation 0x0: Write Asynchronous 0x1: Write Synchronous | RW | 0x0 |
| 26:25 | CLKACTIVATIONTIME | Output GPMC_CLK activation time 0x0: First rising edge of GPMC_CLK at start access time 0x1: First rising edge of GPMC_CLK one GPMC_FCLK cycle after start access time 0x2: First rising edge of GPMC_CLK two GPMC_FCLK cycles after start access time 0x3: Reserved | RW | 0x0 |
| 24:23 | ATTACHEDDEVICEPAGELENGTH | Specifies the attached device page (burst) length 0x0: 4 Words 0x1: 8 Words 0x2: 16 Words 0x3: Reserved (1 Word = Interface size) | RW | 0x0 |

| Bits | Field Name | Description | Type | Reset |
|-------|---------------------|---|------|-------|
| 22 | WAITREADMONITORING | Selects the Wait monitoring configuration for Read accesses (Reset value is BOOTWAITEN input pin sampled at IC reset) 0x0: Wait pin is not monitored for read accesses 0x1: Wait pin is monitored for read accesses | RW | 0x- |
| 21 | WAITWRITEMONITORING | Selects the Wait monitoring configuration for Write accesses 0x0: Wait pin is not monitored for write accesses 0x1: Wait pin is monitored for write accesses | RW | 0x0 |
| 20 | RESERVED | Write 0s for future compatibility. Read returns 0. | RW | 0x0 |
| 19:18 | WAITMONITORINGTIME | Selects input pin Wait monitoring time 0x0: Wait pin is monitored with valid data 0x1: Wait pin is monitored one GPMC_CLK cycle before valid data 0x2: Wait pin is monitored two GPMC_CLK cycle before valid data 0x3: Reserved | RW | 0x0 |
| 17:16 | WAITPINSELECT | Selects the input WAIT pin for this chip-select (Reset value is BOOTWAITSELECT input pin sampled at IC reset for CS0 and 0 for CS1-7) 0x0: Wait input pin is WAIT0 0x1: Wait input pin is WAIT1 0x2: Wait input pin is WAIT2 0x3: Wait input pin is WAIT3 | RW | 0x- |
| 15:14 | RESERVED | Write 0s for future compatibility. Reads returns 0 | RW | 0x0 |
| 13:12 | DEVICESTYPE | Selects the device size attached (Reset value is BOOTDEVICESTYPE input pin sampled at IC reset for CS0 and 0x1 for CS1 to CS7) 0x0: 8 bit 0x1: 16 bit 0x2: Reserved 0x3: Reserved | RW | 0x- |
| 11:10 | DEVICETYPE | Selects the attached device type 0x0: NOR Flash like, asynchronous and synchronous devices 0x1: Reserved 0x2: NAND Flash like devices, stream mode 0x3: Reserved | RW | 0x0 |
| 9 | MUXADDDATA | Enables the Address and data multiplexed protocol (Reset value is CS0MUXDEVICE input pin sampled at IC reset for CS0 and 0 for CS1-7) 0x0: Non Multiplexed attached device 0x1: Address and data multiplexed attached device | RW | 0x- |
| 8:5 | RESERVED | Write 0s for future compatibility. Read returns 0s. | RW | 0x0 |
| 4 | TIMEPARAGRANULARITY | Signals timing latencies scalar factor (Rd/WrCycleTime, Rd/WrAccessTime, PageBurstAccessTime, CSOnTime, CSRd/WrOffTime, ADVOnTime, ADVRd/WrOffTime, OEOnTime, OEOffTime, WEOnTime, WEOffTime, Cycle2CycleDelay, BusTurnAround, TimeOutStartValue) 0x0: x1 latencies 0x1: x2 latencies | RW | 0x0 |
| 3:2 | RESERVED | Write 0s for future compatibility. Read returns 0s. | RW | 0x0 |

| Bits | Field Name | Description | Type | Reset |
|-------------|-------------------|---|-------------|--------------|
| 1:0 | GPMCFCLKDIVIDER | Divides the GPMC_FCLK clock 0x0: GPMC_CLK frequency = GPMC_FCLK frequency 0x1: GPMC_CLK frequency = GPMC_FCLK frequency / 2 0x2: GPMC_CLK frequency = GPMC_FCLK frequency / 3 0x3: GPMC_CLK frequency = GPMC_FCLK frequency / 4 | RW | 0x0 |

9.2 SDRAM Controller (SDRC) Subsystem

This section describes the SDRAM controller (SDRC) subsystem.

9.2.1 SDRC Subsystem Overview

NOTE: Some features may not be available or supported in your particular device. For more information, see Chapter 1, the *Device Family* section, and your device-specific data manual.

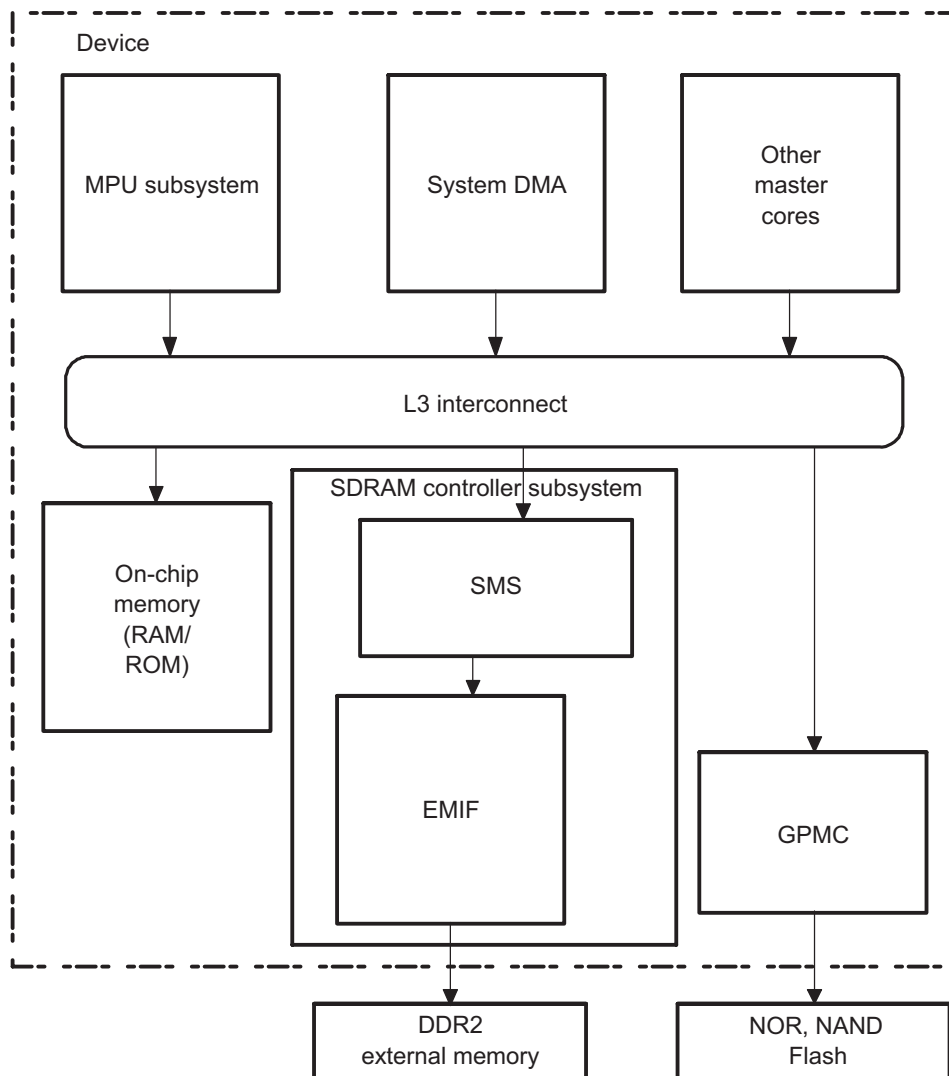

The SDRC subsystem module provides connectivity between the processor and external discrete DDR SDRAM.

The SDRC subsystem provides a high-performance interface to a variety of fast memory devices. It comprises two submodules:

- The SDRAM Memory Scheduler (SMS), consisting of scheduler, security firewall, and virtual rotated frame-buffer (VRFB) modules.
- EMIF (External Memory Interface).

Figure 9-41 shows the SDRC subsystem environment.

Figure 9-41. SDRC Subsystem Environment

sdrc-001

9.2.1.1 Features

The main features of the SDRC subsystem module are:

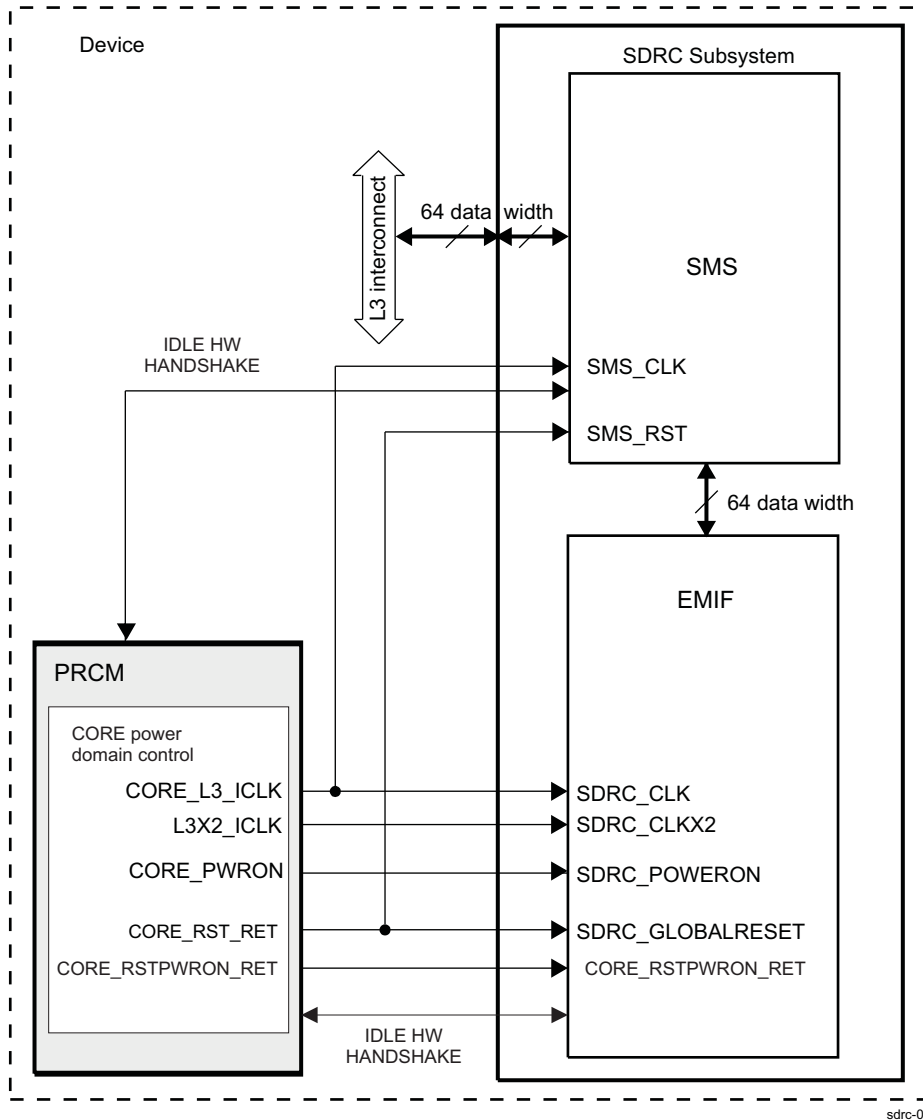

- Security firewall
 - Eight regions can be defined.
 - Independently programmable read/write access control
 - Independently programmable security control
- VRFB module
 - Minimizes SDRAM page-miss penalty when accessing graphics buffer in nonnatural raster-scan order
 - Supports rotations of 0, 90, 180, and 270 degrees
 - Transparent to software applications
 - 12 concurrent rotation contexts
- Memory-access scheduler
 - Optimizes latency and bandwidth usage between initiators
 - Supports secure transactions controlled by security firewall
 - Per-system initiator group quality-of-service (QoS) control
 - 8 × 8 × 64 request queue FIFO for optimal scheduling
 - Programmable arbitration scheme
 - Focus on real-time memory processes (LCD display, camera interface)
 - Focus on MPU memory latency
 - Fair arbitration between other system initiators (DMAs, video subsystem, SGX accelerator)
